Email: gachi@nms.ac.jp

Background and aims: Portal hypertension is the main pathophysiology of liver cirrhosis that forms collateral vessels such as esophageal varices. DAAs have markedly improved treatment outcomes and have been approved for patients with HCV related cirrhosis including decompensated cirrhosis, which is frequently complicated by esophageal varices. Although some studies reported that achievement of SVR with DAAs decreased portal pressure to some extent, post-SVR portal pressure decreased only slightly or not at all in patients with high baseline portal pressure or poor hepatic functional reserve. Recent studies reported post-SVR changes in the morphology of esophagogastric varices in patients with compensated cirrhosis. However, post-SVR esophageal variceal changes in patients with decompensated cirrhosis remain unclear. Therefore, this multicenter retrospective study aimed to clarify the morphological changes in esophageal varices and factors associated with esophageal varix aggravation after achieving SVR with DAAs in patients with cirrhosis, including decompensated cirrhosis.
Method: A total of 1, 768 patients with chronic HCV infection achieved SVR with DAAs at 26 participating institutions in Japan. Among them, 243 patients underwent esophagogastroduodenoscopy before DAAs treatment and after achieving SVR, and the morphological changes in esophageal varices were examined.
Results: This study included 125 males and 118 females with compensated or decompensated cirrhosis with a median age of 68 (range, 44–91) years. Esophageal varices before DAAs treatment were classified into no varix in 155, F1 in 59, F2 in 25 and F3 in 4 patients. The improvement, unchanged, and aggravation rates of esophageal varices after SVR were 11.9%, 73.3%, and 14.8%, respectively. Low platelet count was extracted as an independent factor associated with esophageal varices aggravation. Of the 155 patients without esophageal varices before DAAs treatment, 17 developed de novo post-SVR esophageal varices. High ALBI score was extracted as an independent factor associated with de novo post-SVR esophageal varices. The cumulative incidences of de novo esophageal varices were 0%, 6.7%, and 17.7% at 1, 3, and 5 years, respectively.
Conclusion: In conclusions, patients with cirrhosis can experience esophageal varices aggravation despite achieving SVR. In particular, patients with low platelet count and high ALBI score such as decompensated cirrhosis had a high likelihood of developing esophageal varices aggravation and de novo esophageal varices, respectively, even after achieving SVR, and should periodically undergo esophagogastroduodenoscopy in patients with such factors.

SAT-102
The safety and technical success of endoscopic ultrasound-guided portal pressure gradient measurement: a systematic review and meta-analysis

Yousaf Zafar[1], Hamid Ullah[2], Faisal Bukeirat[2], Brett Fortune[3].
[1]University of Mississippi Medical Center, Madison, United States; [2]University of Mississippi Medical Center, Jackson, United States; [3]Montefiore Medical Center- The University Hospital for Albert Einstein College of Medicine, Bronx, United States
Email: yousuf.zafar.iqbal@gmail.com

Background and aims: Portal hypertension (PH) is a serious complication that is linked to significant morbidity and mortality in patients with cirrhosis. Unlike the indirect measurement of the hepatic venous pressure gradient, the portal pressure gradient (PPG) directly reflects the degree of PH including presinusoidal causes of PH. As endoscopic sonography techniques expand, the use of endoscopic ultrasound-guided porto-systemic pressure gradient (EUS-PPG) provides a novel procedure that is minimally invasive and can obtain direct portal pressure measurements, thus providing potentially clinically meaningful information. Our aim of using this systematic review is to assess the technical success and safety of this procedure in liver patients.
Methods: A comprehensive literature search was conducted in PubMed, EMBASE, Web of Science and Google Scholar to query for studies that assessed the safety and technical success of EUS-PPG. All articles published from inception to January 2024 were included. The primary outcomes were the overall technical success rate, and incidence of adverse events. The risk of bias was assessed by Egger's test. Results were synthesized using I2 to test heterogeneity.
Results: Six published studies including 212 patients met inclusion criteria. In 4 of the studies with mean age 59.6 years, 59% male while two had no mention of demographics. The pooled technical success rate of EUS-PPG measurements was 97.1% with (95% CI 92.9%–98.8%, I2 = 0%). A 25-gauge needle was used in 84.3% (135/160) of patients. The mean PPG was 12.99 (range 5.63–20.35) mmHg. Ninety-five patients underwent simultaneous EUS-LB using 19G needle with wet suction technique. The technical success rate of EUS-LB was 100% and specimen was adequate in 99% (94/95) patients to establish histological diagnosis. There were no major life-threatening complications of the EUS-PPG procedure. The pooled incidence of adverse events for EUS-PPG was 6.8% (95% CI 3.8–11.8%; I2 = 0%). Low heterogeneity was noted in the analysis.
Conclusion: EUS-PPG measurement carries a high technical success rate with excellent safety with or without EUS-LB when performed for the assessment of portal pressure in patients with chronic liver disease. Future studies are needed to evaluate whether there is strong correlation between EUS-PPG measurements and histologic fibrosis stage by liver biopsy as well as linkage to meaningful clinical outcomes.

SAT-104-YI
Impact of albumin dosing on the need for terlipressin therapy and prognosis in patients with liver cirrhosis

Eva Maria Schleicher[1,2], Christian Reinhardt[1], Julia Weinmann-Menke[1], Peter R. Galle[1,2], Simon J. Gairing[1,2], Christian Labenz[1,2]. *[1]University Medical Center of the Johannes Gutenberg-University, Mainz, Germany; [2]Cirrhosis Center Mainz (CCM), Mainz, Germany*
Email: eva.schleicher@unimedizin-mainz.de

Background and aims: If acute kidney injury (AKI) is detected in patients with cirrhosis, current guidelines recommend volume expansion with albumin at the dosage of 1 g/kg body weight per day for 48 h. The dosage and its prognostic relevance for albumin therapy have not been supported by conclusive evidence so far but are based on expert consensus. Therefore, this study aimed to investigate the influence of different doses of albumin in the context of volume expansion therapy on the need for therapy with terlipressin and prognosis in patients with liver cirrhosis and AKI.
Method: Data from 124 patients with cirrhosis and AKI were recruited at the Cirrhosis Center Mainz (Germany). Albumin doses within the first 48 h were recorded. To make the doses of albumin comparable between patients, normalization for body weight (BW) (albumin dose in g/kgBW per day) was performed. Patients were followed up for the need for therapy with terlipressin in hepatorenal syndrome (HRS) and liver transplant-free (LTx-free) survival.
Results: Patients received a median of 80 g (IQR 80; 120) albumin within the first 48 h. The median albumin dose normalized to body weight (Alb/kg) was 0.58 (IQR 0.42; 0.83). During the AKI episode, 46 (37%) patients required therapy with terlipressin. In a multivariable

logistic regression model, lower Alb/kgBW (OR 0.048, p = 0.001) was shown to be significantly associated with the need for therapy with terlipressin. The same result was found in a model with the inclusion of Alb/kgBW dichotomized by median (OR 0.320, p = 0.010). A total of 24 (19%) patients died or required LTx within 30 days of diagnosis of AKI. In a multivariable logistic regression model, only a higher MELD (OR 1.082, p = 0.006) was found to be associated with a worse prognosis, while Alb/kgBW was not (p = 0.915). These results were confirmed in a further analysis after 1:1 matching of patients with Alb/kgBW above and below the median (n = 33 per group).
Conclusion: Guideline-recommended administration of intravenous albumin in patients with cirrhosis and AKI is associated with a reduced need for therapy with terlipressin. However, patients' prognosis appears to be independent of albumin dosage.

SAT-105
Neutrophil extracellular traps are not linked to the development of decompensation, ACLF, or death in clinically stable patients with advanced chronic liver disease
Lorenz Balcar[1], Bernhard Scheiner[1], Benedikt Simbrunner[1], Mathias Jachs[1], Lukas Hartl[1], Georg Semmler[1], Benedikt Hofer[1], Nina Dominik[1], Michael Schwarz[1], Albert Friedrich Stättermayer[1], Matthias Pinter[1], Michael Trauner[1], Thomas Reiberger[1], Ton Lisman[2], Mattias Mandorfer[1]. [1]*Medical University of Vienna, Vienna, Austria;* [2]*University of Groningen, Groningen, Netherlands*
Email: lorenz.balcar@meduniwien.ac.at

Background and aims: Neutrophil extracellular traps (NETs) are part of the body's innate immune response. In animal models, they aggravated liver injury and promoted disease progression/portal hypertension by the formation of (micro)thrombi leading to parenchymal extinction. This study aimed to investigate NETosis in patients with clinically stable advanced chronic liver disease (ACLD).
Method: We investigated stable ACLD patients undergoing hepatic venous pressure gradient (HVPG) measurement in whom an extensive panel of laboratory tests related to coagulation and NET biomarkers were assessed. First/further hepatic decompensation (HD; according to disease stage)/liver-related death (LRD; in a multistate model) as well as development of ACLF/LRD and non-tumoural portal vein thrombosis (PVT) were the outcomes of interest.
Results: Overall, 194 patients (70 compensated ACLD [cACLD], 124 dACLD; mean Child-Turcotte-Pugh score (CTP): 7 ± 2 points; mean HVPG: 17 ± 6 mmHg) were included. Compared to healthy controls (n = 29), levels of cell free-DNA (cf-DNA) levels were higher (0.88 [IQR 0.84–0.93] vs. 0.94 [IQR 0.88–1.03] µg/ml; p = 0.001) in ACLD patients, whereas myeloperoxidase-DNA (MPO-DNA) values were similar (0.32 [IQR 0.17–0.54] vs. 0.39 [IQR 0.18–0.76] mAU/ml; p = 0.400). Compared to cACLD, syndecan-1, platelet factor 4 (PF4), and plasmin antiplasmin complex were significantly higher in dACLD, while activated factor XIII was lower. However, after correcting for platelet count, the differences in PF4 disappeared. While these differences were also observed when stratifying according to disease severity indices (i.e., CTP score), there were no differences throughout HVPG strata. Activated factor XIII, soluble platelet (P)-selectin, and cf-DNA but not MPO-DNA were associated with HD/LRD in univariable analysis. However, no coagulation test predicted HD/LRD death after adjusting for established prognostic indicators. Similarly, soluble P-selectin and cf-DNA were also associated with ACLF/LRD univariably, but associations vanished after appropriate adjustment. Finally, while thrombin antithrombin complex was predictive of non-tumoural PVT development in univariable analysis, after adjusting for CTP score, the association was lost.
Conclusion: Patients with clinically stable ACLD showed increased cf-DNA levels (i.e., NETosis, but also apoptosis/necrosis). However, the more specific marker of NETosis, MPO-DNA, was comparable to healthy controls. NETosis does not appear to drive disease progression in humans with clinically stable ACLD, as it was not linked to clinical end points. Thus, findings obtained in animal models may not be translatable to humans.

SAT-106
Gadoxetic acid-enhanced MRI-derived functional liver imaging score (FLIS) predicts acute-on-chronic liver failure in patients with acute decompensation
Lorenz Balcar[1], Sarah Poetter-Lang[1], Ahmed Ba-Ssalamah[1], Nina Bastati[1], Raphael Ambros[1], Antonia Kristic[1], Julia Krawanja[1], Katharina Pomej[1], Benedikt Simbrunner[1], Georg Semmler[1], Viktor Schmidbauer[1], Svitlana Pochepnia[1], Daniel Sobotka[1], Jacqueline Hodge[1], Michael Trauner[1], Thomas Reiberger[1], Lucian Beer[1], Mattias Mandorfer[1]. [1]*Medical University of Vienna, Vienna, Austria*
Email: lorenz.balcar@meduniwien.ac.at

Background and aims: The Functional Liver Imaging Score (FLIS), derived from gadoxetic acid-enhanced MRI (GA-MRI), can identify patients with advanced chronic liver disease (ACLD) who are at increased risk of hepatic decompensation and liver-related death. In decompensated ACLD (dACLD) patients (i.e., combining clinically stable/unstable), a FLIS of 0–3 was independently associated with an increased risk of acute-on-chronic liver failure (ACLF). However, it is unclear whether the semiquantitative FLIS or its individual complex quantitative (GA-MRI) imaging components (i.e., relative liver enhancement [RLE], relative enhancement ratio of the biliary system [REB], and liver-to-portal vein contrast ratio [LPC]), are capable of predicting ACLF in acutely decompensated (AD) patients; the main at-risk population for ACLF development.
Method: ACLD patients with GA-MRI derived semiquantitative FLIS, in whom the RLE, REB and LPC were additionally computed by two independent, experienced radiologists, were included. According to disease stage, patients were stratified into stable ACLD (cACLD and stable, non-hospitalised dACLD) and AD patients (GA-MRI in non-elective liver-related hospitalisation). The predictive values of semiquantitative FLIS and quantitative (GA-MRI) imaging parameters for ACLF development were investigated by Cox regression analyses.
Results: We included 322 patients of whom 253 (69%) were stable ACLD (n = 187, 58% cACLD, n = 66, 21% stable dACLD), and 69 (21%) AD patients. The inter-observer variability was good to excellent for all evaluated GA-MRI parameters. The FLIS was associated with ACLF development/liver-related death in AD patients in univariable and multivariable analyses (adjusted hazard ratio [aHR]: 2.49 [95%CI 1.15–5.37]; p = 0.030), even after adjusting for known predictive factors such as the CLIF-C ACLF-D score. In stable ACLD patients, the FLIS was only associated the end point of interest in univariable analysis; after correction for well-established prognostic indicators, the association did not attain statistical significance (aHR: 2.01 [95%CI 0.96–4.23]; p = 0.070).
Notably, RLE, REB, and LPC did not predict ACLF/liver-related death, neither in AD, nor stable ACLD patients.
Conclusion: The FLIS is a simple imaging biomarker for prognostication of ACLF in AD patients in whom ACLF risk stratification is clinically valuable to identify patients who may benefit from intensified monitoring or timely liver transplant evaluation and potentially enrich study populations of clinical trials investigating preventive measures with high-risk patients.

Assessment of the diagnostic accuracy of cell count on spontaneous bacterial peritonitis
Prebashan Moodley[1], Mohamed Waddah[1], Oliver Bendall[1], Kris Bennett[1], Nigel Keelty[1], Sally Chan[1], Joanne Hosking[2], Wayne Thomas[3], Robert Tilley[4], Juan Acevedo Haro[5]. [1]*South West Liver Unit, University Hospitals Plymouth NHS Trust, Plymouth, United Kingdom;* [2]*Medical Statistics Group Peninsula Clinical Trials Unit, University of Plymouth, Plymouth, United Kingdom;* [3]*Haematology Service, University Hospitals Plymouth NHS Trust, Plymouth, United*

Kingdom; [4]Microbiology Service, University Hospitals Plymouth NHS Trust, Plymouth, United Kingdom; [5]South West Liver Unit, University Hospitals Plymouth NHS Trust, Peninsula Medical School, University of Plymouth, Plymouth, United Kingdom
Email: jacevedo@nhs.net

Background and aims: The current definition of SBP, cell count ≥250 PMN/mm^3 on ascitic fluid (AF), is based on small studies performed in the 70's–80's using the manual cell count method. Only a few published studies showed the automated cell count method has good agreement with the manual method. However, the automated counters assessed are no longer available or have been superseded by new models and no independent comparison was made against the gold standard (GS). The accuracy to diagnose SBP is key to avoid delays in its diagnosis and treatment. Therefore, it is important to employ the most accurate diagnostic method. Our aim is to compare both methods independently against the GS diagnosis of SBP.
Method: This is a 5-year long retrospective study including all cases admitted to University Hospitals Plymouth NHS Trust from Dec. 2017 to Nov. 2022, fulfilling the GS positive-SBP criteria: pathogenic bacteria isolated on AF and at least one sign/symptom of peritonitis. And including all day cases having elective paracentesis between Dec. 2021 and Nov. 2022, fulfilling the GS negative-SBP criteria: no admission to hospital within 4 weeks, asymptomatic, AF culture negative and no antibiotics received. The automated method was performed by the Abbott Alinity HQ high-throughput blood count analyser. Only 1 case per patient per admission was included.
Results: 89 cases in 46 patients were identified, 37 with SBP and 52 without SBP according to GS criteria. GS positive-SBP cases had worse liver function: higher levels of bilirubin (161 ± 159 vs 42 ± 27 µmol/L, p < 0.001), more prolonged INR (2.1 ± 1.8 vs 1.3 ± 0.2, p = 0.001) and higher Child-Pugh score (11.5 ± 2.0 vs. 9.3 ± 1.3 points, p < 0.001); worse renal function: higher creatinine levels (142 ± 110 vs. 69 ± 18 µmol/L, p < 0.001) and MELD score (23.0 ± 10.6 vs 12.2 ± 4.0 points, p < 0.001); and were more critically ill: higher prevalence of ACLF grade 2–3 (30% v s0%, p < 0.001), septic shock (22% vs 0%, p < 0.001), admission to ITU (27% vs 0%, p < 0.001), and in-hospital mortality (42% vs 0%, p < 0.001) compared to GS negative-SBP cases. GS positive-SBP cases showed higher degree of inflammation: higher CRP levels (58 ± 46 vs. 22 ± 17 mg/L, p < 0.001), serum leukocyte count (11.3 ± 5.2 vs 7.3 ± 2.1, p < 0.001) and higher prevalence of Systemic Inflammatory Response Syndrome (SIRS) (52% vs 13%, p < 0.001) than GS negative-SBP cases. In order to compare the sensitivity and specificity of the manual and automated cell count methods, only those cases having both methods performed (76/89) were selected and compared with the GS cases. The sensitivity of the automated method was superior to the manual method, 79% vs. 59%, p = 0.02. Both methods showed Specificity of 100%.
Conclusion: The sensitivity of the modern automated method is superior to the classic manual cell count. It is also cheaper and readily available out of hours. The diagnosis of SBP should be made using a modern automated cell counter.

SAT-111

Lower levels of Insulin-like growth factor 1 are independently associated with unfavorable prognosis in patients with advanced chronic liver disease

Lukas Hartl[1], Michael Schwarz[1], Benedikt Simbrunner[1], Mathias Jachs[1], Peter Wolf[2], David Bauer[1], Bernhard Scheiner[1], Lorenz Balcar[1], Georg Semmler[1], Benedikt Hofer[1], Nina Dominik[1], Rodrig Marculescu[3], Michael Trauner[1], Mattias Mandorfer[1], Thomas Reiberger[1]. *[1]Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria; [2]Division of Endocrinology, Department of Medicine III, Medical University of Vienna, Vienna, Austria; [3]Department of Laboratory Medicine, Medical University of Vienna, Vienna, Austria*
Email: thomas.reiberger@meduniwien.ac.at

Background and aims: Insulin-like growth factor 1 (IGF-1) acts as the primary mediator of growth hormone's (GH) anabolic effects. Secretion of liver-derived circulating IGF-1 is affected by GH, insulin, and nutritional status. In advanced chronic liver disease (ACLD), low IGF-1 levels are linked to insulin resistance, disturbances in lipid and carbohydrate metabolism, malnutrition, hypogonadism, and osteopenia.
Method: We assessed consecutive patients with suspected ACLD (i.e., liver stiffness measurement [LSM] ≥10 kPa), who underwent hepatic venous pressure gradient (HVPG) measurement between 05/2018 and 01/2022 within the prospective VICIS (NCT03267615) study. Exclusion criteria were hepatocellular carcinoma out of Milan criteria, vascular liver disease, occlusive portal vein thrombosis, and a history of liver transplantation/TIPS. Patients were stratified into seven clinical stages of ACLD: pACLD: probable ACLD with LSM ≥10 kPa, but HVPG <6 mmHg; S0: non-significant portal hypertension (PH), i.e. HVPG 6–9 mmHg; S1: clinically significant portal hypertension (CSPH), i.e. HVPG ≥10 mmHg, without esophageal varices; S2: CSPH with esophageal varices; S3: CSPH with previous variceal bleeding; S4: CSPH with previous non-bleeding decompensation event; S5: further decompensation. Competing risk regression considering liver transplantation and death as competing events was performed.
Results: Overall, we included 283 patients (pACLD: 7.1%; S0: 11.0%, S1: 7.8%, S2: 13.8%, S3: 3.9%, S4: 33.9%, S5: 22.6%) and alcohol-related liver disease (45.2%) was the main liver disease etiology. Median GH levels significantly increased with progressive clinical stages (from pACLD: 1.7 ng/ml [IQR 0.3–4.2] to S5: 2.2 ng/ml [IQR 1.1–5.7]; p = 0.006), while median levels of IGF-1 decreased (from pACLD: 83.5 ng/ml [IQR 60.5–108.0] to S5: 51.0 ng/ml [37.0–69.9], p < 0.001). IGF-1 showed a moderate inverse correlation with MELD (rho = –0.433), HVPG (rho = –0.307), and interleukin 6 (rho = –0.445, all p < 0.01), but did not correlate with GH (rho = –0.063, p = 0.288). In multivariate competing risks analyses adjusted for age, sex, body mass index, MELD, albumin, sodium, HVPG, and C-reactive protein, lower IGF-1 was independently associated with (further) decompensation (adjusted subdistribution hazard ratio [aSHR] 0.99, 95% confidence interval [95%CI] 0.98–1.00), acute kidney injury (aSHR 0.98, 95%CI 0.97–0.99), acute-on-chronic liver failure (ACLF, aSHR 0.98, 95%CI 0.97–0.99), and liver-related death during follow-up (aSHR 0.98, 95% CI 0.96–0.99) (all p < 0.05).
Conclusion: With progression of ACLD severity IGF-1 decreases, while GH increases, suggesting increasing GH resistance. IGF-1 levels correlated with liver disease severity and systemic inflammation. Lower levels of IGF-1 were independently linked to hepatic decompensation and liver-related death during follow-up.

SAT-112

Spleen-dedicated stiffness measurement higher than 50 kPa is sufficient to diagnose clinically significant portal hypertension in cACLD individuals

Xiaofeng Zhang[1]. *[1]Hepatology Unit, Department of Infectious Diseases, Nanfang Hospital, Southern Medical University, Guangzhou, China*
Email: 1282614092@qq.com

Background and aims: The Baveno VII consensus recommends transient elastography derived non-invasive tools including spleen stiffness measurement (SSM) for clinically significant portal hypertension (CSPH) differentiation in compensated advanced chronic liver disease (cACLD) patients. We aimed to prospectively evaluate the performances of these algorithms with spleen-dedicated probe in cACLD individuals.
Method: Consecutive cACLD individuals who underwent hepatic venous pressure gradient (HVPG) measurement, liver stiffness measurement (LSM) and SSM measured with 100 Hz probe were prospectively enrolled.
Results: From July 2021 to December 2023, 303 patients were screened and 160 were enrolled for analysis, and 77 patients were

with CSPH. For ruling in CSPH, the SSM >50 kPa had positive predictive value (PPV) at 97.4% and specificity at 98.8%. The Baveno VII-SSM dual cutoff (50 kPa) model had PPV at 89.1% and specificity at 92.8%, which correctly identified comparable CSPH cases (49/77, 63.6%) with the SSM >50 kPa (37/77, 48.1%, p = 0.051). For ruling out CSPH, 30 individuals met LSM <15 kPa plus platelet count >150, 000/µl, with negative predictive value at 96.7% and sensitivity at 98.7%.
Conclusion: We validated that SSM >50 kPa using 100 Hz shear wave frequency was sufficiently accurate to rule in CSPH in cACLD individuals and initiate non-selective β-blockers. The Baveno VII-SSM dual cutoff (21–50 kPa) algorithm for identifying CSPH still need further studies.

SAT-113

Long-term therapy with intravenous human albumin increase survival in patients with decompensated cirrhosis and refractory ascites

Antonino Lombardo[1], Luigi Capodicasa[2], Domenico Alaimo[3], Francesco Mercurio[3], Angelo Zimbardo[3], Fabio Simone[3], Nicola Alessi[3], Ciro Celsa[3], Grazia Pennisi[3], Giuseppe Cabibbo[3], Salvatore Petta[3], Calogero Camma[3], Vincenza Calvaruso[3], Vito Di Marco[3]. *[1]Section of Gastroenterology and Hepatology, University of Palermo, Palermo, Italy; [2]Section of Gastroenterology and Hepatology, Dipartimento Promozione Della Salute, Materno Infantile, Medicina Interna e Specialistica Di Eccellenza, Palermo, Italy; [3]Section of Gastroenterology and Hepatology, Dipartimento Promozione Della Salute, Materno Infantile, Medicina Interna e Specialistica Di Eccellenza, University of Palermo, Palermo, Italy*
Email: lombanino@gmail.com

Background and aims: Refractory ascites in cirrhosis is associated with 50% survival at six months. International guidelines recommend the use of human albumin in cirrhotics with acute decompensation. Recently, the benefit of long-term human albumin therapy (HAT) was proven by ANSWER study in decompensated cirrhosis and have become best practice in Italian Liver Units, but there is no evidence in patients with refractory ascites.
Method: We reported data of an observational study including 143 patients with cirrhosis and refractory ascites undergoing large-volume paracenteses (LVP) in the Day Hospital of our Liver Unit. The group 1 included 90 patients, observed from January 2019 and April 2022, who received HAT only during LVP. The group 2 of 53 patients, observed from May 2022 and January 2024, received HAT during LVP and long-term (40 grams/week). Chi-square test was used to analyze differences between two groups.
Results: The mean age of patients was 68 years, 70% were male and the mean of MELD score was 14. The mean value of serum albumin was 32 g/L, sodium 135 mmol/L, bilirubin 2 mg/dl and INR 1, 35. The etiology was MASH in 46 patients, alcohol abuse in 37, HCV in 30, HBV 11, autoimmune in 2, while 7 patients had a cryptogenic cirrhosis and 10 had a mixed etiology. Thirty-three patients (23%) had HCC and 19 (13%) had portal thrombosis. There were no significant clinical differences between 2 groups at baseline. In group 1, 8 patients (8%) received liver transplant and in 9 patients (10%) was placed a TIPS, only 1 had a post-TIPS complication. In group 2, 4 patients (7%) received liver transplant, 2 patients (4%) were on the waiting list, 31 patients (58%) had a contraindication to transplantation; in 5 patients (9%) was placed a TIPS, 1 patient had a post-TIPS complication, 31 patients (58%) had a contraindication for TIPS. Seventy-four patients (82%) of group 1 and 23 patients (43%) of group 2 needed at least one hospitalization for complications (p < 0.0001). In group 1 all patients (100%) undergoing LVP during follow-up, while in group 2, 24 patients (45%) no longer performed LVP (p < 0.0001). Finally, during the first year of follow-up 71 patients (78%) of group 1 and 9 patients (16%) of group 2 died during the follow-up (p < 0.0001), with a mean survival of 5 months in patients in the group 1, of 7 months in patients in the group 2.
Conclusion: Long-term human albumin therapy treatment can significantly improve prognosis and reduce mortality in patients with refractory ascites. It is a well-tolerated treatment with no complications or contraindications.

SAT-114

Heartbeats and Platelets: unveiling the symphony of heart failure and congestive hepatopathy

Anas Zaher[1], Jude Elsaygh[1], Harsh Patel[2], Navim Mobin[2], Gres Karim[3,4], Kumudha Ramasubbu[5], Ilan Weisberg[2]. *[1]New York Presbyterian Brooklyn Methodist Hospital-Department of Internal Medicine, Brooklyn, United States; [2]New York Presbyterian Brooklyn Methodist Hospital-Department of Gastroenterology, Brooklyn, United States; [3]New York Presbyterian Brooklyn Methodist Hospital, New York, United States; [4]New York Presbyterian Brooklyn Methodist Hospital, Brooklyn, United States; [5]New York Presbyterian Brooklyn Methodist Hospital-Department of Cardiology, Brooklyn, United States*
Email: qks9002@nyp.org

Background and aims: Heart failure (HF) resulting in elevated central venous pressure is frequently associated with poor cardiac output and decreased hepatic perfusion. This subsequently leads to liver injury due to congestive hepatopathy (CH). Platelets, a surrogate for portal hypertension, have a prognostic value since worsening thrombocytopenia in HF is associated with higher all-cause mortality. This study explores the effect of diuresis on hepatic parameters and platelets during an acute HF (AHF) exacerbation to understand their effect on mortality.
Method: Patients who were >18 years with an ejection fraction (EF) of ≤40% admitted for an AHF exacerbation between 1/2020 to 5/2023 were identified through the electronic medical record at a high-volume New York City hospital. All patients underwent diuresis until they became euvolemic. CH was defined as aspartate transferase (AST) and alanine transaminase (ALT) levels exceeding two times the upper normal limit (35 U/L). Patients were categorized into three groups based on platelet values ($\times 10^9$/L): moderate-severe (≤99), mild (100–149), and normal (≥150). Continuous variables were represented using means, while categorical variables were expressed as percentages.
Results: Among 614 patients, 51 (10.3%) were found to have CH and the majority (56%) were black. On average, those with CH had a lower EF (20% vs 25%), higher mean AST levels on admission (152 vs 35)/ALT levels on admission (126 vs 30), and elevated mean natriuretic peptide (15, 011 vs 14, 140 pg/ml) compared to non-CH patients. Among patients with CH, 6% had moderate-severe thrombocytopenia, 18% had mild thrombocytopenia, and 76% had normal platelets count. Patients with moderate-severe thrombocytopenia had higher in-hospital mortality (19%) when compared to patients with mild thrombocytopenia (7%) and a normal platelet count (3%). Additionally, the mean days of diuresis were longer with moderate-severe thrombocytopenia (6.5 days) compared to mild thrombocytopenia and normal platelets (5.6 and 5 days, respectively). Finally, platelet counts on admission when compared to discharge were significantly different between the two groups (193 and 246 CH vs. 229 and 233 non-CH, p = 0.004). There was an observed 30% improvement in platelet count in the CH group compared to 2% in the non-CH group.
Conclusion: This study highlights the significance of platelets in predicting mortality and assessing HF severity during exacerbations. Patients with CH were noted to have a substantial improvement in platelet count post-diuresis, emphasizing its potential as a therapeutic target in the future. A greater severity of thrombocytopenia on admission was associated with higher mortality, a longer length of stay, and a longer duration of diuresis. Recognizing platelet count as a dual marker for mortality risk and therapeutic response underscores its importance in managing HF patients with CH.

SAT-116

Association between pre-operative TIPS and post-operative mortality in a veterans affairs cohort

Nadim Mahmud[1], David Kaplan[1]. [1]*Hospital of the University of Pennsylvania, Philadelphia, United States*
Email: nadim.mahmud@gmail.com

Background and aims: Patients with cirrhosis have an increased risk of post-operative mortality, a component of which may be attributable to portal hypertension in some patients. Performance of pre-operative TIPS, therefore, may plausibly reduce operative risk. Recent literature suggests benefit with pre-operative TIPS, however these studies are limited by residual confounding and lack of exploration of longitudinal liver function data. To address these limitations we used granular longitudinal data from the Veterans Health Administration (VHA).
Method: This was a retrospective cohort study of well-characterized patients with cirrhosis in the VHA who underwent major surgery between 2008 and 2022. A six-month window prior to surgery was utilized to identify patients who underwent pre-operative TIPS. Detailed data regarding demographics, comorbidities, surgery type, ASA class, and longitudinal laboratory data were collected and incorporated into a propensity score using 3:1 caliper matching for receipt of TIPS. Cox regression was then used to evaluate the impact of TIPS on post-operative mortality through 12 months. This process was iterated an additional 500 times using a random number generator to identify variability around the hazard ratio point estimate. Liver function parameters were descriptively compared between TIPS and no TIPS groups 6 months prior to surgery and immediately prior to surgery.
Results: After comprehensive propensity matching including by surgery type, 47 patients underwent pre-operative TIPS and 134 did not. Cohort data included median age 63 years, 94.5% male, and 58.6% ALD-related cirrhosis. In Cox regression, pre-operative TIPS was associated with increased risk of post-operative mortality (HR 1.94, 95% CI 1.02–3.69, $p = 0.04$). In random 500 resampling events, the samples demonstrated an HR >1 and the median HR was 1.91. In evaluating longitudinal lab data, TIPS and no TIPS patients had similar albumin, bilirubin, INR, and platelet count 6 months prior to surgery (each $p > 0.05$), however immediately prior to surgery patients with TIPS patients had lower albumin ($p = 0.004$) and platelet counts ($p = 0.02$), and higher bilirubin ($p = 0.03$) and INR ($p = 0.02$).
Conclusion: In this propensity matched analysis, pre-operative TIPS was associated with increased post-operative mortality in patients with cirrhosis undergoing major surgery. Patients with TIPS had worsened liver synthetic function in the immediate pre-operative period, suggesting that theoretical operative benefits of portal pressure reduction are likely offset by worsened liver synthetic function that may drive increased risk.

SAT-117

Evaluation of Baveno VII criteria and other non-invasive tests for clinically significant portal hypertension in chronic hepatitis D

Mathias Jachs[1,2], Lisa Sandmann[3,4,5], Lukas Hartl[1,2], Tammo Lambert Tergast[3], Michael Schwarz[1,2], David Bauer[2,6], Lorenz Balcar[1,2], Alena Friederike Ehrenbauer[3], Benedikt Hofer[1,2], Markus Cornberg[3,4,5,7,8], Henrike Lenzen[3], Katja Deterding[3], Michael Trauner[1], Mattias Mandorfer[1,2], Heiner Wedemeyer[3,4,5,7], Thomas Reiberger[1], Benjamin Maasoumy[3,7]. [1]*Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria;* [2]*Vienna Hepatic Hemodynamic Lab, Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria;* [3]*Department of Gastroenterology, Hepatology, Infectious Diseases and Endocrinology, Hannover Medical School, Hannover, Germany;* [4]*D-SOLVE consortium, an EU Horizon Europe funded project (No 101057917), Hannover, Germany;* [5]*Excellence Cluster RESIST, Excellence Initiative Hannover Medical School, Hannover, Germany;* [6]*Department of Medicine IV, Klinik Ottakring, Vienna, Austria;* [7]*German Center for Infection Research (DZIF), Braunschweig/Hannover, Germany;* [8]*Centre for Individualised Infection Medicine, Helmholtz Centre for Infection Research/Hannover Medical School, Hannover, Germany*
Email: mathias.jachs@meduniwien.ac.at

Background and aims: Non-invasive tests (NIT) have been endorsed by international guidelines for the diagnosis of clinically significant portal hypertension (CSPH) in compensated advanced chronic liver disease (cACLD) patients, but limited data exists on their utility in chronic hepatitis delta (CHD).
Method: This study included CHD-cACLD (LSM ≥10 kPa or F3/4) patients from two specialized European centers who underwent paired assessment of the hepatic venous pressure gradient (HVPG) and NIT from 2013 to 2023. Liver stiffness measurement (LSM), platelet count (PLT), von Willebrand factor to PLT ratio (VITRO), and spleen stiffness measurement (SSM) were assessed, and the utility of previously proposed models/algorithms for CSPH risk estimation (ANTICIPATE, 3P/5P) or diagnostic algorithms (Baveno-VII criteria, Baveno-VII-VITRO, and Baveno-VII-SSM) was evaluated.
Results: Fifty-one CHD-cACLD patients (HDV-RNA detectable: 90.2%, median HDV-RNA: 3.8 [25th–75th percentile: 3.2–5.0] $\log_{10}$ IU/ml) with a CSPH prevalence (HVPG ≥10 mmHg) of 62.7% were included. CSPH patients showed higher LSM (25.8 [17.2–31.0] vs. 14.0 [10.5–19.8] kPa; $p < 0.001$), VITRO (n = 31, 3.5 [2.7–4.5] vs. 1.3 [0.6–2.0] %/[G/L]; $p < 0.001$), and SSM (n = 20, 53.8 [41.7–75.5] vs. 24.0 [17.0–33.9] kPa; $p < 0.001$), as compared to patients without CSPH. The ANTICIPATE (0.885), 3P (0.903) and 5P (0.912) models yielded excellent AUC for CSPH. When applying the Baveno-VII criteria, CSPH could be ruled out (LSM <15 kPa and PLT >150 G/L) in 15.7% of patients with 100% sensitivity and ruled in (LSM ≥25 kPa) in 43.2% of patients with 84.2% specificity. The diagnostic 'grey zone' of Baveno-VII criteria (41.1%) could be significantly reduced whilst maintaining diagnostic accuracy when applying the previously proposed Baveno-VII-VITRO (final 'grey zone': 19.4%) and Baveno-VII-SSM (final 'grey zone': 15.0%) sequence, respectively.
Conclusion: NIT for CSPH show a high diagnostic accuracy in CHD-cACLD, thereby facilitating individualized surveillance for portal hypertension, prognostication and prioritization for novel antiviral treatment options against CHD.

SAT-118

Ongoing alcohol use after TIPS implantation is associated with increased rates of ACLF and liver related death among individuals with alcohol related ACLD

Caroline Schwarz[1,2], Andrea Kornfehl[1], Reema Abid[1], Theresa Müllner-Bucsics[1], Michael Schwarz[1], Benedikt Hofer[1], Nina Dominik[1], Benedikt Simbrunner[1], Mathias Jachs[1], Lukas Reider[1], Maria Schoder[1], Mattias Mandorfer[1], Michael Trauner[1], Thomas Reiberger[1], Lukas Hartl[1]. [1]*Medical University of Vienna, Vienna, Austria;* [2]*Klinik Ottakring, Vienna, Austria*
Email: thomas.reiberger@meduniwien.ac.at

Background and aims: Transjugular intrahepatic portosystemic shunt (TIPS) placement is the recommended treatment for severe complications of portal hypertension (PH). Alcohol-related liver disease (ALD) represents the most common cause of cirrhosis and PH, yet data on the effect of alcohol use (AU) after TIPS implantation remain scarce.
Method: Individuals with ALD cirrhosis undergoing TIPS implantation at two Viennese tertiary care centers were included with a pooled prospective cohort (AUTIPS study, NCT03409263: 01/2017 to 11/2022; n = 41) and retrospective cohort (09/2000 to 09/2019, n = 235). Demographic, laboratory, and clinical parameters (decompensation events; acute-on-chronic liver failure = ACLF; bacterial infections, mortality) were recorded. AU after TIPS implantation was determined by documentation of the treating physician and patients' reporting.

Results: A total of 276 patients with ALD cirrhosis receiving a TIPS were included in the study and followed for a median of 29 (IQR 54) months. Main indications for TIPS were bleeding in 80 (29.0%) of the patients and refractory ascites in 196 (71.0%). Two-hundred and fifteen (77.9%) were male, the median age was 56 (IQR 13) years, and 24 (8.7%) had coexisting viral hepatitis. At TIPS implantation (baseline, BL) the median MELD was 11 (IQR 9) and 38 (13.8%) were classified as Child-C. Overall, 85 (30.8%) of the study population reported AU after TIPS implantation. Baseline characteristics were similar between individuals with and without ongoing AU, including prevalence of ascites (p = 0.51), variceal bleeding (p = 0.87), encephalopathy (p = 0.87), and hepatocellular carcinoma (p = 0.54). Bacterial infections occurred more frequently in patients with post TIPS AU (log-rank p = 0.002). Importantly, patients with ongoing AU had a higher incidence of ACLF (log-rank p < 0.001) and had higher overall mortality (log-rank p = 0.005; including liver-related death [log-rank p < 0.001]). The cumulative incidence of ACLF (p = 0.014) and liver-related death (p = 0.004) was significantly higher in patients with ongoing AU. In multivariable competing risk analysis, adjusted for age, MELD and PPG after TIPS implantation, ongoing AU was independently associated with ACLF (asHR: 1.66; 95%CI: 1.13–2.44; p = 0.010) and liver-related death (asHR: 2.09; 95%CI: 1.32–3.33; p = 0.002).

Conclusion: Our data reveal an alarming deterioration in outcomes associated with ongoing AU after TIPS implantation as an independent risk factor. These findings underline the paramount role of harm reduction measures and linkage to psychiatric care to treat AU and promote abstinence in addition to optimized hepatologic treatment after TIPS implantation.

SAT-119

Frequency of chronic liver disease after chemotherapy for gastrointestinal tumors

Fernanda Sales[1], Liana Codes[2], Gabriel Nogueira[3], Beatriz Cunha[3], Vivianne Mello[4], Anelisa Coutinho[4], Paulo Bittencourt[5]. *[1]Bahina School of Medicine and Public Health, AMO Oncology Clinic, Salvador, Brazil; [2]Bahiana School of Medicine and Public Health, AMO Oncology Clinic, Salvador, Brazil; [3]Bahiana School of Medicine and Public Health, Salvador, Brazil; [4]AMO Oncology Clinic, Salvador, Brazil; [5]Bahiana School of Medicine and Public Health, Unit of Gastroenterology and Hepatology, Portuguese Hospital, Salvador, Bahia, Salvador, Brazil*
Email: nandaspmelo@gmail.com

Background and aims: Chronic liver disease (CLD) either due to steatosis, steatohepatitis or sinusoidal obstructive syndrome (SOS) has been increasingly reported in long-term survivors of gastrointestinal (GI) tumors treated with 5-fluorouracil (5-FU), irinotecan and/or oxaliplatin based chemotherapy. Cumulative prevalence of CLD in those patients, its major risk factors and liver-related outcomes remain largely unknown. The aim of this study is to investigate the frequency and risk factors for CLD in long-term survivors of GI tumors treated with chemotherapy as well as to assess their liver-related outcomes. Method: All patients with GI tumors older than 18 years admitted to AMO oncology clinic between January 2017 and January 2022 were retrospectively reviewed. Evaluation of CLD was carried out in all patients without prior evidence of CLD who survived more than 12 months after chemotherapy. The diagnosis of CLD was assumed in the presence of radiologic features of cirrhosis or portal hypertension by imaging, advanced fibrosis, or cirrhosis by histology or esophagogastric varices at GI endoscopy. In addition, vibration-controlled transient elastography (VCTE) was offered to all patients irrespective of CLD diagnosis.

Results: 328 patients (165 males, mean age: 64 ± 13 years) were studied. Most had colorectal cancer (58%) and grade III or IV (69, 6%) tumors by TNM staging system. They were treated with 15, 5 (8–28) cycles mainly with oxaliplatin (86%), 5-FU (76%), irinotecan (49%), capecitabin (43%). After a mean follow-up of 30, 5 (21–49) months, CLD was observed in 47 (14, 3%) subjects. 2% of patients developed decompensated cirrhosis due to ascites (n = 5) and hepatic encephalopathy (n = 1), but only one patient died due to end-stage liver disease. No difference in survival was observed in patients without CLD when compared to their counterparts with CLD (85, 7 [69–102] vs. 77, 0 [51–102] months in those with CLD, p = 0.385). Number of chemotherapeutic agents (4 [2–4] vs. 3 [3–4], p = 0, 002) and number of chemotherapy cycles (21 [12–37] vs. 13 [8–27]) of those patients without CLD, p = 0, 005) employed, exposure to 5-FU (89% vs. 73% of those patients without CLD, p = 0, 02) and irinotecan (66% vs. 46% of those patients without CLD, p = 0, 01) were significantly correlated to development of CLD, but only number of chemotherapy cycles was independently associated with CLD on multivariate analysis.

Conclusion: Evidence of CLD was observed in a considerable number of patients treated with chemotherapy due to GI tumors. Few developed either decompensation or liver-related mortality. Number of chemotherapy cycles was independently associated with CLD. Screening for CLD should be recommended for long-term survivors of GI tumors, particularly those previously exposed to several cycles of chemotherapy.

SAT-121

Point-of-care ultrasound of the inferior vena cava for intravascular volume assessment in patients with cirrhosis during intravenous albumin infusion

Daniel Segna[1], Pompilia Radu[1], Gerard Angeles Fite[1], Jaime Bosch[1,2], Annalisa Berzigotti[1,2]. *[1]Department of Visceral Surgery and Medicine, Hepatology, Inselspital, Bern University Hospital, Bern, Switzerland; [2]Department for BioMedical Research, Visceral Surgery and Medicine, University of Bern, Bern, Switzerland*
Email: daniel.segna@insel.ch

Background and aims: In patients with decompensated cirrhosis, current guidelines recommend intravenous (i.v.) albumin for different indications (i.e. large volume paracentesis; hepatorenal syndrome; spontaneous bacterial peritonitis). However, an increasing number of studies reported on iatrogenic volume overload related to albumin i.v. in this population. Point-of-care ultrasound (POCUS) of the inferior vena cava (IVC) is a non-invasive tool for monitoring intravascular volume status, but data in cirrhosis is scarce. Our aim is to explore the use of POCUS of the IVC for assessing changes in diameters and collapsibility reflecting intravascular volume status during passive leg raise (PLR) and its potential prediction of volume response after albumin i.v.

Method: In this prospective proof-of-concept study including 55 patients with decompensated cirrhosis and absent right heart failure requiring albumin i.v. for clinical indications, we assessed changes in minimal and maximal IVC diameters (IVC min, IVC max) and collapsibility (IVCCI) during an entire respiratory cycle during PLR and after albumin i.v. using POCUS (Venue Fit, GE Healthcare). We defined intravascular volume overload as IVC max >2.1 cm and IVCCI <20%.

Results: In our study population (78% male, median age 61 years, 53% alcohol-related cirrhosis, 57% Child-Pugh stage B, median model for end-stage liver disease score 16), 94% received albumin i.v. (median 40 g) following paracentesis (median 5.2 l ascites). We found a significant increase in IVC min and IVC max both during PLR (mean IVC min 9.5 to 11.2 cm, mean IVC max 14.1 to 16.1 cm, all p < 0.01) and after albumin i.v. (mean IVC min 9.8 to 14.9 cm, mean IVC max 14.0 to 20.4 cm, all p < 0.01). Moreover, we observed a significant decrease in IVCCI during PLR (mean IVCCI 33% to 31.3%, p < 0.01) and after albumin i.v. (mean IVCCI 31.2% to 27.1%, p < 0.01). After albumin i.v., changes in IVC min, IVC max, but not IVCCI, were significantly higher than during PLR. In multivariate regression models adjusting for age, sex and body mass index, only an increase in IVC min (p = 0.03), but not IVC max and IVCCI during PLR, was significantly associated with an increase in IVC min after albumin i.v. Intravascular volume overload significantly increased after albumin i.v. (3 patients at baseline vs. 11 patients after albumin i.v., p = 0.02).

Conclusion: Patients with decompensated cirrhosis showed significant increases in IVC diameters and decreases in IVCCI after albumin i.v., thereof 13% with intravascular volume overload. Changes in IVC max and IVCCI during PLR did not accurately predict the same parameters after albumin i.v., potentially related to variable extents of intra-abdominal pressure. However, increases in IVC min during PLR were found to correlate with corresponding increases after albumin i.v. The clinical use of POCUS of the IVC individualizing albumin i.v. should be further investigated.

SAT-122

Biomarkers of extracellular matrix remodelling are linked to portal hypertension and disease progression in patients with stable advanced chronic liver disease

Benedikt Simbrunner[1], Ida Falk Villesen[2], Lorenz Balcar[1], Georg Semmler[1], Lukas Hartl[1], Benedikt Hofer[1], Mathias Jachs[3], Michael Schwarz[1], Nina Dominik[1], Bernhard Scheiner[1], Rodrig Marculescu[4], Michael Trauner[1], Morten Karsdal[5], Thomas Reiberger[1], Diana Leeming[6], Mattias Mandorfer[1]. *[1]Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria; [2]Department of Gastroenterology and Hepatology, Center for Liver Research, Odense University Hospital, Odense, Odense, Denmark; [3]Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria; [4]Department of Laboratory Medicine, Medical University of Vienna, Austria, Vienna, Austria; [5]Nordic Bioscience, Hepatic and Pulmonary Research, Herlev, Denmark, Herlev, Denmark; [6]Nordic Bioscience, Hepatic and Pulmonary Research, Herlev, Denmark, Herlev, Denmark*
Email: benedikt.simbrunner@meduniwien.ac.at

Background and aims: Advanced liver fibrosis in advanced chronic liver disease (ACLD) results from excessive remodeling of the extracellular matrix (ECM) characterized by collagen deposition in the interstitial matrix (ISM) and basement membrane (BM). Accumulating liver fibrosis induces portal hypertension (PH), and promotes clinical complications. This study assessed collagen remodeling biomarkers and their relationship with PH and clinical outcome.
Method: Patients with stable ACLD (n = 232) undergoing hepatic venous pressure gradient (HVPG) measurement were included. Blood biomarkers reflecting collagen formation and degradation of the interstitial matrix (collagen III: PRO-C3, C3M; VI: PRO-C6, C6M) and basement membrane (collagen IV: PRO-C4, C4M; XVIII: PRO-C18L), as well as tissue inhibitor of metalloproteinases-1 (TIMP-1) were measured. Using Cox regression models the predictive value was assessed for the composite end point of first/further decompensation, acute-on-chronic liver failure, or liver-related death.
Results: The study cohort comprised 131 (57%) patients with decompensated ACLD (dACLD), median HVPG and MELD were 18 (13–21) mmHg (HVPG 6–9: n = 28, 10–19: n = 124, ≥20: n = 80) and 11 (9–14) points, respectively. Biomarkers of ISM and BM formation (PRO-C3 and PRO-C6: $p < 0.001$; PRO-C4: $p = 0.033$) significantly increased across HVPG strata, except for PRO-C18L ($p = 0.231$). Collagen degradation markers C3M and C4M also increased with HVPG ($p < 0.01$), while no difference was observed for C6M ($p = 0.542$). A relative increase of collagen III and VI formation (PRO-C3/C3M and PRO-C6/C6M ratios; i.e. ISM) but not collagen IV ratio ($p = 0.729$; i.e. BM) was associated with PH severity: 0.90 (0.58–1.14) vs. 1.34 (0.89–1.92) vs. 1.12 (0.73–2.04, $p < 0.001$) and 33.9 (22.5–39.8) vs. 45.3 (33.3–61.4) vs. 48.6 (32.6–64.0, $p < 0.001$) across HVPG groups. Notably, the ECM degradation inhibitor TIMP-1 was significantly linked to PRO-C3/C3M and PRO-C6/C6M ratios in linear regression models adjusted for HVPG and MELD (all $p < 0.001$), but not to PRO-C4/C4M ($p = 0.671$). Multivariate Cox regression models assessing the prognostic value of ECM biomarkers (median follow-up 28.9 months, IQR 12.0–43.6) for the composite end point were adjusted for established prognostic indicators. Next to HVPG and dACLD at baseline, PRO-C4 (aHR per 100 ng/ml: 1.12, 1.02–1.23, $p = 0.019$) and TIMP1 (aHR per 100 ng/ml: 1.20, 1.05–1.36, $p = 0.006$) remained independently linked to disease progression.
Conclusion: ECM remodeling biomarkers are closely linked to PH in patients with stable ACLD. While a net increase of ISM formation primarily corresponds with PH severity, BM formation markers were prognostic for disease progression independently from PH severity. These data indicate that distinct compartments of ECM remodeling and their individual pathophysiological and prognostic impact should be explored further.

SAT-123

Evaluation of portal hemodynamics after etiological factor removal and persistence of varices in patients with an HVPG <10 mmHg and NITs within the grey zone

Background and aims: Etiological factor removal (ER) drives recompensation and improves portal hypertension (PH) in cirrhosis. Non-invasive tests (NITs) effectively identify patients at both low and high risk of clinically significant Ph after viral elimination. However, a substantial grey zone persists. Interestingly, varices and portosystemic shunts (PPS) have been found in patients despite hepatic vein pressure gradient (HVPG) dropping below 10 mmHg after ER, questioning its accuracy in reflecting true portal pressure. The role of persistent presinusoidal vascular changes, resistant to regression, in potentially contributing to a pre-sinusoidal component of PH not captured by HVPG remains unclear. Our aim is to evaluate the correlation of HVPG with direct portal pressure in patients with persistence of varices after ER despite having an HVPG below 10 mmHg, and NITs in the grey zone and provide insights into the management of PH in cirrhosis regression.
Method: Bicentric "proof of concept" study in patients with HCV or alcohol-related cirrhosis with persistent varices, liver stiffness measurement (LSM) <25 kPa but >12 kPa and HVPG <10 mmHg after at least 5 years of ER. Evaluation of PH. Gastroscopy, LSM, spleen stiffness measurement (SSM), abdominal image, and simultaneous US-guided direct portal vein pressure and HVPG.
Results: 7 patients with HCV and 3 with alcohol-related cirrhosis were included. Median years of SVR and abstinence were 6 (5–7) and 14 (5–17) respectively. Before ER, all patients have varices and 3 were decompensated. At time of evaluation, all patients had a patent portal vein and were compensated. Median platelet counts were 129.5 (95–145) 10^9/ml, median SSM 35.1 (29.3–43.6) kPa, and median LSM 16.5 (14.4–22.3) kPa. In 7 patients, varices remained the same size despite ER (4 large and 3 small), and 3 downsized to small. Median HVPG was 7 (6–9) mmHg and median portal pressure gradient (PPG) 6 (5–8) mmHg. The correlation between wedge hepatic vein pressure and portal pressure was excellent (R 0.926 $p < 0.0001$). All patients had both PPG and HVPG below 10 mmHg.
Conclusion: In the context of ER and cirrhosis regression, varices may persist despite HVPG <10 mmHg. Due to its excellent correlation with direct portal pressure, HVPG is useful in identifying patients without PH despite the presence of varices. Whether these patients would require prophylaxis is unknown. Future studies with clinical end points are need to validate our findings.

SAT-124

Lower post-transjugular intrahepatic portosystemic shunt overt hepatic encephalopathy and mortality in patients with hepatic venous communication

Li Ma[1], Jingqin Ma[1], Yaozu Liu[1], Wen Zhang[1], Zhiping Yan[1], Jianjun Luo[1]. [1]Department of Interventional Radiology, Zhongshan Hospital, Fudan University, Shanghai, China, Shanghai, China
Email: luo.jianjun@zs-hospital.sh.cn

Background and aims: Intrahepatic venovenous shunt (IHVS) can result in underestimation of wedged hepatic venous pressure (WHVP), but its prognostic value remains unknown.
Method: The single-center data (2020–2022) of patients with sinusoidal portal hypertension (PHT) undergoing concurrent balloon-occluded hepatic venography and transjugular intrahepatic portosystemic shunt (TIPS) were retrospectively analyzed. The study hypothesized that patients with IHVS have less preexisting intrahepatic portal shunting.
Results: 131 patients (male/female: 94/37, mean age: 56.3 years) were eligible and classified by the presence (n = 49, 37.4%) or absence (n = 82, 62.6%) of IHVS. Model of end-stage liver disease score and blood ammonia were lower in IHVS group ($p < 0.001$). Agreement between WHVP and portal venous pressure (PVP) was poor in IHVS group (intraclass correlation coefficients [ICC]: 0.133, difference: 13.4 mmHg, $p < 0.001$), but almost perfect in non-IHVS group (ICC: 0.827, difference: 1 mmHg, $p = 0.005$). The WHVP/PVP ratio in non-IHVS group, reflecting total/functional portal perfusion, was negatively correlated with hepatic function and post-TIPS pressure reduction ($p < 0.05$). Within 1-year post-TIPS, IHVS group had a lower incidence of overt hepatic encephalopathy (HE) (12.4% vs. 32.0%, $p = 0.015$, HR: 0.35, 95% CI: 0.14–0.85) and an improved liver transplantation-free survival (98.0% vs. 87.8%, log-rank/Cox: $p = 0.046/0.081$, HR: 0.16, 95% CI: 0.02–1.25). The 1-year incidences of clinical relapse ($p = 0.767$), shunt dysfunction ($p = 0.916$), and survival ($p = 0.095$) were not significantly different between groups.
Conclusion: For patients with sinusoidal PHT treated with TIPS, IHVS was associated with a reduced risk of overt HE and a potential survival benefit. Abnormal hepatic venous communication should be well-identified to evaluate prognosis.

SAT-125

Comparison of endoscopic variceal ligation and endoscopic cyanoacrylate injection for the treatment of acute variceal bleeding from the cardia to the lesser curvature of the stomach

Yu-Fu Chen[1,2], Tsung-Chieh Yang[3,4,5], Ping-Han Hsieh[1,5], Yu-Jen Chen[6,7], Jiing-Chyuan Luo[5], Ming-Chih Hou[1,7,9]. [1]Therapeutic and Research Center of Liver Cirrhosis and Portal Hypertension, Taipei Veterans General Hospital, Taipei, Taiwan; [2]Division of Gastroenterology and Hepatology, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan; [3]Therapeutic and Research Center of Liver Cirrhosis and Portal Hypertension, Taipei Veterans General Hospital, Taipei, Taiwan; [4]School of Medicine, College of Medicine, National Yang Ming Chiao Tung Universit, Taipei, Taiwan; [5]Division of Gastroenterology and Hepatology, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan; [6]Therapeutic and Research Center of Liver Cirrhosis and Portal Hypertension, Taipei Veterans General Hospit, Taipei, Taiwan; [7]School of Medicine, College of Medicine, National Yang Ming Chiao Tung University, Taipei, Taiwan; [9]Division of Gastroenterology and Hepatology, Department of Medicine, Taipei Veterans General Hospital, Tapei, Taiwan
Email: tcyang@vghtpe.gov.tw

Background and aims: Practice guidelines endorse endoscopic variceal ligation (EVL) for the treatment of esophageal variceal bleeding and endoscopic cyanoacrylate injection (ECI) for the treatment of fundal variceal bleeding. However, the optimal treatment for acute variceal bleeding (AVB) from the cardia to the lesser curvature of the stomach is undefined. This study aims to compare the efficacy of EVL and ECI for the treatment of AVB from the cardia to the lesser curvature of the stomach. Varices extending for 0 to 2 cm below the gastroesophageal (GE) junction are defined as cardiac varices (CVs), and varices extending for 2 to 5 cm below the GE junction along the lesser curvature of the stomach are defined as type 1 gastroesophageal varices (GOV1 s).
Method: Patients with bleeding from CVs or GOV1 s who were treated by EVL or ECI at Taipei Veterans General Hospital were retrospectively evaluated. Clinical indicators, such as the presence of active spurting, active oozing, blood clots, or white nipple sign over CVs or GOV1 s were documented carefully during endoscopy. Outcomes including the cumulative incidences of six-week rebleeding and probability of six-week survival were compared between the EVL group and the ECI group by Kaplan-Meier method and log-rank test. Cox proportional hazards regression analysis was used to determine the indicators of six-week rebleeding and mortality. Subgroup analyses based on the bleeding location were performed.

Results: Between February 2006 and August 2023, a total of 97 patients (mean age 59 years, 71.1% male) were evaluated. Fifty-two and 45 patients were treated with EVL and ECI, respectively. Baseline characteristic were similar between the two groups. Both groups achieved high hemostasis rates with no significant differences regarding to five-day treatment failure rates ($p = 0.246$). No significant differences were noted between the two groups in terms of the cumulative incidences of six-week rebleeding ($p = 0.874$) and probability of six-week survival ($p = 0.715$). In multivariate analyses, ALT >40 U/L was the only independent predictor of six-week rebleeding (HR 5.281, 95% CI 1.066–26.172, $p = 0.042$), and Child-Pugh class C (HR 4.235, 95% CI 1.578–11.361, $p = 0.004$) as well as creatinine >1.3 mg/dL (HR 3.684, 95% CI 1.448–9.376, $p = 0.006$) were the independent predictors of six-week mortality. In subgroup analyses, the cumulative incidences of six-week rebleeding were lower in the EVL group than in the ECI group for bleeding from CVs ($p = 0.031$), but not for bleeding from GOV1 s ($p = 0.840$).
Conclusion: EVL and ECI offer similar efficacy for the treatment of AVB from the cardia to the lesser curvature of the stomach. Notably, EVL displays a lower six-week rebleeding rate then ECI for bleeding from CVs, but not for bleeding from GOV1 s.

SAT-126

Clinical Value of 4D Flow MRI in Assessing Varices Needing Treatment in Cirrhotic Patients with Portal Hypertension: A Prospective Study

Qian Zhang[1], Mingfeng Wu[2], Xinhua Luo[1], Hong Peng[1]. *[1]Guizhou Provincial People's Hospital, Guiyang, China; [2]Guizhou Provincial People's Hospital, Guiyang, China*
Email: 331610287@qq.com

Background and aims: Esophageal and gastric variceal (EGV) bleeding poses a critical threat in liver cirrhosis. Early identification of varices prone to hemorrhage is crucial for primary prevention, significantly reducing mortality rates. Non-invasive models for assessing portal hypertension are still evolving. 4D flow MRI, an advanced imaging technique, offers a comprehensive view of blood flow patterns and precise hemodynamic parameter quantification. Our study aims to fill this research gap, prospectively assessing the efficacy of 4D flow MRI in cirrhotic portal hypertension, validating its role as a non-invasive tool for risk stratification in this susceptible population.
Method: This study constitutes a cross-sectional analysis derived from our ongoing prospective cohort at Guizhou Provincial People's Hospital (Clinical Trial.gov: ChiCTR2300076380). We enrolled 85 participants, comprising 12 with compensated cirrhosis, 44 with decompensated cirrhosis, and 29 healthy volunteers. The study focuses on profiling portal circulation utilizing hemodynamic parameters obtained through 4D flow MRI.
Results: Comparing baseline characteristics between compensated and decompensated cirrhotic patients, we observed significant differences in sex, laboratory indicators, non-invasive markers, and endoscopic findings. 4D flow MRI enabled direct anatomic visualization of varices in 14 of 56 (25.0%) cirrhotic patients, with 13 (92.9%) of them having varices needing treatment (VNT). We conducted a quantitative analysis using 4D flow MRI and observed significant differences in portal vein fractional flow change (FFC), maximum pressure gradient, cross-sectional area, and wall shear stress for the portal vein, splenic vein, and superior mesenteric vein among the three groups ($p < 0.05$). In multivariable logistic regression models, portal vein's maximal pressure gradient, cross-sectional area, and FFC were independent predictors of VNT ($p < 0.05$). We constructed a 4D flow model model using the three mentioned indicators. The model had a sensitivity of 96.4%, negative predictive value of 95.7%, and negative likelihood ratio of 0.045, which avoided esophagogastroduodenoscopy (EGDs) comparable to the Baveno VII criteria (76.2% vs. 71.4%), while the missed VNT rate of the 4D flow model was lower than the Baveno VII criteria (3.6% vs. 14.3%).
Conclusion: Our initial findings suggest that FFC, portal vein maximum pressure gradient, and portal vein cross-sectional area measured through 4D flow MRI serve as valuable markers for stratifying esophagogastric varices in liver cirrhosis patients. The model built on these indicators demonstrates superior performance in identifying varices requiring treatment while minimizing unnecessary endoscopic examinations. Compared to the latest Baveno VII algorithm, our model shows improved efficacy and broader applicability.

SAT-128

Circulating fibronectin levels are linked to endothelial dysfunction, fibrogenesis, and portal hypertension in advanced chronic liver disease

Benedikt Simbrunner[1], Lorenz Balcar[1], Fabian Hammer[1], Benedikt Hofer[1], Georg Semmler[1], Mathias Jachs[1], Lukas Hartl[1], Nina Dominik[1], Philipp Schwabl[1], Rodrig Marculescu[2], Peter Quehenberger[3], Bernhard Scheiner[1], Michael Trauner[1], Mattias Mandorfer[1], Thomas Reiberger[1]. *[1]Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria; [2]Department of Laboratory Medicine, Medical University of Vienna, Austria, Vienna, Austria; [3]Department of Laboratory Medicine, Medical University of Vienna, Austria, Vienna*
Email: benedikt.simbrunner@meduniwien.ac.at

Background and aims: Fibronectin (FN) is considered an important mediator of extracellular matrix remodelling and angiogenesis in the context of liver fibrosis. FN also interacts with von Willebrand factor (VWF) and may thereby impact on the haemostatic equilibrium. We investigated the relationship between FN and portal hypertension (PH), hepatic dysfunction, and biomarkers reflecting liver fibrogenesis and endothelial dysfunction in patients with advanced chronic liver disease (ACLD).
Method: Patients with stable ACLD (n = 236) undergoing measurement of hepatic venous pressure gradient (HVPG) without active malignancies, intake of platelet inhibitors or antithrombotic medication were included. FN levels and biomarkers of extracellular matrix (ECM) remodelling (ELF score, including single components P3NP, TIMP1, HA), endothelial activation/dysfunction (VWF, factor VIII [FVIII]) were measured.
Results: The study cohort displayed a median HVPG of 17 (12–21) mmHg (HVPG 6–9: n = 37, 10–19: n = 118, ≥20: n = 81), median MELD was 11 (9–16), and 138 (58%) had decompensated ACLD. FN levels decreased across HVPG strata (median [IQR]: 38.5 [31–45.6] vs. 32.5 [25.2–41.8] vs. 29.5 [24.1–36.6] mg/dL; $p < 0.001$) and exhibited a significant negative correlation with MELD ($r = -0.521$, $p < 0.001$), VWF ($r = -0.232$; $p < 0.001$), ELF ($r = -0.207$; $p = 0.001$; particularly HA: $r = -0.322$; $p < 0.001$), but not with FVIII ($p = 0.082$). Multivariable linear regression models suggested an independent link between FN and biomarkers of endothelial dysfunction and ECM remodeling, since FN exhibited a positive coefficient to ELF ($\beta = 0.022$, $p < 0.001$) and to VWF ($\beta = 0.810$, $p = 0.067$) after adjusting for MELD and HVPG.
Conclusion: FN decreases in ACLD patients with severe PH and more pronounced hepatic dysfunction. Mechanistically, FN seems to be involved in ECM remodelling and endothelial dysfunction-as we observed a positive association after accounting for hepatic dysfunction and PH severity. Future studies should investigate the pathophysiological role of FN in liver fibrogenesis and sinusoidal dysfunction in ACLD.

SAT-129

Role of serum Mac-2 binding protein glycosylation isomer in identifying patients with chronic liver diseases at risk for portal hypertension-related complications

Kessarin Thanapirom[1,2,3], Pisit Tangkijvanich[4], Sirinporn Suksawatamnuay[1,2,3], Panarat Thaimai[1,2,3], Sakunkan Marnmana[1], Sombat Treeprasertsuk[1], Piyawat Komolmit[2,3,5]. *[1]Division of Gastroenterology, Department of Medicine, Faculty of Medicine, Chulalongkorn University and King Chulalongkorn Memorial Hospital, Bangkok, Thailand; [2]Center of Excellence in Liver Fibrosis and Cirrhosis, Chulalongkorn University, Bangkok, Thailand; [3]Excellence Center in Liver Diseases, King Chulalongkorn Memorial Hospital, Thai Red Cross Society, Bangkok, Thailand; [4]Center of Excellence in Hepatitis and Liver Cancer, Department of Biochemistry, Faculty of Medicine, Bangkok, Thailand; [5]Division of Gastroenterology, Department of Medicine, Faculty of Medicine, Chulalongkorn University and King Chulalongkorn Memorial Hospital, Bangkok, Thailand*
Email: kessarin.t@chula.ac.th

Background and aims: BAVENO VII consensus classifies portal hypertension (PHT) as compensated advanced chronic liver disease (cACLD) and clinically significant portal hypertension (CSPH) based on liver stiffness measurement (LSM) using transient elastography (TE). However, the availability of TE is still limited. The Mac-2 binding protein glycosylation isomer (M2BPGi) has emerged as a novel serum biomarker for liver fibrosis. This study aims to assess the association between serum M2BPGi, cACLD, and CSPH, as well as the role of M2BPGi in predicting liver decompensation (LD) during one-year follow-up.

Method: We prospectively enrolled patients with chronic liver diseases at Chulalongkorn University Hospital in Bangkok, Thailand, from June 2021 to October 2023. cACLD and CSPH are identified by LSM ≥10 kPa and ≥25 kPa, respectively. LD is characterized by the acute development of ascites, variceal bleeding, overt hepatic encephalopathy, or any combination of these complications.

Results: Overall, 376 patients were included, with 98 (26.1%) and 142 (37.8%) having cACLD and CSPH, respectively. At enrollment, 57 (15.2%) patients met the criteria of LD. Chronic liver diseases were caused by HBV (n = 114, 30.3%) and HCV (n = 77, 20.5%). M2BPGi levels were associated with the severity of PHT stages with a median of 0.79 (IQR: 0.41–1.34), 1.75 (IQR: 0.97–4.36), and 5.38 (IQR: 3.11–9.71) cutoff index (COI) in those with no cACLD, cACLD, and CSPH, respectively. The optimal M2BPGi cutoff for identifying cACLD was 1.71 COI (AUROC = 0.80, sensitivity 86%, specificity 74%) and 2.07 COI (AUROC 0.79, sensitivity 74.6%, specificity 83.6%) for CSPH. Patients with LD had higher M2BPGi than those without [6.95 (IQR: 4.17–11.56) vs 1.51 (IQR: 0.73–4.16) COI, p < 0.001]. At baseline, serum M2BPGi (OR = 1.13, 95%CI: 1.00–1.27, p = 0.04) and albumin (OR = 0.27, 95%CI: 0.13–0.56, p < 0.001) were independent factors associated with LD. During one-year follow-up, 21/319 (6.6%) patients without LD at baseline developed LD. Baseline serum M2BPGi (OR = 1.19, 95%CI: 1.07–1.32, p < 0.001) was associated with an increased risk of developing LD.

Conclusion: Serum M2BPGi is associated with stages of PHT and may be a potential serum biomarker for identifying risk for PHT-related complications in patients with chronic liver diseases.

SAT-130

Three-dimensional transjugular intrahepatic portosystemic shunt geometry predicts shunt dysfunction in decompensated liver cirrhosis

Markus Kimmann[1], Carsten Meyer[2], Sebastian Nowak[2], Alba Maria Paar Pérez[3], Jörn Arne Meier[1], Sara Noemi Reinartz Groba[1], Juliana Goediker[1], Torid Jacob[1], Feras Sanoubara[1], Karsten Wolter[2], Chang Johannes[3], Jonel Trebicka[1], Alois Martin Sprinkart[2], Michael Praktiknjo[1]. *[1]University Hospital Münster, Department of Internal Medicine B, Münster, Germany; [2]University Hospital Bonn, Department of Radiology, Bonn, Germany; [3]University Hospital Bonn, Department of Internal Medicine I, Bonn, Germany*
Email: markus.kimmann@googlemail.com

Background and aims: Patients with decompensated liver cirrhosis are at risk for complications of portal hypertension, especially refractory ascites or variceal bleeding. Transjugular intrahepatic portosystemic shunt (TIPS) is the most effective mean to reduce portal hypertension and treat these complications. However, development of TIPS dysfunction may lead to recurrence of these complications. This study investigated the prognostic value of three-dimensional (3D) TIPS geometry to predict TIPS dysfunction.

Method: We screened 330 patients undergoing TIPS insertion between 2014 and 2019 for this retrospective monocentric study. Overall, 108 patients could be included for the final analysis. Multiplanar reconstructions of computer tomography (CT) scans, which were performed after TIPS insertion, were used to investigate 3D TIPS geometry. Exclusion criteria were non-availability or insufficient quality of CT after TIPS insertion. Parameters of 3D TIPS geometry were calculated using a semi-automated algorithm. Additionally, angiograms were reviewed to determine two-dimensional (2D) geometric characteristics of the TIPS. Primary outcome was the development of TIPS dysfunction, which was defined by need for invasive TIPS revision. Uni- and multivariate Cox regression analysis with TIPS dysfunction as end point was performed to identify predictors for the development of TIPS dysfunction.

Results: Overall, 32 patients developed TIPS dysfunction and were compared to 76 patients without TIPS dysfunction. Both groups were comparable in regard of general characteristics (e.g., age, MELD and Child-Pugh Score). The median time from TIPS insertion to TIPS dysfunction was 539 days. In terms of 3D TIPS geometry parameters, a longer distance of the cranial stent end to the inferior vena cava (p < 0.001, hazard ratio 1.069, 95% confidence interval 1.039–1.101) and a more pronounced stent curvature (p = 0.001, hazard ratio 1.023, 95% confidence interval 1.009–1.037) were significantly associated with the development of TIPS dysfunction in a multivariate Cox regression analysis. Of note, none of the 2D TIPS geometry parameters was significantly associated with TIPS dysfunction in the univariate Cox regression analysis, while a distance of the cranial stent end to the inferior vena cava of more than one centimeter closely failed to reach statistical significance (p = 0.053, hazard ratio 2.333, 95% confidence interval 0.989–5.501).

Conclusion: This monocentric study demonstrates the prognostic value of 3D TIPS geometry using an algorithmic approach for the first time. Overall, a longer distance of the cranial stent end to the inferior vena cava as well as a more pronounced stent curvature could be identified as independent predictors of TIPS dysfunction.

SAT-131

End-procedural complete hemodynamic response may not be essential for the clinical success of tips in patients with cirrhosis

Davide Roccarina[1], Valentina Adotti[1], Martina Rosi[1], Dario Saltini[2], Marco Senzolo[3], Silvia Nardelli[4], Tomas Guasconi[5], Silvia Aspite[1], Stefano Gitto[1], Umberto Arena[1], Lara Biribin[6], Stefania Gioia[4], Federica Indulti[5], Claudia Campani[1], Patrizia Burra[6], Oliviero Riggio[4], Fabio Marra[7], Filippo Schepis[5], Francesco Vizzutti[1]. *[1]Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy; [2]Unit of Gastroenterology, Hepatic Hemodynamic Laboratory, Azienda Ospedaliero-Universitaria Policlinico di Modena and University of Modena and Reggio Emilia, Modena, Italy; [3]Gastroenterology, Multivisceral Transplant Unit, Department of Surgical and Gastroenterological Sciences, University of Padua, Padua; [4]Department of Translational and Precision Medicine, Sapienza University of Rome, Rome, Italy; [5]Division of Gastroenterology, Modena Hospital, University of Modena and Reggio Emilia, Modena, Italy; [6]Gastroenterology,*

Multivisceral Transplant Unit, Department of Surgical and Gastroenterological Sciences, University of Padua, Padua, Italy; [7]Department of Experimental and Clinical Medicine, University of Florence, Center for Research, High Education and Transfer DENOThe, University of Florence, Florence, Italy
Email: davideroccarina@gmail.com

Background and aims: Transjugular intrahepatic portosystemic shunt (TIPS) is a well-established treatment for variceal bleeding (VB) and refractory ascites (RA) in liver cirrhosis. Immediate post-TIPS complete haemodynamic response (CHR), defined as a post-TIPS porto-caval gradient (PCG) <12 mmHg in VB and RA, or 50% PCG reduction in VB, is used to define a treatment success. TIPS underdilation reduces post-derivative complications, although with this strategy CHR is not always achieved, raising concerns on control of PH complications and survival.
We compared ascites control, bleeding recurrence and mortality rate among patients achieving CHR or partial (PHR) haemodynamic response after TIPS.
Method: From the prospective Italian TIPS Registry (RI-TIPS), we retrospectively analysed a series of cirrhotic patients who consecutively received TIPS for RA or secondary prophylaxis of VB at four referral Italian Centers from 2007 to 2021.
Results: 415 patients with liver cirrhosis, median age 61 (15), 28% females were enrolled. TIPS was indicated in 51% for VB and in 49% for RA. Fifty-percent received underdilated TIPS (<8 mm). Overall, a CHR was achieved in 65%, with a median post-TIPS PCG of 8 (4) mmHg and a median percentage of PGC reduction of 60 (19)%. In PHR, post-TIPS PCG was 15 (4) mmHg while percentage of PGC reduction was 36 (14)%. Non-significant differences were observed in rebleeding rate (5% vs 4%, p = 0.73, in CHR vs PHR, respectively). On binary logistic regression, stent dysfunction was the only predictor of rebleeding. The grade of ascites or the need for large volume paracentesis at 3, 6, 12 months did not significantly differ (p = 0.76, 0.77, 0.86, respectively) between CHR and PHR. The median overall survival was 24 (34) months. Regardless of TIPS indication, survival as well as cumulative incidence of mortality were not significant different between CHR and PHR accounting for liver transplantation as a competing risk event. Advanced age and disease severity before TIPS turned out to be predictors of mortality.
Conclusion: CHR immediately after TIPS may not be essential to define the clinical success, with a substantial reduction in PCG exerting a pivotal role. Further studies are needed to identify a minimal threshold for PCG reduction.

SAT-134

Paired assessment of the hepatic venous pressure gradient with the push-wedge versus balloon-occlusion technique: impact of intrahepatic collaterals

Naomi Gestels[1], Wilhelmus Kwanten[1,2], Jolien Derdeyn[1], Toon Steinhauser[1], Luisa Vonghia[1,2], Sven Francque[1,2], Thomas Vanwolleghem[1,2]. *[1]Antwerp University Hospital, Edegem, Belgium; [2]Laboratory of Experimental Medicine and Paediatrics (LEMP), Antwerp, Belgium*
Email: naomi.gestels@uza.be

Background and aims: Two methods exist for hepatic venous pressure gradient (HVPG) assessment: the balloon-occlusion and push-wedge technique, but little information exists on comparability and influencing factors of both methods to assess portal hypertension (PHT).
We performed a pairwise comparison of the push wedge versus occlusion balloon technique and examined influencing factors of discordance.
Method: Clinical, biochemical, histological data and haemodynamic measurements were analysed for consecutive transjugular HVPG measurements between January 2018 and October 2023. Included variables were: 1) liver histology, on simultaneous transjugular biopsies; 2) MELD and Child-Pugh score; and 3) presence of intrahepatic or extrahepatic collaterals on imaging. HVPG with both occlusion balloon and end-hole catheter were compared. A pressure difference of ≥2 mmHg ("disagreement") between the methods was considered clinically relevant. A separate analysis stratified patients as having PHT (HVPG >5 mm Hg) or clinically significant PHT (CSPH, HVPG ≥10 mm Hg), according to the technique.
Results: From 725 cases, 274 had a paired measurement and a complete dataset for analyses; 159 (57.6%) were male, mean age was 56.1 ± 12.9 years (SD); and 182 (66.4%) had advanced fibrosis (F3-F4). Most common aetiologies were alcohol-related liver disease (34.3%) and metabolic dysfunction-associated steatotic liver disease (29.9%). Intra- and extrahepatic collaterals were observed in 13.5% and 30.3% of cases respectively. Mean HVPG was 11.01 mmHg ± 6.63 and 11.13 mmHg ± 6.67 for the occlusion-balloon and push wedge technique respectively (ns). Disagreement was observed in 80 cases (29.2%) independent of the liver disease aetiology (Chi-Square 0.37), but significantly more in case of intrahepatic collaterals (Kruskal-Wallis p 0.019). Intrahepatic collaterals were observed in 37 cases; HVPG disagreement was found in 16/37 (43.2%). In case of HVPG disagreement in presence of collaterals a clear pattern was noted: in 11/16 the push wedge technique yielded the highest HVPG value whilst in 5/16 it was the opposite (Kruskall Wallis p < 0.01). Discordance was not related to the severity of liver disease (Child-Pugh) or MELD in the subgroup of patients with advanced fibrosis. The PHT classification changed according to the applied technique in 32/274 (11.7%) of cases: 15/274 (5.5%) were discordantly classified concerning presence or absence of PHT, whereas 17/274 (6.2%) were differently classified regarding CSPH. When restricted to those with a disagreement between techniques, 19/80 cases (23.8%) were differently classified.
Conclusion: Occlusion balloon and push wedge technique yield comparable HVPG measurements in most patients (70.1%). In case of intrahepatic collaterals discordance occurred more frequently. We suggest using the push wedge technique when intrahepatic collaterals are found.

SAT-135

Soluble urokinase plasminogen activator receptor (suPAR) levels predict survival in patients with portal hypertension undergoing TIPS

Sven H. Loosen[1], Fabian Benz[2], Raphael Mohr[2], Philipp Reuken[3], Theresa Hildegard Wirtz[4], Wenyi Gu[5], Lioba Junker[4], Christian Jansen[6], Carsten Meyer[7], Michael Praktiknjo[5], Alexander Wree[2], Johanna Reissing[4], Münevver Demir[2], Mihael Vucur[8], Robert Schierwagen[5], Andreas Stallmach[3], Anselm Kunstein[8], Johannes Bode[8], Christian Trautwein[4], Frank Tacke[2], Tom Luedde[8], Tony Bruns[4], Jonel Trebicka[5], Christoph Roderburg[8]. *[1]Department of Gastroenterology, Hepatology and Infectious Diseases, University Hospital Düsseldorf, Medical Faculty of Heinrich Heine University Düsseldorf, Düsseldorf, Germany; [2]Department of Gastroenterology and Hepatology, Campus Virchow Klinikum and Campus Charité Mitte, Charité Universitätsmedizin Berlin, 13353 Berlin, Germany, Berlin, Germany; [3]Department of Internal Medicine IV, Jena University Hospital, Am Klinikum 1, 07747 Jena, Germany, Jena, Germany; [4]Department of Medicine III, University Hospital RWTH Aachen, Pauwelsstrasse 30, 52074 Aachen, Germany, Aachen, Germany; [5]Department of Internal Medicine B, University of Münster, Münster, Germany, Münster, Germany; [6]Department of Internal Medicine I, University Clinic Bonn, Bonn, Germany, Bonn, Germany; [7]Department of Radiology, University Clinic Bonn, Bonn, Germany, Bonn, Germany; [8]Department of Gastroenterology, Hepatology and Infectious Diseases, University Hospital Düsseldorf, Medical Faculty of Heinrich Heine University Düsseldorf, 40225 Düsseldorf, Germany, Düsseldorf, Germany*
Email: Sven.Loosen@med.uni-duesseldorf.de

Background and aims: Transjugular intrahepatic portosystemic shunt (TIPS) is the most effective therapy for complications of

portal hypertension. However, clinical outcomes following TIPS placement vary widely between patients and identifying ideal candidates remains a challenge. Soluble urokinase plasminogen activator receptor (suPAR) is a circulating marker of immune activation that has previously been associated with liver inflammation, but its prognostic value in patients receiving TIPS is unknown. In the present study, we evaluated the potential clinical relevance of suPAR levels in patients undergoing TIPS insertion.
Method: suPAR concentrations were measured by enzyme-linked immunosorbent assay (ELISA) in hepatic vein (HV) and portal vein (PV) blood samples from 99 patients (training cohort), as well as peripheral venous blood samples from additional 150 patients (validation cohort) undergoing TIPS placement. The association between suPAR levels and patients' outcome was assessed using Kaplan-Meier methods and Cox-regression analyses.
Results: suPAR concentrations were significantly higher in HV samples compared to PV samples and correlated with the presence of ascites, renal injury, and consequently with the Child-Pugh and MELD scores. Patients with higher suPAR levels had a significantly worse short- and long-term survival after TIPS insertion, which remained robust after adjustment for confounders in multivariate Cox-regression analyses. Sensitivity analysis showed an improvement in risk prediction in patients stratified by Child-Pugh or MELD score. In an independent validation cohort, higher levels of suPAR predicted poor transplant-free and overall survival after TIPS, particularly in patients with Child-Pugh A/B cirrhosis.
Conclusion: suPAR seems to largely derive from the injured liver and its levels may predict of outcome in patients undergoing TIPS. suPAR, as a surrogate of hepatic inflammation, may be used to stratify care in patients undergoing TIPS insertion.

SAT-136

The modified child-turcotte-pugh score based on plasma ammonia to predict survival in patients with cirrhosis after transjugular intrahepatic portosystemic shunt: a multicenter validation

Binlin Da[1], Wei Wu[2], Wuhua Guo[3], Kai Xiong[4], Chao Cheng[5], Qiao Ke[3], Moran Zhang[4], Taishun Li[1], Jiangqiang Xiao[1], Lei Wang[1], Ming Zhang[1], Feng Zhang[1], Yuzheng Zhuge[1]. *[1]Nanjing Drum Tower Hospital Clinical College of Nanjing Medical University, Nanjing, China; [2]The First Affiliated Hospital of Wenzhou Medical University, Wenzhou, China; [3]Mengchao Hepatobiliary Hospital of Fujian Medical University, Fuzhou, China; [4]The Second Affiliated Hospital of Nanchang University, Nanchang, China; [5]The First Affiliated Hospital of Wenzhou Medical University, Wenzhou, China*
Email: yuzheng9111963@aliyun.com

Background and aims: The modified Child-Turcotte-Pugh score based on plasma ammonia (aCTP) score was created to predict survival for patients with decompensated cirrhosis. Aims: The aim of this study was to perform the first external validation of the aCTP score and compare it with other risk scoring systems to predict survival in patients with cirrhosis after transjugular intrahepatic portosystemic shunt (TIPS) placement.
Method: We retrospectively reviewed 473 patients from three cohorts between January 2016 and June 2022 and compared the aCTP score with the Child-Turcotte-Pugh (CTP) score, albumin-bilirubin (ALBI), model for end-stage liver disease (MELD) and sodium MELD (MELD-Na) in predicting transplant-free survival by the concordance index (C-index), area under the receiver operating characteristic curve (AUROC), calibration plot, and decision curve analysis (DCA).
Results: The median follow-up time of the cohort was 29 months, during which a total of 62 (20.74%) patients died or underwent liver transplantation (LT). The survival curves for the three aCTP grades differed significantly. Patients with aCTP grade C had a shorter expected lifespan than patients with aCTP grades A and B ($p < 0{\cdot}0001$). The aCTP score showed the best discriminative performance using the C-index compared with other scores at each time point during follow-up, it also showed better calibration in the calibration plot and the lowest Brier scores, and it also showed a higher net benefit than the other scores in the DCA curve.
Conclusion: The aCTP score outperformed the other risk scores in predicting survival after TIPS placement in patients with cirrhosis and may be useful for risk stratification and survival prediction.

SAT-137

Multivariable models for prediction of decompensation in compensated advanced chronic liver disease often lack external validation and measures of calibration

Vincent Haghnejad[1,2], Laura Burke[3], Richard Parker[4], Ian Rowe[2]. *[1]Department of hepatology and gastroenterology, University Hospital of Nancy, University of Lorraine, INSERM UMR_S 1256, Nutrition, Genetics, and Environmental Risk Exposure (NGERE), Faculty of Medicine of Nancy, Nancy, France; [2]Leeds Institute for Medical Research, University of Leeds, Leeds, United Kingdom; [3]Leeds Liver Unit, Leeds Teaching Hospitals NHS Trust, Leeds Institute for Medical Research, University of Leeds, Leeds, United Kingdom; [4]Leeds Teaching Hospitals NHS Trust, St. James's University Hospital, Leeds, United Kingdom*
Email: v.haghnejad@chru-nancy.fr

Background and aims: Prediction of decompensation in persons with compensated advanced chronic liver disease (cACLD) provides opportunities to personalise therapy. Prediction of decompensation is however challenging and multiple predictive models have been developed. The aim of this study was to systematically identify, collate, and critically appraise the performance of published multivariable models for the prediction of decompensation in patients with cACLD or compensated cirrhosis.
Method: From inception to November 2023, MEDLINE and EMBASE databases were searched for studies deriving and/or validating prediction models for the development of decompensation. The study was registered on PROSPERO (CRD42023488395) done according to the Checklist for critical Appraisal and data extraction for systematic Reviews of prediction Modelling Studies (CHARMS).
Results: We included 17 retrospective and 3 prospective studies. 9 studies were focused on a single aetiology, most commonly MASLD and HCV. There was no study describing a model specifically predicting outcomes in persons with alcohol-related liver disease. Outcome definition was heterogeneous across studies with 6 models predicting hepatocellular carcinoma together with decompensation. In total, 29 predictors of decompensation were included in the models assessed. The most frequent predictors were albumin, platelets, age, liver stiffness, bilirubin, MELD score, the presence of esophageal varices, and international normalized ratio. 7 predictors were non-standard analytes. Only 2 studies included an a priori power calculation to guide predictor selection. All studies reported discrimination measures, such as area under the curve (AUC), yet only 11/20 had any evaluation of calibration. External validation was done in 10/20 studies.
Conclusion: For clinical utility a predictive model must accurately describe future risks. Models developed for the prediction of decompensation in persons with cACLD are often poorly described and lack external validation. The inclusion of non-standard analytes and parameters limits opportunities for independent external validation and clinical applicability. Future model development should focus on the context in which models will be used, incorporation of routinely measured parameters, and ensuring that model performance is appropriately reported.

Dual alpha-v/beta-6 and alpha-v/beta-1 integrin inhibitor bexotegrast targets TGF-beta inhibition to specific cell types in human liver explant tissue with biliary fibrosis

Johanna Schaub[1], Richard Ahn[1], Chris Her[1], Steve Ho[1], Vikram Rao[1], Jessie Lau[1], Mahru An[1], Jennifer Yuzon[1], Scott Turner[1], Martin Decaris[1]. [1]*Pliant Therapeutics, South San Francisco, United States*
Email: jschaub@pliantrx.com

Background and aims: TGF-beta is a master regulator of fibrotic disease, however systemic inhibition of TGF-beta signaling has limited therapeutic utility due to the pleiotropic nature of TGF-beta in regulating homeostatic cellular pathways. Bexotegrast (PLN-74809) is a dual inhibitor of the TGF-beta-activating integrins alpha-v/beta-6 (expressed by injured cholangiocytes) and alpha-v/beta-1 (expressed by myofibroblasts) currently in clinical development for the treatment of primary sclerosing cholangitis (PSC). The aim of this study was to combine 10× single nuclei RNA sequencing with the precision-cut liver slice (PCLivS) platform to test the hypothesis that bexotegrast targets reduction of TGF-beta signaling to specific liver cell types in biliary fibrosis.
Method: Liver explants were collected from patients with PSC (n = 3) and primary biliary cholangitis (n = 1) at the time of transplant. PCLivS were generated and cultured for 2 days with bexotegrast, TGF-beta receptor I kinase inhibitor (ALK5i, R-268712), or vehicle. Nuclei were isolated and processed for single nuclear barcoding using 10× Chromium Next GEM 3′ HT kits. Resulting libraries were sequenced, processed using CellRanger, and analyzed using Seurat. Custom annotation of cell types was performed using gene markers from published data sets. Differentially expressed genes (DEGs) were determined using a non-parametric Wilcoxon rank sum test and defined as genes with absolute log2 fold-change ≥0.5 and an FDR ≤0.05.
Results: Differential gene expression analysis of PCLivS from explants with biliary fibrosis revealed a strong overlap in the pharmacodynamic effects of bexotegrast and ALK5i in key pathologic cell types. A similar number of DEGs and similar pathways (e.g. extracellular matrix organization) were downregulated in myofibroblasts (124 vs 153 DEGs), cholangiocytes (71 vs 56 DEGs), and scar-associated endothelial cells (183 vs 227 DEGs) following treatment with bexotegrast or ALK5i, respectively. In contrast, bexotegrast treatment induced fewer gene expression changes in immune cell types than ALK5i. Notably, effects of bexotegrast differed from ALK5i in B cells (27 vs 317 total DEGs) and Kupffer cells (149 vs 415 total DEGs). Pathway enrichment analysis identified interferon signaling (B cells) and immune system (B cells and Kupffer cells) as pathways altered by ALK5i, consistent with the immunomodulatory role of TGF-beta.
Conclusion: Dual alpha-v/beta-6 and alpha-v/beta-1 integrin inhibition with bexotegrast showed clear differences from ALK5 inhibition in PCLivS from human liver explants with biliary fibrosis, targeting reduction of TGF-beta signaling pathways to fibrogenic cell populations. These findings provide valuable insight into the mechanism of action of bexotegrast and demonstrate the utility of this approach for distinguishing the cell-specific effects of anti-fibrotic therapies.

Proteomics analysis of liver fibrosis reveals Fibulin-3 as a new regulator of hepatic stellate cells

Célia Thomas[1], Dominique Bonnier[2], Vincent Legagneux[2], Nathalie Théret[2]. [1]*Univ Rennes, Inserm, EHESP, Irset (Institut de recherche en santé, environnement et travail)-UMR_S1085, Rennes, France;* [2]*Univ Rennes, Inserm, EHESP, Irset (Institut de recherche en santé, environnement et travail)-UMR_S 1085, Rennes, France*
Email: celia.thomas@univ-rennes.fr

Background and aims: Chronic liver diseases (CLD) are associated with the development of liver fibrosis, characterized by excessive accumulation of extracellular matrix (ECM). This fibrotic microenvironment affects tissue homeostasis and favors initiation and progression of hepatocellular carcinoma (HCC). During liver injury, hepatic stellate cells (HSCs) are activated and differentiate into myofibroblasts that secrete ECM components, therefore contributing to fibrosis. The present study aimed to identify and investigate new proteins involved in the remodeling of the hepatic microenvironment in order to decipher the mechanisms of CLD progression.
Method: A proteomics screening was conducted using ECM-enriched samples from adjacent non-tumor tissues from 20 patients with HCC and data were compared to the matrisome signature (Naba et al., 2015). Analyses of Fibulins mRNA expression were performed in cultured human hepatocytes (HHs) and HSCs using RT-qPCR. The expression of Fibulin-2 and -3 was silenced using RNA interference in the human HSC-derived cell line, LX-2. Protein extracts were analyzed using Western Blot. Phenotypic changes were assessed by immunofluorescence studies using Phalloidin for actin fibers and Paxillin antibody for focal adhesions. Cell migration and spreading were evaluated using transwell assay and xCELLigence real-time cell analysis, respectively. Integrative analyses of protein-protein interaction (PPI) networks were performed using PSICQUIC web service from EMBL-EBI database (Aranda et al., 2011).
Results: Proteomics analyses of human fibrotic liver tissues identified three members of the Fibulin family, Fibulin-2, -3 and -5, associated with fibrosis progression. mRNA analyses from cultured hepatic cells revealed that these Fibulins are highly expressed in cultured HSCs compared to HHs. We showed that LX-2 cell line express Fibulin-2 and -3 while Fibulin-5 is only detected after TGF-β stimulation. Upon silencing, we observed smaller, less spread-out cells with shorter cell body extensions in Fibulin-3 but not Fibulin-2 depleted cells. These cells displayed a disorganized cytoskeleton network and smaller nuclei indicating that less tensions are exerted through the stress fibers. Silencing Fibulin-3 also affects cell spreading and migration. Consistently, both focal adhesions and the activity of the focal adhesion-associated protein kinase, FAK, are impaired in Fibulin-3 depleted cells. In line with the differential effects of Fibulin-2 and -3 silencing, PPI networks demonstrated that Fibulin-2, -3 and -5 have different binding partners, suggesting involvement in different biological processes.
Conclusion: While Fibulin-2, -3 and -5 are all upregulated in liver fibrosis, our study suggest that Fibulin-3 plays an important role in regulating contact of HSC with the microenvironment.

THU-523

Single cell resolution of hepatic heterogeneity in liver fibrosis progression and regression

Le Thi Thanh Thuy[1], Pham Minh Duc[2], Hoang Hai[2], Nguyen Thi Ha[2], Norifumi Kawada[2]. [1]*Department of Global Education and Medical Sciences, Graduate School of Medicine, Osaka Metropolitan University, Department of Hepatology, Graduate School of Medicine, Osaka Metropolitan University, Osaka, Japan;* [2]*Department of Hepatology, Graduate School of Medicine, Osaka Metropolitan University, Osaka, Japan*
Email: kawadanori@omu.ac.jp

Background and aims: Single Cell Fixed RNA Profiling (FRP) is a novel technology that measures RNA expression in single cells from frozen tissues fixed with formaldehyde, using probes targeting the whole transcriptomes. Here we applied this novel technology in the murine model of advanced liver fibrosis progression and regression to discover novel targets for anti-fibrosis therapy.
Method: scRNA-seq was performed on primary cells isolated from frozen mouse liver tissues of the age-matched control, 10 weeks TAA-induced liver fibrosis group, and 2 weeks recovery after TAA injection group (n = 3, each group) using the 10X Genomics Chromium platform. Computational analysis was performed in R.
Results: Integration and annotation of liver cells from control, fibrosis, and recovery revealed 10 cell types. Reclustering of Hepatocytes identified 20 subpopulations. Two main phenotypes in liver fibrosis were pericentral apoptotic and periportal proliferation hepatocytes. The fibrosis recovery generated a specific hepatocytes subcluster associated with antioxidant pathways by gene set enrichment analysis and exposed marked increased genes such as Cat, Gpx1, Sod1, Adh1, Gsta3. Reclustering of hepatic stellate cells (HSCs) identified 13 subpopulations. The fibrotic livers had 3 distinct subclusters, including one representing fibrogenic myofibroblast, and two intermediate-activated subclusters. Recovery of liver fibrosis revealed two specific HSCs subsclusters, both reduced expression of fibrogenic markers, and restored expression of quiescence markers, whereas upregulated unique markers including Agtr1a, Ehd3, Cadm3, Gpx3, Emp1, and Fmo2. Receptor-ligand interaction analysis between Hepatocytes and HSCs by CellChat revealed significantly upregulated interaction pairs including Vitronectin Vtn- (Itga8+Itgb1), Fn1- (Itga8 +Itgb1), Gdf15-Tgfbr2, Igf1- (Itga6+Itgb4), and Agt-Agtr1a.
Conclusion: Hepatocytes and HSCs in liver fibrosis progression and regression exposed cellular heterogeneity and their interaction play important role in both liver fibrosis progression and regression. Regulating receptor-ligands interactions could be potential targets for anti-fibrosis therapy.

THU-524-YI
Single-cell atlas reveals conserved HSC activation process and therapeutic opportunities

Vincent Merens[1], Vincent De Smet[1], Stefaan Verhulst[1], Leo van Grunsven[1]. [1]*Vrije Universiteit Brussel, Brussels, Belgium*
Email: vincent.merens@gmail.com

Background and aims: Chronic liver diseases are a major cause of death globally. Hepatic stellate cells (HSC) will produce most of the excessive scar-tissue that disrupts the liver function. Although HSCs have been extensively investigated in the past decades, we do not know if their activation process from quiescent HSC to a scar-tissue producing cell is similar in different liver disease settings. In this project, we pool recently generated single-cell RNA-sequencing (scRNA-Seq) datasets containing HSCs in different injury settings to investigate what ligands and transcription factors drive HSC activation in different injury settings.
Method: 10 different mouse scRNA-Seq datasets, representing 7 different liver injuries, were integrated to create the mouse HSC activation atlas. Similarly, 3 different human scRNA-Seq datasets were integrated consisting of varying chronic liver diseases. Comparison of ligands and transcription factors inducing HSC activation was done using the Seurat, pySCENIC, Slingshot and NicheNet packages in R and Python. Plasma levels of COLEC10 were assessed with ELISA. Parathyroid hormone induced HSC activation was assessed in primary mouse HSC-hepatocyte cultures with qPCR for fibrosis related genes and sirius red stainings for scar tissue formation.
Results: We found that in all investigated liver injuries, HSCs can be divided into 3 subtypes: quiescent HSCs, initiatory HSCs and myofibroblasts. The genesets and transcription factors defining these subtypes are conserved between liver injuries in mice and men: *Rxra*, *Nr1h4* and *Foxf1* for quiescent HSCs, *Fosl1*, *Egr3* and *Nfkb2* drive the initiatory phenotype while *Wt1*, *Prrx1* and *Mef2c* drive the myofibroblast phenotype. The ligands inducing this activation process are conserved as well, with TGFB1, SPP1 and EGF being the top predicted ligands inducing activation in almost all liver injuries. Additionally, we identified parathyroid hormone as a novel HSC activating ligand and validated its profibrotic effect in primary mouse HSCs-hepatocyte spheroid cultures. Finally, we identified COLEC10 as a gene that is almost exclusively expressed by quiescent HSCs in mice and humans. Strikingly, plasma levels of COLEC10 are correlated with the fibrosis stage of chronic liver disease patients and outperforms FIB-4 and APRI to predict the fibrosis stage.
Conclusion: We generated a mouse and human single cell HSC activation atlas and show that HSC activation is a very conserved process between different species and liver injuries, and is driven by a limited set of ligands and transcription factors across 3 conserved HSC stages. Additionally, we validate the use of COLEC10 as a biomarker for fibrosis as well as the profibrotic effect of a novel ligand, parathyroid hormone. Finally, we provide a user-friendly explorable versions of both the human and mouse HSC atlas through https://livr.research.vub.be/rnaseq-projects.

THU-525-YI
Temporal and spatial development of cholestasis induced liver injury

Jonas Øgaard[1,2], Kathrine Sivertsen Nordhus[1,2,3], Markus S. Jördens[1,2,3,4], Brian K. Chung[1,2,3], Espen Melum[1,2,3,5,6]. Email: jonas.ogaard@medisin.uio.no

Background and aims: Cholestasis is a hallmark of liver diseases, resulting from a functional impairment of bile formation or mechanical obstruction of bile-flow through the bile ducts. Several animal models of this phenotype using either chemical or surgical interventions exist. Here we used the well described bile-duct ligation (BDL) model as this allows us isolate the biophysical consequences of bile duct obstruction which is commonly seen in primary sclerosing cholangitis, cholangiocarcinoma, and primary biliary cholangitis without being biased by the disease process itself. To assess the transcriptomic and cellular feature to an unprecedented temporal and spatial granularity we used high dimensional transcriptomic data along with spatial barcoding to track changes in different morphological compartments.
Method: C56Bl/6 mice underwent BDL or sham surgery and were sacrificed at 6 timepoints to capture transcriptomic events during the acute phase (4 h, 8 h, 24 h), as well as the recovery phase (3 d, 5 d, 7 d). Liver samples were snap frozen and processed for spatial transcriptomics using 10X Visium technology. The sequencing data was adjusted, normalized and finally spatially and cellularly deconvoluted using CARD, to generate a spatiotemporal map of cellular identities.
Results: Based on the transcriptomic data we clearly observed liver zonation and differential disease characteristics in periportal vs perivenous zones in a temporal manner. The CARD deconvolution predicted presence of hepatocytes matching the observed morphology and reduced abundance of hepatocytes was seen periportally. Known markers for liver disease activity were altered both spatially and temporally with *Alb* ($P_{adj} = 4.3 \times 10^{-9}$) and *Acta2* ($P_{adj} = 0.02$) exhibiting a zonated pattern, whereas *Ptprc* ($P_{adj} = 0.034$), *Timp1* (P_{adj}

= 0.04), *Acta2* (P_{adj} = 0.015) and *Mki67* (P_{adj} = 0.011) showed chronological modulations. Notably, *Ptprc* expression was dampened during the acute phase (fold-change (FC) = 0.51 to sham), while increased during the recovery phase (FC = 1.23), while *Timp1, Acta2* displayed an increasing, monotonic development over time.
Conclusion: Herein we have developed a spatiotemporal map of cellular and molecular development of cholestatic fibrosis during the extended acute phase. By integrating the spatial and temporal dimensions of this model condition, we have identified changes in key factors to a granularity no achievable using traditional technologies that can be of key relevance for developing novel treatment approaches targeting these pathways. Specifically, we demonstrate that molecular disease development in the BDL-model aligns with morphological and chronological expectations. The current results demonstrate the potential of dissecting cholestatic damage in 4 dimensions, giving promise to further investigate cholestasis despite challenges posed by morphological heterogeneity.

THU-526

The hepatoprotective role of ECM1: inhibition of mediators of latent TGF-β1 activation and implications for anti-fibrotic treatment strategies in chronic liver disease

Frederik Link[1], Yujia Li[1], Jieling Zhao[2,3], Stefan Munker[4,5], Weiguo Fan[6], Zeribe Nwosu[7], Ye Yao[8], Seddik Hammad[8], Peter ten Dijke[9], Matthias Ebert[1,10,11], Roman Liebe[12], Honglei Weng[8], Dirk Drasdo[2,3], Steven Dooley[8], Sai Wang[8]. *[1]University Medical Center Mannheim, Medical Faculty Mannheim, Heidelberg University, Department of Medicine II, Mannheim, Germany; [2]INRIA, Paris, France; [3]IfADo, Dortmund, Germany; [4]Department of Medicine II, University Hospital, LMU, Munich, Germany; [5]Liver Center Munich, University Hospital, LMU, Munich; [6]School of Medicine, Stanford University, Palo Alto, United States; [7]Department of Molecular Biology and Genetics, Cornell University, Ithaca, NY, United States; [8]Department of Medicine II, University Medical Center Mannheim, Medical Faculty Mannheim, Heidelberg University, Mannheim, Germany; [9]Oncode Institute and Department of Cell and Chemical Biology, Leiden, Netherlands; [10]DKFZ-Hector Cancer Institute at the University Medical Center Mannheim, Mannheim, Germany; [11]Molecular Medicine Partnership Unit, European Molecular Biology Laboratory, Heidelberg, Germany; [12]Clinic of Gastroenterology, Hepatology and Infectious Diseases, Otto-von-Guericke-University, Magdeburg, Magdeburg, Germany*
Email: Frederik.Link@umm.de

Background and aims: Extracellular Matrix Protein 1 (ECM1) serves as a gatekeeper of hepatic fibrosis by maintaining liver tissue homeostasis, whereas its knockout causes lethal hepatic fibrosis resulting from an excessive activation of latent transforming growth factor-β1 (TGF-β1). In patients suffering from chronic liver disease (CLD) and HCC, the expression of ECM1 is decreased. We sought to investigate the mechanisms underlying the regulation of TGF-β1 bioavailability by ECM1 and its impact on CLD progression.
Method: RNAseq was performed to analyze hepatic gene expression in Ecm1-knockout (Ecm1-KO) mice. Functional assays were performed using matrix metalloproteinases (MMP)-2/9 and thrombospondin 1 (TSP-1) or ADAMTS1 as extracellular matrix-resident mediators of latent TGF-β1 activation in primary and immortalized hepatic stellate cells (HSCs) and TSP-1/ADAMTS1-derived peptides in WT or Ecm1-KO mice, and patient liver tissue. Computer modeling was employed to demonstrate consistency of experimental findings.
Results: Ecm1-KO mice sequencing data indicated the presence of severe liver fibrosis, in addition to an upregulation of mediators of latent TGF-β1 activation including TSPs, ADAMTS proteases and MMPs. ECM1 overexpression or the addition of the recombinant protein abrogated TSP-1, ADAMTS1, MMP-2/9-mediated latent TGF-β1 activation in HSCs. Interaction studies pinpointed ECM1's inhibitory effect to an interaction with intrinsic latent TGF-β1-activating amino acid sequences of TSP-1 and ADAMTS1, KRFK and KTFR, respectively, while also reducing MMP-2/9 proteolytic activity. In mice, ECM1 overexpression prevented KRFK-induced liver injury and fibrosis, whereas KTFR mimicked ECM1 and reverted Ecm1-KO-induced liver injury and fibrosis. In patients suffering from alcohol- or virus-related liver disease, ECM1 was inversely correlated with increasing expression of TSP-1, ADAMTS1 and MMP-2/9 and TGF-β1 activation. Lastly, we integrated our findings into a computational model for validation.
Conclusion: Our findings underscore the hepatoprotective effect of ECM1 that inhibits mediators of latent TGF-β1 activation. Strategies for maintaining or restoring ECM1 expression or functions in diseased livers could inform novel and safe anti-fibrotic therapies for CLD.

THU-527

Aging-associated liver sinusoidal endothelial cell dysfunction is involved in the progression of diet-induced liver steatosis and fibrosis

Qingqing Dai[1], Quratul Ain[1], Michael Rooney[1], Alexander Zipprich[1]. *[1]Jena University Hospital, Jena, Germany*
Email: alexander.zipprich@med.uni-jena.de

Background and aims: Aging increases the susceptibility to fatty liver and accelerates liver fibrosis progression, but the underlying mechanisms are still not fully understood. Liver sinusoidal endothelial cells (LSECs) possess distinctive location and function in the liver microenvironment. Therefore, the aim of this study was to investigate the effect of aging-associated LSECs dysfunction on the hepatic microcirculation and the progression of diet-induced liver steatosis and fibrosis.
Method: Young (8 weeks) and aged (78 weeks) rats were subjected to methionine-choline deficient (MCD) diet-induced liver steatosis and fibrosis. Afterwards the liver tissue and blood samples were collected for histology staining and biochemistry tests. Moreover, bivascular liver perfusion (portal vein and hepatic artery) including measurement of sinusoidal resistance was performed in the presence of vasodilator Acetylcholine and nitric oxide donor S-Nitroso-N-acetyl-DL-penicillamine (SNAP) or vasoconstrictor methoxamine (MTX) with and without NOS inhibitor NG-Methyl-L-arginine acetate salt (L-NMMA) to evaluate hepatic hemodynamics and liver endothelial microcirculatory function.
Results: MCD-rats showed higher levels of serum alanine aminotransferase, hepatic triglyceride, and hepatic alpha-smooth muscle actin protein ($p < 0.05$ for all parameters, N = 6), which exacerbates with aging ($p < 0.05$ for all parameters, N = 6). Aged MCD-rats also showed higher basal portal venous vascular resistances (PVR; 0.32 VS 0.29 $mmHg*ml^{-1}*min^{-1}$, $p < 0.05$, N = 9–12) and sinusoidal vascular resistances (SVR; 0.20 VS 0.16 $mmHg*ml^{-1}*min^{-1}$, $p < 0.05$) than young-MCD rats. Hepatic arterial vascular resistance (HAR) was significantly lower in aged-MCD rats (3.01 VS 5.54 $mmHg*ml^{-1}*min^{-1}$, $p < 0.05$). The hepatic p-eNOS protein level was significantly reduced in MCD-fed rats ($p < 0.05$ for both young and aged groups, N = 6) and more noticeable in aged MCD-rats ($p < 0.05$). Endothelial impairment and microcirculatory dysfunction were also considerably more pronounced in aged MCD-rats as evidenced by decreased sensitivity to Acetylcholine-induced vasodilation in PVR and SVR and increased sensitivity to MTX-induced vasoconstriction in HAR ($p < 0.05$, N = 9–12). In contrast, no significant difference in SNAP-induced vasodilation was observed between young and aged MCD-rats in PVR and SVR ($p > 0.05$, N = 9–12). L-NMMA supplementation abolished the difference in MTX-induced vasoconstriction in HAR between the two groups ($p > 0.05$, N = 9–12).
Conclusion: Aging aggravates MCD diet-induced liver injury, steatosis, and fibrosis. Moreover, LSECs dysfunction was also more severe in aged rats, putatively contributing to hepatic stellate cells activation and fibrosis. Therefore, aging-related LSECs dysfunction may serve as a potential therapeutic target to treat the progression of liver steatosis and fibrosis.

THU-530

Roles of intrahepatic IgA on the fibroblast activation in livers with steatotic liver diseases

Jae-Sung Yoo[1], Jong Geun Park[2], Sung Woo Cho[2], Jeong Won Jang[1], Jong Young Choi[1], Pil Soo Sung[1]. [1]*Department of Gastroenterology and Hepatology, Seoul St Mary's Hospital, The Catholic University of Korea, Seoul, Korea, Rep. of South;* [2]*The Catholic University Liver Research Center, College of Medicine, Department of Biomedicine and Health Sciences, The Catholic University of Korea, Seoul, Korea, Rep. of South*
Email: pssung@catholic.ac.kr

Background and aims: Immunoglobulin A (IgA) is known to facilitate inflammation and dismantle anti-tumor immunity in the inflamed liver. In this study, we aimed to elucidate the role of intrahepatic IgA complex on the fibroblast activation in the inflamed livers with steatotic liver diseases (SLDs).
Method: Serum levels of IgA were measured in various chronic liver diseases with diverse fibrosis stages. Fibroblasts isolated from SLD livers were characterized using flow cytometry. In vitro IgA treatment on cultured patient-derived fibroblasts was done. A choline-deficient, L-amino acid-defined, high-fat diet (CDAHFD) as a dietary NASH model with rapidly progressing fibrosis was used.
Results: Patients with SLD showed increased levels of serum IgA levels than other chronic liver diseases ($p < 0.01$) and SLD patients with advanced fibrosis stages (F3, 4) showed higher serum IgA levels than those with F1 or F2 fibrosis ($p < 0.01$). Flow cytometry using ex vivo fibroblasts in livers with SLD showed higher levels IgA binding and PD-L1/FAP expression in patients with advanced fibrosis ($p < 0.01$). Moreover, SLD transplant explants with very high serum IgA levels (>800 mg/dL) showed the highest number of IgA+FAP+PD-L1+ fibroblasts. In vitro treatment of IgA complex to cultured, SLD patient-derived fibroblasts provoked STAT3 phosphorylation and PD-L1/FAP/CXCL12 upregulation, suggesting the inflammatory and pro-tumorigenic fibroblasts. In vivo experiments using CDAHFD mouse model demonstrated that increased levels of IgA+FAP+PD-L1+ fibroblasts were found in the 3rd week livers. Treatment of nindentanib, an approved drug for idiopathic pulmonary fibrosis, to these activated fibroblasts selectively induced killing of these cells at a very low concentration, suggesting that nintendanib may be used to treat fibrotic SLD with activated fibroblasts.
Conclusion: Our data demonstrate that intrahepatic IgA activates fibroblasts in SLD liver, leading to pro-tumorigenic phenotype changes in these cells.

THU-531

DA-1241, a GPR119 agonist, combined with Semaglutide synergistically improved liver fibrosis in mice with CCl4-induced liver fibrosis

Il Hoon Jung[1], Tae Hyoung Kim[1], Sujin Lee[1], Yuna Chae[1], Hyung Heon Kim[2], Mi-Kyung Kim[3]. [1]*Dong-A ST Co., Ltd., Yongin-Si, Korea, Rep. of South;* [2]*NeuroBo Pharmaceuticals Inc., Cambridge, United States;* [3]*Dong-A ST Co., Ltd, Yongin-Si, Korea, Rep. of South*
Email: kmk@donga.co.kr

Background and aims: DA-1241 is a novel chemical drug candidate that selectively and efficiently activates GPR119 and is currently in Phase 2a clinical development for the treatment of metabolic dysfunction-associated steatohepatitis (MASH). Previously, we confirmed that anti-MASH effect of DA-1241 combined with a dipeptidyl peptidase 4 (DPP4) inhibitor was synergistically enhanced through increasing plasma active GLP1 levels compared to each treatment alone. In connection with this, we attempted to determine the combination effects of DA-1241 and a GLP-1 analogue *per se* on liver fibrosis in this study.
Method: Liver fibrosis mice were generated by feeding a western diet in adjunctive with CCl_4 injections. After administering CCl_4 twice weekly for 3 weeks, mice with elevated plasma ALT levels were allocated to receive DA-1241 (oral) or semaglutide (subcutaneous) alone and in combination for 4 weeks.
Results: At the end of treatment, semaglutide reduced body weight by approximately 17% ($p < 0.05$ vs. vehicle control), while DA-1241 (−2.8%) showed little effect. There was no additional weight loss in the combination group (−19%, $p < 0.05$) compared to semaglutide alone. After four-week-treatment, three drug-treated groups had significantly lower plasma ALT levels than the vehicle control group, suggesting alleviation of liver damage. Collagen fiber deposition was prominent in mice treated with vehicle compared to the normal control group. However, DA-1241 or semaglutide alone lowered collagen-positive area compared to the vehicle-treated group (17.8%, 17.1% vs. 25.8%, $p < 0.05$), and their combination therapy elicited a further reduction to 6.05% ($p < 0.05$) compared with each treatment alone, which was recapitulated in changes of fibrosis score. Hepatic hydroxyproline contents and gene expression of various collagen subtypes (*Col1a1, Col3a1, Col5a1, Col6a1*) were also altered correspondingly, supporting the beneficial combination effects against the liver fibrogenesis. Notably, gene expression of Hedgehog-interacting protein (*Hhip*), a suppressor of hepatic stellate cell activation, was lower in mice with liver fibrosis than in normal mice, and were increased by DA-1241 or semaglutide alone. Intriguingly, their combination therapy fully restored the gene expression of *Hhip*. Additionally, the expression of inflammatory cytokines (*Tnfa, IL1b, Ccl2, Cxcl10*) was significantly reduced by each monotherapy, and combination treatment reduced gene expression of *Tnfa* and *Cxcl10* more than monotherapy. These data indicate that liver inflammation status has improved as well.
Conclusion: For the first time, we suggest a beneficial combination effect of DA-1241 and semaglutide in the treatment of liver fibrosis, which may be attributed to augmented inhibition of fibrogenesis and inflammation in the liver.

New insight of liver fibrosis: altered chromatin accessibility in hepatic stellate cells

Tingting Jia[1], Yi Shen[1]. [1]*Department of Gastroenterology and Hepatology and Sichuan University-University of Oxford Huaxi Joint Centre for Gastrointestinal Cancer, West China Hospital of Sichuan University, Chengdu, Sichuan, China, Chengdu, China*
Email: 2018151621145@stu.scu.edu.cn

Background and aims: The treatments for liver fibrosis are still in need so far. As the crucial initiators, activated hepatic stellate cells (aHSCs) undergo a series of epigenetic changes. The study intends to explore transcription factors (TFs) that facilitate HSCs activation and provide novel therapeutic targets for liver fibrosis.
Method: Three distinct HSCs activation models were established in present study. Firstly, *in vitro* activation involved isolating primary HSCs from normal Sprague-Dawley rats and culturing them for two days ($n = 5$) and seven days ($n = 5$), namely natural activation model. Secondly, *in vivo* activation entailed isolating primary HSCs from bile duct ligated rats ($n = 4$) and normal controls ($n = 4$), followed by culturing until the next day. Lastly, transforming growth factor-β (TGF-β, 2.5 ng/ml) ($n = 10$) or control buffer ($n = 10$) were added to the human HSCs cell line LX2 and cultured for 24 hours. Subsequently, Assay for transposase-accessible chromatin using sequencing (ATAC-seq) was conducted on the abovementioned cells, along with motif prediction. RNA sequencing (RNA-seq) was employed to analyze gene expression profiles of primary HSCs in the natural activation model ($n = 4$). The integration of ATAC-seq and RNA-seq further identified potential key TFs. Finally, RT-qPCR and differential expression analysis was utilized to confirm the dysregulation of TFs.
Results: For ATAC-seq, primary HSCs exhibited higher chromatin accessibility after activation compared with the controls. In the motif enrichment analysis, 150 aHSCs related TFs and 54 quiescent HSCs (qHSCs) related TFs were identified in the *in vitro* activation model. The three models shared 12 aHSCs related TFs, namely *Runx-aml*, *Runx1*, *Runx2*, *Runx*, *Ets:Runx*, *Atf2*, *Atf4*, *Atf7*, *c-Jun-Cre*, *Creb5*, *Smad3* and *CArG*; and 19 qHSCs related TFs, including *Foxf1*, *Foxo3*, *Foxk1*,

Foxp1, *Hoxa1*, *Hoxa2*, *Stat3*, *Hnf4a*, *Hnf6*, *Elk1*, *Elk4*, *Cux1*, *Crx*, *Duxbl*, *Vdr*, *Tr4*, *Ebf2*, *Gata2*, *Gata6*. Integration of ATAC-seq and RNA-seq showed that gene expression was significantly correlated with chromatin accessibility, among which *Runx2*, *Creb5*, and *Smad3* were significantly upregulated in aHSCs at transcription level. Finally, the dysregulation of *Runx2* and *Smad3* in different HSCs activation models was verified.

Conclusion: We generated chromatin accessibility profiles of different HSCs activation models, highlighting the significance of *Runx2* and *Smad3* as key TFs mediating HSCs activation. These findings proposed these TFs as promising targets for future liver fibrosis treatment.

THU-533

MCPIP1 RNase inhibits liver fibrosis by targeting TGF-β1 mRNA

Natalia Pydyn[1], Anna Ferenc[1], Katarzyna Trzos[1], Mateusz Wilamowski[1], Pedro Miguel Rodrigues[2], Jesus Maria Banales[2], José María Herranz[3], Matías A. Avila[4], Jolanta Jura[1], Jerzy Kotlinowski[1]. [1]*Jagiellonian University, Krakow, Poland;* [2]*Biodonostia Health Research Institute, San Sebastian, Spain;* [3]*Center of Applied Medical Research (CIMA), Pamplona, Spain;* [4]*CIMA, CCUN, University of Navarra, Pamplona, Spain*
Email: j.kotlinowski@uj.edu.pl

Background and aims: Monocyte-chemoattractant protein-induced protein 1 (MCPIP1) is an RNase that degrades a wide variety of transcripts, for example, those coding for proinflammatory cytokines such as IL-1β, IL-6 or IL-2. Hepatic fibrosis is characterized by enhanced deposition of extracellular matrix (ECM), which results from the wound-healing response of the liver to a chronic and repeated injury. Liver fibrosis is commonly associated with non-alcoholic steatohepatitis, HCV infection, alcoholic liver disease, cholestatic disorders or autoimmune hepatitis. In the present study, we analyzed the role of MCPIP1 in liver fibrosis and its levels in fibrotic liver samples collected from patients. Next, we evaluated the impact of MCPIP1 on the activation status of hepatic stellate cells (HSCs).

Method: Effect of Mcpip1 on HSCs activation was studied by coculture of Mcpip1 KO or WT primary hepatocytes with HSCs and by modulating ZC3H12A expression in LX-2 cell line. Next, We analyzed MCPIP1 level in patients' fibrotic livers and hepatic cells isolated from fibrotic murine livers. We used both CCl4 treated mice and livers from Mcpip1 knock-out animals (Mcpip1fl/flAlbCre).

Results: MCPIP1 levels are induced in patients' fibrotic livers compared to their nonfibrotic counterparts. Similarly, in murine models of fibrosis Mcpip1 level is increased in HSCs and hepatocytes. Overexpression of MCPIP1 in LX-2 cells led to decreased mRNA expression of HSCs activation markers e.g. ACTA2, TGFB1, COL1A1 and α-SMA protein level. Protein-RNA IP experiments demonstrated binding of TGFB1 mRNA by MCPIP1 RNase indicating its involvement in degradation of TGFB1 transcript. Contrary, MCPIP1 silencing in LX-2 cells resulted in their increased activation status. Moreover, hepatocytes with Mcpip1 deletion trigger HSCs activation in a paracrine manner via the release of connective tissue growth factor (CTGF).

Conclusion: MCPIP1 inhibits activation of HSCs in autocrine manner by targeting TGFB1 mRNA and in paracrine manner via regulating CTGF expression. This study was supported by National Science Centre, grant number K/PBM/000672 and 2017/27/B/NZ5/01440.

THU-534-YI

Circulating matricellular fibrosis markers TSP2, IGFBP7, TSP4 and M2-macrophage marker CD163 as predictors of fibrosis and outcome in people with primary sclerosing cholangitis

Ludwig J. Horst[1], Rambabu Surabattula[2], Füssel Katja[1], Marcial Sebode[1], Ansgar W. Lohse[1], Detlef Schuppan[2,3], Christoph Schramm[1,4]. [1]*I. Department of Medicine, University Medical Centre Hamburg-Eppendorf, Hamburg, Germany;* [2]*Institute of Translational Immunology and Research Center for Immunotherapy, University Medical Center, Johannes Gutenberg University, Mainz, Germany;* [3]*Division of Gastroenterology, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, United States;* [4]*Martin-Zeitz Center for Rare Diseases, University Medical-Center Hamburg-Eppendorf, Hamburg, Germany*
Email: l.horst@uke.de

Background and aims: Primary sclerosing cholangitis (PSC) remains one of the most complex, least understood liver diseases. There is a lack of biomarkers for the assessment of fibrosis stage and disease progression. This poses a continuous challenge for clinical trials and drug development. The four serum markers Thrombospondin-2 and -4 (TSP2/-4), Insulin-like growth factor-binding protein 7 (IGFBP7) and Cluster of Differentiation 163 (CD163) reflect key pathogenic mechanisms in general liver and biliary fibrosis. We therefore hypothesised that these markers may serve as predictors of fibrosis and outcome in PSC.

Method: 142 people with PSC were selected from the biobank of the University Medical Center Hamburg-Eppendorf. All patients had their serum marker levels determined by validated in-house sandwich ELISAs. Liver stiffness was measured by transient elastography (TE). In addition, parameters of disease activity and patient outcome were assessed.

Results: In multivariable regression analyses adjusted for ALT, ALP and creatinine, TSP2, IGFBP7, CD163 and TSP4 were independently and positively associated with liver stiffness assessed by TE ($p < 0.001$, $p < 0.001$, $p = 0.014$, $p < 0.001$). The association between fibrosis stage and elevated serum markers was verified in a sub-cohort of people with PSC ($n = 26$) and histologically confirmed fibrosis status. ROC curve analyses showed that all markers were able to distinguish patients with and without cirrhosis. TSP2 in particular showed excellent discrimination with an area under the receiver characteristic curve (AUC) of 0.898 (95% CI: 0.841–0.955, $p < 0.0001$). A newly developed fibrosis score, encompassing TSP2 and IGFBP7 was able to further improve the discriminatory value for cirrhosis with an AUC of 0.932 (95% CI: 0.890–0.975, $p < 0.0001$). Patients with baseline serum levels of TSP2, IGFBP7 and CD163 indicating advanced fibrosis (≥F3) had significantly reduced transplant-free survival (Log Rank $p < 0.001$). An external validation of the present results on persons with PSC is currently in preparation.

Conclusion: Circulating TSP2, IGFBP7, CD163 and TSP4 levels were highly associated with the presence of advanced fibrosis and cirrhosis in people with PSC. TSP2, IGFBP7 and CD163 serum levels were associated with transplant-free survival in PSC, indicating their potential as prognostic biomarkers in cholestatic liver disease.

SOX9 is influential in type 2 immune mediated liver fibrosis

Kim Su[1,2], Alice Costain[3], Elliot Jokl[4], Kara Simpson[4], Andrew MacDonald[5], Karen Piper Hanley[6]. [1]*University of Manchester, Manchester;* [2]*Stepping Hill Hospital, Manchester, United Kingdom;* [3]*Lydia Becker Institute of Immunology and Inflammation, University of Manchester, Manchester, United Kingdom;* [4]*University of Manchester, Manchester, United Kingdom;* [5]*Lydia Becker Institute of Immunology and Inflammation, University of Manchester, Manchester, United Kingdom;* [6]*Wellcome Trust Centre for Cell-Matrix Research, University of Manchester, Manchester, United Kingdom*
Email: kim.su@nhs.net

Background and aims: *Schistosomiasis mansoni is* a neglected tropical disease affecting over 200 million people worldwide. *S mansoni* egg deposition in affected organs elicit an intense type 2 (Th2) immune reaction, triggering granuloma formation around the schistosome egg. Progressive granuloma fibrosis in the liver leads to development of complications of portal hypertension and hepatic synthetic dysfunction. Despite the high burden of disease related to schistosomiasis, there is a paucity of anti-fibrotic targets in Th2 mediated liver fibrosis. Previous work in our group has shown that SRY-Box Transcription Factor 9 (SOX9) expression in hepatic stellate cells (HSCs) and disease-associated hepatocytes is influential in regulating Th1/17 liver fibrosis. In this study, we investigated whether *in vivo* SOX9 depletion could diminish Th2 immune mediated fibrosis in the murine *S. mansoni* model of liver fibrosis.
Method: Control and SOX9 knockout (KO) mice infected with *S. mansoni* were utilised. Immunohistochemistry (IHC), immunofluorescence staining (IF), and immunoblotting were undertaken to assess SOX9 expression, granuloma size and markers of fibrosis. Hepatic cytokine subsets, myeloid and T-cell populations were determined using flow cytometry. Statistical analyses utilised Graphpad Prism v8.
Results: SOX9 expression was significantly increased in *S. mansoni* infected livers, in contrast to uninfected controls ($p < 0.05$). SOX9 levels correlated with hepatic fibrosis ($R^2 = 0.77$) and localised to areas of granuloma fibrosis and HSC activation, reflected in picrosirius red (PSR) and alpha-smooth muscle actin (ASMA) staining. Dual IF revealed SOX9 co-localises with ASMA, indicative of expression by activated granuloma HSCs. SOX9 was also detected in hepatocytes, where it co-localises with Hepatocyte Nuclear Factor 4-alpha (HNF4a). Significantly, *in vivo* SOX9 depletion was associated with reduced granuloma size ($p < 0.01$), reduced granuloma fibrosis and reduction in hepatic collagen I protein levels ($p < 0.01$). SOX9 KO animals displayed marked alterations in hepatic immune profile, with increased hepatic IL4 and IL5, reduced proinflammatory Ly6C^{hi} monocytes ($p < 0.01$) and upregulation of CD4$^+$ T cell subsets expressing ST2 ($p < 0.001$) and CD25 ($p < 0.001$).
Conclusion: SOX9 is relevant in the pathogenesis of Th2 mediated liver fibrosis. Excitingly we provide novel evidence that SOX9 depletion reduces hepatic granuloma fibrosis in the setting of chronic *S. mansoni* infection, rendering it a potential anti-fibrotic target in Th2 mediated liver fibrosis. Our data also reveals marked immune alterations are associated with fibrosis abrogation. Deciphering the interplay between fibrosis biology and the hepatic immune niche is of crucial importance and could pave the way towards developing combination anti-fibrotic and immunology-based treatments in chronic liver disease.

Delivery of antimiR-155 using lipid nanoparticles ameliorate liver fibrosis by alleviating macrophage-driven liver inflammation

Vishal Tuli[1,2], Miranda Turkal[1,2], Cheng Lin[2], Eline Geervliet[1], Matthias Bartneck[2], Ruchi Bansal[1]. *[1]University of Twente, Enschede, Netherlands; [2]Uniklinik RWTH Aachen, Aachen, Germany*
Email: v.tuli@utwente.nl

Background and aims: Upon liver injury, (resident) macrophages get activated and contribute to liver inflammation. MicroRNAs (miRs) are implicated in liver inflammation and disease progression. miR-155 is considered as a master regulator of inflammation and has shown to promote liver inflammation and fibrosis. The aim of this project is to deliver antimiR-155 to macrophages to attenuate liver inflammation. Lipid nanoparticles (LNPs) are one of the most advanced non-viral delivery platforms for negatively charged nucleic acids. We evaluated different LNPs with various helper lipids for their biodistribution, more specifically for liver uptake, *in vivo*, and used DSPC-based LNPs to deliver antimiR-155 *in vitro* and *in vivo*.
Method: DSPC/DOPC/DOPE-LNPs were prepared using a microfluidic device by injecting volumes of lipid mix (12.5 mM) containing ionizable MC3 lipid/helper lipids (DSPC or DOPC or DOPE)/cholesterol/structural lipid DSPE-PEG at respective mol% ratios of 50/10/38.5/1.5 in ethanol with aqueous phase containing negative control (NC)-antimiR or antimiR-155 (amine-to-phosphate ratio of 4). Following the successful synthesis of the LNPs, their organ specific uptake as well as cellular uptake was performed using DiR- and DiD-LNPs respectively. Therapeutic efficacy of antimiR-155-LNPs (DSPC) was evaluated *in vitro* in LPS/IFNγ-stimulated RAW264.7 macrophages and *in vivo* in a chronic CCl_4-induced liver injury mouse model.
Results: Average size of empty LNPs, DiD-LNPs, antimiR-155-LNPs were 110 nm, 126 nm, 142 nm respectively. The size of DiR-LNPs with DSPC, DOPC and DOPE helper lipids were 81.8 nm, 119 nm and 114 nm respectively. Among other LNPs, DSPC-LNPs showed highest liver accumulation *in vivo* and higher uptake in macrophages *in vitro*. LPS/IFNγ-stimulated mouse macrophages showed higher miR-155 expression levels, compared to non-stimulated or IL4/IL13 stimulated macrophages, that correlated with higher TNFα and IL6 expression. AntimiR-155-LNP treatment significantly reduced miRNA-155 levels and mRNA and protein levels of IL6 and TNFα, without affecting cell viability. AntimiR-155-LNP treatment in CCl_4-induced chronic liver injury mouse model attenuated liver inflammation and fibrosis as assessed by immunostainings and by decrease in the mRNA levels of major inflammation and fibrotic markers.
Conclusion: We have developed a LNP platform to deliver antimiR-155 to ameliorate macrophage-driven liver inflammation and liver fibrosis.

Exploring novel targets in hepatic stellate cell activation: interference with the mitochondrial function as part of the antifibrogenic effect of Rilpivirine

Ana Benedicto[1,2], Federico Lucantoni[3], Isabel Fuster-Martínez[1,2], Cristina Benavides[1,2], Pedro Díaz[2], Dimitri Dorcaratto[4], Elena Muñoz[4], Victor M. Víctor[2], Ángeles Álvarez[1,2], Juan V. Esplugues[1,2,5], Ana Blas-García[2,5,6], Nadezda Apostolova[1,2,5]. *[1]Departamento de Farmacología, Facultad de Medicina, Universidad de Valencia, Valencia, Spain; [2]FISABIO-Hospital Universitario Dr. Peset, Valencia, Spain; [3]Centro Investigación Príncipe Felipe, Valencia, Spain; [4]Departamento de Cirugía, Unidad de Hígado, Biliar y Páncreas, Instituto de Investigación Biomédica, INCLIVA, Hospital Clínico, Universidad de Valencia, Valencia, Spain; [5]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Valencia, Spain; [6]Departamento de Fisiología, Facultad de Medicina, Universidad de Valencia, Valencia, Spain*
Email: a.benedictoelena@gmail.com

Background and aims: Activation and subsequent trans-differentiation of hepatic stellate cells (HSC) from quiescent to myofibroblast-like (activated, aHSC) are pivotal in the liver's response to injury and development of liver fibrosis. This energy-intensive transformation involves major reprogramming of the mitochondrial function. Our group demonstrated the hepatoprotective effects of the anti-HIV drug Rilpivirine (RPV) interfering with aHSC, in vivo and in vitro. The current study investigates whether changes in mitochondrial function contribute to RPV's antifibrogenic action in aHSC.
Method: HSC (the human cell line LX-2 or primary HSC isolated from healthy human liver samples (hHSC) were activated with the profibrotic cytokine TGF-b (2.5 ng/ml) and co-exposed to clinically relevant concentrations of RPV (1–8 µM) or vehicle (DMSO) for 48 h. A set of parameters indicative of mitochondrial function and morphology were analyzed through Western blot, qRT-PCR, live-cell fluorescence microscopy (Leica) and the Seahorse Cell Mito Stress kit (Agilent). RNA sequencing analysis was performed through a single read of 75 cycles (1 × 75 bp) (Agilent).
Results: LX-2 cells activated with TGF-b (48 h) displayed altered mitochondrial function (increased oxygen consumption and diminished mitochondrial membrane potential), morphology (diminished branching) and dynamics (increased fission). They were much bigger

(hypertrophied) and displayed enhanced mitochondrial signal (NAO). Co-treatment with RPV fully or partially rescued virtually all these TGF-b-induced effects. mRNA sequencing analysis of hHSC resulted in the generation of expression data for 13156 protein-coding sequences. Mitochondria-related genes were identified among the differentially expressed genes (DEG) using the MitoCarta 3.0 database. Altered expression patterns of genes encoding mitochondrial proteins (mitoDEG) were detected when cells were exposed to TGF-b, with 139 up- and 199 down-regulated genes. Co-treatment with RPV led to substantial changes in mRNA levels of 90 mitoDEG (4 µM RPV) and 110 mitoDEG (8 µM RPV). Notably, a portion (31 in 4 µM and 80 in 8 µM) of these genes displayed reversed expression compared to TGF-b, some of them shared between both concentrations. Further investigation into the mitoDEG common for both RPV concentrations (compared to TGF-b alone) and their involvement in mitochondrial pathways revealed essential processes such as the "Mitochondrial central dogma," "Metabolism," and "OXPHOS" for up-regulated mito-DEG, and "Protein import, sorting and homeostasis," "Signaling," and "Mitochondrial dynamics and surveillance" for down-regulated mitoDEG.

Conclusion: RPV interferes with mitochondrial function in TGF-b aHSC. This underscores the potential of targeting mitochondria in the pursuit of novel therapies for liver fibrosis.

Email: katharina.bonitz@meduniwien.ac.at

Background and aims: Liver fibrosis regression and improvement of portal hypertension (PH) has been observed both in patients and in experimental models after cure of the primary liver disease and cessation of liver injury. However, the dynamics of liver disease regression and the underlying molecular mechanisms remain poorly understood. We characterized two murine liver disease models at different stages of regression in regards to fibrosis and PH severity.

Method: Liver fibrosis was induced in male wildtype C57BL/6 mice by either oral gavage of carbon tetrachloride (CCl_4, 2 ml/kg, 3× per week) for 8 or 12 weeks or repeated intraperitoneal injections of thioacetamide (TAA, 150 mg/kg, 3× per week) for 8 or 12 weeks, while healthy controls received olive oil gavage or NaCl injections. Animals were sacrificed at peak injury (W8 or W12) or 1 (R1) or 2 (R2) weeks after last CCl_4/TAA dose. We measured portal pressure (PP) and spleen/bodyweight ratio for PH, collagen proportionate area (CPA) for fibrosis, and AST/ALT for liver injury severity, respectively.

Results: Increasing fibrosis severity was confirmed for CCl_4 (CPA in OO-W8: 1.55 ± 0.88% vs. CCl_4-W8: 8.53 ± 5.04%, OO-W12: 0.83 ± 0.16% vs CCl_4-W12: 16.9 ± 3.90%) and for TAA (CPA in NaCl-W8: 0.89 ± 0.14% vs. TAA-W8: 3.03 ± 0.18%, NaCl-W12: 0.87 ± 0.20% vs. TAA-W12: 3.87 ± 0.36%) induction. The CCl_4 model animals developed more pronounced PH (PP: OO-W8: 4.92 ± 0.78 mmHg vs CCl_4-W8: 8.45 ± 1.28 mmHg, OO-W12: 5.19 ± 0.20 mmHg CCl_4-W12: 9.99 ± 1.17 mmHg) than the TAA model (PP: NaCl-W8: 5.30 ± 0.29 mmHg vs TAA-W8: 6.80 ± 0.35 mmHg, NaCl-W12: 5.51 ± 0.42 mmHg vs TAA-W12: 7.71 ± 0.57 mmHg). Serum AST/ALT levels regressed to levels non-significantly different to healthy control animals already at R1 across all models. During regression, fibrosis decreased in both the CCl_4 (CPA: W8 + R1: 8.47 ± 3.69%, p = ns; W8 + R2: 5.40 ± 2.20%, p = ns; W12+R1: 10.90 ± 3.05%, p = 0.01; W12 + R2: 5.43 ± 1.44% p < 0.001) and the TAA (CPA: W8 + R1: 2.60 ± 0.28%, p = 0.01; W8 + R2: 2.34 ± 0.21% p < 0.001; W12 + R1: 3.49 ± 0.63%, p = ns; W12 + R2: 2.90 ± 0.30%, p < 0.001) models. PP decreased in both the CCl_4 (W8 + R1: 5.84 ± 0.24 mmHg, p = 0.004; W8 + R2: 6.02 ± 0.92 mmHg, p = 0.004; W12 + R1: 8.35 ± 0.79 mmHg, p = 0.01; W12 + R2: 7.89 ± 1.16 mmHg, p = 0.008) and the TAA (W8 + R1: 6.74 ± 0.40 mmHg, p = ns; W8 + R2: 6.01 ± 0.22 mmHg, p < 0.001; W12 + R1: 7.28 ± 0.47 mmHg, p = ns; W12 + R2: 6.04 ± 0.52 mmHg, p < 0.001) models.

Conclusion: Peak fibrosis and PP were more severe in the CCl_4 than the TAA models. Normalized AST/ALT levels at all R1 timepoints suggested rapid cessation of liver injury. Fibrosis regressed significantly after 2 weeks except for the 8-week CCl_4 model. PP decreased significantly in all regression models. Both severity and the therapeutic window were most prominent in the 12-week CCl_4 model, qualifying this animal model for pre-clinical testing of therapeutics aiming at promoting fibrosis resolution and improving PH after etiologic cure.

THU-541

Cell communication network in diseased livers reveals lymphotoxin beta as a potential inducer of hepatic stellate cell activation

Stefaan Verhulst[1], Vincent Merens[1], Ayla Smout[1], Leo van Grunsven[1]. *[1]Vrije Universiteit Brussel, Brussels, Belgium*
Email: stefaan.verhulst@vub.be

Background and aims: Liver pathologies cause approximately 2 million deaths per year worldwide, including 1 million due to complications of liver cirrhosis. Common causes include hepatitis infection, excessive alcohol intake or unhealthy diets. Cirrhosis is an advanced stage of fibrosis characterized by an excessive accumulation of extracellular matrix proteins. Key players in this fibrotic process are hepatic stellate cells (HSCs). During any type of liver injury, HSCs start to activate into a myofibroblast phenotype which produce large amounts of ECM that results in an increased stiffness of the liver. There are currently no approved anti-fibrotic therapies available in the clinic that can cure patients with liver fibrosis.In this study we aimed to create an interactive network that incorporates available scRNA seq data of healthy and diseased human and mouse livers. With this network, we want to further unravel the signalling pathways that drive HSC activation.

Method: To establish an intercellular communication network between diverse liver cell types, we used publicly available single-cell RNA sequencing (scRNAseq) datasets from human cirrhotic livers (GSE48452) and different diseased mouse livers, including fatty livers (GSE192742, GSE129516) and fibrotic livers (GSE171904, GSE145086). We extracted potential ligands capable of activating HSCs using an in-house developed cell communication algorithm (LiNiCom) and validated these through in vitro experiments, using 2D monolayer cultures of primary mouse HSCs and primary multicellular mouse liver spheroids containing HSCs, liver sinusoidal endothelial cells, Kupffer cells, and hepatocytes.

Results: To create a comprehensive cell communication network in diseased livers, we developed a novel cell communication tool that combined LIANA and NicheNet. Using this integrative cellular communication network tool, we identified ligands capable of promoting HSC activation; 39 ligands in cirrhotic human livers and 49 in diseased mouse livers, with an overlap of 12 ligands in both species. Overlapping ligands include the well-known activators such as TGFβ, TNFα, and LGALS3, alongside less known ligands, including lymphotoxin beta (LTB), calreticulin, and lumican. None of these

newer ligands were able activate mHSCs in 2D cultures, however, LTB activated HSCs in primary liver spheroid cultures by increasing the gene expression of HSC activation markers Acta2, Lox, Col1a1 and Col3a1.

Conclusion: Using LiNiCom we successfully generated a cell communication network between all cell types in diseased and revealed potential ligands that promote HSC activation, including LTB, that can effectively activate HSCs in primary liver spheroid cultures. While in vivo validation is required to further establish the role of LTB in chronic liver disease, we believe that LTB can be a new target for the development of anti-fibrotic therapies.

Inhibition of hyaluronic acid synthesis by hyaluronan synthase 2 targeting siRNA downregulates expression of chemokine (C-X-C motif) ligand 16 and suppresses liver fibrosis in mice

Noreen Halimani[1], Mikhail Nesterchuk[1], Alexandra Tsitrina[2], Marat Sabirov[3], Irina Andreichenko[4], Nataliya Dashenkova[3], Alexey Kulikov[3], Timofei Zatsepin[5], Roman Romanov[6], Arsen Mikaelyan[3], Yuri Kotelevtsev[1]. *[1]Skolkovo Institute of Science and Technology, Moscow, Russian Federation; [2]IKI-Ilse Katz Institute for Nanoscale Science and Technology, Nem Gurion University of the Negev, Beersheba, Israel; [3]Koltzov Institute of Developmental Biology of Russian Academy of Sciences, Moscow, Russian Federation; [4]AO Reproduction Head Centre of Agricultural Animals, Moscow, Russian Federation; [5]Lomonosov Moscow State University, Moscow, Russian Federation; [6]Center for Brain Research, Medical University of Vienna, Vienna, Austria*
Email: Noreen.Halimani@skoltech.ru

Background and aims: Hepatic fibrosis remains a major clinical challenge characterised by excessive deposition of extracellular matrix components (ECM). Recent studies have shown that Hyaluronic acid synthase 2 (HAS2) is critical in driving hepatic stellate cell (HSC) activation and liver fibrosis, making it an important pharmacological target for therapeutic intervention. Our study aimed to investigate the suppression of liver fibrosis by knocking down HAS2 using small interfering RNA (siRNA). Additionally, we aimed to elucidate the molecular mechanisms underlying the antifibrotic effects of this approach through total liver transcriptome analysis.

Method: Female BALB/c mice were exposed to repeated intraperitoneal administration of CCl_4 twice a week for two weeks to induce liver fibrosis. Nanoparticle-encapsulated HAS2 targeting siRNA (siHAS2) was administered twice a week intravenously, and to the control mice, luciferase targeting siRNA was administered.

Results: Iterative CCl_4 administration induced excessive HA deposition in the periportal zone of the liver, inferring elevated HAS2 activity. Furthermore, HA serum levels were also elevated post-repeated CCl_4 injections. Knockdown of HAS2 decreased the deposition of both collagen and HA. Transcriptome analysis showed that downregulated genes were enriched in cell chemotaxis, ECM organisation and collagen biosynthesis. In contrast, upregulated genes were enriched in meiotic chromosome segregation and epigenetic regulation of gene expression. Interestingly, transcriptomics identified the CXCR6-CXCL16 as a potential therapeutic target network due to its role in lymphocyte trafficking. Our analysis revealed that CXCL16 expression was significantly downregulated, which was confirmed with real-time PCR.

Conclusion: Our analysis of the hepatic transcriptome has shed light on the antifibrotic effect of knocking down HAS2. This effect is primarily achieved by reducing cell chemotaxis, extracellular organisation, and response to growth factor stimuli. These processes play a crucial role in the initiation and progression of hepatic fibrosis. Additionally, we demonstrate that RNA inference therapy using siHAS2 is a feasible and practical approach to ameliorating fibrosis. Our findings highlight the potential of siHAS2 as a promising agent for combating hepatic fibrosis and targeting its critical pathways.

THU-546

The improvement of Bortezomib on cirrhosis and its potential mechanism

Ling Wu[1,2], Feng Li[1,3], Xiaoquan Huang[1], Chenyi Rao[1], Detlef Schuppan[4,5], Shiyao Chen[1,3]. *[1]Zhongshan Hospital, Fudan University, Shanghai, China; [2]Institute of Translational Immunology and Research Center for Immunotherapy, University Medical Center, Johannes Gutenberg University, Mainz, Germany; [3]Minhang Hospital, Fudan University, Shanghai, China; [4]Institute of Translational Immunology and Research Center for Immunotherapy, University Medical Center, Mainz, Germany; [5]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, United States*
Email: wuling01@uni-mainz.de

Background and aims: Bortezomib (B), a proteasome inhibitor, has been shown to attenuate fibrosis of skin, lung and kidney. We therefore aimed to evaluate the efficacy of B to improve advanced parenchymal and biliary liver fibrosis in rats and potential underlying mechanisms.

Method: Advanced liver fibrosis was induced in 8-week-old rats by intraperitoneal injection of thioacetamide (TAA) for 12 weeks or bile duct ligation (BDL) for 3 weeks. Rats with advanced fibrosis were divided into 2 groups: intravenous injection of B at 0.1 mg/kg in PBS (B) or injection of PBS alone three times a week for 3 weeks (fibrotic controls, FC). Age matched rats with no intervention served as normal controls (NC). Portal vein pressure was measured after anesthesia before sacrifice. Liver and renal function parameters were determined to evaluate liver inflammation and potential toxicity of B. HE and Masson staining were used to evaluate liver inflammation and fibrosis. Liver collagen was quantified via hydroxyproline content. Fibrosis-related gene and protein expression were determined by RT-qPCR and Western blot. Liver samples were subjected to NGS analysis. LX-2 human hepatic stellate cells and LO2 human hepatocytes were cultured with different concentrations of B for 24 h. Cell apoptosis was quantified via flow cytometry.

Results: Portal vein pressure (mmHg) showed a decrease after B treatment, though the p values did not yet reach statistical significance in the two fibrosis models (B vs FC: TAA, 6.86 ± 0.76 vs 11.42 ± 2.37; BDL, 9.49 ± 2.92 vs 18.57 ± 16.83). ALT and AST decreased with B treatment in both fibrosis models, and serum creatinine and bilirubin levels remained unchanged, indicating a beneficial effect of B on liver function with no apparent liver or renal toxicity. Morphometry and biochemical quantification showed a significant amelioration of fibrosis, as evidenced by a 50% decrease of liver hydroxyproline content (B vs FC: TAA, 0.21 vs 0.41, $p = 0.001$; BDL, 0.13 vs 0.20, $p = 0.016$) and a 70% reduction of Masson-positive area in both fibrosis models. Fibrosis related protein and transcript levels showed significant downregulation of aSMA, Col1a1, and fibronectin 1. Gene set enrichment analysis indicated the upregulation of pro-inflammation-related Ugt2b7 and anti-proliferation-related gene Marvled1, and downregulation of Cdc 20, which is a key regulator in ubiquitin-mediated proteolysis and cell cycle pathways upon treatment with B. B-treated hepatic stellate cells but not hepatocytes showed prominent apoptosis.

Conclusion: Bortezomib induces activated hepatic stellate cell apoptosis and has a prominent antifibrotic potential in parenchymal and biliary fibrosis.

Ex-vivo translational assay of hepatic stellate cells using patient-derived serum characterizes the anti-fibrotic activity of CM-101

Johnny Amer[1], Ahmad Salhab[1], Raanan Greenman[2], Tom Snir[2], Avi Katav[2], Revital Aricha[2], Matthew Frankel[2], John Lawler[2], Francesca Saffioti[3], Douglas Thorburn[4], Massimo Pinzani[4], Ilan Vaknin[2], Adi Mor[2], Rifaat Safadi[1]. *[1]Hadassah Hebrew University Medical Center, Jerusalem, Israel; [2]Chemomab, Tel Aviv, Israel; [3]UCL Institute for Liver and Digestive Health, University College of London, Oxford University Hospitals NHS Foundation Trust, London, United*

Kingdom; [4]UCL Institute for Liver and Digestive Health, University College of London, Sheila Sherlock Liver Centre, Royal Free London NHS Foundation Trust, London, United Kingdom
Email: raanan@chemomab.com

Background and aims: CCL24, a chemokine that regulates inflammatory and fibrotic activities, was found to be highly expressed in livers of patients with liver fibrosis including those with primary sclerosing cholangitis (PSC) and metabolic dysfunction-associated steatohepatitis (MASH). Treatment with CM-101, a first-in-class humanized antibody targeting CCL24, has impacted consequential biomarkers of liver fibrosis in patients with MASH (NCT05824156) and in multiple PSC preclinical models. This study aimed to further characterize CM-101's anti-fibrotic activity in patients using an ex-vivo hepatic stellate cells (HSC) activation model.
Method: Activation of HSC was evaluated using the human LX2 cell line by quantification of the fibrotic marker alpha-SMA (smooth muscle actin). Cell activation was assessed following a 24-hour incubation period with either CCL24, CCL24 in the presence of CM-101, or with sera from MASH patients before or after 16 weeks of exposure to either placebo (vehicle) or CM-101 (5 mg/kg subcutaneous every 3 weeks). Placebo MASH participants without clinical response vs. CM-101 which showed improved liver fibrosis biomarkers were included. The secretome of CCL24-stimulated LX2 was examined by RayBio L-507 protein array. To compare the LX2 secretome to serum proteins of PSC patients, sera from PSC patients and healthy controls were analyzed using Olink proximity extension assay.
Results: CCL24 activated HSC, as manifested by increased alpha-SMA expression, while pre-incubation of CCL24 with CM-101 restored alpha-SMA expression to baseline levels. Notably, the expression of alpha-SMA in HSC was significantly lower after incubation with sera from CM-101-treated MASH patients, compared to placebo-treated patients. Moreover, it was found that proteins secreted by CCL24-activated HSC were upregulated in sera from PSC patients with extensive fibrosis (as defined by an enhanced liver fibrosis (ELF) score >9.8). Five of the CCL24-dependent secreted proteins demonstrated a high predictive area under the receiver operator characteristic (AUROC) curve for both PSC and fibrosis severity (by ELF score), while their combination achieved AUROC of more than 0.95.
Conclusion: A serum-based ex-vivo assay derived from MASH patients treated with CM-101 restored HSC activation. Additionally, a protein signature generated from CCL24-activated HSC predicted PSC disease and its severity, underscoring the relevance of this translational assay to PSC. These findings support CM-101's mode of action in liver fibrosis and may serve as a translational tool in the ongoing clinical trial in PSC.

THU-548-YI

Activation of the GABAA receptor counteracts hepatic steatosis and fibrosis: a novel first-in-class approach for MASH therapy

Elisabeth Rohbeck[1,2], Leonie Koester[1], Juergen Eckel[1]. *[1]CMR CureDiab Metabolic Research GmbH, Düsseldorf, Germany; [2]CMR CureDiab MEtabolic Research GmbH, Düsseldorf, Germany*
Email: juergen.eckel@curediab.de

Background and aims: Liver fibrosis represents a pathological wound-healing response to chronic liver injury, characterized by the excessive accumulation of extracellular matrix proteins. The degree of liver fibrosis predicts the long-term prognosis of metabolic-dysfunction associated steatohepatitis (MASH). However, no specific pharmacological therapy has been approved for the treatment of liver fibrosis. Therefore, the proposed study aimed to investigate if the hepatoprotective thioacrylamide compound, HK3, could also ameliorate fibrosis in a human 3D spheroid MASH model.
Method: Cryopreserved primary human hepatocytes and non-parenchymal cells from patients with clinically confirmed MASH were seeded in ultra-low attachment plates and further analyzed at HepaPredict, Sweden. After forming spheroids, the media were supplemented with 10 ng/ml insulin (control group) or 10 μg/ml insulin and 240 μM albumin-conjugated palmitic acid (PA) and 240 μM oleic acid (OA) (MASH group). The CellTiter-Glo Luminescent Cell Viability Assay kit was used to assess viability in an upfront toxicity test for up to two weeks with repeated exposure to HK3. Subsequently, the effects of HK3 (1, 3, and 10 μM) for 1 week on intracellular lipid content were quantified using the AdipoRed Assay. The secreted cytokines IL-6 and IL-8 or pro-Collagen alpha 1-type I (COL1A1) were measured in the culture supernatants using a customized Magnetic Luminex Assay or ELISA.
Results: Acute exposure to HK3 did not result in hepatotoxicity at any concentration tested. A moderately strong time-dependent reduction in viability was apparent upon concentrations of 30 μM. The PA/OA-induced hepatic lipid content of spheroids exposed to HK3 was reduced by 51–54% (all $p < 0.001$). A concentration of 3 μM HK3 led to a reduction in IL-6 levels to 55% ($p < 0.01$), while IL-8 levels decreased to 80% ($p < 0.05$), compared to MASH group. In line, HK3 resulted in a significant reduction in pro-COL1A1 levels. Exposure was dose-dependent and reached levels of 82%, 73% ($p < 0.05$), and 64% ($p < 0.01$), respectively.
Conclusion: Our thioacrylamide compound promotes the regression of hepatic fibrosis mediated by anti-steatotic and anti-inflammatory properties. Consequently, this compound might represent an innovative pharmacological approach to treat or prevent fibrosis as a first-in-class drug.

THU-549

Pioglitazone ameliorates fibrotic niche of HBV transgenic mice by restoring NK cell function and inhibiting macrophage activation

Huanyu Xiang[1], Taiyu He[1], Jing Xiao[1], Yong Sun[1], Ming-Li Peng[1]. *[1]Department of Infectious Diseases, Key Laboratory of Molecular Biology for Infectious Diseases (Ministry of Education), Institute for Viral Hepatitis, The Second Affiliated Hospital, Chongqing Medical University, Chongqing, China, Chongqing, China*
Email: peng_mingli@hospital.cqmu.edu.cn

Background and aims: The restoration of NK cell function and inhibition of macrophage activation are novel strategies to improve HBV-related liver fibrosis. Recent Studies have shown PPARγ agonists can effectively promote IFNγ secretion in NK cells and inhibit macrophage activation. Therefore, the study is aimed to investigate the efficacy of pioglitazone, a clinically used PPARγ agonist, in HBV-related liver fibrosis.
Method: Histopathological characteristics and serum markers were used to evaluate the efficacy of pioglitazone in CCl_4-induced fibrotic HBV transgenic mice. Flow cytometry was used to explore the effects of pioglitazone on macrophages and NK cells in the liver and peripheral blood.
Results: Pioglitazone effectively reduced serum ALT, AST and liver extracellular matrix deposition, and significantly improved liver inflammation and fibrosis. Interestingly, in vivo, we found pioglitazone significantly reduced serum HBV DNA levels in HBV-Tg mice, but no significant inhibition of HBV DNA by pioglitazone was observed in vitro. The above results suggested the reduction in serum HBV DNA levels caused by pioglitazone treatment may act through non-hepatic parenchymal cells rather than hepatocytes. The flow cytometry results showed pioglitazone increased the proportion of $NKG2D^+$ NK, $NKG2A^+$ NK cells and promoted IFN-γ secretion in hepatic NK cells. Meanwhile, pioglitazone reduced the proportion of hepatic pro-inflammatory $Ly6c^{high}$ macrophages and peripheral blood $Ly6c^{high}$ monocytes and inhibited TNF-α secretion in both cells.
Conclusion: Pioglitazone inhibits HBV replication by promoting IFNγ secretion in NK cells, and inhibits macrophage activation to attenuate hepatic inflammation and fibrosis. Therefore, pioglitazone deserves further study in treating HBV-related liver fibrosis.

Magnetic levitation culture: a step towards quiescent hepatic stellate cell in vitro models

Nataliya Rohr-Udilova[1], Martha Seif[1], Matthias Pinter[2], Michael Trauner[1]. [1]*Medical University of Vienna, Division of Gastroenterology and Hepatology, Internal Medicine III, Vienna, Austria;* [2]*Medical University of Vienna, Division of Gasroenterology and Hepatology, Internal Medicine III, Vienna, Austria*
Email: nataliya.rohr-udilova@meduniwien.ac.at

Background and aims: Hepatic Stellate Cells (HSCs) play a pivotal role in the development of hepatic fibrosis. There is a substantial need for experimental models that facilitate the study of HSC activation. Traditional 2D in vitro cell culturing leads to the activation of HSCs upon adherence to plastic surfaces used in labware, which results in a switch to an activated HSC phenotype. Magnetic levitation is a technique that involves the nonspecific binding of nanomagnetic beads to the cell surface, followed by the application of a magnetic field above the cell culture flask. This method enables cells to form 3D spheroids that levitate in the medium, thereby avoiding contact with labware plastic. This study aimed to establish a 3D spheroid culture of HSCs using magnetic levitation to revert them to their quiescent state and to assess its effectiveness as an in vitro model for studying HSC activation.
Method: The human LX-2 stellate cell line was used as a model for HSCs and cultured in DMEM under standard tissue culture conditions. Nanoshuttle-PL beads combined with a Bioassembler magnet were utilized to induce magnetic levitation. Cell viability was evaluated using the ATP-Glow assay, and the expression levels of alphaSMA and Col1A1 were quantified via real-time RT-PCR.
Results: We have developed an optimized protocol for LX-2 cell treatment with magnetic beads which resulted in stable 3D spheroid formation without impairing cell viability. After eight days of culture, magnetic levitation led to a significant reduction in Col1A1 mRNA levels by 20.1 ± 3.1% and alphaSMA mRNA levels by 74.2 ± 4.1% ($p < 0.01$, $n = 3$), compared to traditional 2D adherent controls. Additionally, levitated 3D LX-2 spheroids retained responsiveness to TGF-beta, a known inducer of HSC activation.
Conclusion: Magnetic levitation effectively reduces the in vitro activation of HSCs by preventing direct contact with labware plastic, favoring a more quiescent HSC state that is conducive to studying their activation. This technique offers a promising approach for the in vitro study of hepatic stellate cell biology, especially in the context of fibrotic disease research.

Evaluation of liver fibrosis: reproducibility of transient elastography

Cyrine Ben Mehrez[1], Meriam Sabbah[1], Jlassi Houssaina[2], Sabrine Soua[3], Norsaf Bibani[4], Dalila Gargouri[3]. [1]*Habib Thameur Hospital, Department of Gastroenterology, Tunis, Tunisia;* [2]*Habib Thameur Hospital, Department of Gastroenterology, Tunis, Tunisia;* [3]*Habib Thameur Hospital Department of Gastroenterology, Tunis, Tunisia;* [4]*Habib Thameur Hospital, Department of Gastroenterology, Tunis, Tunisia*
Email: cyrine.benmehrez@etudiant-fmt.utm.tn

Background and aims: Transient elastography is considered a reliable surrogate marker for assessing the severity of liver fibrosis. The aim of our study was to evaluate the reproducibility of this examination and the factors associated with discordance between experienced and novice operators.
Method: This was a prospective cross-sectional study over a period of eight months, including patients for whom a transient elastography was indicated in the diagnostic or monitoring of liver disease. An experienced operator is defined as an operator who has previously performed more than 100 examinations. Discordance was defined by a difference of at least one fibrosis stage between the results of the operators. Cohen's Kappa coefficient was calculated to study the agreement between fibrosis stages. The overall agreement rate between two qualitative variables was estimated based on the value of the Kappa coefficient (K): Excellent if K >0.81, good if K between 0.61 and 0.8, moderate if K between 0.21 and 0.6, poor if K between 0 and 0.2, and very poor if K <0. The agreement was assessed using the intra class correlation coefficient (Ric) for quantitative variables: Excellent if Ric >0.9, good if Ric between 0.75 and 0.9, moderate if Ric between 0.5 and 0.75, and poor if Ric <0.5. We defined the variables crude and relative differences to identify factors associated with a significant difference between the two operators.
Results: One hundred and thirty-two patients, with a mean age of 51.5 years and a male-to-female ratio of 0.9, were included.
The results showed excellent inter-observer agreement with an intra class correlation coefficient of 0.99 ($p < 0.001$). Inter-observer agreement was good for elasticity values ≤6.5 kPa (Ric = 0.736) and excellent when elasticity >6.5 kPa (Ric = 0.99; $p < 0.001$). The agreement between the two operators was excellent with (K = 0.834; $p < 0.001$). However, the discordance rate for METAVIR fibrosis stages was high in F2 (25%) and F3 (50%), and low in F1 (9%) but absent in F4. Multivariate analysis revealed that male gender, waist circumference, Alanine Aminotransferase, and Hemoglobin A1C were independently associated with discordant results. The crude difference was significantly associated with high body mass index, waist circumference, and elevated Alanine Aminotransferase level, fasting glucose, and Hemoglobin A1C. It decreased with increasing elasticity ($p = 0.01$). The relative difference was significantly associated with elevated levels of Aspartate and Alanine Aminotransferase, Gamma-Glutamyl Transferase, and hyperbilirubinemia. It was inversely proportional to the degree of fibrosis ($p = 0.005$).
Conclusion: In conclusion, although the Fibroscan® is a reproducible technique, this study emphasizes the importance of operator training and result confirmation by an experienced operator in the presence of discordance risk factors.

THU-555

The effect of the novel selective and orally bioavailable CXCR7 modulator in carbon tetrachloride (CCl4)-induced liver fibrosis using mouse model

Yunhee Kim[1], Yoon Suk Lee[1], Eun Hee Chae[1]. [1]*IleadBMS Ltd., Hwaseong-si, Korea, Rep. of South*
Email: lisa.kim@ileadbms.com

Background and aims: Liver fibrosis is the process underlying chronic liver diseases, characterized by the repeated destruction and regeneration of liver cells. This leads to an abnormal deposition and distribution of extracellular matrix components like collagen, glycoproteins, and proteoglycans in the liver. Emerging research suggests that CXCR7 plays a role in both liver regeneration and fibrosis. In this study, we investigate whether our novel compound, CXCR7 modulator has a therapeutic impact in CCl_4-induced hepatic fibrosis in mice.
Method: Male C57BL/6N mice were injected intraperitoneally with carbon tetrachloride (CCl_4) twice a week for a period of 6 weeks. The treatment (vehicle, IL1512 and Elafibranor) commenced right before the administration of CCl_4 on day 0 and was sustained for a duration of 6 weeks, concurrently with the administration of CCl4. After the termination of dosing, liver injury was evaluated through liver weight, serum AST, ALT, liver hydroxyproline, Ishak fibrosis score, and % collagen proportion area (% CPA).
Results: In the disease control group, levels of liver hydroxyproline and liver enzymes ALT and AST were significantly higher than those in the normal control group. However, treatment with Elafibranor (30 mg/kg, po) and IL1512 (10, 30, and 60 mg/kg, po) demonstrated a significant reduction in hydroxyproline and ALT levels compared to the disease control group. Moreover, the administration of Elafibranor and IL1512 resulted in a notable, dose-dependent decrease in liver fibrosis when compared to the disease control group.

Conclusion: Prophylactic treatment with IL1512 in a CCl_4-induced liver fibrosis model demonstrated a potent efficacy equal to or greater than Elafibranor. This study identified IL1512 as the first CXCR7 modulator showing notable efficacy in an animal model of liver fibrosis.

THU-556

Liver fibrosis in NLRP3tm1Hhf/J knockout mice suffering from apical periodontitis

Cristiane Cantiga[1], Mariana Justo[1], Flávio Faria[1], Pedro Oliveira[1], Laís Barroti[1], Almir Rodrigues[1], Nathália Machado[1], Juliana Goto[1], Edilson Ervolino[1], Tiago Pinheiro[2], Luciano Cintra[1]. [1]*School of Dentistry, São Paulo State University (Unesp), Araçatuba, São Paulo, Brazil;* [2]*School of Health Sciences, Amazonas State University (UEA), Manaus, Amazonas, Brazil*
Email: cristiane.cantiga@unesp.br

Background and aims: Aimed to evaluate the effect of NLRP3 silencing on the immunological response of liver fibrosis (LF) alone or combined with apical periodontitis (AP).
Method: Forty C57BL/6J wild type (*wt*) mice were used, divided into 4 groups (n = 10): C*wt*-control; AP*wt*-with AP; LF*wt*-with LF; APLF*wt*-with AP and LF. Another forty Nlrp3$^{tm1Hhf/J}$ knockout (*ko*) mice were divided into 4 groups (n = 10): C*ko*-control; AP*ko*-with AP; LF*ko*-with LF; APLF*ko*-with AP and LF. The animals were induced to liver fibrosis by injecting intraperitoneally 0.2 µl/g of carbon tetrachloride (CCl_4) twice a week for 60 days. On day 30, dental pulp exposure of the 1st and 2nd right upper molars was performed to induce AP. On day 60 the animals were euthanized. Histological analysis of AP was performed by HandE staining. Livers were analyzed by HandE, PSR staining and immunohistochemistry. Statistical tests were applied ($p < 0.05$).
Results: Periapical inflammation was more severe in the *wt* mice. These animals presented larger periapical bone resorption. In the livers, hepatic inflammation was more severe in *wt* animals compared to *ko* and between LF*wt* and APLF*wt* ($p < 0.05$). There was no difference between the LF*ko* and APLF*ko* groups ($p > 0.05$). The stage of liver fibrosis was higher in the *wt* animals compared to *ko* ($p < 0.05$). There was no difference between the LF*wt* and APLF*wt*, LF*ko* and APLF*ko* groups ($p > 0.05$). Immunostaining revealed greater activity of IL-1β, IL-17, IL-18 and CD20 in the *wt* mices compared to *ko* ($p < 0.05$). NLRP3 and IL-17 had a significant difference between the LF*wt* and APLF*wt* groups ($p < 0.05$). There was no difference in immunostaining between the LF*ko* and APLF*ko* groups ($p > 0.05$).
Conclusion: NLRP3 inflammasome silencing plays an important role in modulating LF, reducing inflammatory mediators. Furthermore, the presence of AP influences the increase in NLRP3 and IL-17, aggravating liver fibrosis in *wt* mice.

Gut microbiota and liver disease – Liver-organ crosstalk

Butyrate induces epigenetic and metabolic reprogramming in myeloid-derived suppressor cells to alleviate primary biliary cholangitis

Rui Wang[1], Bo Li[1], Zhengrui You[1], Xiong Ma[1], Ruqi Tang[1]. [1]*Shanghai Jiao Tong University School of Medicine Affiliated Renji Hospital, Shanghai Institute of Digestive Disease, Shanghai, China*
Email: azureocean0107@gmail.com

Background and aims: Gut dysbiosis and myeloid-derived suppressor cells (MDSCs) are implicated in primary biliary cholangitis (PBC) pathogenesis. However, it remains unknown whether gut microbiota or their metabolites can modulate MDSCs homeostasis to rectify immune dysregulation in PBC.
Method: We measured fecal short-chain fatty acids (SCFAs) levels by targeted GC/MS and analyzed circulating MDSCs by flow cytometry in two independent PBC cohorts. Human and murine MDSCs were differentiated *in vitro* in the presence of butyrate, followed by transcriptomic, epigenetic (CUTandTag-seq and ChIP-qPCR) and metabolic (untargeted LC/MS, mitochondrial stress test, and isotope tracing) analyses. The *in vivo* role of butyrate-MDSCs was evaluated in 2-octynoic acid-BSA-induced cholangitis murine model.
Results: Decreased butyrate levels and defective MDSCs function were found in patients with incomplete response to ursodeoxycholic acid (UDCA), compared to those with adequate response. Butyrate induced expansion and suppressive activity of MDSCs in a manner dependent on PPARD-driven fatty acid β-oxidation (FAO). Pharmaceutical inhibition or genetic knockdown of the FAO rate-limiting gene *CPT1A* abolished the effect of butyrate. Furthermore, butyrate inhibited HDAC3 function, leading to enhanced H3K27ac modifications at promoter regions of *PPARD* and FAO genes in MDSCs. Therapeutically, administration of butyrate or adoptive transfer of butyrate-MDSCs alleviated immune-mediated cholangitis in mice. Importantly, reduced expression of FAO genes and impaired mitochondrial physiology were detected in MDSCs from UDCA non-responders, and their impaired suppressive function was restored by butyrate.
Conclusion: We identify a critical role for butyrate in modulation of MDSCs homeostasis by orchestrating epigenetic and metabolic crosstalk, proposing a novel therapeutic strategy for treating PBC.

KYNA induced by short-term fasting through gut microbiota remodelling ameliorates hepatic ischemia/reperfusion injury via activating AhR-YAP signalling in mice

Xiaolong Chen[1], Xiaowen Wang[2], Genshu Wang[3], Wenfeng Zhu[4], Xuejiao Li[5], Haoqi Chen[4], Zhilong Liu[1], Zhiwei Chen[1]. [1]*Department of Hepatobiliary Surgery, The First Affiliated Hospital of Jinan University, Guangzhou, China;* [2]*The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China;* [3]*Department of Hepatic Surgery, Liver Transplantation, Guangdong Provincial Hospital of Chinese Medicine, Guangzhou, China;* [4]*Department of Hepatic Surgery, Liver Transplantation, The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China;* [5]*The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*
Email: 519781497@qq.com

Background and aims: Hepatic ischemia-reperfusion (IR) injury often occurs during liver transplantation (LT), partial liver resection and shock, and is an important factor affecting the prognosis of corresponding patients. Fasting is thought to improve a variety of inflammatory diseases, but its role in IR injury remains controversial. Our study aimed to determine the role of fasting in liver IR injury and to identify its underlying mechanisms.
Method: A mice model of hepatic IR injury with pretreatment of a 24-hour fasting was established first. Gut microbiota and metabolites were obtained for analyse by 16S rRNA sequencing and targeted/non-targeted metabolomics approaches. The effects of fasting on the changes of RNA in liver were further examined by RNA sequencing. Finally, clinical liver samples after LT were collected for further study.
Results: Short-term fasting remarkably attenuated liver IR injury, which relied on gut microbiota remodeling. The metabolite Kyna induced by *A.muciniphila* is necessary for the protection effect of fasting, and the administration of Kyna significantly reduce hepatocytes apoptosis and promote their proliferation during IR. Mechanistically, liver RNA sequencing results suggested that the AhR-YAP signaling axis plays an important role in the Kyna-dependent hepatocyte protection, which was confirmed by inhibiting AhR and knocking down YAP. Further, the correlation between

AhR-YAP signal and hepatic IR injury in post reperfusion liver grafts after transplantation was validated.
Conclusion: Our results demonstrated that metabolite Kyna induced by short-term fasting through gut microbiota remodelling ameliorates hepatic ischemia/reperfusion injury via activating AhR-YAP signalling in mice.

Phages targeting Enterococcus B bacteria associated with increased short-term mortality and proven bacterial infection in patients with decompensated liver cirrhosis and ACLF
Lore Van Espen[1], Lila Close[2], Robert Schierwagen[3], Wenyi Gu[3], Marisa Isabell Keller[4], Anthony Fullam[4], Michael Kuhn[4], Wim Laleman[5], Peer Bork[4], Maria Papp[6], Jonel Trebicka[3], Jelle Matthijnssens[2]. *[1]KU Leuven, Rega Institute, Leuven, Belgium; [2]KU Leuven, Leuven, Belgium; [3]Universitätsklinikum Münster (UKM), Münster, Germany; [4]EMBL, Heidelberg, Germany; [5]University Hospitals Leuven, Leuven, Belgium; [6]University of Debrecen, Debrecen, Hungary*
Email: lore.vanespen@kuleuven.be

Background and aims: Bacterial infections and translocation are not only key precipitants, but also complications of ACLF. Especially the gut microbial ecosystem seems to play hereby an important role. Gut phages play are key players in the human gut microbial ecosystem, mainly through their influence on the interaction of the gut bacteria with the human host. This study will explore the relevance of the human gut virome in the context of decompensated liver cirrhosis and acute-on-chronic liver failure (ACLF).
Method: The fecal virome was longitudinally assessed in 93 patients with decompensated liver cirrhosis or ACLF from the PREDICT study. Phages were grouped according to their predicted bacterial host and lifestyle to associate them with clinical parameters.
Results: Phage alpha-diversity was higher in ACLF patients and increased with ACLF severity (CLIF-C ACLF score, Pearson's correlation coefficient = 0.41). In the absence of ACLF, the phageome was dominated by virulent phages, whereas the emergence of ACLF diminished this dominance of virulent phages at the expense of more temperate phages. This shift suggests ACLF causes induction of prophages, potentially as a consequence of inflammation. Inflammation status (white blood cell count, R2 <1%), as well as markers of liver damage (R2 <1%), timepoint (R2 <1%), and most importantly patient-identifier (R2 = 32%) were contributing to the between-sample phage diversity. Furthermore, Lactococcus A phages were identified as potential predictors for ACLF development and were associated with increased short-term (90-day) mortality. While their phages were implicated, Lactococcus A bacteria themselves were not associated with disease progression. An elevated relative abundance and prevalence of Enterococcus B phages and Enterococcus B bacteria were observed in case of systemic bacterial infection and their presence was linked to worsened 90-day survival rates. Due to the novelty of this dataset, only the association between Enterococcus B phages and bacterial infection could be validated in an external cohort.
Conclusion: This study provides a first evidence that gut virome alterations are implicated in patients with decompensated liver cirrhosis and ACLF. Specifically, Lactococcus A phages may predict ACLF development, and especially Enterococcus B phages, in parallel to Enterococcus B bacteria, are associated with bacterial infection and mortality. This insight may be instrumental for development of strategies to prevent ACLF and improve outcome.

Oatmeal a day does not keep the doctor away: the impact of the combination of inulin and exercise on MASLD amelioration and gut-liver crosstalk
Artemiy Kovynev[1,2], Mikolaj Charchuta[1,2], Quinten Ducarmon[3,4,5], Patrick CN Rensen[1,2], Milena Schönke[1,2]. *[1]Division of Endocrinology, Department of Internal Medicine, Leiden University Medical Center, Leiden, Netherlands; [2]Einthoven Laboratory for Experimental Vascular Medicine, Leiden University Medical Center, Leiden, Netherlands; [3]Structural and Computational Biology Unit, European Molecular Biology Laboratory, Heidelberg, Germany; [4]Experimental Bacteriology, Department of Medical Microbiology, Leiden University Medical Center, Leiden, Netherlands; [5]Center for Microbiome Analyses and Therapeutics, Leiden University Medical Center, Leiden, Netherlands*
Email: a.kovynev@lumc.nl

Background and aims: Lifestyle interventions such as diet and exercise are currently the only available therapies against metabolic dysfunction-associated steatotic liver disease (MASLD). We have earlier shown that late active period exercise training was associated with fat loss and the enrichment of fiber-digesting gut microbiota, so here we studied the impact of the combination of exercise training and a fiber-rich diet on the amelioration of MASLD vie the gut-liver axis.
Method: Male APOE*3-Leiden.CETP mice, a model susceptible to MASLD, were fed a high fat-high-cholesterol diet with or without the addition of 10% inulin and exercise trained on a treadmill for 5 days a week for 1 hour at ZT22, or remained sedentary.
Results: Exercise training alone or in combination with fiber reduced the gain of fat mass throughout the study and lowered plasma glucose levels. Only the combination of fiber and exercise training, however, also decreased plasma triglyceride levels compared to sedentary control mice. Exercise training both with (3.3 ± 1.35) and without the addition of fiber (4.06 ± 1.78) had a similar ameliorating effect on the MASLD score compared to sedentary controls (5.675 ± 1.32), while fiber alone did not result in any improvement (5.57 ± 1.86). Interestingly, only exercise without fiber significantly decreased the expression of inflammatory markers in the liver. Both interventions remodeled the gut microbial composition. Exercise and fiber in combination enriched the fat-lowering and fiber-digesting bacterium *Anaerostipes hadrus*, while exercise training alone or in combination with fiber decreased the abundance of the genus *Alistipes* that has been linked to MASLD in mice and rats. Finally, exercise training increased the levels of health-promoting short-chain fatty acids (SCFA) in the portal vein blood, with the combination of exercise and fiber leading to the highest levels, which also correlated with the lowest levels of plasma triglycerides.
Conclusion: The combination of exercise training and dietary fiber decreases fat mass and restores insulin sensitivity, but does not have an additional positive effect on liver health compared to exercise training alone, despite the shift of the gut microbiota towards a healthier, SCFA-producing profile.

WED-518-YI
Protein-modulated microbiota for fecal transplantation improves metabolic functions in alcohol-related liver disease model
Nishu Choudhary[1], Ashi Mittal[2], Kavita Yadav[3], Jaswinder Maras[2], Anupama Parasar[3], Shiv Kumar Sarin[3], Shvetank Sharma[3]. *[1]Institute of Liver and Biliary Science, New Delhi, India; [2]Institute of Liver and Biliary Sciences, New Delhi, India; [3]Institute of Liver and Biliary Sciences, New Delhi, India*
Email: shvetanks@gmail.com

Background and aims: Fecal microbiota transplantation (FMT) is a promising treatment for alcohol-related liver disease (ALD). To understand FMT-induced metabolic alterations post-FMT, we

investigated the outcome of protein-modulated FMT (pFMT) vs standard FMT in murine ALD model.
Method: Male C57BL/6N mice (n = 8 each group) were pair-fed control or ethanol (22%) Lieber-DeCarli diet with thioacetamide (TAA, 150 mg/kg body weight, i.p.) for 8 weeks to induce ALD. FMT from standard diet and high protein (isocaloric, 20% from soya protein) fed donors was performed in ALD animals. Tissue, blood, and stool were collected at baseline and post-FMT day 7. Liver injury and inflammatory markers were assessed. Fecal 16S rRNA sequencing was performed to capture microbiota variations. Fecal and plasma metabolome was assessed by high-resolution mass spectrometry.
Results: There was a decrease in opportunistic taxa *Staphylococcus, Jeotgalicoccus,* and *Sporosarcina* (8 fold, $p < 0.001$), and *Desulfovibrio* (2.3 fold, $p < 0.001$) post pFMT.which was increased in ALD. Liver histopathology showed pericellular lesion in ALD and post pFMT showed significant overall improvement: steatosis (15 fold reduction, $p = 0.002$), fibrosis (6 fold reduction, $p = 0.005$), AST (3 fold reduction, $p = 0.016$), ALT (3 fold reduction, $p = 0.04$), serum bilirubin (2 fold reduction, $p = 0.04$). Significant reduction in hepatic pro-inflammatory markers IL6 (3 fold, $p = 0.03$) and TNFa (2.5 fold, $p = 0.06$) was observed after pFMT. Metabolomics identified a total of 503 plasma and 647 fecal metabolites across all groups. pFMT significantly ($p < 0.05$) altered 212 fecal and 124 plasma metabolites. 33 plasma metabolites were significantly ($p < 0.05$) upregulated, involved in: bile acid metabolism [taurocholic acid (9 ± 1.2 vs 6.2 ± 0.9 $p = 0.04$), chenodeoxycholic acid (9 ± 1.7 vs 7.0 ± 1.15 $p = 0.09$), deoxycholic acid (15.4 ± 1.9 vs 12.0 ± 1.2 $p = 0.08$)] and oxidative stress reducers glutamate, glutathione, and methionine metabolism [involving glutathione (10.9 ± 0.3 vs 8.9 ± 0.3 $p = 0.006$), s-adenosylmethionamine (14.5 ± 0.2 vs 12.6 ± 0.4 $p = 0.001$) and 5-Phosphoribosylamine ($7.9 \pm 6.1 \pm 0.07$ $p = 0.001$) metabolites]. There was also an increase in mitochondrial beta-oxidation [3-oxododecanoic acid (12.7 ± 0.2 vs 11.5 ± 0.5 $p = 0.001$), octanoylcarnitine (12.3 ± 0.4 vs 11.3 ± 0.5 $p = 0.008$)], and amino acid metabolism, indicating the enhanced energy production, and concurrent increase in purine and histidine metabolism (deoxyuridine, 11.1 ± 0.6 vs 10 ± 0.2 $p = 0.02$) related to cell proliferation. 59 plasma metabolites were significantly down-regulated, including arachidonic acid (2 fold, $p = 0.009$) and linoleic acid (2.4 fold, $p = 0.001$) metabolism.
Conclusion: In alcohol-related liver disease, pFMT reduces the load of opportunistic taxa and expression of inflammatory pathways concomitantly increasing bile acid and energy metabolism, resulting in hepatic recovery.

WED-519-YI

Criss-cross fecal microbiota transplant identifies hepatic steroid biosynthesis and linoleic acid metabolism linked with liver injury and dysbiosis in rat

Manisha Yadav[1], Jaswinder Maras[2], Neha Sharma[2], Nupur Sharma[2], Gaurav Tripathi[2], Sadam H. Bhat[3], Sushmita Pandey[2], Vasundhra Bindal[2], Babu Mathew[2], Anupama Kumari[2], Shiv Kumar Sarin[2]. *[1]Institute of Liver and Biliary Sciences, New Delhi, India; [2]Institute of Liver and Biliary Sciences, New Delhi, India; [3]Institute of Liver and Biliary Sciences, New Delhi, India*
Email: jassi2param@gmail.com

Background and aims: Chronic and excessive alcohol consumption induces signifant inflammation oxidative stress and produce hepatic lesions, including steatosis, hepatitis, and fibrosis/cirrhosis. Fecal microbiota transplant (FMT) has shown promise in ameliorating liver disease by modulating the gut microbiota. However, systemic change in the metabolome profile post FMT from healthy to ALD model or vice versa (criss-cross) are obscure and identification of such metabolic pathways may have therapeutic importance.
Method: We used human associated rats, Criss-cross FMT (intestinal microbiota of healthy donors given to ALD rats and intestinal microbiota from ALD patients given to healthy rats) was performed to look onto the pathways regulated by alcohol associated bacteria. Metabolomics evaluation was performed in the liver, plasma, intestine and stool to understand pathways and metabolites which specifically got altered post FMT at different sites i.e., in liver, intestine, plasma and stool.
Results: Six-month chronic ethanol consumption in Long Evans rats led to significant liver injury, and perturbed butanoate, amino acid, bile acids, arachidonic acid, linoleic acid, microbial metabolism, tryptophan, steroid biosynthesis, and others in liver, intestine, stool, and plasma ($p < 0.05$) as seen in SAH patients and led to high Streptococcus and low Bifidobacterium prevalence. The chronic ethanol exposure reduced energy metabolism in liver ($p < 0.05$). FMT from healthy to ALD rats, significantly reduced inflammation, fibrosis ($p < 0.05$) and pathways such as arachidonic acid, tryptophan, linoleic acid, bile acid synthesis (liver, plasma and intestine) compared to control groups ($p < 0.05$). Conversely, FMT from ALD patients to healthy rats majorly impacted liver metabolism and specifically upregulated linoleic acid (4.5 folds), steroid biosynthesis, NAD and tryptophan metabolism ($p < 0.05$). The stool showed higher prevalence Streptococcus, Salmonella, Bacillus, Helicobacter, Haemophilus. Also, hepatic gene expression showed increase in cyp1a1 (50 fold), noxo1 and mcp1 (5 fold) in the rat model treated with ALD microbiota ($p < 0.05$). A higher expression of cyp1a1 is associated with increased linoleic, steroid and arachidonic metabolism. Together hepatic gene expression and metabolome analysis of healthy rat treated with ALD microbiota outlines that alcohol associated microbiota induces cyp1a1 mediated increase in steroid biosynthesis (11 fold), linoleic acid (4 fold) and arachidonic acid metabolism (3 fold) which corroborated with ROS/inflammation as seen in SAH.
Conclusion: Our findings suggest that alcohol associated microbiome change in the intestine impact liver metabolism with significant effect on steroid biosynthesis and linoleic acid metabolism. Thus, targeting hepatic steroid biosynthesis and linoleic acid metabolism may have therapeutic importance in ALD.

WED-521-YI

Tissue-specific roles of Farnesoid X Receptor in gut-liver axis and influence on progressive cholestatic liver injury

Lina Ludwigs[1], Ines Volkert[1], Mona Peltzer[1], Antonio Molinaro[2], Marcus Henricsson[3], Hanns-Ulrich Marschall[4], Karolina Edlund[5], Kai Markus Schneider[6], Thomas Longerich[7], Peter Boor[8], Jan G. Hengstler[9], Christian Trautwein[6], Lena Susanna Candels[1]. *[1]University Hospital RWTH Aachen, Aachen, Germany; [2]The Sahlgrenska Academy, Gothenburg, Sweden; [3]University of Gothenburg, Gothenburg, Sweden; [4]Department of Molecular and Clinical Medicine, Gothenburg, Sweden; [5]University Dortmund, Dortmund, Germany; [6]Uniklinik RWTH Aachen, Aachen, Germany; [7]Universitätsklinikum Heidelberg, Heidelberg, Germany; [8]Rheinisch-Westfälische Technische Hochschule Aachen, Aachen, Germany; [9]IfADo, Aachen, Germany*
Email: lludwigs@ukaachen.de

Background and aims: The Farnesoid X Receptor (FXR) is a broadly expressed receptor with diverse functions. Extensive research has been conducted on FXR and FXR agonist have been tested for the treatment of chronic liver diseases e.g., primary biliary cholangitis (PBC). However, a deeper understanding of the distinct functions of FXR within the gut-liver axis is still lacking. The aim of this study was to explore the tissue-specific roles of FXR in the gut and liver.
Method: We developed a novel mouse model using tissue-specific FXR knockouts for hepatocytes ($FXR^{\Delta hepa}$), intestinal epithelial cells ($FXR^{\Delta IEC}$), and a combination of both—the $FXR^{\Delta hepa\Delta IEC}$ animals. We analysed liver tissue, ileal tissue, blood, and caecum stool samples after eight and 52 weeks.
Results: $FXR^{\Delta IEC}$ mice only showed a mild cholestatic phenotype with liver function tests within the normal range, while $FXR^{\Delta hepa}$ mice exhibited a more severe phenotype with elevated transaminases, moderate cholestasis, and hepatic inflammation. In contrast, 8-week-old combined $FXR^{\Delta hepa\Delta IEC}$ animals demonstrated exacerbated liver damage with elevated transaminases, increased hepatic infiltration of

inflammatory cells, and strongly upregulated fibrosis markers. Gene pathway analysis of hepatic tissue confirmed these results, showing minor changes in gene regulation in $FXR^{\Delta IEC}$ mice, slightly more in $FXR^{\Delta hepa}$ mice, but a severe dysregulation in $FXR^{\Delta hepa\Delta IEC}$ animals. While in $FXR^{\Delta IEC}$ mice and $FXR^{\Delta hepa}$ mice bile acid synthesis was only mildly upregulated, it was severely increased in the $FXR^{\Delta hepa\Delta IEC}$ mice. Furthermore, we found changes in bile acid transporter expression, which, in combination with the increased bile acid synthesis, led to cholestatic liver disease in the $FXR^{\Delta hepa\Delta IEC}$ mice. Age progression led to an aggravation of this cholestatic phenotype after 52 weeks in $FXR^{\Delta hepa\Delta IEC}$ mice. Severe fibrosis and dysplastic nodules were evident.

Conclusion: Our data show that the loss of either the intestinal or the hepatic FXR, respectively, leads to minor dysregulations of gut-liver axis related pathways without any strong impact on the phenotype of these mice. The combined FXR loss however, leads to severe cholestatic liver injury associated with increased liver fibrogenesis and malignant growth. It appears that the interaction of both receptors is needed to maintain a balanced bile acid homeostasis. $FXR^{\Delta hepa\Delta IEC}$ animals are a novel model of progressive cholestatic liver injury and can contribute to a better understanding of the tissue-specific roles of FXR within the gut-liver axis.

WED-522-YI

Effect of various edible exosomes in restoring gut homeostasis and hepatic metabolic axis: a comparative study

P. Debishree Subudhi[1], Jitendra Kumar[2], Anupama Kumari[1], Shivani Gautam[1], Shruti Sureshan[1], Dinesh Mani Tripathi[1], Chhagan Bihari[1], Shiv Kumar Sarin[1], Sukriti Baweja[1]. *[1]Institute of Liver and Biliary Sciences, New Delhi, India; [2]Department of Immunology, Mayo Clinic, College of Medicine and Science, Rochester, United States*
Email: sukritibiochem@gmail.com

Background and aims: Edible Exosomes known to restore gut commensals and integrity, hence could configure gastro-hepatic alignment, attribute of hyperammonemia. We investigated the effects of Edible Exosomes on gut-microbiome and hepatic injury.

Method: Edible Exosomes isolated from carrot (CarEx), ginger (GinEx), garlic (GarEx), turmeric (TurEx) and lemon (LemEx) by differential ultracentrifugation, characterized by TEM and NTA. Cargoes evaluated by proteomics. Stability assessed by *in vitro* stomach/intestine-like digestion. Prophylactic oral administration of exosomes assessed in Thioacetamide (TAA) induced hyperammonemia model, compared to vehicle and lactulose. Biochemical markers of hepatic injury, ammonia, histology and behaviour were assesed. Microbiomics assessed by stool metagenomics and untargeted LC-MS metabolomics and by *in vitro* coculture of exosomes with probiotic Lactobacillus rhamnassus GG (LGG).

Results: Size and concentration of exosomes ranges 52 nm-200 nm and $2.65 \times 10^9 \pm 0.65$particles/ml with zeta potential −7 to −16.0 ± 2.4 mV. Cargoes found enriched with anti-oxidants and proteins associated to metabolism, gingipain, allinase, and defensin. After *in-vitro*-digestion, particle size was reduced ($p = 0.02$) with intact zeta potential. Edible Exosomes administration in TAA rats reduced plasma ammonia [Vehicle-97.9 ± 22.9; lactulose-157.9 ± 46.6 umol/L ($p = 0.42$); CarEx-92.2 ± 13.6 umol/L ($p = 0.002$); GinEx-124.2 ± 11.9 umol/L ($p = 0.004$); GarEx-179.9 ± 66.5 umol/L; LemEx-159.6 ± 36.7 umol/L], ALT and bilirubin ($p < 0.004$; $p < 0.008$) but only CarEx improved albumin ($p = 0.03$). Edible Exosomes improved motor activity ($p < 0.0001$), cognitive caper ($p = 0.004$), hepatic cholestasis, necrosis and inflammation. Edible Exosomes altered the gut flora in TAA rats (β-diversity; $p = 0.001$) but CarEx ($p = 0.02$)/TurEx ($p = 0.01$) decreases growth of urease positive *Escherichia-Shigella* responsible for elevated ammonia levels. CarEx improved colonisation of Firmicutes [Lachnospiraceae ($p = 0.03$), Ruminococcaceae ($p = 0.017$), Lactobacillaceae ($p = 0.028$)] that maintains gut homeostasis and upon coculture with probiotic microbe LGG *in-vitro* showed enhanced growth ($p = 0.004$). Stool metabolome of CarEx found enriched metabolites guanidosuccinic acid, $p = 0.030$, D-proline, $p = 0.05$, 8amino7oxononanate, $p = 0.017$ associated with ammonia excretion, converting through urea/L-arginine/biotin metabolism pathways and improves gut integrity (glutathion, retinol metabolism). Meanwhile D-glutamine associates with ammonia scavanging, N-acetyl-DL-serine improves cognition, malic acid/arctigenin having anti-inflammatory/microbial effects found upregulated in serum of CarEx administered rodents.

Conclusion: CarEx potentiates ammonia excreation helps alleviating hyperammonemia, configures gut and improves cognition, considered 'Ammonia scavengers'.

WED-523

Sulphated progesterone metabolites undergo apical sodium bile acid transporter-mediated enterohepatic recycling and stimulate glucagon-like peptide 1 and peptide YY release

Alice Mitchell[1,2], Iain Tough[1], Caroline Ovadia[1], Anita Lövgren-Sandblom[3], Jenny Chambers[2], Anastasia Tsakmaki[1], Patricia Pedro[1], Gavin Bewick[1], Helen Cox[1], Catherine Williamson[1,2]. *[1]King's College London, London, United Kingdom; [2]Imperial College London, London, United Kingdom; [3]Karolinska Institute, Sweden, United Kingdom*
Email: am13309@ic.ac.uk

Background and aims: Sulphated progesterone metabolites (PMxS) increase during gestation and are elevated further in intrahepatic cholestasis of pregnancy (ICP), characterised by elevated serum bile acids (BA). Both PMxS and BA are derived from cholesterol and have a steroid backbone, and PMxS have previously been shown to activate BA receptors. We investigated whether PMxS could undergo enterohepatic recycling and stimulate intestinal Takeda G-protein coupled receptor 5 (TGR5)-mediated release of gut hormones glucagon-like peptide-1 (GLP-1) and peptide YY (PYY).

Method: Ussing chambers were used to evaluate colonic ion secretion changes (ΔI_{sc}) in wildtype, $TGR5^{-/-}$, and $PYY^{-/-}$ mice by two PMxS metabolites, PM3S and PM5S, and in wildtype mice with or without apical sodium bile acid transporter (ASBT) inhibition ($n = 6$/condition). PM3S/PM5S and taurodeoxycholic acid (TDCA) stimulation of GLP-1 release from wildtype and $TGR5^{-/-}$ murine crypts and human colonoids was measured by ELISA ($n = 3$). PMxS were quantified in faeces ($n = 18$) and pre-/postprandial serum samples ($n = 20$) by ultra-performance liquid chromatography-tandem mass spectrometry in prospectively recruited third trimester of pregnancy outpatients with uncomplicated pregnancy or ICP.

Results: Apical and basolateral PM3S and PM5S stimulated PYY-mediated $-\Delta I_{sc}$ in wildtype ($p < 0.01$) but not $TGR5^{-/-}$ or $PYY^{-/-}$ colons. PM3S and PM5S stimulated GLP-1 secretion in murine crypts and human colonoids ($p < 0.001$) to levels comparable to a canonical agonist, TDCA. PMxS are present in faeces; ASBT inhibition blunted $-\Delta I_{sc}$ by 68% after apical PM3S and PM5S addition ($p < 0.001$). Serum PMxS increase postprandially in women with ICP but are unaltered in uncomplicated pregnancies.

Conclusion: ASBT can transport steroid-based progesterone metabolites alongside the canonical conjugated bile acids and may be involved in the postprandial rise in serum PMxS levels in cholestatic pregnancies. PMxS were able to stimulate GLP-1 and PYY release via activation of TGR5 to a similar extent as TDCA, suggesting they may play a role in modulating gut hormone response during pregnancy. This work demonstrates a novel substrate for ASBT beyond bile acids and suggests a role for hormone metabolites elevated in pregnancy undergoing enterohepatic recycling to modify metabolic responses in the gut.

WED-524-YI

Multi-omics study of chronic liver diseases with rifaximin treatment

Yingjie Ai[1], Sitao Ye[1], Xiaoquan Huang[1], Shiyao Chen[1]. [1]*Zhongshan Hospital, Fudan University, Shanghai, China*
Email: 23111210016@m.fudan.edu.cn

Background and aims: Chronic liver diseases including cirrhosis and non-alcoholic fatty liver disease (NAFLD) are worldwide health concerns and are closely interrelated. Multiple clinical and experimental studies have found that rifaximin, an oral non-absorbable antibiotic, can be used in the treatment of cirrhosis and NAFLD and their complications but the common mechanisms and targets of rifaximin for the treatment of both chronic liver diseases still need to be clarified. The aim of this study was to investigate the biomolecular characteristics and targets of rifaximin for the treatment of two chronic liver diseases by multi-omics.
Method: Rat and mouse models of cirrhosis and NAFLD were constructed and followed by rifaximin gavage intervention for 2 weeks. The therapeutic effects of rifaximin on dual chronic liver diseases were verified by pathological and hematological tests. Common hepatic genetic targets regulated by rifaximin were discovered by liver transcriptome sequencing of rats and validated with experiments in mouse, biochemical indices of clinical patients and public transcript data. Fecal 16S rDNA sequencing was performed to explore the regulatory effect of rifaximin on intestinal flora and explore the common microbial targets.
Results: Staining and other assays demonstrated that rifaximin could improve liver fibrosis in cirrhotic model and hepatic steatosis in NAFLD model. Hepatic transcriptome analysis of rats suggested that rifaximin could regulate metabolism-related pathways in both models, and metabolism-related genes such as Ephx1 and Cbr1 were significantly dysregulated. Identical rifaximin-induced transcriptional changes were observed in mouse by RT-PCR. Meanwhile, lipid levels in cirrhotic patients showed a decrease in cholesterol, LDL, and non-HDL after rifaximin intervention, corresponding with the transcriptional changes. Analysis of public datasets showed that hepatic EPHX1 and CBR1 in patients with NAFLD showed corresponding pathological dysregulation. Rifaximin could affect the structure and function of gut microbiome in rats with cirrhosis and NAFLD as alpha diversity and beta diversity of the microbiota were altered. Plentiful intestinal taxa showed reversible alterations after rifaximin intervention, including Candidatus Saccharibacteria, Actinobacteria, Firmicutes, and Bacteroidetes, which are reported to undergo dysregulation during the pathological process and predicted to have metabolic function. Shared differential-abundant taxa were mostly related with carbohydrate metabolism and amino acid metabolism.
Conclusion: The multi-omics study of chronic liver disease with rifaximin treatment uncovered common hepatic genetic and gut microbial targets of rifaximin for treating both cirrhosis and NAFLD, providing novel ideas to advance and understand the clinical application of rifaximin.

Hepatocellular carcinoma risk associated with circulating metabolites of gut microbiome origin assessed by targeted mining of high-resolution untargeted metabolomics data

Anastasia Chrysovalantou Chatziioannou[1], Nikolaos Papadimitriou[1], David Hughes[2], Mazda Jenab[1,3], Pekka Keski-Rahkonen[1].
[1]*International Agency for Research on Cancer (IARC-WHO), Lyon, France;* [2]*University College Dublin, Dublin, Ireland;* [3]*International Agency for Research on Cancer, Nutrition and Metabolism Branch, Lyon, France*
Email: chatziioannouc@iarc.who.int

Background and aims: Alterations in the composition and metabolic activity of the human gut microbiome, favoring the growth of pathogenic or unhealthy species, have been implicated in the development of hepatocellular carcinoma (HCC). Some gut-derived microbial metabolites may be pro-inflammatory and growth-promoting, while others may be cancer protective. Much of the current knowledge about metabolic alterations occurring in HCC is derived from case-control studies, while information from prospective, observational cohort studies remains limited. We explored associations between circulating metabolites related to gut microbial metabolism and HCC risk in a case-control study nested within the European Prospective Investigation into Cancer and Nutrition (EPIC) cohort.
Method: A detailed literature search of peer-reviewed articles and on-line metabolite databases was conducted to compile a diverse target list of microbial metabolism-related metabolites to be examined in association with HCC development. We employed untargeted, high-resolution liquid chromatography-mass spectrometry (LC-MS), using reversed phase and hydrophilic interaction chromatography both in positive and negative polarities, to detect thousands of metabolic features in pre-diagnostically collected serum samples from n = 110 first incident HCC cases matched 1:1 with healthy control participants from the EPIC cohort. In EPIC detailed lifestyle data and biospecimens were collected at baseline from >520, 000 apparently healthy participants from 10 European countries who were then followed up over time for cancer diagnoses. Gut microbiome-related metabolites were annotated from LC-MS features detected in the serum samples. Multivariable adjusted conditional logistic regression models were applied to assess the relationship between each matched metabolite and HCC risk.
Results: The detailed literature search identified 473 microbiome-related metabolites. A large number of LC-MS features were successfully matched to these metabolites based on chemical formula and isotopic pattern. After Benjamini-Hochberg correction for multiple testing, HCC risk associations were observed for 14 annotated metabolites from diverse chemical classes. In general, bile acids, amino acids and their metabolites, tocopherols, amines and cholines were associated with risk of HCC, suggesting a role for microbiome alterations in the development of this cancer.
Conclusion: These novel findings contribute to the evidence base on microbial metabolism-related compounds and HCC risk, providing preliminary insight into metabolic perturbations linked to gut microbiome composition and metabolic activity and their potential involvement in HCC development. They also highlight a unique approach of targeted analysis of specific metabolites from within high-resolution untargeted metabolomic features.

Email: yasmina.tashkent@gmail.com

Background and aims: Steatotic liver disease (SLD) is a leading cause of chronic liver disease worldwide. The gut microbiome and the metabolites that are produced by intestinal microbes (e.g. short-chain fatty acids [SCFA]), are increasingly linked to SLD risk, with specific bacterial taxa associated with steatosis in children, adolescents and older adults. We aimed to characterise changes to the gut microbiome in young adults with steatosis, previously undescribed in this age group.

Method: 1082 participants of the longitudinal population-based Raine Study underwent cross-sectional assessment at the age of 27 years, including magnetic resonance imaging (MRI) of the liver and fasting serum biochemistry. Clinical metadata and stool samples were also collected. Hepatic steatosis was quantified using a validated MRI volumetric liver fat fraction (VLFF) equation (HepaFat) and a previously established cut-off of greater than 3.55% was used to indicate the presence of steatosis. Participants were divided into three groups for analysis (no steatosis [NS]: VLFF≤3.55%, mild-moderate [MM] steatosis: VLFF 3.56–13.55% and severe steatosis [SS]: VLFF>13.55%). Gut microbiome profiling was performed using 16S rRNA V4 amplicon sequencing to assess microbial alpha diversity (Shannon entropy, Pielou evenness and observed features) and microbiota composition similarity (based on weighted UniFrac distance).
Results: Of 588 participants (305 [51.9%] female) who had complete data, 488 (83%) had NS, 76 (12.9%) had MM steatosis and 24 (4.1%) had SS. Compared to NS, individuals with SS exhibited significantly lower microbiota alpha diversity. Faecal microbiota composition also differed significantly between NS and both MM (p = 0.0064) and SS groups (p = 0.0015). Compared to NS, the SS group exhibited significantly lower relative abundance of a number of SCFA-producing bacterial taxa, including Christensenellaceae R.7 group, Lachnospiraceae ND3007 group, Lachnospiraceae NK4A136 group, *Eubacterium xylanophilum* group, *Eubacterium eligens* group, *Alistipes*, *Coprococcus*, *Odoribacter* and *Clostridia vadin* BB60 group (False-Discovery Rate [FDR] corrected p < 0.05). UCG-001 (family XIII), UCG-002 (family Oscillospiraceae) and UCG-005 (Oscillospiraceae) were also significantly lower in SS compared to the NS group. In contrast, members of the SS group displayed significantly increased levels of *Lachnoclostridium* and *Ruminococcus gnavus* group (FDR corrected p < 0.05), bacterial taxa that have been implicated in cardiovascular disease and SLD pathogenesis.
Conclusion: Hepatic steatosis in young adults is associated with reduced intestinal microbial diversity compared to those without hepatic steatosis, including lower relative levels of bacteria that are capable of SCFA biosynthesis and higher relative levels of bacterial clades associated with cardiovascular disease.

WED-527-YI
Protein-educated fecal cell-free transplant enhances remission better than protein-educated fecal microbiota transfer in alcohol-related liver disease
Ashi Mittal[1], Nishu Choudhary[1], Kavita Yadav[1], Anupama Kumari[1], Jaswinder Maras[1], Shiv Kumar Sarin[1], Shvetank Sharma[1]. [1]*Institute of Liver and Biliary Sciences, New Delhi, India*
Email: shvetanks@gmail.com

Background and aims: Fecal microbiota transfer (FMT) is an effective treatment for alcohol related liver disease (ALD). During FMT, cell free component consisting of metabolites, proteins and other molecules from host and gut bacteria is also transferred. Cell free transfer (CFT) is known to be as beneficial as FMT. We compared the efficacy of protein pre-educated (PE)-FMT and CFT.
Method: Male C57BL/6N mice were fed ethanol Lieber-DeCarli diets along with thioacetamide (150 mg/kg bw, i.p., twice weekly) for 8 weeks to induce ALD. Donors were fed soya protein diet (1000 kcal/L, 50% protein, 36% fat, 14% carbohydrate) for 2 weeks. Fecal slurry was prepared for FMT and CFT (slurry was sterile filtered using 0.22 micron filter). Standard (Std) FMT/CFT and abstinence served as controls. Microbiota was assessed using 16 s rRNA sequencing post-day7 of transplant. PICRUSt analysis was used to assess microbial functional pathways. Hepatic recovery was assessed by histopathology, serum biomarkers and gene expression of inflammatory markers.
Results: PE-CFT showed significant reduction in AST (1.4 fold change (FC) p = 0.008; 1.3 FC p = 0.02), ALT (1.4 FC p = 0.05), steatosis (1.5 FC p = 0.04; 1.4 FC p = 0.05) and fibrosis (1.2 FC p = 0.06; 1.3 FC p = 0.05) as compared to Std CFT and Std FMT respectively. Comparison of PE-CFT with PE-FMT showed reduction in serum biomarkers [ALT (1.2 FC p = 0.05), AST (1.2 FC p = 0.02)], steatosis (2 FC p = 0.04) and fibrosis (1.1 FC p = 0.07). PE-CFT also resulted in a reduced gene expression of hepatic pro-inflammatory markers IL1 beta (1.7 FC p = 0.01), TNF alpha (1.4 FC p = 0.01) and TLR4 (1.7 FC p = 0.07) along with an increased expression of anti-inflammatory marker IL10 (1.7 FC p = 0.0005) when compared to PE-FMT, suggests enhanced efficacy of PE-CFT over PE-FMT in remission of liver injury. PE-FMT and PE-CFT led to significant variation (76% p = 0.001) in gut microbiota composition. PE-CFT increased the relative abundance of probiotic taxa *Akkermansia muciniphila* and *Parabacteroides golsteinii* over PE-FMT. Though PE-CFT increased the abundance of pathogenic taxa significantly (*Citrobacter freundii*, 5.7 FC p = 5.2E-05; *Enterococcus faecalis*, 3.5 FC p = 0.007; *Helicobacter typhlonius*, 3.7 FC p = 0.02), they did not exert any adverse effect on outcome. Bacterial pathways involved in energy, amino acid, lipid, and carbohydrate metabolism were significantly modulated by PE-CFT (NAD salvage pathway II: 4.7 FC, p = 2.1E-04; polyamine biosynthesis: 3.4 FC p = 3.0E-07; fatty acid and beta-oxidation: 2 FC p = 0.02; TCA cycle: 2 FC p = 0.03; glycolysis (−1.3 FC p = 0.03).
Conclusion: Protein pre-educated CFT alleviates the ALD injury better than protein pre-educated FMT. It improves the energy and amino acid metabolism accompanied with significant reduction in hepatic inflammation and steatosis. Thus, donors gut milieu may be pre-educated with high protein diet prior to cell-free transfer in ALD subjects.

WED-528-YI
Isolation and characterization of extracellular vesicles in faecal matter: implications for future biomarker discovery
Hector Leal-Lassalle[1], Olga Estévez-Vázquez[1], Raquel Benedé-Ubieto[1], Raquel Castillo-González[1,2], Lucía Sancho-Temiño[1], Aranzazu Cruz-Adalia[1,2], Rafael Bañares[1,3,4,5], Javier Vaquero[3,4,5], Francisco Javier Cubero[1,3,4], Yulia Nevzorova[1,3,4]. Email: hecleal@ucm.es

Background and aims: Extracellular vesicles (EVs) are microscopic particles (with size ranging from 30 nanometers to 10 micrometers) abundantly released into body fluids by all types of cells. EVs are of growing interest due to their potential diagnostic, disease surveillance, and therapeutic applications. While several studies have evaluated EV isolation methods in various biofluids, there are only few data on these techniques when applied to stool. However, the feces are an ideal biospecimen for studying intestinal inflammation and damage. In this study, we aimed to assess EVs from murine feces (fEVs) for reproducibility, purity, and protein expression in stool supernatant as well as to evaluate their effects *in vivo* and *in vitro*.
Method: We used stool from 33 weeks old C57BL/6J male mice. fEVs were isolated by ultracentrifugation, and fully characterized by flow cytometry, Nanoparticle Tracking Analysis (NTA), western blotting and Transmission Electron Microscopy (TEM). HepG2 cells were cocultured with different amounts of isolated fEVs marked with a fluorescent probe, assessing their survival and proliferation at different timepoints. The morphology of the cells was analyzed by fluorescent staining and observation under a Leica TCS SP5 confocal microscope.
Results: NTA of the isolated fEVs confirmed size homogeneity in the nanoparticle population at the range of 50–100 nanometers, together with high fEV concentration and high protein yield in the isolated samples. TEM visualization confirmed crucial EV characteristics, i.e. shape and size as well as purity of the preparation. Vesicle-associated

markers CD63, CD81 and Alix were present in fEV fractions. Importantly we showed, the fEVs are released by two main domains-eukaryotes and bacteria. The presence of fEVs from gram-negative and gram-positive bacteria was detected by western blot using anti-lipid A and anti-lipoteichoic acid antibodies, whereas western blot using anti-beta-actin antibody was employed to detect host-derived EVs. Furthermore, bacteria-free fEVs were administered into healthy C57BL/6J mice by intraperitoneal injection and did not cause any peritoneal inflammation as it has been confirmed by flow cytometry analysis of intraperitoneal liquid. Consistently, fluorescently labeled fEVs applied to HepG2 human hepatoma culture did not affect cellular morphology and have been localized either in the cytoplasm or the nuclei of treated cells.
Conclusion: These findings serve as the groundwork for future studies in order to investigate the potential of fEVs as a source for novel biomarkers for diagnosis of intestinal homeostasis.

WED-529
Transplantation of fecal microbiota derived from idiosyncratic drug-induced liver injured patients caused by amoxicillin-clavulanate determines a specific bile acid profile in germ-free mice
Sara Román-Sagüillo[1], María Juárez-Fernández[1,2], Alba González-Robles[1], Raisa Quiñones Castro[3], Susana Martínez-Flórez[1], Javier González-Gállego[1,2], Francisco Jorquera[1,2,3], María-Victoria García-Mediavilla[1,2], Esther Nistal[1,2], Sonia Sánchez-Campos[1,2]. *[1]Instituto Universitario de Biomedicina (IBIOMED), Universidad de León, León, Spain; [2]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas, Instituto de Salud Carlos III, Madrid, Spain; [3]Servicio de Aparato Digestivo, Complejo Asistencial Universitario de León, León, Spain*
Email: sroms@unileon.es

Background and aims: Drug-induced liver injury is a multifactorial hepatic disease and amoxicillin-clavulanate (AC) is one of the main causing agents of its idiosyncratic (iDILI) and cholestatic form. Bile acids are important signaling molecules related to the progression and development of cholestatic iDILI. In this sense, gut microbiota composition is linked not only to the onset and progression of various hepatic diseases, but also to the enterohepatic circulation of bile acids. Thus, our aim is to evaluate the effect of fecal microbiota transplantation (FMT) from patients with iDILI caused by AC (iDILI-AC) on bile acid metabolism in germ-free mice (GFm).
Method: Two patients with iDILI-AC (diDILI-AC+), two patients treated with AC who did not develop iDILI (diDILI-AC-) and a healthy subject (dC) were selected as FMT donors based on iDILI-related biochemical parameters and gut microbiota characterization. Stool samples from these donors were processed for FMT to GFm. Then, GFm were divided in 3 groups per donor being treated with amoxicillin (A), AC or its vehicle. After 7 days of treatment, serum, liver and fecal samples were obtained to evaluate biochemical parameters, hepatic gene expression, fecal bile acid quantification and gut microbiota composition. Moreover, correlation analysis between fecal bile acids and gut microbiota composition were performed.
Results: Serum biochemical analysis showed an increase in bilirubin levels referred to diDILI-AC+ in comparison with the other groups. Moreover, an altered expression of hepatic genes related to bile acid synthesis and transport (*Cyp8b1* and *Abcg5*) was observed not only associated with the treatment, but also with the donor. In this sense, the quantification of fecal bile acids showed a modification in primary (cholic and ursodeoxycholic acid) and secondary (deoxycholic, lithocholic and 12-Ketolithocholic acid) bile acid concentration in feces. These alterations in bile acid concentration levels were affected by both donor and treatment, highlighting a significant reduction of secondary bile acids in dC/A and dC/AC compared to dC/H2O, a trend that was not observed in diDILI-AC+ and diDILI-AC−. Furthermore, secondary fecal bile acids were positively correlated with specific gut microbial genera, remarking *Barnesiella*, *Desulfovibrio* and *Howardella*. The relative abundance of these genera was affected by the donor type, while *Barnesiella* also showed a higher abundance after AC treatment regardless of the donor.
Conclusion: Transfer of a particular gut microbiota profile associated with iDILI-AC could affects the enterohepatic circulation of GFm bile acids and the response to treatment. However, further studies are needed. Funding: PID2020-120363RB-I00, LE017-P20. CIBERehd funded by ISCIII.

Email: elisa.castillo@uah.es

Background and aims: Liver-gut axis comprehension is crucial in cirrhosis research, yet the specific alterations in animal models of cirrhosis with this domain remain under-characterized. Addressing this gap, our study conducts an in-depth comparative structural and functional analysis of the gut analysis of the two most used preclinical models of cirrhosis: bile duct ligation (BDL) and carbon tetrachloride (CCl_4). Our aim was to elucidate differences in the structure and function of the gut barrier and microbiota in these models.
Method: Cirrhosis with ascites was induced in Wistar rats by CCl_4 oral gavage or bile duct ligation (BDL). Once animals developed ascites, we evaluated different aspects of the structure and function of the gut at the terminal ileum: muco-epithelial barrier (PAS), structure (by endothelial co-expression PV1/CD34) and function (4kD dextran-FITC visualized in liver after intestinal loop assay) of the gut vascular barrier, microbiota adhered to the mucosa and feces (by 16S metagenomic, NGS) and bacterial translocation (BT) to the mesenteric lymph nodes (by MALDI-TOF).
Results: Compared to the BDL model, the muco-epithelial barrier of the ileum in the CCl_4 model showed lower mucus thickness (27.0 [20.2–29.1] vs. 32.7 [27.9–38.5] μm, $p < 0.05$) and fewer goblet cells (0.17 [0.13–0.19] vs. 0.32 [0.30–0.35]/μm villus, $p < 0.05$). Impairment of the gut vascular barrier was also more severe in CCl_4 cirrhosis, indicated by higher PV1 expression (0.80 ± 0.08 vs. 0.57 ± 0.14, $p < 0.05$) and increased passage of dextran-FITC particles from the intestine to the liver (10.7 ± 2.3 vs. 6.7 ± 1.5 particles/field, $p < 0.05$) compared to the BDL model. In terms of microbiota composition, the CCl_4 model showed significantly greater relative abundance of Firmicutes and Bacteroidetes, while Proteobacteria were similar to the BDL model. Small intestinal bacterial overgrowth was more frequent in BDL (12.1 ± 1.1 vs. 6.9 ± 0.4CFU/g, $p < 0.05$). Conversely, BT was more common in CCl_4 (86% vs. 60%, $p < 0.05$). Transcriptomic analysis revealed distinct expression patterns with upregulation of immune genes in BDL and of cholesterol homeostasis genes in the CCl4.
Conclusion: The abnormalities of the intestinal barrier and microbiota of the CCl_4 and the BDL models of cirrhosis exhibit distinctive differences. These disparities underscore the importance of analysing the results in both models when studying abnormalities in the gut-liver axis in cirrhosis and identifying potential therapeutic targets.

WED-531

The double-edged sword of bariatric surgery: extending the excluded limb can trigger bacterial translocation, liver inflammation and death

Louis Onghena[1], Anneleen Heldens[2], Milton Antwi[2], Lindsey Devisscher[3], Hans Van Vlierberghe[2], Sarah Raevens[2], Xavier Verhelst[2], Anne Hoorens[4], Yves Van Nieuwenhove[5], Anja Geerts[2], Sander Lefere[2]. [1]*Liver Research Center Ghent, Ghent University, Ghent University Hospital, Ghent, Belgium;* [2]*Hepatology Research Unit, Ghent, Belgium;* [3]*Liver Research Center, Ghent, Belgium;* [4]*Department of Diagnostic Sciences, Ghent, Belgium;* [5]*Department of Gastrointestinal Surgery, Ghent, Belgium*
Email: Louis.onghena@ugent.be

Background and aims: Bariatric surgery (BS) is an effective treatment for obesity and associated comorbidities, including metabolic dysfunction-associated steatotic liver disease (MASLD). We applied several novel BS procedures in mice to examine the effects of surgery selection and biliary limb length on metabolic health, bacterial translocation, and survival.

Method: Mice were fed a Western diet (WD) for 12 weeks, followed by surgery with continued WD feeding and sacrifice at weeks 13 and 20. Six different types of BS (vertical sleeve gastrectomy and plication, Roux-en-Y gastric bypass (RYGB), and one-anastomosis gastric bypass (OAGB) with three different biliary limb lengths (25% = Ω_1, 50% = Ω_2, 75% = Ω_3)) were performed and compared with sham surgery procedure. Gut decontamination with an oral antibiotic cocktail (amoxicillin, vancomycin, neomycin, and metronidazole) was performed in a subset of Ω_3 mice, starting one week before surgery until the end of the experiment. Statistical differences between groups were assessed by one-way ANOVA with Tukey post-hoc tests.

Results: Relative weight loss differed significantly amongst the groups at week 20. In RYGB, Ω_{1and2}, significantly lowered relative visceral adipose tissue weight ($p < 0.0001$) and ALT ($p < 0.01$) compared to sham surgery. Histologically, sham-operated mice had developed severe liver steatosis, moderate inflammation, and mild fibrosis after 20 weeks of WD feeding, which was attenuated by RYGB and Ω_{1and2}. Bacterial translocation to the liver was observed in RYGB, Ω_{1and2} ($p < 0.001$).

Unexpectedly, the Ω_3 surgery resulted in 100% mortality after 20 days. To further dissect the cause of this event, we sacrificed mice with the varying Ω loop limb lengths one week after surgery. The number of bacterial colonies in the spleen and biliary limb were significantly higher after Ω_3 ($p < 0.05$), combined with higher levels of hepatic inflammation and bacterial content ($p < 0.05$), compared to sham. Liver histology in Ω_3 mice was characterized by a mediovesicular steatosis, which we compared to histopathology features in humans. This entity closely resembled the typical histological picture observed in patients with end-stage liver disease after BS. Critically, oral gut decontamination significantly increased one-week-survival of Ω_3 mice from 31.3% to 80.0%. Antibiotic treatment not only prevented bacterial overgrowth in biliary fluid ($p < 0.05$) and spleen ($p < 0.01$), but also significantly decreased serum ALT and AST levels ($p < 0.01$) in these mice.

Conclusion: BS procedures in mice, especially RYGB, Ω_{1and2} improve MASLD. Our studies show that mortality in longer biliary limb surgery is caused by bacterial overgrowth and inflammation of the gut-liver axis, which can be treated with oral gut decontamination. Our novel procedures open the field of research into the mechanisms of action of BS on hepatic and intestinal physiopathology.

WED-533

The narcolepsy drug sodium oxybate improves metabolism in developing and existing obesity

Cong Liu[1,2], Sen Zhang[1,2], Mik Zwaan[1,2], Aswin Verhoeven[3], Mink Schinkelshoek[2,4], Yanan Wang[2,4,5], Martin Giera[3], Mariëtte Boon[2,4], Patrick CN Rensen[2,4,5], Milena Schönke[2,4]. [1]*Department of Medicine, Division of Endocrinology, Leiden University Medical Center, Leiden, Netherlands;* [2]*Einthoven Laboratory for Experimental Vascular Medicine, Leiden University Medical Center, Leiden, Netherlands;* [3]*Center for Proteomics and Metabolomics, Leiden University Medical Center, Leiden, Netherlands;* [4]*Department of Medicine, Division of Endocrinology, Leiden University Medical Center, Leiden, Netherlands;* [5]*Med-X institute, Center for Immunological and Metabolic Diseases, and Department of Endocrinology, First Affiliated Hospital of Xi'an Jiaotong University, Xian, China*
Email: c.liu@lumc.nl

Background and aims: Clinical studies have reported that sodium oxybate (SXB), the sodium salt of gamma-hydroxybutyric acid (GHB) used for the treatment of narcolepsy, exerts weight loss-promoting effects. These metabolic effects of SXB are believed to be mediated by peripheral organs, particularly the liver. In addition, GHB is a short-chain fatty acid (SCFA) and other structurally closely related SCFAs have been shown to alleviate obesity-associated metabolic diseases at least partially through the beneficial modulation of the gut microbiota.

Method: The anti-obesity effect of SXB was investigated in both existing and developing obesity in mice. In existing obesity, male C57BL/6J mice were first fed a high fat diet (HFD) for 8 weeks to induce obesity, and then treated with either SXB or water by daily oral gavage for 8 weeks. In developing obesity, mice were subjected to HFD feeding and concurrently received either daily SXB treatment or water for 8 weeks. In a follow-up experiment to study the contribution of the gut microbiota to the SXB treatment effect, we performed a fecal microbiota transplantation (FMT) from SXB-treated mice (SXB donor) to untreated mice (SXB recipient) for 6 weeks following an antibiotics-induced microbiota depletion. For this, fresh feces from donor mice were collected and fecal bacteria were transferred to recipient mice by oral gavage three times per week.

Results: SXB treatment reduced body weight gain and plasma glucose levels only in existing but not in developing obesity. In both conditions, SXB treatment, however, reduced liver steatosis and alleviated liver damage. This was likely associated with improved hepatic mitochondrial function, as suggested by the upregulated expression of hepatic genes encoding mitochondrial respiratory complexes. 16S rRNA sequencing furthermore indicated that SXB beneficially modulated the gut microbiota composition both in existing and developing obesity. FMT from SXB-treated to untreated mice attenuated HFD-induced body weight gain accompanied by decreased plasma glucose levels in the untreated recipient mice. In line, FMT alleviated hepatic steatosis in the recipient mice as evidenced by decreased liver triglyceride levels and lipid droplets.

Conclusion: SXB treatment counteracts obesity and the associated metabolic dysfunction of the liver, at least in part, through the improvement of gut microbiota dysbiosis.

Email: eithang@hadassah.org.il

Background and aims: MiR-122 is downregulated in many liver pathologies all associated with chronic liver inflammation e.g. NASH, AIH and others and may have a role in regulating the immune tolerance of the liver. We generated miR-122 KO mice and found that they develop spontaneous liver inflammation.
Method: This model enables to study the the immune response developing in the absence of miR-122.
Results: The liver of the miR-122 KO is inflamed and fibrotic from 3 weeks of age. In the inflamed livers of these mice, there is an increase in Kupffer and T cells as well as an increase in liver damage markers-including fibrosis, ductular proliferation and apoptosis. Gene expression analysis demonstrates overexpression of TLR genes in miR-122 KO mice and enrichment of genes that are associated with TNFα and NFκB signaling. In microbiome depleted miR-122 KO mice, the liver damage was mildly decreased. Specific subsets of T cells were analyzed and we found that in effector CD8 cells, immune checkpoints are downregulated. In a preliminary Comparing RNAseq data of these mice with humans with AIH showed a significant overlap. In AIH patients an anti-correlation between levels of miR-122 in the liver and inflammation activity index was observed. Specifically, TLR signaling, NFκB signaling and Th17 signaling pathways are all significantly differentially expressed in AIH patients with high inflammation activity index as in the miR-122 KO mice.
Conclusion: We hypothesize that the immune response exhibited in the miR-122 KO mice is a result of a dysregulated response to the natural microbiome in the absence of miR-122. Overexpression of TLRs could lead to excessive NFκB activation and TNFα signaling. Further analysis is required in order to determine the pathways and specific cellular responses involved in regulation of the liver immune tolerance by miR-122.

WED-535-YI
Association of HLA alleles with Oral Microbiome in Liver Cirrhosis patients

Rosmy Babu[1], Shruti Sureshan[2], Satender Singh[2], Chhagan Bihari[2]. [1]*Institute of Liver and Biliary Sciences, Delhi, India;* [2]*Institute of Liver and Biliary Sciences, Delhi, India*
Email: rosmy.1995@gmail.com

Background and aims: The composition of gut microbiome can be influenced by host immunity, which is partly regulated by HLA. HLA classes play an important role in inducing tolerance, through its immunosuppressive effects on all types of immune cells. Immune tolerance is a key issue in the liver, both in liver homeostasis and in the response to liver injury. It would therefore appear likely that association between HLA motifs and gut microbiome plays an important role in liver diseases. We profiled the salivary microbiome and tested the association between each microbial taxa with HLA motifs.
Method: Saliva and blood samples of cirrhosis patients (n = 52) between the age group 18–65 years were collected. V3-V4 Amplicon sequencing and HLA typing (HLA-A, -B, -C, -DRB1, -DQB1 and -DPB1) were performed to see any plausible relation between HLA and oral microbiome in cirrhosis patients. We used Generalized linear models to test the association between HLA motifs and microbial taxa.
Results: Upon sequencing of HLA-A, B, C, DQB1, DPB1 and DRB1 to see any plausible relation between HLA and oral microbiome, the generated data identified 68 distinct HLA alleles, and these alleles were used to determine their association with the oral microbiome. Presence of HLA-DRB1*07 had positive effect on the relative abundance of Lactobacillaceae (p = 0.019) in cirrhosis patients. Lactobacillaceae activate hepatic Nrf2 to protect against oxidative liver injury and acute ethanol toxicity. Similar positive co relation were observed between pairs HLA-DQB1*06-Flavobacteriaceae (p- = 0.046), Bifidobacteriaceae (p = 0.001) HLA-DRB1*07-Lactobacillaceae (p = 0.019) and HLA-B*15-Prevotellaceae (p = 0.025). These bacterial classes produce SCFAs from dietary fibre, have anti-inflammatory and modulating effects on the intestinal mucosa, maintaining gut health. When HLA-A*11 was present in the patient samples, we observed a decline in the relative abundance of family Veillonellaceae (p = 0.042). Higher abundance of Veillonellaceae, affects the clinical benefit response associated with energy metabolism which may modulate the clinical response to immunotherapy in liver cirrhosis.
Conclusion: We see plausible relation between HLA and oral microbiome in cirrhosis patients based on the positive effect of presence of different HLA alleles on abundance of certain bacterial taxa.

WED-538-YI
Toll-like receptor 2 signaling cascades are a trigger of aging-associated liver decline in mice

Annette Brandt[1], Patricia Olivera Prada[1], Anja Baumann[1], Julia Jelleschitz[2], Annika Höhn[2], Ina Bergheim[1]. [1]*University of Vienna, Vienna, Austria;* [2]*German Institute of Human Nutrition Potsdam-Rehbrücke, Nuthetal, Germany*
Email: ina.bergheim@univie.ac.at

Background and aims: Old age has been identified as an independent risk factor in the development of various liver diseases. Indeed, across species, even healthy aging is associated with the development of hepatic inflammation and fibrosis. Studies further suggest that intestinal microbiota composition, an impairment of intestinal barrier function and an induction of toll-like receptors (TLRs) in liver tissue and dependent signaling cascades are critical herein. Here, employing different mouse models, we assessed the role of TLR2 in the development of aging-related liver degeneration.
Method: In the first experiment, markers of liver damage, senescence and inflammation were assessed in 4 and 20 months old male C57BL/6 and TLR2 Knockout (TLR2 KO, B6.129-Tlr2tm1Kir/J) mice. In a second experiment, old male C57BL/6 mice (17 months) showing signs of impaired intestinal barrier function and senescence were treated either with the TLR2 inhibitor ortho-vanillin (60 mg/kg BW in drinking water) or plain water for 4 months and markers as determined for the first experiment were assessed.
Results: As expected, 20 months old wild-type mice developed clear signs of aging including an increase in markers of senescence such as p16, and liver inflammation as well as liver fibrosis. In contrast, 20 months old TLR2 KO mice were significantly protected from these alterations showing significantly lower levels of markers of senescence but also less hepatic inflammation (e.g. significant lower number of neutrophil granulocytes, significant lower expression of interleukin 1beta mRNA) and significantly less fibrotic alterations in the liver such as lower expression of alpha smooth muscle actin mRNA. In line with these findings, treatment of old mice, showing beginning signs of senescence and intestinal barrier dysfunction, with the TLR2 inhibitor significantly attenuated the development of inflammatory and fibrotic alterations in liver tissue. Also, markers of senescence like p16 in blood were significantly lower than in untreated mice.
Conclusion: Taken together, our data so far suggest that an alteration of TLR2 and associated signaling cascades may be critical in aging-associated liver degeneration in mice. (funded by FWF and DFG).

Gut dysbiosis-induced humoral dysregulation in metabolic dysfunction-associated steatotic liver disease

Hong Sheng Cheng[1], Yolanda Wei Ling Koo[1], Esha Bharathwaj Vijay[1], Damien Chua[1], Sunny Hei Wong[1], Nguan Soon Tan[1]. *[1]Nanyang Technological University Singapore, Singapore, Singapore*
Email: hscheng@ntu.edu.sg

Background and aims: Metabolic associated steatotic liver disease (MASLD), a silent and chronic liver disease, poses a growing threat with limited treatment options. The gut microbiome is increasingly known to interact with the adaptive immunity during the progression of MASLD but the underpinning mechanism remains largely elusive. Hence, this study aims to explore deeper understanding of the gut-immune-liver crosstalk by investigating the dynamic changes of humoral response in gut dysbiosis-exacerbated MASLD.
Method: We humanized the gut microbiome of male C57BL/6 mice via fecal microbiota transplantation (FMT) and performed MASLD induction using a specialized Liver Disease Progression Aggravation Diet (LIDPAD) and thermoneutral housing. Fecal microbiome was obtained from the humanized mice that developed metabolic dysfunction-associated steatotic liver (MASL) and metabolic dysfunction-associated steatohepatitis (MASH) and subsequently transplanted into naïve mice to study the impact of MASL- and MASH-associated microbiome on the humoral response and liver histology.
Results: Mice with humanized gut microbiome developed gut dysbiosis upon MASLD induction, characterized by the emergence of *Romboutsia-Marvinbryantia* cluster and loss of *Akkermansia-Bifidobacterium* cluster. Gut dysbiosis in MASLD were associated with the onset of auto-immunogenicity against liver antigens which are positively correlated with disease severity scores. We identified an increased abundance of $CD19^{+}CD45R^{+}CD93^{-}IgM^{hi}IgD^{lo}$ B-cells in the livers, blood circulation and large intestine of MASLD mice. FMT of MASL- and MASH-associated microbiome markedly accelerated MASLD progression and the onset of IgG- and IgM-mediated auto-immunogenicity, suggesting a causative role of gut dysbiosis in dysregulated humoral response and MASLD deterioration.
Conclusion: Our results highlight a potential role of gut-immune-liver axis in the exacerbation of MASLD.

WED-540-YI

Gender-dependent HCC development in X/MYC mouse model

Vincenzo Alfano[1], Alexia Paturel[1], Valerio Iebba[2], Giulia Canarutto[3], Massimiliano Cocca[1], Alice Lombard[1], Francesca De Nicola[4], Jamila Faivre[5], Silvano Piazza[3], Massimo Levrero[1], Claude Caron de Fromentel[1], Francesca Guerrieri[1]. *[1]Cancer Research Center of Lyon (CRCL), INSERM U1052, Lyon, France; [2]Università di Trieste, Trieste, Italy; [3]ICGEB, Trieste, Italy; [4]IRCCS Regina Elena National Cancer Institute, Rome, Italy; [5]INSERM U785, Paris, France*
Email: vincenzo.alfano@inserm.fr

Background and aims: Hepatocellular carcinoma (HCC), the most frequent primary malignancy of the liver, is among the leading causes of cancer-related death worldwide. The vast majority of HCCs is associated with chronic liver disease due to a known underlying aetiology, including chronic viral hepatitis (B and C), alcohol intake and non-alcoholic steatohepatitis (NASH). It has been reported that epigenetics plays an important role in liver oncogenesis and gut microbiome changes in HCC patients, but the relationship between them over the course of carcinogenesis is not clear. Finally, epidemiological reports indicate that the incidence of HBV-related HCC is higher in males and postmenopausal females than other females, but the cause underlie this notion is largely unknown. The aim is to understand the interplay between the transcriptomic profiles and the microbiome in the hepatocarcinogenesis of X/MYC mice model.
Method: WT and X/Myc double transgenic mice, expressing in the liver both HBV HBx under control of viral regulatory elements and c-myc, were characterized by liver tumor (T) and peri-tumor (PT) RNA-seq (75 × 2 Novaseq Illumina). 16 s rRNA of mice stools was sequenced by Miseq Illumina platform at 10 and over 20 months, during liver carcinogenesis and at the development of HCC respectively.
Results: Integrative transcriptome analysis of T and PT indicated that X/MYC mice correlated with human subclass S2 HCC, characterized by proliferation as well as stemness. RNA species of WT, PT and T tissues showed a different transcriptomic profile depending on the gender. This difference could explain the low penetrance of HCC in females' mice. In particular we found a different pattern of mitochondrial metabolism according to sex. The distinctive sex molecular etiologies were confirmed by rRNAs 16 s results both during the carcinogenesis and at HCC development. The ecological parameters of males and females X/MYC mice are different and females' mice, while presenting a dysbiosis, they would seem to have a less harmful microbial community than males. The X/MYC females' distinctive species have been previously reported have a role in clinical response to anti-PD-1 immunotherapy. Finally, we defined a specific network of relevant RNA and bacterial species that characterized females and male hepatocarcinogenesis.
Conclusion: We found that X/MYC females and males mice developed a different liver tumor (time and transcriptomic profile) and that they exhibited a specific microbiota profile depending on the gender.

WED-541

Gut Akkermansia improves liver injury in D-penicillamine treated copper exposure model

Xi Huang[1], Yanqi Jin[2], Tianyuan Wang[3], Danting Fu[4], Yu Chen[4], Ren Yan[3], Yimin Zhang[5]. *[1]The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China; [2]The First Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou First People's Hospital, Hangzhou, China; [3]The First Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou, China; [4]Zhejiang Academy of Traditional Chinese Medicine, Hangzhou, China; [5]The First Affiliated Hospital, School of Medicine, Zhejiang University, Hang, China*
Email: 1307020@zju.edu.cn

Background and aims: Accumulation of copper is toxic to organs such as liver. Metal-chelators such as D-penicillamine (DPA) are commonly used in the treatment of copper overload. Proper manipulation of gut microbial composition can improve drug efficacy and safety. The objective of this study is to examine how targeted intervention of gut microbiota affects the effectiveness of copper removal in a copper exposure model while undergoing DPA treatment.
Method: First, after a 4-week treatment of DPA, the liver copper concentration and gut microbial composition in the copper exposure mice were evaluated to identify potential candidates for specific regulation of gut microbiota. Second, after 8 weeks of manipulating the gut microbiota during DPA treatment, the blood liver function indicators, tissue copper load, hepatic histopathological features and gut microbiota in copper exposure mice were investigated.
Results: The result showed that *Akkermansia* can enhance the effectiveness of DPA in treating copper exposure mice, whereas *Butyricimonas* has a counteractive impact. Supplementing with *Akkermansia muciniphila* (Akk) improved the effectiveness of DPA in eliminating copper from tissues, leading to a greater improvement in liver injury, liver dysfunction and gut dysbiosis in copper exposure mice. Gene function prediction analysis results indicated that the altered gut microbial function by DPA and Akk is primarily linked to the energy generation/utilization, amino acid, fatty acid, lipid and nucleic acid metabolism.
Conclusion: Our findings offered an experimental basis for the possible uses of targeted regulation of gut microbiota in the supplementary therapy of copper dysregulation disease.

WED-542-YI

Unravelling bacterial metabolites using high-resolution magic angle spinning nuclear magnetic resonance spectroscopy in intact hepatocellular carcinoma liver tissue

Wendy Fernandes[1,2], Nicola Harris[1,2], Lissette Adofina[3], Ane Zamalloa[3], Nigel Heaton[3], Krishna Menon[3], Parthi Srinivasan[3], Rosa Miquel[4], Yoh Zen[4], Geoff Kelly[5], James Jarvis[6], Alain Oregioni[5], Shilpa Chokshi[1,2], Antonio Riva[2,7], I. Jane Cox[1,2]. *[1]The Roger Williams Institute of Hepatology, Foundation for Liver Research, London, United Kingdom; [2]King's College London, Faculty of Life Sciences and Medicine, London, United Kingdom; [3]Institute of Liver Studies, King's College Hospital and King's College London, London, United Kingdom; [4]Liver Histopathology Laboratory, Institute of Liver Studies, King's College Hospital, London, United Kingdom; [5]MRC Biomedical NMR Centre, The Francis Crick Institute, London, United Kingdom; [6]Randall Centre for Cell and Molecular Biophysics and Centre for Biomolecular Spectroscopy, King's College London, London, United Kingdom; [7]The Roger Williams Institute of Hepatology, Foundation for Liver Research, London, United Kingdom*
Email: wendy.fernandes@kcl.ac.uk

Background and aims: Hepatocellular carcinoma (HCC) ranks among the top 5 global causes of cancer mortality, with 5-year survival rates of only 18%. Immune checkpoint inhibitors (ICIs) show promise in treating advanced HCC, achieving objective response rates (ORR) of 15%–20%. However, ICI resistance is still high, limiting efficacy, and has recently been linked to the gut microbiota, a pivotal factor in the development of anti-tumour immunity. Notably, increased intestinal permeability, bacterial translocation and high immune checkpoint expression in cirrhosis, a precursor to HCC, suggest possible links between gut microbiota, HCC, and ICI treatment response. This study used High-Resolution Magic-Angle-Spinning Nuclear Magnetic Resonance spectroscopy (HRMAS-NMR) to detect bacterial signatures in intact HCC tumour (TUM) and adjacent non-tumour (ADJ) tissue.
Method: Paired TUM/ADJ HCC tissue samples [n = 10 patients, M/F = 5/5, median (IQR) age 70 (65–79) years underwent HRMAS-NMR analysis [16.7 (16.0–18.0) mg] at stable 5000 Hz spinning rate and temperature (4°C) on a 600 MHz magnet, within 30 minutes of preparation. The human metabolome database and gutSMASH were used to curate a preliminary list of bacterial metabolites of interest. Untargeted analysis of HRMAS-NMR spectra was performed using KnowItAll and Metaboanalyst, in correlation with clinical/histological assessments.
Results: HRMAS-NMR identified dominant lipids with histopathological assessments indicating steatotic liver disease (SLD) and glucose in correlation with type-2 diabetes mellitus (T2DM) diagnoses. Distinctive HRMAS-NMR bacterial metabolite peaks, specifically formate and TMAO, were also identified in 7 patients, with variations in matched TUM/ADJ tissue. Ethanol detection was consistent in tumour tissue only from alcohol-consuming patients. No distinct clustering based on tissue, patient, or sex was observed even when considering non-bacterial metabolites.
Conclusion: HRMAS-NMR reveals bacterial metabolites in intact HCC liver tissue, reinforcing the gut microbiota-HCC connection. Tissue metabolic profiles dynamically characterise diverse histological patterns, offering crucial patient-specific information for improved data interpretation. This understanding can potentially shape subject-centric approaches for innovative HCC treatment strategies.

WED-543

Crosstalk between liver spheroids and pancreatic islets in the anterior chamber of the eye promotes growth and vascularization

Noah Moruzzi[1], Francesca Lazzeri-Barcelo[1], Nuria Vilarnau[1], Barbara Leibiger[1], Ingo Leibiger[1], Per-Olof Berggren[1]. *[1]Karolinska Institutet, Stockholm, Sweden*
Email: noah.moruzzi@ki.se

Background and aims: Metabolic disorders such as type 2 diabetes mellitus (T2DM) and metabolic associated fatty liver disease (MASLD) are comorbid and characterized by dysfunctional lipid and glucose homeostasis controlled by the endocrine pancreas and the liver. Therefore, monitoring of functional changes in these organs, currently hindered by their anatomical localization, and their crosstalk during disease development is pivotal to identify early disease mechanisms. The anterior chamber of the eye (ACE) has been proven to be a suitable transplantation site to monitor pancreatic islets non-invasively and longitudinally at cellular resolution. Recently, we showed that liver spheroids transplanted into the ACE engraft, become vascularized, innervated, and preserve the liver-like features and functions. The aim of this study is to implement our in vivo platform to study crosstalk between endocrine pancreas and liver in health and disease and identify responsible factors.
Method: Mouse liver spheroids generated in vitro and isolated pancreatic islets are transplanted singularly or together into the ACE of recipient mice and imaged by confocal microscopy. Human liver spheroids and islets are co-transplanted into immunodeficient mice. Light backscatter is used to longitudinally measure the size of the spheroids. Fluorescent probes are administered intravenously during in vivo imaging to identify vascularization. Islets and spheroids from FUCCI reporter mice are used to identify cell cycle/proliferation. Aqueous humor extracted from the ACE is subjected to mass-spectrometry to identify secreted factors. Mice transplanted with islets/spheroids are fed a high-fat-high-sucrose/fructose diet to identify changes in crosstalk factors during MASLD/T2DM development.
Results: Preliminary results show that liver spheroids and islets from mouse transplanted to mouse recipients engraft on the iris and become vascularized. Co-transplantation in the same eye results in growth of the liver spheroids compared to the spheroids transplanted without islets in the contralateral eye. Human liver spheroids solely made by purified hepatocytes fail to engraft on their own while co-transplantation with human islets results in fast and full vascularization.
Conclusion: We established a co-transplantation platform for non-invasive imaging of liver spheroids and islets in vivo, which enables identification of key factors involved in crosstalk between these two tissues. Our preliminary data suggest that crosstalk between islets and liver-like tissue from humans allows rapid vascularization while increased proliferation/hypertrophy occurs when tissues are derived from mouse. This ongoing study will help understanding the communication between the endocrine pancreas and the liver in physiology and during MASLD/T2DM development.

WED-544

Aging promotes liver injury: studies on C57Bl/6 mice

Karuna Rasineni[1,2], Sathish Kumar Perumal[1,2], Natalia Osna[1,2], Kusum Kharbanda[1,2]. *[1]VA Medical Center, Omaha, United States; [2]University Nebraska Medical Center, Omaha, United States*
Email: kkharbanda@unmc.edu

Background and aims: Many extrahepatic factors determine the liver disease phenotype and outcome. Among these, aging is a predominant risk factor for the development of advanced chronic liver diseases of various etiologies. Emerging evidence indicates that advanced age alters liver anatomy and physiology and causes dysfunction in many other organs including the gut that can increase the pro-inflammatory environment of the liver. Since the global population is aging and is predicted to double by 2050, this study was undertaken to establish a baseline of liver injury parameters in the young and old mice.
Method: Young (8–10 weeks old) and aged (20–22 months old) C57Bl/6 mice were purchased from the Charles River Laboratories (Wilmington, MA, USA). These chow-fed mice were housed in an AAALAC-accredited Animal Research Facility at the Omaha VA Medical Center. Metabolic phenotyping was conducted using the Sable Systems International Promethion system. The animals were

euthanized, and the serum and tissues (liver and gut) removed for subsequent analyses.
Results: Aged mice exhibited higher body weight and fat mass compared to their younger counterparts despite aged females exhibiting lower food and water consumption, and higher energy expenditure. Aged mice of both sexes showed higher hepatic triglycerides, elevated lipid peroxidation products and lower lysosomal acid lipase activity compared to their younger counterparts. However, only aged females displayed reduced hepatic S-adenosylmethionine levels, methylation potential, trypsin-like proteasome and lysosomal cathepsin B and cathepsin L activities compared to young female mice. Further, the increased hepatic expression of chemokine (C-C motif) ligand 2 and chemokine (C-X-C motif) ligand 2 in aged female mice was associated with a lower ileal methylation potential and increased intestinal permeability. Aging had no effect on serum AST and ALT levels, hepatic activities of alcohol metabolizing enzymes or the liver's ability to utilize betaine.
Conclusion: To conclude, chow-fed aged mice of both sexes exhibited some parameters of liver injury compared to their younger counterparts. However, more severe liver injury was seen in aged female mice. The data from this study will be used as a baseline to determine the effect of alcohol on gut-liver axis in aged versus younger mice.

WED-545-YI
Restoration of mucosa-associated invariant T (MAIT) cell function and metabolism in cirrhosis with rifaximin-a
Thomas Tranah[1,2], Juan Carlos Lopez Rodriguez[2], Lindsey Edwards[1,3], Patricia Barral[2], Debbie L. Shawcross[1]. [1]*King's College London, Institute of Liver Studies, Department of Inflammation Biology, School of Immunology and Microbial Sciences, Faculty of Life Sciences and Medicine, London, United Kingdom;* [2]*King's College London, Centre for Inflammation Biology and Cancer Immunology, School of Immunology and Microbial Sciences, Faculty of Life Sciences and Medicine, London, United Kingdom;* [3]*King's College London, Centre for Host Microbiome Interactions, Faculty of Dentistry, Oral and Craniofacial Sciences, London, United Kingdom*
Email: t.tranah@nhs.net

Background and aims: Reduced gut microbial diversity with increased pathobionts is a hallmark of cirrhosis and is associated with liver disease progression and susceptibility to infection. Mucosa-associated invariant T (MAIT) cells are an innate-like population of T cells that represent a sentinel system for homeostatic sensing of the intestinal microbiota and mucosal antimicrobial defence as they respond to riboflavin metabolites produced by bacteria. We aimed to characterise circulating MAIT cell function in cirrhosis before and following manipulation of the intestinal microbiota with rifaximin-α.
Method: Peripheral blood mononuclear cells were isolated from healthy donor controls and from cirrhotic patients at baseline and 7, 30 and 90 days after administration of the non-absorbable antibiotic, rifaximin-α 550 mg, twice daily. We utilised a combination of bulk RNA sequencing, flow-cytometry and *in vitro* experiments to characterise MAIT cell function, metabolic requirements and response to inflammatory stimulus.
Results: Circulating MAIT cells are present at reduced frequency in cirrhotic patients and display an activated phenotype with distinct gene expression profiles indicating enrichment of cytotoxic effector clusters with cytotoxic transcriptional programmes [normalised enrichment score (NES) 1.893; $p < 0.0001$]. This corresponded with upregulation of canonical markers of early and late T cell activation CD69 (31.5 vs 10.9%, $p < 0.0001$), HLA-DR (53.2 vs 12.1%, $p < 0.0001$) and the cytolytic agent granzyme B (43.5 vs 6.5%, $p < 0.0001$). MAIT cells from cirrhotic patients demonstrate enrichment of oxidative phosphorylation gene signatures (NES 2.758; $p < 0.0001$) with enhanced mitochondrial mass ($p < 0.001$) and membrane potential ($p < 0.001$). Hyperammonaemic conditions *in vitro* enhanced healthy control MAIT cell mitochondrial energy metabolism ($p < 0.001$) and cytotoxic effector responses to stimulation ($p < 0.001$). Rifaximin-α treatment led to a reduction in circulating ammonia levels ($p = 0.007$) in cirrhotic patients and was associated with reduced MAIT cell metabolic requirements and an improvement in the cytotoxic effector phenotype.
Conclusion: MAIT cells display enrichment of cytotoxic effector clusters in cirrhotic patients underpinned by distinct cellular metabolic requirements with enhanced mitochondrial oxidative phosphorylation observed in the context of circulating hyperammonaemia that is improved with rifaximin-α treatment.

WED-546
Evidence of gut microbiome differences in post-menopausal females with metabolic dysfunction-associated liver disease compared to pre-menopausal females and males
Laura Martinez-Gili[1,2], Roberta Forlano[2,3], Jesus Miguens Blanco[2], Panteleimon Takis[1], Mark R. Thursz[2,3], Julian R. Marchesi[2], Benjamin H. Mullish[2], Pinelopi Manousou[2,3]. [1]*Division of Systems Medicine, Department of Metabolism, Digestion and Reproduction, Imperial College London, London, United Kingdom;* [2]*Division of Digestive Diseases, Department of Metabolism, Digestion and Reproduction, Imperial College London, London, United Kingdom;* [3]*Department of Hepatology, St Mary's Hospital, Imperial College Healthcare NHS Trust, London, United Kingdom*
Email: laura.martinez@imperial.ac.uk

Background and aims: Prevalence and severity of metabolic dysfunction-associated liver disease (MASLD) is increased in females after menopause compared to age-matched males. The gut microbiome could be an important contributor to sex-specific phenotypes by modulating reproductive hormones. We investigated clinical, metabolic and gut bacterial differences between pre- and post-menopausal females and males in a prospective cohort of patients with type-2 diabetes mellitus (T2DM) screened for liver disease.
Method: Gut bacterial composition was determined by 16S rRNA gene sequencing, metabolomic profiling done with ultra-high performance liquid chromatography mass spectrometry and proton nuclear magnetic resonance spectroscopy and cytokines assessed by ELISA. Microbiome and metabolic signatures were analysed in post- versus pre-menopausal females, and post-menopausal females versus age-matched males diagnosed with MASLD. We used Mann-Whitney U test for continuous and Fisher test for categorical variables. ANCOMBC was used to assess bacterial composition. Linear mixed models (LMM) were fitted to metabolic and cytokine features and p values obtained with likelihood ratio test. All models were adjusted for age, alcohol, PPI, metformin, insulin use and index of multiple deprivation (random intercept in the LMM).
Results: Overall, 285 patients were enrolled. MASLD prevalence, based on US and CAP score, was 74% (210/285), while the prevalence of advanced fibrosis was 13% (36/285) and newly diagnosed cirrhosis secondary to MASLD was 3% (8/285). 128 were females; 87 post-menopausal. Post-menopausal females had a lower controlled attenuation parameter score than pre-menopausal ones ($p = 0.04$) and no difference in stiffness. Gut bacterial alpha diversity evenness was higher, and *Bacteroidota* phylum lower in post-menopausal than pre-menopausal females. Microbial-derived bile acids in stool, including taurodeoxycholic acid-3 sulfate and taurolithocholic acid, were lower in post-menopausal compared to pre-menopausal females, as well as tricarboxylic acid cycle metabolite fumaric acid. Serum interleukin-6 (IL-6) was higher, while stool IL-2, IL-13, tumour necrosis factor-alpha and interferon-gamma lower in post-menopausal with respect to pre-menopausal females. Compared to males, post-menopausal females had higher BMI, serum cholesterol, HDL and alkaline phosphatase, but lower alanine aminotransferase levels ($p = 0.002$). *Oscillospiraceae* NK4A214 genus was lower in post-menopausal females, as well as serum metabolites glutamic acid, citric acid and leucine.

Conclusion: We identified changes in systemic and gut inflammation and a lower abundance of bacterial-derived bile acids that were specific to post-menopausal females. The gut microbiome may be important in developing a personalised and sex-tailored therapeutical approach in females.

Amelioration of metabolic dysfunction-associated steatohepatitis by Lactobacillus delbrueckii subsp. lactis CKDB001 restoring gut microbiota

Hyunchae Joung[1], Yoojin Kwon[1], Yukyung Choi[1], Kyunghwan Kim[1].
[1]*CKDBiO, Seoul, Korea, Rep. of South*
Email: hcjoung@ckdbio.com

Background and aims: Many studies have reported on the prevention or treatment of various diseases, including inflammatory and metabolic diseases, cancer, and even mental disorders, by promoting a balanced gut microbiome, known as eubiosis. The gut microbiome can be influenced using probiotics, prebiotics, synbiotics, and postbiotics. In particularly, live biotherapeutic products (LBPs) have been suggested as innovative therapeutic substances. We isolated numerous bacteria from different sources and conducted *in vitro* screening to assess their safety and probiotic effects. Following screening, *Lactobacillus delbrueckii* subsp. *lactis* (*L. lactis*) CKDB001 was selected, and this *in vivo* study was carried out to evaluate the therapeutic efficacy of *L. lactis* CKDB001 against metabolic dysfunction-associated steatohepatitis (MASH).
Method: The genome of *L. lactis* CKDB001 was sequenced using PacBio RS II and assembled by Canu. Antimicrobial resistance (AMR) genes were identified based on the public databases. *L. lactis* CKDB001 was prepared for this animal study, and the viable cell concentration was measured. To evaluate the therapeutic effect against MASH, 5-week-old C57BL/6J male mice were fed a Gubra amylin NASH (GAN) diet for 16weeks to induce the disease. Following disease induction, *L. lactis* CKDB001 was orally administered for 8 weeks at varying doses: 1.0 × 10^8, 1.0 × 10^9, or 1.0 × 10^10 CFU/day. At the end of the administration, body and tissue weights were measured. Liver samples were fixed in 10% formalin and stained with HandE. RNA-sequencing analysis was performed on liver tissues, and metagenomic analysis was conducted using cecum samples.
Results: The genome of strain CKDB001 was fully sequenced, revealing a single circular chromosome of 2, 052, 085 base pairs without any plasmids. Bioinformatic analysis confirmed *L. lactis* CKDB001's safety as a probiotic, showing no harmful genes like AMR genes. Treatment with *L. lactis* CKDB001 led to a reduction in liver weight and fat mass in mice, coupled with improvements in liver enzyme concentrations and lipid profiles in the serum. The decrease in hepatic triglycerides and cholesterol showed a dose-dependent response in *L. lactis* CKDB001-treated groups. No side effects were observed in any of study groups over its duration. Moreover, the *L. lactis* CKDB001-treated groups showed enhanced alpha- and beta-diversity in the gut microbiota, accompanied by a decrease in the *Firmicutes/Bacteroidetes* (F/B) ratio. Additionally, RNA expression levels associated with inflammation significantly decreased in *L. lactis* CKDB001-treated mice.
Conclusion: The findings from our study suggest that *L. lactis* CKDB001 exhibits therapeutic potential for MASH by restoring the gut microbiome and reducing inflammation and lipid accumulation in the liver.

WED-548

Rifaximin-alpha acts through increased abundance of Lactobacillus spp. in murine models of chronic liver disease

Maximilian Joseph Brol[1], Camila Alvarez-Silva[2], Robert Schierwagen[1], Frank Erhard Uschner[1], Sabine Klein[1], Jonel Trebicka[1,3], Manimozhiyan Arumugam[2]. [1]*Department of Internal Medicine B, University Hospital Münster, Münster, Germany;* [2]*Novo Nordisk Foundation Center for Basic Metabolic Research, University of Copenhagen, Copenhagen, Denmark;* [3]*European Foundation for the Study of Chronic Liver Failure-EF Clif, Barcelona, Spain*
Email: maximilian.brol@ukmuenster.de

Background and aims: Rifaximin-alpha is a poorly absorbable broad spectrum antibiotic used for the prevention of recurrent hepatic encephalopathy. Despite its well-proven clinical benefit, the mechanism of action is not understood. In this study, we aim to investigate the effects of rifaximin-alpha on the microbiome in murine models of alcohol-related liver disease (ArLD) and metabolic dysfunction-associated steatotic liver disease (MASLD) without the use of lactulose.
Method: 12-week-old, C57Bl/6 mice were treated for 7 weeks with either a Methionine-Choline deficient diet (MCD), Western diet (WD), carbon tetrachloride (CCl_4) inhalations or a standard chow with or without ethanol treatment. Mice were further divided whether to receive rifaximin-alpha (30 µg/mouse/day) or not (n = 5 per group, total 16 groups). 16S sequencing was performed on fecal samples collected before and after injury induction. The experiment was repeated with a resolution phase of 7 weeks afterwards (control chow ± rifaximin-alpha). Liver phenotype was analyzed with regard to fibrosis (Sirius red, *col1a1* expression), steatosis (Oil Red O stains, *fasn* expression) and inflammation (*ccl2*, *ccr2*, *emr1* expression).
Results: MCD-treated mice showed the strongest decrease in alpha-diversity, though not significant, followed by WD and CCl4, irrespective of ethanol intake. Permutational multivariate analysis of variance (PERMANOVA) revealed that changes in beta-diversity are mostly driven by diet (p value = 0.001, R2 = 47.6%), with MCD showing the strongest effect compared to WD and control chow. Differential abundance analysis, adjusted for diet and ethanol intake, revealed a statistically significant difference only in the abundance of *Lactobacillus spp*. between the treated and untreated rifaximin groups (adj. p value = 0.0013). Interestingly, after further 7 weeks of resolution, *Lactobacillus* and *Bifidobacterium* are more abundant in non-rifaximin-alpha treated mice. Despite limited changes in hepatic cytokine expression, liver phenotypes were not significantly altered by rifaximin-alpha treatment.
Conclusion: Rifaximin-alpha treatment lead to an increase of *Lactobacillus* in different murine models of steatotic liver disease, possibly explaining fair effects in patients treated with lactulose.

WED-549

Urobilinogen promotes leaky gut by impacting intestinal integrity in a three-dimension intestinal organoid model system

Manisha Yadav[1], Jaswinder Maras[2], Abhishak Gupta[3], Babu Mathew[4], Nishu Dalal[5], Neha Sharma[2], Gaurav Tripathi[6], Vasundhra Bindal[6], Nupur Sharma[7], Sushmita Pandey[8], Rita Singh[9], Ashima Bhaskar[10], Ved Dwivedi[11], Anil Kumar[12], Niraj Kumar[13], Shvetank Sharma[14], Shiv Kumar Sarin[15]. [1]*Institute of Liver and Biliary Sciences, New Delhi, India;* [2]*Institute of Liver and Biliary Sciences, New Delhi, India;* [3]*Artimis Hospital, Gurgaon, India;* [4]*Institue of Liver and Biliary Sciences, New Delhi, India;* [5]*National Institute of Immunology, New Delhi, India;* [6]*Institute of Liver and Biliary Sciences, New Delhi, India;* [7]*Institue of Liver and Biliary Sciences, New Delhi, India;* [8]*Institute of Liver and Biliary Science, New Delhi, India;* [9]*Translational Health Science and Technology Institute, Faridabad, India;* [10]*International Centre for Genetic Engineering and Biotechnology, New Delhi, India;* [11]*National Institue of Immunology, New Delhi, India;* [12]*National Institute of Immunology, New Delhi, India;* [13]*Translational Health Science and Technology Institute, New Delhi, India;* [14]*Institute of Liver and Biliary Sciences, New Delhi;* [15]*Institute of Liver and Biliary Sciences, New Delhi, India*
Email: jassi2param@gmail.com

Background and aims: Severe alcohol related hepatitis (SAH) is accompanied by compromised liver functions with high levels of bilirubin and its derivatives production, with metabolic conversions occurring primarily in the intestine. Previously, we reported in 223 SAH patients, increased urobilinogen (bilirubin metabolic byproduct) levels resulting in inflammation and glucocorticoid receptor

suppression (https://doi.org/10.1101/2023.03.06.23286831). We investigated the effects of high urobilinogen on intestinal integrity and inflammation contributing to progression of SAH.
Method: We used a 3-D intestinal organoid model system as they provide more accurate representation of the in vivo microenvironment compared to traditional two-dimensional cell cultures. which was developed using HCT116 cell line was used to develop the organoid. This was exposed to different doses of urobilinogen (40 uM, 120 uM, and 120 uM). Various assessments were conducted to gauge the integrity of intestinal cells, including Transwell and TEER assays to measure permeability and resistance changes as compared to ethanol. The treatment dose of urobilinogen was comparable to that seen in SAH. Confocal microscopy for intestinal junction proteins along with genomic and proteomic evaluation were performed to elucidate effect of urobilinogen on the organoids as compared to ethanol.
Results: Progressive increase in urobilinogen concentration enhanced FITC-labelled dextran permeabilization through HCT116 monolayer by 6 folds similar to ethanol treatment ($p < 0.05$). We observed significant decrease in the transepithelial electrical resistance from 150 to 63.5 ohm cm-2, indicating leakage in the monolayer post urobilinogen and ethanol treatment compared to control ($p < 0.05$). Exposure of intestinal organoids with 40 uM, 120 uM, and 120 uM urobilinogen (conc. observed in SAH) significantly reduced the expression of critical proteins like TJP1 (4 folds) and claudin 1 (5.5 folds) (>1.5 FC, $P < 0.05$). Notably, genes responsible for maintaining cell integrity, such as desmoplakin, plakoglobin, desmoglein, and occludin, were downregulated both at the gene and protein level urobilinogen treatment ($p < 0.05$). Urobilinogen exposure stimulated proteins linked to inflammatory pathways, including interleukins, mTOR, and TNF-alpha, while simultaneously suppressed pathways associated with maintaining cell integrity (30% genes), such as focal adhesion and integrin ($p < 0.05$) suggesting inflammatory and intestinal compromising nature of urobilinogen.
Conclusion: Our findings demonstrate that urobilinogen, at concentrations comparable to those observed in SAH patient's blood, can detrimentally impact intestinal epithelial permeability, and promote leaky gut akin to the effects of ethanol. Clearance of urobilinogen may lead to therapeutic benefits in ALD patients.

WED-550
Unveiling the myth and truth of "Yellow Soup" in managing acute liver injury

Sen-Yung Hsieh[1]. [1]*Chang Gung Memorial Hospital, Taoyuan, Taiwan*
Email: siming.shia@gmail.com

Background and aims: The historical use of feces for treating acute ailments traces back to China's 4th Century, notably termed as "yellow soup" in Li Shizhen's *Compendium of Materia Medica* (Bencao Gangmu) during the 16th Century. However, the application in treating human diseases had not been widely recognized. Recently, fecal microbiota transplantation (FMT), specifically via colonic administration, has shown promise in treating certain diseases. Although oral fecal administration is more acceptable and accessible to patients, the microbe selection in the upper gastrointestinal tract (UGIT) through oral administration remains unclear. This study aimed to explore the effects of gut microbes and their metabolites post oral-route administration in addressing acetaminophen-induced liver injury (AILI) in mice.
Method: Acetaminophen was intraperitoneally administered to conventionally housed or germ-free C57BL/6 mice. Oral gavage of fresh or pasteurized fecal samples collected from healthy mouse donors was performed. Assessment of fecal microbiota and metabolites pre- and post-gavage was conducted. Mechanistic investigations were carried out in cultured hepatocytes and verified in AILI mice.
Results: Despite varying effects of commensal microbes on AILI in antibiotic-treated mice, short-term oral fecal gavage (OFG) consistently mitigated AILI severity and mortality. Oral gavage with pasteurized feces (OPG) produced comparable AILI alleviation to OFG. Microbiota profiling revealed time-dependent shifts in gut microbiome composition, particularly the enrichment of Lachnospiraceae post three-dose OFG within one week. Crucially, short-term OFG enriched butanoate biosynthesis pathways and short-chain fatty acids (SCFAs) in feces, among which butyrate significantly alleviated AILI in mice. Mechanistically, butyrate inhibited acetaminophen-induced ferroptosis by activating the AMPK-ULK1-p62 pathways, stimulating Nrf2 antioxidant responses, and promoting mitophagy. A combination of N-acetylcysteine and butyrate synergistically improved survival rates in AILI mice.
Conclusion: Oral administration of fecal microbiota exhibits a time-dependent shifts in gut microbiota composition. Our findings underscore the UGIT's role in reshaping administrated fecal microbiota and its importance in healthcare management. Further, this study provides a new paradigm by employing oral FMT and microbial metabolites to treat acute liver injury.

WED-551
Nitrogen recycling by the gut microbiome in sarcopenia

Rosa Haller[1,2], Olha Hazia[1,2], Julia Traub[3], Angela Horvath[1,2], Vanessa Stadlbauer[1,2]. [1]*Department of Gastroenterology and Hepatology, Medical University of Graz, Graz, Austria;* [2]*Center of Biomarker research in Medicine (CBmed) GmbH, Graz, Austria;* [3]*Department of Clinical Medical Nutrition, University Hospital Graz, Graz, Austria*
Email: rosa.haller@medunigraz.at

Background and aims: Sarcopenia is the loss of skeletal muscle mass and strength, and affects up to 70% of patients with cirrhosis. As many animals survive hibernation without extensive muscle loss, they are often studied in the context of sarcopenia. It was recently shown that the abundance of urease-producing bacteria is increased in hibernating squirrels and that the resulting nitrogen is incorporated into muscle protein. In the light of that finding, we aimed to gain a better understanding of nitrogen recycling potential in sarcopenia with a specific focus on sex differences since cirrhosis and sarcopenia have a male predominance.
Method: Stool samples of 152 patients (96 cirrhotics, 56 non-cirrhotics) with and without sarcopenia were obtained. We predicted the functional profiles of microbial communities based on 16S rRNA sequencing data (Tax4Fun2) and extracted the predicted abundance of urease subunits (alpha, beta and gamma). In addition, we conducted a systematic literature search to identify urease-producing taxa, extract their abundance from 16S rRNA sequencing data to compare them between patients with and without sarcopenia.
Results: Sarcopenia, but not cirrhosis nor sex was associated with lower urease gene abundance ($p < 0.05$). In women irrespective of cirrhosis ($n = 49$; 28 sarcopenic) and in patients with cirrhosis irrespective of sex ($n = 64$; $p < 0.05$) urease gene abundance was lower in sarcopenia. The systematic literature search yielded 120 taxa, of which 35 were present in sequencing data. Overall abundance of potentially urease-producing taxa was comparable between the groups with only slight and divergent differences in abundance of Bacteroides fragilis, Micrococcaceae and Clostridiaceae 1.
Conclusion: We found lower levels of predicted urease gene abundance in patients with sarcopenia. This gives first indications for the potential role of the gut microbiome and its nitrogen recycling potential in sarcopenia. More pronounced differences in women and patients with cirrhosis, two groups who are disproportionally affected by sarcopenia, point towards a potential precision medicine target.

WED-554

Lean and non-lean non-alcoholic fatty liver disease patients differ significantly with regard to gut microbiota expression: results of an observational study

Prajna Anirvan[1], Zaiba Khan[2], Pallavi Bhuyan[3], Giriprasad Venugopal[2], Manas Kumar Panigrahi[2], Balamurugan Ramadass[2], Shivaram Prasad Singh[1]. *[1]Kalinga Gastroenterology Foundation, Cuttack, India; [2]All India Institute of Medical Sciences, Bhubaneswar, India; [3]Dharanidhar Medical College and Hospital, Keonjhar, India*
Email: prajnaeatchiranjeet@gmail.com

Background and aims: Lean non-alcoholic fatty liver disease (NAFLD) has been described as a distinct pathophysiological entity. Gut microbiota dysbiosis has been linked to the pathophysiology of NAFLD. But studies comparing the expression of gut microbiota between lean and non-lean NAFLD patients are few. We aimed to compare the gut microbiota profile between lean and non-lean NAFLD patients.
Method: Fecal microbiome analysis was carried out on 71 (33 lean and 38 non-lean) NAFLD patients and an equal number of matched controls. Duration of study was two years-from January 2020 to December 2021. A total number of 1048727 sequence reads were obtained through 16 s rRNA gene sequencing and clustered into 685 OTUs, at the 3% dissimilarity threshold. 28 phyla, 133 genus and 259 species were identified. At species level, 259 OTUs were obtained. Data filtering was performed to improve downstream statistical analysis. By removing counts less than 4 and 20% prevalence and 10% low variance from inter quartile range, 44 OTUs were obtained.
Results: Firmicutes, Bacteroidetes, Actinobacteria and Proteobacteria comprised the 44 OTUs.
Proteobacteria were more prevalent in the NAFLD group as compared to the controls. Non-lean NAFLD patients had less Bacteroidetes and more Firmicutes whereas the opposite trend was observed for Lean NAFLD group. Although, there was no difference in alpha diversity between lean and non-lean NAFLD patients, beta diversity was found to be significantly different across all groups ($p < 0.05$). Higher abundance of *Coprococcus eutactus* in the lean group and *Streptococcus luteciae* in the non-lean group was observed. *Streptococcus anginosus and Rothia mucilaginosa* were found to be indicators of Lean NAFLD whereas *Veilonella dispar* was found to be an indicator of non-lean NAFLD group. Regression analysis revealed strong positive and negative association of microbes with various clinical parameters. *Bifidobacterium adolescentis* was positively associated with fibrosis in lean NAFLD patients while *Coprococcus catus* was negatively associated with fibrosis in the obese NAFLD group. Species network analysis too showed significant association of microbes with clinical parameters.
Conclusion: Although there was significant difference in beta diversity among lean NAFLD, non-lean NAFLD, lean control and non-lean control groups, lean and non-lean NAFLD patients did not differ with regard to alpha diversity. We hypothesise a shift in the gut microbiome profile of lean patients towards that of the non-lean phenotype to account for this finding. Longitudinal studies are required to prove this. There is also strong correlation of gut microbiota with clinical parameters in NAFLD patients.

WED-555

Metabolic dysfunction-associated steatotic liver disease and gut microbiota

Vitalii Petryna[1]. *[1]Ivano-Frankivsk National Medical University, Ivano-Frankivsk, Ukraine*
Email: petryna.vitaliy@gmail.com

Background and aims: Metabolic syndrome, cardiovascular disease, type 2 diabetes, obesity, and their complications lead to increased mortality and reduce quality of patient's life. Metabolic dysfunction-associated steatotic liver disease (MASLD) is currently recognized as one of the most common causes of chronic liver disease worldwide. Current scientific evidence suggests that there is a close relationship between the gut microbiota and chronic pathologies.
Method: To evaluate the frequency of development of bacterial overgrowth syndrome in the small intestine in MASLD and to determine the relationship between the presence of this syndrome, cytolytic activity, and the degree of liver fibrosis.
Results: Analysis of the frequency of bacterial overgrowth syndrome showed that changes in microbiota of the small intestine were observed in 75.0% of patients with MASLD. In 37.5% of patients, the level of liver transaminases at the time of the study did not exceed the reference values, in 42.7% moderate biochemical activity was noted (within 2–5 norms), in 20.8% of cases the level of transaminases was 5–10 norms, which indicated the pronounced activity of the process. Moderate fibrosis predominated in 70.8% of patients, while a significantly smaller number of patients (29.2%) had severe fibrosis. As a result of the correlation analysis of the data, no connection between the bacterial overgrowth syndrome and the degree of cytolytic activity in patients with MASLD was found (the value of the $\chi 2$ criterion was 0.879; the critical value of χ^2 at the significance level of $p < 0.05$ is 5.662; the relationship between factorial and outcome features statistically insignificant, probability level $p > 0.05$ ($p = 0.547$). There was also no relationship between bacterial overgrowth syndrome and the degree of fibrosis in the liver tissue (criterion $\chi^2 = 0.211$; the critical value of χ^2 at the significance level $p < 0.05$ is 3.752, the relationship between factor and outcome features is statistically insignificant, the probability level is $p > 0.05$ ($p = 0.580$).
Conclusion: The results of studies have established the existence of cause and effect relations between impaired microbiota of the intestine, imbalance of the immune system, as well as in one of the key pathogenetic roles in the development and progression of MASLD, reducing the protective properties of mucosa, enhancing translocation of microorganisms into the systemic circulation. Disturbance of small intestinal microbiota observed in three quarters of MASLD patients. However, the relationship between the presence of this syndrome and severity of cytolytic activity, as well as the degree of fibrotic changes in the liver were not detected.

WED-556

Gut microbiota promotes macrophage M1 polarization in hepatic sinusoidal obstruction syndrome via regulating intestinal barrier function mediated by butyrate

Si Zhao[1], Jiangqiang Xiao[2], Bing Xu[2], Yuzheng Zhuge[2]. *[1]Department of Gastroenterology, Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, Jiangsu, China, Nanjing, China; [2]Department of Gastroenterology, Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, Jiangsu, China, Nanjing, China*
Email: 2469981887@qq.com

Background and aims: Hepatic sinusoidal obstruction syndrome (HSOS) is a rare disease targeting hepatic sinusoids, sublobular veins and central veins of the hepatic lobules, which results in destructive damage of hepatic sinusoidal endothelial cells, congestion of hepatic sinusoids, and intrahepatic portal hypertension. The intestinal-liver axis is associated with various liver diseases. Here, we verified the role of the gut microbiota and macrophage activation in the progression of pyrrolizidine alkaloids-induced hepatic sinusoidal obstruction syndrome (PA-HSOS), and explored the possible mechanisms and new treatment options.
Method: The HSOS murine model was induced by gavage of monocrotaline (MCT). An analysis of 16S ribosomal DNA (16S rDNA) of the feces was conducted to determine the composition of the fecal microbiota. Macrophage clearance, fecal microbiota transplantation (FMT), and butyrate supplementation experiments were used to assess the role of intestinal flora, gut barrier, and macrophage activation and to explore the relationships among these three variables.

Results: Activated macrophages and low microflora diversity were observed in HSOS patients and murine models. Depletion of macrophages attenuated inflammatory reactions and apoptosis in the mouse liver. Moreover, compared with control-FMT mice, the exacerbation of severe liver injury was detected in HSOS-FMT mice. Specifically, butyrate fecal concentrations were significantly reduced in HSOS mice, and administration of butyrate could partially alleviated liver damage and improved the intestinal barrier in vitro and in vivo. Furthermore, elevated lipopolysaccharides in the portal vein and high proportions of M1 macrophages in the liver were also detected in HSOS-FMT mice and mice without butyrate treatment, which resulted in severe inflammatory responses and further accelerated HSOS progression.
Conclusion: These results suggested that the gut microbiota exacerbated HSOS progression by regulating macrophage M1 polarization via altered intestinal barrier function mediated by butyrate. Our study has identified new strategies for the clinical treatment of HSOS.

WED-557
Investigating gut microbial biomarkers for early detection of sarcopenia in individuals at various stages of alcohol-related liver disease
Haripriya Gupta[1], Seol Hee Song[2], Jeong Ha Park[2], Jeong Su Kim[2], Min Ju Kim[2], Sang Jun Yoon[2], Young Lim Ham[3], Ki Tae Suk[2]. [1]*Hallym University College of Medicine, Chuncheon;* [2]*Hallym University College of Medicine, Chuncheon, Korea, Rep. of South;* [3]*Daewon University, Jaecheon, Korea, Rep. of South*
Email: ktsuk@hallym.ac.kr

Background and aims: Sarcopenia and alcohol-related liver disease (ALD) are closely connected, affecting the liver and muscles. Excessive alcohol exacerbates protein breakdown during stress, influencing muscle function. Gut dysbiosis is explored in ALD, but its link to sarcopenia is underexplored. Our objective is to examine gut microbiota at early stage and correlate sarcopenia indices in ALD patients.
Method: Total 142 subjects were enrolled and categorized under non-sarcopenia (HC = 13, alcoholic hepatitis (AH) = 25, alcoholic cirrhosis (AC) = 27, alcoholic hepatocellular carcinoma (HCC) = 16) and sarcopenia (SC = 11, S-AH = 18, S-AC = 20, S-HCC = 12) having ALD for the study. Sarcopenia was assessed by Skeletal muscle area (SMA) divided by height (meter) squared index. Liver function test and stool microbiome analysis by 16S rRNA-based sequencing were examined.
Results: Sarcopenia indices ($p < 0.01$) were significantly decreased in sarcopenia vs non-sarcopenia ALD. Microbiome analysis showed significant shifts in sarcopenia vs non-sarcopenia ALD. In stagewise comparison, species *Parabacteroides goldsteinii*, *Phocaeicola dorei*, *Parasutterella excrementihominis* and *Prevotella copr*i were significantly low ($p < 0.05$, LDA>2.5, AUC of >0.69) in S-AH vs AH. Differentiating S-AC vs AC, species *Phocaeicola dorei, Bacteroides ovatus*, *Bifidobacterium catenulatum* were significantly low ($p < 0.05$, LDA>2.5, AUC of >0.67). S-HCC vs HCC, *Bacteroides faecis, Megamonas rupellensis* were significantly low ($p < 0.05$, LDA > 2.1, AUC > 0.74). Correlating those bacteria, increased and decreased bacteria in sarcopenia at different ALD stages were inversely and directly significantly correlated with sarcopenia indices ($p < 0.05$).
Conclusion: These findings suggest that early-stage ALD patients with sarcopenia, displaying a depleted Bacteroides species profile, may benefit from modifying gut microbiota. This could enhance clinical outcomes and improve the quality of life in ALD with sarcopenia individuals.

WED-558
Inhibition of miR-21 improves muscle activity in experimental metabolic dysfunction-associated steatotic liver disease
Diogo Fernandes[1], Mariana Moura Henrique[1], José Rodrigues[1], Ana Brígido[1], Carolina Palma[1], Laura Izquierdo-Sanchez[2,3,4], Jesus Maria Banales[3,4,5], Pedro Miguel Rodrigues[3,4,5], Rui E. Castro[1], André Simão[1]. Email: diogoaefernandes@gmail.com

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) presents as a complex multifactorial disease, in which dysregulation of metabolic homeostasis in the liver, as well as in distant organs, plays a substantial role. Recent evidence places skeletal muscle and the muscle-liver axis at the center of the MASLD pathogenic cascade. In fact, low muscle mass and muscle fat infiltration associates with increased risk of advanced MASLD, namely metabolic-associated steatohepatitis (MASH). In parallel, we showed that microRNA-21 (miR-21) is increased in the liver and skeletal muscle of MASH patients, with its abrogation ameliorating disease progression in vivo. Here, we investigated the effects of miR-21 on muscle function in the context of experimental MASLD.
Method: miR-21 knockout (KO) and wild-type (WT) mice were fed ad libitum with a high-fat/calorie diet (HFD) with high fructose/glucose corn syrup in drinking water for 20 weeks, or with a standard diet (SD), to recapitulate key, complementary metabolic features of human MASLD. Muscle phenotype and function were evaluated through grip strength and wheel running assays one week before sacrifice. In parallel, glucose tolerance test was also performed.
Results: Comparing to WT mice, HFD-fed miR-21 KO mice displayed lower weight increments and increased voluntary wheel-running distance, similarly to SD-fed WT mice. In parallel, mir-21 KO mice exhibited higher grip strength levels and presented with a glucose area under the curve lower than those of HFD-fed WT mice.
Conclusion: Our results suggest that miR-21 abrogation may ameliorate MASLD by acting upon the skeletal muscle, improving tissue function. These findings highlight the relevance of the muscle-liver axis in MASLD pathogenesis and, possibly, therapeutic targeting (PTDC/MED-PAT/31882/2017, 2022.08837.PTDC, FCT).

Establishing a Liver-on-Chip using tissue-resident progenitor cells from adult human liver
Defu Kong[1], Hans Blokzijl[2], Vincent de Meijer[3], Klaas Nico Faber[4]. [1]*Renji Hospital, Shanghai Jiao Tong University, School of Medicine, Shanghai, China;* [2]*Department of Gastroenterology and Hepatology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands;* [3]*Department of Surgery, Division of Hepato-Pancreato-Biliary Surgery and Liver Transplantation, University Medical Center Groningen, Groningen, Netherlands;* [4]*Department of Gastroenterology and Hepatology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands*
Email: dfkong@163.com

Background and aims: Organoids derived from tissue-resident liver progenitor cells (LPC) are increasingly recognized as valuable *in-vitro* models to study hepatic function and pathophysiological

mechanisms underlying liver disease. Also, Organ-on-Chip (OoC) microfluidic systems have become available that aim to reconstruct organ functions of selected or a combination of specific cell types. So far, LPC-derived organoids have not been applied in an OoC to build a Liver-on-Chip (LoC). Here, we aimed to culture LPC-derived cells in an OoC to study hepatocyte specific features.

Method: LPC-derived organoids were established from healthy human liver, digested into single cells, and then seeded in the MIMETAS Organoplate® 3-lane 40. After generating 3D tubular structures, cells were differentiated to mature hepatocytes. Hepatocyte markers (HNF4A, albumin, MRP2, BSEP) were visualized by immunofluorescence, and MRP2 functionality was analyzed by fluorescent bile acids. LoCs were incubated with troglitazone or free fat acids to analyze drug-induced toxicity and mimic the process of MASH.

Results: Human LPC-derived cells expanded and formed cellular tubules in the Organoplate OoC. After differentiation, the cells expressed albumin, MRP2 and BSEP of which both transporter proteins accumulated in the plasma membrane. The fluorescent bile acid CDFDA accumulated in an intercellular network, resembling canaliculi, in hepatocyte-differentiation conditions, while this was not observed in undifferentiated cellular tubules. Troglitazone disturbed the subcellular location of MRP2 and BSEP and impaired CDFDA transport to the intercellular network. In addition, Free fat acids led to an increasing ROS accumulation and lipid storage, without injuring cell viability in Organoplate OoC.

Conclusion: We developed a liver-on-chip system based on human tissue-resident hepatic progenitor cells, which can be used to study hepatocyte functions in health and diseases and allows mechanistic analysis of therapeutic drugs.

Email: maavila@unav.es

Background and aims: Transforming growth factor β (TGFβ) is a pluripotent cytokine that participates in all stages of liver disease. TGFβ has antiproliferative effects in hepatocytes and controls liver regeneration. High levels of TGFβ results in the activation of stellate cells to myofibroblasts. During liver tumorigenesis, TGFβ behaves as a suppressor factor at early stages; however, there is strong evidence that overactivation of TGFβ signaling might contribute to later tumor progression, once cells escape from its cytostatic effects. Recent findings indicate that the histone lysine-methyltransferase G9a is involved in the cellular responses to TGFβ but its contribution and the underlying mechanisms of action are still unclear. This work aims at elucidating the role of G9a in TGFβ signaling and to explore its potential as a mechanistic target in different aspects of liver disease.

Method: G9a overexpression and inhibition was performed in human and murine HCC cells. G9a chemical inhibitors (CM272 and UNC0642) were used. The effects of G9a gene expression manipulation and enzymatic inhibition on TGFβ1 actions were evaluated by RNAseq. Mechanistic studies were carried out by gene and protein expression analyses, promoter-luciferase reporter and ChIP assays. The role of G9a in TGFβ1 pathway was assessed in primary hepatocytes from mice with hepatocyte-specific G9a deletion ($G9^{\Delta hep}$) and in a model of acute liver damage induced by CCl4 administration in wild type and $G9^{\Delta hep}$ mice.

Results: Inhibition of G9a in HCC cell lines resulted in an impaired transcriptional response to TGFβ1 stimulation. These results were supported by the use of specific G9a inhibitors and observations in primary hepatocytes from $G9^{\Delta hep}$ mice. Transcriptomic analyses in Huh7 human HCC cells revealed significant alterations in TGFβ-mediated gene expression regulation when G9a was knocked down. G9a inhibition led to a profound decrease in TGFBRI mRNA and protein levels. Luciferase assays confirmed that G9a inhibition or overexpression negatively or positively modulated TGFBRI promoter activity, respectively. Analysis of regulatory elements controlling TGFBRI promoter activity identified SMAD3 as a likely candidate. G9a inhibition resulted in a downregulation of SMAD3 expression. ChIP analyses showed binding of G9a to a specific site in the SMAD3 gene promoter, suggesting a potential role for G9a as a coactivator of this central effector in the TGFβ pathway. In an acute liver injury mouse model induced by CCl_4, the upregulation of genes involved in fibrogenic and reparative processes mediated by TGFβ1 was significantly attenuated in $G9^{\Delta hep}$ mice compared to WT.

Conclusion: G9a acts as a potent regulator of the TGFβ pathway, directly modulating the expression of its central effector SMAD3. These findings provide a novel regulatory mechanism for a signaling pathway highly relevant in liver pathophysiology.

FRI-539

EGF/STAT1 signals to maintain ECM1 expression in hepatic homeostasis are disrupted by IFNγ/NRF2 in chronic liver disease

Yujia Li[1], Frederik Link[2], Weiguo Fan[3], Rilu Feng[4], Seddik Hammad[4], Honglei Weng[4], Matthias Ebert[4], Steven Dooley[5], Sai Wang[4]. *[1]Medical Faculty Mannheim, Heidelberg University, Mannheim, Germany; [2]Medical Faculty Mannehim, Heidelberg University, Mannheim, Germany; [3]Stanford University, Stanford, United States; [4]Heidelberg University, Mannheim, Germany; [5]Heidelberg University, Mannheim University, Germany*
Email: yujia.li@medma.uni-heidelberg.de

Background and aims: In healthy livers, latent TGF-β (LTGF-β) is stored in the extracellular matrix and kept quiescent by extracellular matrix protein 1 (ECM1). Upon damage, ECM1 is downregulated in hepatocytes, facilitating LTGF-β activation and hepatic fibrosis. This study investigates the regulatory mechanism of ECM1 expression in the liver under pathophysiological conditions.

Method: *In silico* promoter analysis was used to predict pathways for ECM1 transcription regulation. Functional assays were performed in AML12 cells, mouse and human primary hepatocytes (MPHs, HPHs), and in liver tissue of mice and patients.

Results: In healthy liver, EGF/EGFR signaling maintains ECM1 expression through phosphorylation of STAT1 at S727, which promotes its binding to the *Ecm1* gene promoter to enhance gene transcription. During inflammatory liver injury, accumulated IFNγ interferes with EGF signaling by downregulating EGFR expression and by disrupting EGF/EGFR/STAT1-mediated *Ecm1* promoter binding. Mechanistically, IFNγ induces STAT1 phosphorylation at position Y701, which is competing with the ability of p-STAT1 S727 to bind to the *Ecm1* gene promoter. Additionally, IFNγ induces NRF2

nuclear translocation and repressive binding to the *Ecm1* gene promoter, thus further reducing ECM1 expression. As a result, decreased levels of ECM1 facilitate LTGF-β activation, TGF-β signaling and fibrogenesis. Importantly, patients suffering from liver cirrhosis lacking nuclear expression of NRF2 consistently maintain higher levels of ECM1, inferring a better prognosis.
Conclusion: ECM1 expression in healthy livers is controlled by EGF/EGFR/STAT1 signaling. Upon liver injury, ECM1 expression is repressed by accumulating IFNγ/NRF2, which results in the activation of LTGF-β and the onset of hepatic fibrosis.

FRI-540
Role of hepatocyte-intrinsic humoral factors in establishing bioscaffold that regulates the fate determination of primary hepatocytes
Yuji Ishida[1,2], Go Sugahara[1,2], Chihiro Yamasaki[2], Sho Morioka[2], Mikaru Yamao[2], Jae-Jin Lee[3], Yasuhito Tanaka[4], Meng Li[5], Hyungjin Eoh[3], Chise Tateno[2], Takeshi Saito[6]. *[1]Department of Medicine, Division of Gastrointestinal and Liver Diseases, Keck School of Medicine, University of Southern California, Los Angeles, United States; [2]RandD, PhoenixBio Co., Ltd., Higashi Hiroshima, Japan; [3]Department of Molecular Microbiology and Immunology, Keck School of Medicine, University of Southern California, Los Angeles, United States; [4]Faculty of Life Sciences, Kumamoto University, Kumamoto, Japan; [5]USC Libraries Bioinformatics Service, University of Southern California, Los Angeles, United States; [6]Department of Medicine, Molecular Microbiology and Immunology, and Pathology, Division of Gastrointestinal and Liver Diseases, Keck School of Medicine, University of Southern California, Los Angeles, United States*
Email: saitotak@usc.edu

Background and aims: In vitro culture of human hepatocytes (HH) results in rapid quality deterioration, attributed to both the injury inflicted during cell procurement processes and the absence of a tissue-specific microenvironment. Our refined 2D culture approach, however, demonstrates that freshly isolated single-cell suspension HH undergo dynamic processes of in vitro wound healing, resulting in the reinstatement of genuine characteristics. These processes include the restoration of tight junctions, proper cellular polarity, morphological architecture, and the expression of hepatocyte marker genes at levels comparable to those observed in liver tissue. Our work also shows that the degree of fate restoration and maintenance is inversely correlated with the frequency of culture medium replacement, indicating the involvement of hepatocyte-derived humoral factors in this process. This study aims to decipher the autocrine role of hepatocyte-intrinsic humoral factors in determining the cell fate of HH.
Method: HH, either primary or derived from humanized liver chimeric mice (HLCM), were seeded onto collagen-coated plates and cultured for 14 days in medium containing hepatocyte-specific supplements. Subsequently, the culture medium was pooled as the conditioned medium (CM), and its impact on the fate restoration and maintenance of freshly isolated HH was compared with that of fresh medium (FM) via transcriptome analysis to identify responsible pathways, and loss of function approaches were employed for validation. Immunofluorescent and electron microscopic analyses were also conducted to characterize the impact of the conditioned medium (CM) on cellular and extracellular architectures. Lastly, HH cultured with the CM or FM were transplanted into uPA/SCID mice to determine their fate status by assessing the capacity to establish HLCM.
Results: The transcriptome of HH cultured with the CM exhibits a pattern highly resembling that of freshly isolated HH, normal human liver tissue, as well as the liver of HLCM. In contrast, HH cultured with FM show a significant upregulation of the TGFβ-YAP/TAZ pathway, as well as signature genes indicative of dedifferentiation or trans-differentiation to cholangiocytes. Microscopic analyses reveal that CM treatment promotes the accumulation of extracellular matrix (ECM) composed of fibrin, fibronectin, laminin, and vitronectin, preventing HH from developing morphological deformities. Studies employing a loss-of-function approach indicate that ECM formation is the key fate-protective effect of the CM. Lastly, the transplantation of HH cultured with the CM, but not with FM into HLCM host mouse showed efficient engraftment.
Conclusion: This study demonstrates the critical role of hepatocyte-derived humoral factors in shaping the fate of in vitro cultured HH by establishing ECM that mimics the liver tissue microenvironment.

FRI-541-YI
Taurine supplementation plays hepato-protective role against steatosis in mouse hepatocytes
Pavitra Kumar[1], Frank Tacke[1], Cornelius Engelmann[1,2]. *[1]Charité—Universitätsmedizin Berlin, Department of Hepatology and Gastroenterology, Berlin, Germany; [2]University College London, Institute for Liver and Digestive Health, Berlin, Germany*
Email: cornelius.engelmann@charite.de

Background and aims: Taurine, a semi essential micronutrient is taken up by cells through taurine transporter (SLC6A6). It has anti-aging potential shown in multiple organisms including humans. In liver, aging is associated with hepatic steatosis, fibrosis, dysregulated metabolism, and immune cells infiltration leading to metabolic dysfunction-associated steatotic liver disease (MASLD). A few anti-aging studies have shown 'what' taurine does to the liver however there is no study exploring 'how' taurine improves liver health. Therefore, the present study explores 'how' taurine supplementation affects the steatosis and steatosis-associated metabolism in hepatocytes.
Method: Primary mouse hepatocytes (PMH) were cultured overnight, were supplemented with optimized dose of 1 mM taurine for 24 hours, followed by 0.3 mM free fatty acids (FFA) (1:1 palmitic acid and oleic acid) for 24 hours. Neutrophils were isolated by negative selection-based microbeads and bone marrow-derived microphases (BMDM) were isolated by anti-F4/80 microbeads from mice bone marrow. Cellular bioenergetics and fuel dependency were assessed using XFe Seahorse analyser.
Results: FFA treatment increased SLC6A6 expression. Taurine-supplemented PMH showed 2-fold reduced lipid accumulation ($p < 0.001$) compared to FFA-treated cells. Taurine suppressed fatty acid uptake and lipogenesis, maintaining this even during FFA treatment. Taurine did not increase fatty acid oxidation, indicating reduced lipid accumulation resulted from decreased FFA uptake and lipogenesis. The metabolic landscape saw distinctive shifts in fuel preferences for ATP generation. Steatotic hepatocytes prioritized fatty acids, glucose, and glutamine, in that order. In contrast, taurine-supplemented steatotic PMH had a preference for glucose as their primary fuel source for ATP generation, followed by fatty acids and glutamine. Notably, taurine alone led to a reduction in glucose-dependent oxidative phosphorylation 2-fold ($p < 0.001$). Taurine's influence extended beyond fatty acid metabolism reaching into the inflammatory milieu. FFA treatment triggered an upregulation of pro-inflammatory cytokines and chemokines (IL6, TNFα, CCL2, and CXCL2), with taurine effectively suppressing all except CXCL2. Furthermore, the pro-inflammatory response translated into increased migration of neutrophils 1.5-fold ($p < 0.001$) and BMDM 2-fold ($p < 0.001$) in a trans well migration assay. Taurine alone, however, demonstrated a remarkable reduction in the migration of both neutrophils and BMDM, underscoring its potential anti-inflammatory impact.
Conclusion: Taurine supplementation robustly impacted hepatocyte metabolism and inflammation by suppressing fatty acid uptake and de novo lipogenesis. This effect persisted post-FFA treatment, highlighting taurine's hepato-protective role against free fatty acids-induced steatosis.

FRI-542

Induced pluripotent stem cell-derived hepatocytes revisited: improved liver functionality compared to liver cancer cell lines and a better model for pre-clinical large-scale therapeutic screening and drug safety

Magdalena Lukasiak[1], Gemma Gatti[1], George Kiloh[1], Samuel Chung[1], Ka Cheung[1], Chloe Robinson[1], Bhavik Chouhan[2], Dominic Williams[3], Lia Panman[1], Carlos Gil[1], Nikolaos Nikolaou[1]. [1]*DefiniGEN Ltd., Cambridge, United Kingdom;* [2]*AstraZeneca, Gothenburg, Sweden;* [3]*AstraZeneca, Cambridge, United Kingdom*
Email: nikolaos.nikolaou@definigen.com

Background and aims: Liver disease is a rising cause of mortality worldwide. Despite careful approaches taken during drug development, most therapeutics fail to reach clinical trials due to the lack of translatability between pre-clinical models and the clinic. Primary human hepatocytes (PHH) and hepatocellular cancer cells (e.g., HepG2) are currently used, however, they come with limitations, including short life-span, rapid loss of function, and malignant origin. We have hypothesized that induced pluripotent stem cell (iPSC)-derived hepatocytes can overcome these limitations, offering a sustainable *in vitro* platform in pre-clinical liver research.
Method: Healthy iPSCs were differentiated to hepatocytes (Opti-HEP) for six weeks. Characterisation of Opti-HEP, HepG2, and PHH functionality was assessed, including liver maturity marker expression and secretion by qPCR and ELISA, *de novo* gluconeogenesis by qPCR and glucose assays, urea synthesis by western blotting and urea assays, and cytochrome P450 expression and activity by qPCR and luciferase assays. Suitability of Opti-HEP to predict drug-induced liver injury (DILI) was evaluated by cell viability assays following 48 h treatment with 27 drugs of known DILI liability.
Results: HepG2, Opti-HEP, and PHH expressed similar levels of *ALB*, *A1AT*, and *HNF4A*, however, albumin secretion was higher in Opti-HEP and HepG2 cells compared to PHH (HepG2: 23.0 ± 2.6 vs. Opti-HEP: 25.0 ± 4.5 vs. PHH: 1.4 ± 0.9 μg/day/10^6 cells, n = 3–4). Urea-synthesizing enzyme expression (OTC, ASS1, ASL, CPS1, ARG) were higher in Opti-HEP compared to HepG2 cells, consistent with higher urea secretion (HepG2: 4.3 ± 0.3 vs. Opti-HEP: 18.5 ± 0.5 μg/day/10^6 cells, n = 3–4). *De novo* gluconeogenesis in Opti-HEP was investigated revealing increased *G6PC* and *PEPCK* mRNA levels following 0.1 mM dbcAMP treatment, consistent with enhanced glucose secretion upon pyruvate (PYR) challenge (0 mM PYR: 1.6 ± 0.01 vs. 1 mM PYR: 2.5 ± 0.02 vs. 2 mM PYR: 3.2 ± 0.03, fold change, n = 3). *CYP3A4*, *2B6*, *2C9*, *2C19*, *2A6*, and *ABCB11* mRNA levels were higher in Opti-HEP compared to HepG2 cells, in line with higher basal CYP3A4 activity (HepG2: 12.3 ± 2.2 vs. Opti-HEP: 338.7 ± 104.5 nmol Luciferin/μmol ATP). Crucially, Opti-HEP treatment with 1a, 25-hydroxy-vitamin D3 (CYP3A4 inducer; 100 nM) resulted in a >2.5-fold change increase in CYP3A4 activity, confirming successful CYP3A4 induction. Cell viability assessment following treatment with 27 drugs of known DILI liability showed similar levels of accuracy in predicting DILI between Opti-HEP and HepG2 cells.
Conclusion: Opti-HEP is a superior hepatocyte model compared to HepG2 cells, with liver functionality comparable to PHH. This data alongside the expansion capacity and amenability of Opti-HEP showcase the spectrum of opportunities this model can offer in the fields of disease modelling, large-scale therapeutic screening, and drug safety.

Background and aims: Males and females show different susceptibility, progression and outcome of several acute and chronic liver diseases. Among the factors that may account for these differences are estrogens, acting mainly through estrogen receptor alpha (ERa) at the hepatic level. We previously demonstrated that, in the liver of females, hepatic ERa acts as a sensor of food availability and regulates the hepatic metabolism according to the needs of the several stages of reproduction, thus linking metabolism and reproduction to each other. In particular, hepatic ERa activation by nutrients such as amino acids (AA) is necessary for the proper progression of the estrous cycle. The role of hepatic ERa in the regulation of liver metabolism and reproduction could be even more complex and relevant during pregnancy; however, it still needs to be investigated. Deregulations of hepatic estrogen signaling could also be implicated in pathological liver conditions related to pregnancy, such as intrahepatic cholestasis and acute fatty liver of pregnancy. In this view, a better understanding of the role of hepatic ERa during physiological progression of pregnancy could be crucial for the development of strategies to prevent or limit the progression of these conditions. Therefore, the aim of this study was to assess the specific relevance of hepatic ERa in the physiological adaptation of liver metabolism in different stages of pregnancy.
Method: To assess the specific relevance of hepatic ERa in the metabolic adaptation during pregnancy, we compared female control (CTRL) and liver-specific ERa-knockout (LERKO) pregnant mice at different timepoints (gestational day 6.5, 14.5 and 17.5). Virgin females at proestrus (the phase of the estrous cycle in which circulating 17beta-estradiol levels are highest) were used as the reference group.
Results: Results show that in the livers of female pregnant mice most of the genes analyzed, that are involved in lipid metabolism, glucose homeostasis and amino acid metabolism, display different expression patterns according to the progression of pregnancy. Moreover, hepatic ERa concurs to regulate the expression of some of the genes analyzed, especially those involved in AA metabolism. These findings are in line with our previous data and further demonstrate the tight connection between ERa and AA metabolism in the female liver.
Conclusion: Altogether, our results suggest that liver adapts its metabolism according to the different stages of pregnancy, to sustain the energetic needs of the developing embryo. Moreover, a contribution of hepatic ERa can be observed in the regulation of some of the analyzed pathways, hinting to this receptor as a possible key player in the orchestration of the metabolic adaptation during pregnancy.

FRI-544

KLB depletion fosters stem-like properties and epithelial-mesenchymal transition plasticity in HepG2 cells

Nadia Panera[1], Marica Meroni[2], Nicolò Cicolani[1], Francesca Tiano[1], Anna Ludovica Fracanzani[2], Paola Dongiovanni[2], Anna Alisi[1]. [1]*Bambino Gesù Children's Hospital, IRCCS, Rome, Italy;* [2]*Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milan, Italy*
Email: anna.alisi@opbg.net

Background and aims: Beta-Klotho (KLB), the co-receptor of fibroblast growth factor receptor 4, was found reduced at circulating and hepatic levels in both pediatric and adult patients with non-alcoholic fatty liver disease (NAFLD). This reduction was associated with inflammation, ballooning, and fibrosis. The genetic ablation of KLB in hepatocytes resulted in enhanced oxidative stress and inflammation, supporting its role in liver homeostasis but also suggesting a potential involvement of KLB in the hepatocyte transformation toward a neoplastic phenotype.
Here, we evaluated the impact of KLB depletion on the acquisition of stem-like properties and epithelial-mesenchymal transition (EMT) plasticity in the HepG2 in vitro model.
Method: We generated a complete full knock-out model of the KLB gene (KLB-KO) in HepG2 hepatoma cells by using CRISPR/Cas9. Subsequently, we performed functional assays to investigate cell

proliferation, self-renewal, and pluripotency. Critical EMT effectors were explored through gene and protein expression analysis.
Results: KLB mRNA and protein levels were reduced in KLB-KO cells ($p < 0.01$). Functional assays revealed the increase of cell proliferation ($p < 0.001$) and cell cycle S-phase ($p < 0.01$) in KLB-KO cells, if compared to Cas9 controls. The self-renewal ability of KLB-KO cells was assessed by analyzing the formation of free-floating cell aggregates in a 3D multicellular Tumor Spheroid model (TS) over 96 hours. Thus, KLB-KO cells reported the enlargement of the TS area and diameter at the last timepoints (72 hours, $p < 0.01$; 96 hours, $p < 0.0001$). Furthermore, the expression of 609 stem and pluripotency-related genes was analyzed by TaqMan OpenArray Human Stem Cell Panel, resulting in the upregulation of a total of 114 genes and the downregulation of a total of 49 genes. Among the enriched genes we found several mediators of the EMT process, such as the transforming growth factor beta 2 ($p < 0.01$), the matrix metalloproteinase-14, ($p < 0.01$), WNT3a ($p < 0.05$) which is involved in the modulation of beta-catenin and c-Myc ($p < 0.01$). Moreover, several effectors involved in lipid metabolism and storage and the alpha-fetoprotein (AFP) ($p < 0.0001$) were found downregulated in KLB-KO cells, suggesting the loss of the hepato-specific proprieties. Interestingly, the epithelial markers E-cadherin ($p < 0.001$), N-cadherin ($p < 0.01$), and cytokeratin 18 ($p < 0.001$) were found downregulated at gene and protein levels in KLB-/- cells, while the mesenchymal effectors Vimentin ($p < 0.0001$) and phosphorylated-FAK ($p < 0.01$) were increased in our model.
Conclusion: We demonstrated that KLB-KO confers in in vitro stemness and pluripotency features and may mediate the down-regulation of epithelial markers prompting the EMT. Thus, we hypothesize that KLB depletion may have a central role in the switching towards a phenotype that could have acquired pro-oncogenic features.

FRI-545
Dickkopf-1 inhibitor treated with sorafenib inhibited Wnt/PI3 K/Akt pathway in hepatocellular carcinoma

Seung Up Kim[1], Sang Hyun Seo[1], Hye Won Lee[1], Beom Kyung Kim[1], Jun Yong Park[1], Do Young Kim[1], Sang Hoon Ahn[1]. [1]*Yonsei University College of Medicine, Seoul, Korea, Rep. of South*
Email: ksukorea@yuhs.ac

Background and aims: Sorafenib prolongs overall survival of patients with advanced hepatocellular carcinoma (HCC). Overexpression of Dickkopf-1 (DKK1) was detected in HCC patients. Therefore, we studied combination effects and signaling pathways of sorafenib treated with DKK1 inhibitor in HCC models.
Method: Human HCC cells (Huh7 and Hep3B) were used to identify the IC_{50} values of sorafenib and DKK1 inhibitor. Hep3B cells and hydrodynamic tail vein injection were used to conduct HCC xenograft mouse and transgenic mouse. Mouse models were orally treated with sorafenib (32 mg/kg) and/or DKK1 inhibitor (16 mg/kg) for 10 days. Signaling pathways of sorafenib treated with DKK1 inhibitor were confirmed by immunoblot assays (western blot, IHC, IF staining) and qRT-PCR.
Results: Combination treatment of sorafenib and DKK1 inhibitor reduced the expression levels of Wnt/PI3 K/Akt related molecules [p110α, p-Akt (all $P < 0.05$), β-catenin (all $P < 0.05$), p-GSK3β-Ser9], but the expression level of p-GSK3-Tyr216 was augmented, compared to a single treatment in HCC models. The expression levels of PI3 K/Akt pathway inhibitory genes were augmented and the expression levels of canonical Wnt pathway target genes were reduced by combination treatment of sorafenib and DKK1 inhibitor (all $P < 0.05$), compared to a single treatment. Moreover, co-expression of Hras, miRp53 and PI3 K significantly augmented the expression levels of Wnt/PI3 K/Akt pathway molecules, compared to injected with Hras and miRp53 in transgenic mouse model.
Conclusion: Combination treatment of sorafenib and DKK1 inhibitor significantly inhibited Wnt/PI3 K/Akt pathway through regulation of GSK3β in HCC. Accordingly, inhibition of DKK1 may be a novel strategy in HCC. inhibition of DKK1 may be a novel strategy in HCC.

Email: nadir.abbas@uhb.nhs.uk

Background and aims: Obeticholic acid (OCA) is the only licensed second-line therapy for primary biliary cholangitis (PBC). However, real-world evidence is limited to data captured over 1–2 years following treatment initiation. The aim of this study was to evaluate long-term safety, tolerability and efficacy amongst the index series of patients (pts) treated with OCA following initial market approval in the United Kingdom (UK).
Method: Our cohort consisted of PBC pts who initiated OCA between 2017–19, with follow-up continuing to 2023. Pts were censored at the date of last clinic visit free of a clinical event, or at the point of switching from OCA to non-licensed therapy in fibric acid derivatives (fibrates), or on starting fibrates in combination with OCA.
Results: In all, we accrued data from 240 pts who initiated OCA (216 women; 218 also treated with ursodeoxycholic acid). Median transient elastography at baseline was 9.5 kPa IQR 7–14 kPa with 20% of pts having cirrhosis. Median ALT, ALP and bilirubin values at baseline (ratio to upper limit of normal) were 1.35 (1.02–2.04), 2.81 (2.02–3.96) and 0.55 (0.35–0.95). Over 48 months, 106 pts (44%) discontinued OCA because of side effects, most often pruritus (26%). Moreover, 45/106 pts switched from OCA to fibrates due to persistent biochemical non-response, with an additional 74 starting fibrates alongside OCA as combination therapy. In the group of pts who continued OCA (without switching/starting fibrates), the median reduction in serum ALP from baseline to 12-, 24-, 36- and 48 months was 27% (21–31%), 40% (35–51%), 43% (32–49%) and 54% (40–60%) ($p < 0.001$ for all). In turn, median reductions in serum ALT at 12-, 24-, 36- and 48 months were 25% (17–34%), 40% (32–56%), 42% (39–52%) and 43% (35–54%) ($p < 0.001$ for all). Biochemical response rates according to POISE and normal range criteria (normalisation in bilirubin, ALT and ALP) were 30% and 2%, 46% and 9%, 62% and 10% and 64% and 17% at 12-, 24-, 36- and 48 months, respectively ($p < 0.01$ for all). Forty pts experienced at least one clinical event; including hepatocellular carcinoma (n = 4); decompensation (n = 29); referral for transplantation (n = 27); or death from any cause (n = 13). Cirrhosis (hazard ratio [HR] 3.93; 95% CI: 2.09–7.38), not being treated with UDCA (HR: 1.96; 1.67–5.70), high bilirubin (HR: 1.08; 1.04–1.12), low albumin (HR: 0.91; 0.93–0.97), low platelets (HR: 0.98; 0.97–0.99) and being a non-responder according to POISE

criteria at 12 months of OCA therapy (HR: 5.49; 2.29–13.72) were risk factors for developing clinical events (p < 0.01 for all).
Conclusion: Biochemical response rates increase over time among pts under long-term OCA treatment. We also show, for the very first time, that the POISE criteria can be used to stratify risk of developing clinical events in an OCA-treated PBC cohort. However, drug discontinuation rates remain high, underscoring need for new treatment paradigms in PBC.

Interleukin-2 mediated regulatory T cell expansion is associated with dual outcomes of ductular reaction and liver fibrosis
Man Chun Wong[1], Gareth Hardisty[1], Naruhiro Kimura[2], Wei-Yu Lu[1].
[1]Institute for Regeneration and Repair, University of Edinburgh, Edinburgh, United Kingdom; [2]Division of Gastroenterology and Hepatology, Niigata University, Niigata, Japan
Email: s2425254@ed.ac.uk

Background and aims: Regulatory T cells (Tregs) exert immune-modulatory functions through suppressing immune responses. Expanding Tregs number has become an attractive option for controlling excessive inflammation during liver disease. Methods to manipulate Tregs as therapeutics have been performed in mouse models and clinically, including the use of IL-2 aiming to control the development and proliferation of CD4+ T cells. However, mixed results have been reported from these studies. To investigate the underlying mechanisms of the discrepancy using Tregs to contain disease progression, we explore the possibility of using IL2-antibody complex to expand Tregs in biliary and hepatocellular injury models to make IL2-mediated Tregs expansion more efficient.
Method: Tamoxifen was given to the Foxp3CreERTAi14 Tregs fate-mapping mice, inducing the expression of red fluorescence (RFP) in Tregs. A low dose of IL-2 complexes (IL-2 protein and anti-IL2 antibody) or PBS control was injected into the mice. All mice were then given the 3, 5-Diethoxycarbonyl-1, 4-Dihydrocollidine (DDC) diet to induce biliary injury. Immunostaining and PSR staining examined the degree of liver damage, ductular reaction and liver fibrosis. Immune cells, intrahepatic Tregs and their subsequent populations were analysed by flow cytometry. Similar experiments were also conducted in the context of hepatocellular injury using the $Mdm2^{fl/fl}$ mice receiving hepatotropic AAV-8 Cre.
Results: We found that Tregs expansion decreases the magnitude of ductular reaction, indicating less liver inflammation during the start of biliary injury. Interestingly, the decrease in the ductular reaction was not linked to a decrease in fibrosis as the fibrosis level was increased three-fold in the IL2 complex injected group. Flow cytometry analysis indicated that the IL-2 complex preferentially doubled the Foxp3+ Tregs population; however, a three-fold increase in the Foxp3– Tregs population was also observed. Using the fate mapping mice, we concluded that the expanded Foxp3– Tregs are "ExTreg," which originally belonged to the Foxp3+ population but acquired a pro-inflammatory phenotype.
Conclusion: IL-2 complex successfully expanded intrahepatic Treg during biliary injury. Tregs expansion does not decrease liver fibrosis during injury but causes a reduction in ductular reaction. The magnitude of the ductular reaction does not positively correlate to liver fibrosis, suggesting cholangiocytes are not the main driver of fibrogenesis. Further investigation is required on the dose and timing of Tregs expansion and the effects of expanded ExTreg. This study highlights the plasticity of Tregs in the liver and precautions for Tregs' stability if we aim to use Tregs expansion as a therapeutic approach.

Email: peni.arvaniti@gmail.com

Background and aims: More than 50% of patients with autoimmune hepatitis (AIH) relapse after immunosuppression (IS) withdrawal. Unfortunately, there are no available biomarkers for predicting disease flares after treatment discontinuation. Circulating microRNAs (miRNA) are associated with disease activity and could potentially serve as predictors of relapse in AIH. We aimed to evaluate the capacity of a circulating miRNA panel to predict relapse after treatment discontinuation in patients with AIH.
Method: This was a multicenter prospective study of IS withdrawal in 30 patients with AIH. Treatment was progressively tapered until complete withdrawal according to published guidelines. Circulating plasma expression of miR155-5p, miR122-5p, miR181-5p, miR21-5p, miR221-3p, miR4725-3p, miR6125, miR3196-3p, and miR4634 was assessed by reverse-transcription quantitative PCR using the 2^(-ΔCq) formula in samples obtained before IS withdrawal (T0), during follow-up (T1, before relapse with normal transaminases and IgG), and at the time of relapse (T2, or similar in patients with sustained complete biochemical response, CBR).
Results: Sixteen patients (53%) were female, with a median age of 59 years (IQR 49-70) and a median time of complete biochemical response of 44 months (IQR 37–55). At T0, the median levels of the liver tests were AST 19 IU/L (IQR 16–22), ALT 15 IU/L (IQR 11–22), and IgG 10 g/L (IQR 9–11). All patients were in histological remission (mHAI <4) at T0. After a median follow-up of 7 months (T2), 14 (47%) patients presented with disease relapse. Relapsers presented a significantly higher expression of miR122-5p at T0, T1 (median follow-up of 4 months, IQR 2–12) and T2 (p < 0.05 for all comparisons). In contrast, miR21-5p levels were significantly lower at T1, compared to non-relapsers (21 vs. 31, p = 0.02). No significant differences were detected among the remaining miRNAs analyzed. Using a general linear model with repeated measures, a significant increase in mR122-5p levels over time was observed among relapsers ($F_{(1, 28)} = 8.460$, p = 0.007), with a significant interaction effect on the probability of relapse ($F_{(1, 28)} = 8.772$, p = 0.004). Plasma levels of miR122-5p at T0 (AUC 0.771, 95%CI 0.592–0.951; p = 0.013), as well as the combination of miR122-5p and miR21-5p levels at T1 (AUC 0.901, 95%CI 0.734–0.978; p = 0.001), accurately predicted relapse after IS discontinuation.
Conclusion: Progressive elevation of miR122-5p along with a significant decrease in miR21-5p plasma levels was observed before any alteration in liver biochemistry in patients with AIH who relapsed after IS withdrawal. Assessment of miR122-5p expression before and at consecutive time points after discontinuation of IS can serve as a non-invasive predictor of relapse in AIH.

Email: sarp.uzun@usb.ch

Background and aims: The advent of immune checkpoint inhibitors (ICIs) has led to a major change in the management of different cancer types. However, ICI treatment can trigger treatment-limiting immune-mediated toxicity, so-called immune-related adverse events (irAEs). Checkpoint inhibitor-induced liver injury (ChILI) is a relatively common adverse event of ICI therapy, with a wide range of incidence between 1% to 15%. Although several mechanisms have been proposed, the pathophysiology of ChILI has not been fully understood. In this study, we aimed to perform a molecular comparison of ChILI with autoimmune hepatitis (AIH), a well-characterized immune-mediated liver disease, to enhance our understanding of this disease.
Method: Formalin-fixed and paraffin-embedded (FFPE) liver biopsy samples were collected from ChILI (n = 12), AIH (n = 9), alcoholic steatohepatitis (n = 18), hepatitis C virus hepatitis (n = 13), and normal liver samples (n = 3). Total RNA was isolated from FFPE samples and whole transcriptome sequencing was performed with HTG Transcriptome Panel. To explore the T-cell architecture of ChILI and AIH, FFPE extracted total RNA from AIH, ChILI and matching tumor samples of ChILI samples were sequenced for their T-cell receptor (TCR) by using the Oncomine TCR Beta-SR assay.
Results: Whole transcriptome analysis indicated that ChILI cohort has a different gene expression profile than AIH and other additional cohorts with liver inflammation. Transcriptome deconvolution revealed significantly lower enrichment of B cells and plasma cells in ChILI compared to AIH. Both ChILI and AIH cohorts presented a polyclonal distribution of T-cell clones with no significant differences in the diversity metrics, CDR3 nucleotide length distribution, and VDJ usage. Interestingly, we observed overlapping high-frequency T-cell clones in ChILI samples and their matched tumor samples obtained from the same patient.
Conclusion: ChILI has a different gene expression profile and immune cell distribution than AIH, supporting the notion that they are two distinct disease entities. However, both diseases share a similar T-cell repertoire architecture in liver biopsies. Interestingly, we detected overlapping T cell clones between ChILI and matched tumor samples, suggesting a role for shared epitopes between liver and tumor samples.

SRT-015: Novel therapeutic for cholestatic liver diseases

Kathleen Elias[1], S. David Brown[1], Neil D. McDonnell[1], Artur Plonowski[1]. [1]*Seal Rock Therapeutics, Inc, Seattle, United States*
Email: kelias@sealrocktx.com

Background and aims: SRT-015, a best-in-class apoptosis signal-regulating kinase 1 (ASK1) inhibitor, has demonstrated preclinical efficacy in a therapeutic, diet-induced obese mouse MASH model with biopsy-confirmed fibrosis and in acute models of liver injury including alcohol-related liver disease and acetamenophen overdose. In vitro studies have demostrated direct dose-dependent anti-apoptotic, anti-inflammatory and antifibrotic effects of SRT-015. Human safety and PK profile was established in a phase 1 clinical trial. Here we evaluate SRT-015 effects on fibrosis in a rat 14-day Bile Duct Ligation (BDL) model of severe cholestatic disease.
Method: Male Sprague Dawley rats (7–8 weeks,) were randomized to treatment groups (n = 4–10): 1) Sham vehicle 2) BDL + vehicle 3) BDL + 15 mg/kg SRT-015 4) BDL + 50 mg/kg SRT-015. SRT-015 or vehicle was dosed PO, starting at Day1, 1 h before surgery then daily for 14 days. BDL surgery included ligation of the common bile duct below the junction of the hepatic ducts and above the pancreatic ducts entrance. Sham animals underwent laparotomy without ligation. On terminal Day 14, 2 h after the last dose, whole blood and plasma was collected for blood chemistry (ALT, AST, ALP, TBil and TBA) or SRT-015 levels. Livers were evaluated for SRT-015 concentrations, fibrosis by biochemical hydroxyproline (HP) content, picrosirius red staining (PSR), and stellate cell activation (alpha-smooth muscle actin staining, a-SMA) by histomorphometry (Aperio ImageScope analysis software).
Results: BDL + vehicle group showed increased fibrosis and elevated blood chemistries compared to sham vehicle. The BDL + 50 mg/kg SRT-015 group demonstrated a significant ($p < 0.05$) antifibrotic effect by reducing fibrotic area by −40% (PSR staining) and −33% (HP content), and decreased α-SMA positive area −54% ($p < 0.0001$) vs. BDL + vehicle. BDL + 15 mg/kg SRT-015 group trended to decrease fibrotic area by PSR (−19%) and HP content (−28%) and significantly ($p < 0.01$) decreased α-SMA positive area (−32%) compared to BDL + vehicle. These significant decreases in fibrosis and stellate cell activation with SRT-015 were observed with no significant change in blood chemistries demonstrating the severity of this 14-day model. SRT-015 liver concentrations, in line with previous studies, showed liver-preferred distribution. The observed efficacious exposures of SRT-015 in this BDL model were within the range of observed clinical plasma levels, and predicted hepatic exposure, in the phase 1 clinical trial.
Conclusion: SRT-015 significantly, and dose-dependently, decreased BDL-induced fibrosis shown by multiple end points after 14 days of treatment in this robust model. These antifibrotic data, with previously demonstrated anti-inflammatory activity, suggests that SRT-015 is a promising therapeutic for human cholestatic liver diseases with an established safe clinical dosing regimen.

The role of interleukin-8 in primary sclerosing cholangitis-associated immune cell dysregulation

Lander Heyerick[1,2], Kevin De Muynck[1,2], Zenzi De Vos[1,2], Sander Lefere[2,3], Jana Roels[4,5], Niels Vandamme[4,5], Anja Geerts[2,3], Sarah Raevens[2,3], Xavier Verhelst[2,3], Hans Van Vlierberghe[2,3], Lindsey Devisscher[1,2]. [1]*Department of Basic and Applied Medical Sciences, Gut-Liver Immunopharmacology Unit, Ghent University, Ghent, Belgium;* [2]*Liver Research Center Ghent, Ghent University, Ghent University Hospital, Ghent, Belgium;* [3]*Department of Internal Medicine and Paediatrics, Hepatology Research Unit, Ghent University, Ghent, Belgium;* [4]*VIB Single Cell Core, VIB, Ghent-Leuven, Belgium;* [5]*VIB Center for Inflammation Research, Ghent, Belgium*
Email: lander.heyerick@ugent.be

Background and aims: Primary sclerosing cholangitis (PSC) is a chronic, progressive, fibroinflammatory liver disease. Dysregulated systemic and hepatic immune cell responses are implicated in the pathogenesis of PSC and could serve as a diagnostic and therapeutic target. However, PSC-associated systemic immune cell profiles remain insufficiently characterised. Therefore, we unravelled peripheral immune cell subsets of PSC patients and healthy controls at the single cell level and further investigated its implications in PSC pathogenesis.
Method: Peripheral blood mononuclear cells (PBMCs) were isolated by density gradient centrifugation from fresh EDTA-anticoagulated peripheral blood from PSC patients and healthy controls (HCs). PBMC cell suspensions were FACS-purified, single cell Gel Bead-in-Emulsions were generated and RNA-Sequencing libraries were created and analysed. IL-8 concentrations were determined in the sera of PSC-patients, without prior liver transplantation, and of

healthy controls. Adult male C57BL6/J mice were subjected to common bile duct ligation (CBDL) surgery and monocyte/macrophage populations were sorted by FACS and processed for bulk sequencing.
Results: Based on single cell analyses of PBMCs, we identified a population of CD14-positive monocytes with enriched IL8-expression in PSC patients (n = 7) compared to HCs (n = 4). Serum protein analyses showed that PSC patients are also characterised by increased IL-8 levels in the systemic circulation (n = 57 for PSC, n = 15 for HCs, age- and sex-matched). In addition, PSC patients with advanced fibrosis (Metavir stage F3/F4) had significantly higher serum concentrations of IL-8 compared to patients without advanced fibrosis (F0/F2, $p < 0.05$). AUROC analysis showed good performance of IL-8 to assess risk of liver-transplant free survival at 3 years of follow-up (AUROC 0.78). Bulk sequencing of isolated mouse liver monocytes and monocyte-derived macrophages in CBDL-induced cholestasis showed significantly upregulated expression of the IL-8 mouse homologs Cxcl1 (in monocyte-derived macrophages) and Cxcl2 (in monocytes and monocyte-derived macrophages) 2 weeks after surgery compared to sham-operated mice.
Conclusion: PSC patients are characterised by a population of CD14-positive monocytes enriched in IL8-expression and by elevated IL-8 concentrations in the systemic circulation. Serum IL-8 concentrations might serve as prognostic marker for liver-transplant free survival, but validation in larger cohorts is necessary. Further research is directed towards the role of IL-8 in monocytes and macrophages in the context of PSC pathogenesis to unravel its potential as therapeutic target.

SAT-152

The deletion of PTP1B protects against liver biliary damage by shitting immune cell recruitment and enhancing oval cell proliferation

Silvia Calero Pérez[1,2], Pilar Valdecantos[1,2], Angela Martinez Valverde[1,2]. *[1]IIBm Sols-Morreale (CSIC-UAM), Madrid, Spain; [2]CIBERdem (ISCIII), Madrid, Spain*
Email: scalero@iib.uam.es

Background and aims: Oval cells (OCs) are hepatic progenitor cells implicated in liver regeneration and repair upon injury. However, the impact of the inflammatory environment in oval cell expansion during primary sclerosing cholangitis (PSC) is unclear. Inhibition of protein tyrosine phosphatase 1B (PTP1B encoding by the *Ptpn1* gene) modulates immune cell responses and protects against acute and chronic liver damage. Our aim was to investigate the effect of *Ptpn1* deletion in the inflammatory compartment surrounding the OC niche and to characterize the proliferation/survival of *Ptpn1+/+* and *Ptpn1 –/–* OCs in the context of PSC.
Method: *Ptpn1–/–* and *Ptpn1+/+* mice were fed a diet supplemented with 0.1% of 3, 5-Diethoxycarbonyl-1, 4-Dihydrocollidine (DDC) for 2 weeks. For the analysis of the role of PTP1B in the inflammatory compartment of the OC niche *Ptpn1+/+* mice were transplanted with *Ptpn1–/–* or *Ptpn1+/+* bone marrow (BM) and mice were fed a DDC diet for 2 weeks. *Ptpn1+/+* primary hepatocytes were treated with a mixture of glycochenodeoxycholic and taurocholic acid for 8 h after which the conditioned medium (CM1) was used to stimulate *Ptpn1 +/+* or *Ptpn1–/–* bone marrow-derived macrophages (BMDM) for 16 h. Then, *Ptpn1+/+* OCs were treated for different time-periods with *Ptpn1–/–* or *Ptpn1+/+* BMDM-CM (CM2).
Results: *Ptpn1–/–* mice presents lower plasma bilirubin and porphyrin aggregates in the liver compared to *Ptpn1+/+* mice. Increased A6/SOX9 positive cells and expression levels of the OC markers *Krt19* and *Epcam* were observed in livers from *Ptpn1–/–* mice. Moreover, elevations in the number of recruited monocytes (Ly6c+), macrophages (F4/80+) and lymphocytes (CD3+) were observed in the OC niche from *Ptpn1–/–* mice. Flow cytometry analysis revealed increased M2-like macrophages as well as CD4+, Treg and Th2 lymphocytes in *Ptpn1–/–* mice concurrently with a decrease in M1-like macrophages, CD8+, Th1, Th17 lymphocytes and NKTs. All these parameters were recapitulated in mice transplanted with *Ptpn1–/–* BM. In vitro results demonstrated that stimulation of OCs with *Ptpn1–/–* CM2 enhanced survival signaling cascades (ERK and AKT phosphorylation) and promoted OCs proliferation.
Conclusion: Our results demonstrated that PTP1B deletion protects against biliary damage through the modulation of the inflammatory compartment in the OC niche. Moreover, in vitro studies revealed that the specific deletion of PTP1B in BMDM induced a molecular signature that favors OC proliferation and survival. These results open new therapeutic perspectives in cellular regenerative therapies against PSC.

SAT-153-YI

Single-cell RNA sequencing identifies the fundamental role of intrahepatic CD8+ T cells in the pathogenesis of autoimmune hepatitis

Ignasi Olivas[1,2], Aina Rill[3], Georgios Koutsoudakis[2], Yasmin Roldan[2], Pinelopi Arvaniti[1,2,4], Sergio Rodriguez-Tajes[1,2,5], Sabela Lens[1,2,5], Elisabetta Mereu[3], María Carlota Londoño[1,2,5]. *[1]Liver Unit, Hospital Clínic Barcelona, Barcelona, Spain; [2]Institut d'Investigació Biomedica August Pi y Sunyer (IDIBAPS), Barcelona, Spain; [3]Instituto de Investigación contra la Leucemia Josep Carreras (IJC), Badalona, Spain; [4]Department of Medicine and Research Laboratory of Internal Medicine, Expertise Center of Greece in Autoimmune Liver Diseases, ERN RARE-LIVER, University Hospital of Larissa, Larissa, Greece; [5]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Instituto de Salud Carlos III, Madrid, Spain*
Email: ignasiolivasalberch@gmail.com

Background and aims: The treatment of autoimmune hepatitis (AIH) has remained unchanged since the 70 s. This is partially due to a lack of knowledge regarding the mechanisms involved in the pathogenesis of the disease. Detailed analysis of lymphocyte populations in liver tissue using single-cell RNA sequencing (scRNAseq), single-cell T-cell receptor sequencing (scTCRseq), and flow cytometry (FC) would allow the design of targeted therapeutic strategies that are more effective and have fewer adverse effects. The aims of the study were to: 1) analyze the clonality and characteristics of lymphocytes in liver tissue at diagnosis and during follow-up, and 2) study the differences between patients with or without response to treatment.
Method: Ten patients diagnosed with AIH were prospectively included in this study. Mononuclear cells isolated from liver tissue (using fine needle aspiration) obtained at diagnosis (M0) and at 6 months of treatment (M6) were analyzed by scRNAseq/scTCRseq (Chromium 5′ protocol) and FC. Inflammation in baseline biopsy was evaluated using the modified activity index (mHAI). Complete biochemical response (CBR) was defined as normalization of ALT and IgG at M6.
Results: Most patients were women (n = 8, 80%), with a median age of 59 years. At M0 median ALT was 302 IU/L, IgG 17 g/L, and mHAI 7. Six patients reached M6, 3 of them in CBR. scRNAseq in liver tissue resulted in 35, 509 single cells showing a great diversity of CD4+, CD8 +, and myeloid lineage. By integrating scRNAseq and scTCRseq into liver cells, we observed an expansion of activated CD8+, tissue-resident memory CD8+ (TRM-CD8+), CD8+-NKT "like," and NK cells. Using FC, we confirmed a high frequency of TRM-CD8+, which significantly correlated with mHAI ($r_s = 0.72$; $p = 0.02$). In addition, central memory, and terminal effector memory CD8+ cells correlated with ALT levels ($r_s = 0.68$; $p = 0.04$; $r_s = –0.95$; $p < 0.01$, respectively). Patients who achieved CBR had a significantly lower frequency of NK cells and a higher frequency of macrophages than those without CBR ($p < 0.05$). At M6, we observed an expansion of CD4+ T cells, mainly regulatory T cells. In addition, there was a significant decrease in the frequency of TRM-CD8+ and naïve/transitional B cells and a significant increase in class-switched B cells by CF ($p < 0.05$). By analyzing the TCR repertoire, we observed a pronounced TCR diversity at M0, with a significantly higher proportion of hyper-

expanded clonotypes (100 >x ≤500) in CD8+ subpopulations, especially in patients without CBR. This percentage decreased at M6 in both groups.
Conclusion: CD8+ and NK cells seem to play an essential role in the pathogenesis of AIH and the regulation of the immune response. The diversity of TCR in M0 suggests that further expansion of self-reactive clones could hinder response to treatment. The increase in regulatory T cells might indicate partial recovery of immune homeostasis after treatment.

SAT-154-YI
Studying cholangiocyte properties and functions using a bile duct on a chip
Henry Hoyle[1,2,3,4], Anna Katharina Frank[1,2,3,4,5], Mathias Busek[3,6], Aleksandra Aizenshtadt[3], Fotios Sampaziotis[7,8,9,10], Tom Hemming Karlsen[1,2,4,11], Stefan Krauss[3,6], Espen Melum[1,2,3,4,11]. *[1]Norwegian PSC Research Center, Department of Transplantation Medicine, Division of Surgery, Inflammatory Diseases and Transplantation, Oslo University Hospital Rikshospitalet, Oslo, Norway; [2]Research Institute of Internal Medicine, Division of Surgery, Inflammatory Diseases and Transplantation, Oslo University Hospital Rikshospitalet, Oslo, Norway; [3]Hybrid Technology Hub, Institute of Basic Medical Science, University of Oslo, Oslo, Norway; [4]Institute of Clinical Medicine, Faculty of Medicine, University of Oslo, Oslo, Norway; [5]Scientia Fellowship, European Union`s Horizon 2020 research and innovation program under the Marie Sklodowska-Curie grant agreement No 801133, Norway; [6]Department of Immunology and Transfusion Medicine, Oslo University Hospital, Oslo, Norway; [7]Wellcome Trust-Medical Research Council Cambridge Stem Cell Institute, Jeffrey Cheah Biomedical Centre, University of Cambridge, Cambridge, United Kingdom; [8]Department of Surgery, University of Cambridge, Cambridge, United Kingdom; [9]Department of Medicine, University of Cambridge, Cambridge, United Kingdom; [10]Cambridge Liver Unit, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom; [11]Section of Gastroenterology, Department of Transplantation Medicine, Division of Surgery, Inflammatory Diseases and Transplantation, Oslo University Hospital Rikshospitalet, Oslo, Norway*
Email: h.w.hoyle@medisin.uio.no

Background and aims: Studies of bile duct function and diseases are limited by a lack of effective experimental models with relevance to human physiology. Cholangiocyte organoids have become a powerful *in vitro* tool but suffer drawbacks such as lack of a tubular structure similar to the bile ducts and difficulties in accessing their apical interior. To address these shortcomings, we have created an *in vitro* bile duct on a chip model incorporating patient derived primary human cholangiocytes. This provides a platform for studies ranging from basic cholangiocyte biology to modelling aspects of bile duct diseases. We aimed to demonstrate that this model is effective and scalable in studies of biliary processes with direct relevance for human medicine.
Method: A collagen gel containing a hollow channel was formed within a 3D printed bile duct chip. Primary human cholangiocytes were derived from brushings during endoscopic retrograde cholangiopancreatography (ERCP) and propagated as organoids prior to being seeded as a single cell suspension into the channel. Cells were grown in the chip for approximately 7 days before reaching confluency, forming the bile duct epithelium. The properties of the bile duct on a chip system were investigated using confocal microscopy and biochemical assays. Functional properties of the cholangiocytes were also tested using transport assays, with drug treatments to investigate the impacts of transport inhibition.
Results: Human cholangiocytes formed a robust and well differentiated epithelial monolayer around the channel lumen with clear similarities to a human bile duct. A fluorescent-labeled dextran permeability assay demonstrated that the epithelial layer was effective in blocking passive diffusion of molecules of different sizes (3, 10, 40, 70 kDa). Using lipopolysaccharide (LPS) as an external challenge relevant for inflammation we observed that the barrier was compromised. Staining for proteins such as actin, zonula occludens-1 (ZO-1) and multidrug resistance-associated protein 3 (MRP3) demonstrated a strong apical-basal cellular polarization and active transport of molecules across the epithelium was proven using the rhodamine 123 assay. This transport could be pharmacologically modulated using treatment with verapamil, inhibiting the multidrug resistance protein 1 (MDR1) transporter.
Conclusion: We have established a human and disease relevant bile duct on a chip using cholangiocyte organoids that is robust and scalable, and that can be readily created to study basic biology and disease pathways. When the model is challenged with addition of compounds such as bacterial components and drugs, robust and dynamic changes in the physiological properties were observed. This work paves the way for a completely new generation of future *in vitro* studies of the bile ducts that can probe deeper into disease-specific pathways and drug targets.

SAT-155
Impaired hepatic sympathetic neuronal communication intensifies hepatic inflammation, fibrosis and metabolic dysregulation, exacerbating liver injury

Bhat[1], Nupur Sharma[1], Csaba Adori[2], Anupama Kumari[1], Savneet Kaur[1], Babu Mathew[1], Ravinder Singh[1], Hami Hemati[3], Adil Bhat[4], Manisha Yadav[1], Gaurav Tripathi[1], Sushmita Pandey[1], Neha Sharma[1], Vasundhra Bindal[1], Abhishak Gupta[1], Roshan Koul[1], Viniyendra Pamecha[1], Nilesh Patil[1], Rakhi Maiwall[1], Tore Bengtsson[5], Manoj Kumar[1], Jaswinder Maras[1], Shiv Kumar Sarin[1]. *[1]Institute of liver and biliary sciences, New Delhi, India; [2]Karolinska Institute, Stockholm University, Stockholm, Sweden; [3]University of Kentucky, Lexington, United States; [4]University of California, Los Angeles, Los Angles, United States; [5]Stockholm University, Stockholm, Sweden*
Email: sadam.m11@gmail.com

Background and aims: The predominant innervation within liver is sympathetic. It originates from T7 to T12 segments of the spinal cord and plays crucial role in regulating various liver functions, including metabolism and regeneration. Injury to sympathetic nerves effect these hepatic functions, although their specific roles in disease progression and the associated molecular pathways remained obscure. Our aim is to identify the molecular pathways that altered due to sympathetic neuronal damage and are associated with liver injury.
Method: Liver-specific sympathetic denervation (Sx) models were developed by intraportal injection of 6-OHDA hydrobromide in male Sprague Dawley rats, 8-10 weeks old. Four distinct groups were formed: GR-1 (Veh; n = 21), rats with intact nerves; GR-2 (Sx; n = 24), sympathectomized rats; GR-3 (Veh + BDL; n = 30), rats having intact hepatic sympathetic nerves with BDL; and GR-4 (Sx + BDL; n = 51), sympathectomized rats with BDL. Histological, confocal microscopy, serum AST/ALT, and proteomic analysis were conducted at baseline, Day-7 (D7), D15, and D30 for all groups.
Results: Liver-specific sympathectomy in GR-2 and GR-4 was validated through observable changes including urine coloration, ptosis, and absence of sympathetic nerves marker (tyrosine hydroxylase; TH) in the liver sections. At D7 and D15, GR-2 exhibited mild steatosis and inflammation, but no significant difference in AST and ALT levels compared to GR-1. Histologically, increased fibrosis and inflammation was observed in GR-4 versus GR-3 ($p < 0.05$). Remarkably, at D15, fibrosis in GR-4 resembled that in GR-3 at D30 ($p < 0.05$). GR-4 displayed elevated AST and ALT values versus GR-3 ($p < 0.05$). GR-3 exhibited progressive disorganization of sympathetic nerves correlating with fibrosis severity and inflammation. Hepatic adrenergic receptors and gap junction proteins showed a gradual decrease in gene expression in GR-4 ($p < 0.05$), suggesting an impaired hepatic neuronal communication. Hepatic proteome revealed a significant difference between groups. In GR2 vs GR-1, 127 were upregulated and 80 were downregulated and in GR-4 vs GR-

3, 462 were upregulated and 235 were downregulated. These differentially expressed proteins were involved in the activation of both fibrogenic (TNFR2, Wnt, FGF) and inflammatory (NLRP3, MAPK, PDGF) pathways ($p < 0.05$). Interestingly, we also observed a significant metabolic dysregulation with the upregulation of TCA cycle ($p < 0.05$) and downregulation of urea cycle ($p < 0.05$) not only in GR-4 vs GR-3 but also in GR-2 vs GR-1, suggesting the role of sympathetic fibers in metabolic regulation in both healthy and diseased liver.
Conclusion: Degeneration of sympathetic innervations may lead to impaired hepatic neuronal communication, which is associated with an increased liver inflammation, fibrosis, and metabolic dysregulation resulting in exacerbation of liver injury.

SAT-158
Machine learning-driven identification of serum protein signature for primary sclerosing cholangitis and enhanced liver fibrosis score
Tom Snir[1], Raanan Greenman[1], Avi Katav[1], Revital Aricha[1], Matthew Frankel[1], John Lawler[1], Francesca Saffioti[2], Douglas Thorburn[3], Massimo Pinzani[4], Ilan Vaknin[1], Adi Mor[1].

Email: tom.snir@chemomab.com

Background and aims: Primary sclerosing cholangitis (PSC) is a rare disease, lacking treatment and reliable prognostic biomarkers to assess changes in disease activity. Proximity extension assay (PEA) of sera allows for extensive profiling of patients' proteome, and when combined with machine learning based methods, enables for the discovery of markers of disease presence and severity. CM-101, a monoclonal antibody that neutralizes CCL24, was shown to be safe and active in early clinical trials and is currently tested in a PSC phase 2a clinical study. Here, we present a potential PSC protein signature that may monitor and assess drug activity in clinical trials.
Method: Sera from 30 healthy controls (HC) and 45 patients with PSC were profiled with PEA, quantifying the expression of 2870 proteins (Olink Explore), which are used to train a regularized regression model, accounting for feature abundance. An elastic net model was trained using a 10-fold repeated cross validation, and proteins that contributed most (by importance, averaged across 100 runs) to differentiate between HC or patients with PSC were then tested for their correlation (<0.05, FDR) with their underlying enhanced liver fibrosis (ELF) scores. This signature was then used for overrepresentation analysis to obtain biological pathways and functions. Receiver operating characteristic (ROC) curves were generated for each protein.
Results: Elastic net successfully predicted disease (accuracy 0.98, ±0.2) while handing the relatively large number of variables. When combined with proteins correlated to ELF score, a ranked signature related both to disease presence and severity was apparent. The top-ranked proteins are associated with cell adhesion, immune response, and inflammation-all with area under receiver operator characteristic (AUROC) curves greater than 0.9 for disease presence and greater than 0.85 for ELF level (using a 9.8 threshold). Pathway analysis found that elastic fiber formation, cell adhesion, and extracellular matrix (ECM) organization was over-represented. Heatmaps showed successful unsupervised clustering of HC and patients with PSC with low or high ELF scores, with each individual protein showing a positive correlation to ELF score in patients with PSC.
Conclusion: A data driven, disease-agnostic approach characterizing PSC and its severity highlights potential serum protein biomarkers. The large proteomic data and the use of penalized regression points to a predictive protein signature associated with fibrosis, ECM, cell adhesion and migration. Notably, these functions were shown to be affected by CCL24 neutralization in clinical trials and pre-clinical models. These proteins will be monitored as markers for disease activity in an ongoing clinical trial in PSC patients treated with CM-101.

SAT-159-YI
Mitochondrial integrity and auto (mito)phagy are disrupted in experimental models of primary biliary cholangitis, contributing to disease pathogenesis
Irune Lasa-Elosegi[1], Laura Izquierdo-Sánchez[1,2], Paula Olaizola[1,2], Ainhoa Lapitz[1,2], Luis Bujanda[1,2,3], Matxus Perugorria[1,2,3], Pedro M. Rodrigues[1,2,4], Jesus Maria Banales[1,2,4,5].

Email: irune.lasaelosegui@biodonostia.org

Background and aims: Primary biliary cholangitis (PBC) is a chronic cholestatic and immune-mediated liver disease of unknown origin. Our prior research revealed an increased expression of microRNA-506 (miR-506) in PBC cholangiocytes, targeting the $Cl^-/HCO3^-$ exchanger AE2. This leads to intracellular pH (pHi) disturbances and PBC-like features, including PDC-E2 overexpression and immune activation. Autophagy, and particularly mitophagy, is a crucial cell-intrinsic, quality-control and anti-inflammatory mechanism designed to eliminate dysfunctional organelles, such as mitochondria. Although these processes are critically dependent on pHi, their role in PBC remains unknown. Our aim was to characterize the mitochondrial dynamics and auto (mito)phagy processes in PBC and evaluate their contribution to disease pathogenesis.
Method: Experimental *in vitro* PBC models, including miR-506-overexpressing cholangiocytes (H69 miR-506) and control cells (H69 miR- and H69), were subjected to high-throughput proteomic analysis. Additionally, these cells were assessed for mitochondrial dynamics, integrity, activity, auto (mito)phagy, and cell viability under baseline conditions and in the presence of various anti-cholestatic drugs.
Results: High-throughput proteomics revealed significant alterations in several proteins related to mitochondrial dynamics and autophagy/mitophagy in H69 miR-506 cholangiocytes compared to control cells. Notably, gene-set enrichment analysis (GSEA) indicated a stronger association of processes related to antigen presentation, inflammation, and mitochondrial organization and translation in H69 miR-506 cells. Specifically, genes involved in mitochondrial fusion (linked to increased functionality) were downregulated, while a gene related to mitochondrial biogenesis (associated with *de novo* mitochondrial generation) was upregulated. These changes were accompanied by decreased mitochondrial functionality, as measured by flow cytometry, indicating an accumulation of defective mitochondria and impaired mitophagy. Consistently, the presence of auto (mito)phagy inhibitors potentiated toxic bile acid-induced cell death, particularly in miR-506 cells. Importantly, incubation of H69 miR-506 cholangiocytes with ursodeoxycholic acid (UDCA), obeticholic acid (OCA), or bezafibrate (BZF) improved mitochondrial functionality and energy metabolism, normalizing the overexpression of PDC-E2.
Conclusion: Our findings suggest that cholangiocytes in PBC exhibit disruptions in mitochondrial integrity and auto (mito)phagy, resulting in the accumulation of dysfunctional mitochondria and abnormal presentation of mitochondrial antigens. Current anti-cholestatic and anti-fibrotic drugs used in PBC can modulate these mitochondrial disturbances, emphasizing that the regulation of mitophagy represents a novel target in PBC.

SAT-160

Lysophosphatidic acid (LPA)-receptors, a group of established itch receptors, show elevated agonism during cholestasis and are likely to contribute to cholestasis-associated itch

Frank Wolters[1], Dagmar Tolenaars[1], Michel van Weeghel[2], Rudi de Waart[3], Stan van de Graaf[1], Coen Paulusma[1], Ulrich Beuers[1], Ronald Oude-Elferink[1]. [1]*Tytgat Institute for Liver and Intestinal Research, Amsterdam Gastroenterology Endocrinology Metabolism (AGEM), Amsterdam UMC, Amsterdam, Netherlands;* [2]*Core Facility Metabolomics, Amsterdam UMC, Amsterdam, Netherlands;* [3]*Tytgat Institute for Liver and Intestinal Research, Amsterdam Gastroenterology Endocrinology Metabolism (AGEM), Amsterdam UMC, Amsterdam, Netherlands*
Email: f.wolters@amsterdamumc.nl

Background and aims: The etiology of cholestasis-associated pruritus is poorly understood, resulting in suboptimal treatment. The search for itch factors continues, but is hindered by a lack of molecular understanding of the involved itch receptors in this form of pruritus. Recently, we showed that a panel of established itch receptors (TRPA1, TRPV1, TRPV3, TRPV4 and MRGPRX4) poorly respond to bile salts, bilirubin and patient serum and plasma, questioning their direct involvement in itch (*Wolters et al., manuscript in preparation*). Based on our previous observations that the activity of the lysophosphatidic acid (LPA)-forming enzyme autotaxin correlates with pruritus intensity in cholestasis (PMID: 20546739), we studied which LPA-receptors as established itch receptors are activated due to elevated patient plasma autotaxin activity.
Method: LPAR-TANGO constructs were obtained from the Presto-TANGO library. LPA-receptor activation by patient plasma was quantified by means of dual-luciferase assays in HEK293-HTLA cells. LPA species and concentrations were identified and quantified by means of HPLC-MS in 45 cholestatic patient samples and in 15 healthy controls.
Results: HEK293-HTLA cells, transfected with LPAR-TANGO constructs, showed significantly higher activation upon incubation with patient plasma compared to healthy controls. This activation could be abrogated by the autotaxin inhibitor HA155. Particularly strong activation was observed with LPAR2. The extent of LPAR receptor activation significantly correlated with pruritus intensity in patients ($p = 0.0004$) and with their plasma autotaxin activity ($p = 0.0026$). HPLC-MS analysis showed elevated levels of LPA in patients. Particularly LPA 20:4 levels showed significant correlation with pruritus intensity ($p = 0.0099$).
Conclusion: Unlike the other investigated receptors, LPA receptors show marked activation by cholestatic patient plasma compared to healthy controls. The significant correlation between autotaxin, levels of its product, LPA, and the extent of in situ LPA receptor activation on the one side and itch severity on the other strongly suggests that LPA is a dominant pruritogen in cholestatic itch with LPA 20:4 as the most potent LPA species. Hence, the LPA-receptors, and particularly LPAR2, are likely to be involved in the generation of cholestasis-associated pruritus. The autotaxin-LPA receptor pathway is a promising target for treatment of cholestasis-associated pruritus.

Email: claudia.fuchs@meduniwien.ac.at

Background and aims: In cholestasis, intrahepatic accumulation of bile acids (BAs) results in liver and bile duct injury. We hypothesized that inhibition of BA conjugation, subsequently increasing levels of non-amidated BAs in the BA pool and changing BA composition, may induce bile flow, thus improving cholestatic liver and bile duct injury.
Method: Male FVB/N mice received 3, 5-diethoxycarbonyl-1, 4-dihydrocollidine (DDC) over 4 weeks to induce sclerosing cholangitis-like phenotype/injury and cholestasis with/without siRNA treatment to silence Cyp2c70 (siCyp2c70) to humanize the BA pool. DDC-fed mice with/without siCyp2c70 were treated with siRNA to inhibit BACL (siBACL) and subsequently BA conjugation. Liver injury was assessed biochemically and by (immuno)histology. Bile flow measurements, BA profiling from serum and bile as well as biliary glutathione levels, hepatic hydroxyproline content were also investigated. RNA sequencing from bulk liver tissue as well as mRNA profiling by RT-PCR and immunoblotting were performed.
Results: Silencing BACL in mice challenged with DDC and siCyp2c70 (WT DDC siCyp2c70+siBACL), improved biochemical and histological features of liver and bile duct injury. CK19 and VCAM protein levels-as surrogate markers for reactive cholangiocytes-were significantly reduced by siBACL treatment by 60% and 80%, respectively. Hepatic fibrosis was improved in DDC siCyp2c70+siBACL in comparison to DDC siCyp2c70 controls as reflected by reduction of hydroxyproline levels by 50%. Accordingly, RNA sequencing revealed significant downregulation of fibrosis markers (e.g. Col12e1, Col14a1, Col4a2, Fbn1). Moreover, RNA sequencing showed increased levels of GSTa1, GSTa3, GSTa5, GSTm2 and GSTm3 (all involved in ROS detoxification) among the top upregulated genes in the DDC siCyp2c70+siBACL group. siBACL treatment reduced biliary levels of conjugated BAs (90% in DDC siCyp2c70 vs 50% in DDC siCyp2c70+siBACL mice), with cholic acid being the most prominent unconjugated BA in DDC siCyp2c70 +siBACL animals, that demonstrate a 2-fold and 4-fold increase in bile flow and biliary glutathione output, respectively.
Conclusion: Our data indicate that inhibition of BA conjugation improves liver and bile duct injury, presumably by increasing bile flow and biliary glutathione levels and by reducing oxidative stress.

SAT-163-YI

Spatial characteristics of cell compartments in primary sclerosing cholangitis

Markus S. Jördens[1,2,3,4], Jonas Øgaard[1,2], Tom Luedde[4], Tom Hemming Karlsen[1,2,3,5], Brian K. Chung[1,2,3,6], Espen Melum[1,2,3,5,7]. Email: markus.joerdens@med.uni-duesseldorf.de

Background and aims: Primary sclerosing cholangitis (PSC) is characterized by peribiliary immune infiltration and cholangiocyte destruction. To detect disease driving interactions between immune

cells and cholangiocytes that may represent novel treatment targets, we analyzed explanted early non-fibrotic and late end-stage cirrhotic livers using spatial transcriptomics.
Method: Fresh frozen liver explants (n = 28) were analyzed by spatial transcriptomics (10× Genomics), including 21 PSC patients (4 recurrent cholangitis and no fibrosis, 7 dysplasia and no fibrosis and 10 cirrhosis) and 7 non-PSC controls with advanced cirrhosis. Sequencing data were analyzed by SpaceRanger and unsupervised K-means clustering was performed using Loupe Browser (10X Genomics). Statistical significance for differential gene expression (DEG) analysis was calculated using the exact negative binomial test. All stated DEG have a p value <0.01 (Benjamini-Hochberg corrected). Relative cell abundances were estimated from spatial transcriptomes using a public human liver single cell reference and CIBERSORTx deconvolution analyses.
Results: Clustering analysis identified two parenchymal clusters and two fibrotic clusters closely correlating with tissue morphology visualized by HE staining. Independent of disease, DEG analysis revealed a hepatocyte-dominated profile for the central parenchymal cluster (*ALB, APOC1, HP*) whereas the parenchymal cluster adjacent to fibrosis showed upregulation of several inflammatory markers (*SAA1, SAA2, CRP*) compared to the other clusters. Both fibrotic clusters showed a significant increase in inflammatory markers (*S100A6, TIMP1, CCL19, IGHG1, CD74, HLA-DRA*) relative to parenchymal clusters. Cell type abundances identified mainly hepatocytes and cholangiocytes within the central parenchymal cluster, whereas the parenchymal cluster adjacent to the fibrotic tissue showed immune infiltration dominated by monocytes and pDCs. Fibrotic regions adjacent to the parenchyma contained mesenchymal and endothelial cells, monocytes and ILCs, with the majority of B and T cells localized within the central fibrotic cluster. When comparing PSC and controls, both parenchymal PSC clusters showed higher expression of oxidative stress markers (*MT1H, MT1G*) or immune regulation/response (*HLA-DRB5, HLA-DRB1, FOXP3, CCL18*). In fibrotic clusters, PSC samples also showed increased markers of chronic inflammation (*SAA1, SAA2*), oxidative stress (*MT1H, MT1G*) and immune activation (*THY1, CXCL8, CCL16*).
Conclusion: Diseased PSC livers have distinct gene expression patterns in both fibrotic and non-fibrotic tissues. Gene expression profiling and cell type deconvolution indicate specific upregulation of inflammatory markers in clusters adjacent to fibrotic areas, highlighting a diverse cellular landscape within different liver tissue compartments.

SAT-164-YI
Mice lacking the NO receptor develop primary sclerosing cholangitis
Muhammad Ashfaq-Khan[1], Cornelius Caesar[1], Andreas Friebe[1].
[1]*Physiologisches Institut, Würzburg, Germany*
Email: m.ashfaq_biotech@yahoo.com

Background and aims: Primary sclerosing cholangitis (PSC) is a form of cholestatic liver disease that finally leads to biliary cirrhosis. Lack of full understanding of mechanistic drivers of chronic liver disease in general and of PSC in particular hamper the development of innovative treatment strategies. In the present study, we have characterized the role of the NO receptor, NO-sensitive guanylyl cyclase (NO-GC).
Method: 8–10-week-old male mice carrying a global deletion of NO-GC and their wildtype siblings (C57BL/6J background) were fed control diet and Western diet (21% fat, 0.2% cholesterol) and 42 g/l fructose in drinking water for 16 weeks. Thereafter, mice were sacrificed, and liver tissues were fixed in paraformaldehyde for histological evaluation to assess the rate of disease progression. Analyses included HE, Sirius red staining, immunofluorescence, and confocal microscopy.
Results: In contrast to wildtype siblings, NO-GC knock mice on control diet had altered ductular architecture of the biliary system and increased ductular proliferation (between PSC stage 1 and stage 2) which worsened on Western diet (≥stage 2). Compared to the WT mice on control diet, fibrosis stage in NO-GC KO mice had increased significantly ($p = 0.0001$) which enhanced two-fold upon feeding Western diet. In addition, cytokeratin 19 was upregulated significantly in NO-GC KO mice both on control diet ($p = 0.0179$) and on Western diet ($p = 0.0227$) vs WT mice. Moreover, a-SMA expression was increased in NO-GC KO mice compared to mice on control diet. Furthermore, CD3, CD4 and CD8 expression was increased significantly in NO-GC KO mice on control diet which had upregulated in NO-GC KO mice fed on Western diet. MASLD-related events under Western diet were obvious in WT but absent in NO-GC KO mice.
Conclusion: Deletion of the NO receptor in mice led to spontaneous primary sclerosing cholangitis and biliary fibrosis. The PSC phenotype worsened upon feeding Western diet. Thus, we identify a so far unknown role of NO-GC in primary sclerosing cholangitis.

Impaired muscle metabolism during exercise is associated with elevated IL-6 in PBC patients with fatigue: is this a new therapeutic target?
Aaron Wetten[1,2], Laura Jopson[2], Amardeep Khanna[1,2], Denise Howel[3], Andy Bryant[3], Andrew Blamire[2], Julia Newton[2], Jennifer Wilkinson[4], Alison Steel[5], Jennifer Bainbridge[1], Renae Stefanetti[6], Sophie Cassidy[6], David Houghton[6], Jessica Dyson[1,2], David E. Jones[1,2]. Email: aaron.wetten@nhs.net

Background and aims: Primary Biliary Cholangitis (PBC) is progressive autoimmune cholestatic liver disease. Significant peripheral fatigue affects over 50% of PBC patients, and has the greatest impact on functional status, leading to social isolation and worsening quality of life. Muscle fatigability and mitochondrial dysfunction have been demonstrated in PBC, but mechanisms are poorly understood and there is no effective treatment. Interleukin-6 (IL-6) has a significant role in muscle metabolism during exercise, whilst chronically elevated IL-6 has been implicated in skeletal muscle fatigability and mitochondrial dysfunction. This study explored the association between serum IL-6 and muscle metabolism in a cohort of PBC patients with significant peripheral fatigue.
Method: Forty-one participants enrolled in the phase 2 Rituximab as a treatment for fatigue in PBC (RITPBC) trial had serum IL-6 levels measured using electrochemiluminescence immunoassays. They completed two 180 s cycles of controlled plantar flexion at 25% and then 35% maximal voluntary contractions, using purpose-built exercise apparatus. Muscle metabolism was recorded by phosphorous spectra via novel magnetic resonance spectroscopy. Anaerobic thresholds (AT), the point at which muscles switch from aerobic to anaerobic metabolism, were measured using integrated cardiopulmonary exercise testing on a stationary ergometer.
Results: A positive correlation was observed between serum IL-6 and total pH fall (increased acidosis) during all exercise and as well as recovery time (return to baseline pH), as assessed by area under the curve (AUC) [0.340, CI 95% 0.031–0.590, $p = 0.027$]. A greater fall in pH with individual exercise (increased acidosis) was observed in those with higher serum IL-6 levels [0.324, CI 95% 0.01–0.578, $p = 0.036$]. Overall, the lower the pH during exercise the longer the pH recovery time [−0.522, CI 95% −0.719–−2.46, $p < 0.01$]. A higher baseline pH correlated with a superior AT threshold [0.443, CI 95% 0.148–0.666, $p = 0.004$], but no correlation between serum IL-6 levels and AT was observed.

Conclusion: Impaired muscle metabolism, exhibited by increased muscle acidosis during exercise, was observed in patients with elevated serum IL-6. This translated across all exercise periods, with increased falls in pH (increased muscle acidosis) and extended recovery times to baseline pH (resolving muscle acidosis) after exercise occurring in patients with higher IL-6 levels. This suggests chronic IL-6 elevation may play a pivotal role in PBC peripheral fatigue. IL-6 blockade therapies significantly improve fatigue in other chronic inflammatory conditions and may present a new therapeutic strategy for fatigue in PBC.

SAT-166

Functional relevance of CD44 for hepatocyte proliferation in diet-induced liver injury models

Sophia Bernatik[1], Franziska Ihli[1], Kohnke-Ertel Birgit[1], Fabian Delugré[1], Carolin Mogler[2], Fabian Geisler[1], Roland M. Schmid[1], Ursula Ehmer[1]. *[1]Clinical Department for Internal Medicine II, TUM School of Medicine and Health, University Medical Center, Technical University of Munich, Munich, Germany; [2]Institute of Pathology and Unit of Comparative Experimental Pathology, Klinikum rechts der Isar, Technische Universität München, Munich, Germany*
Email: ge54key@mytum.de

Background and aims: The cellular adhesion molecule CD44 has been linked to liver regeneration and fibrosis development. In animal models of cholestatic liver injury, high expression of CD44 is observed in ductular reactions (DR) around the portal triad, while in acute, diet-induced hepatocyte injury, expression of CD44 is strongly increased in hepatocytes. To date, the functional relevance of CD44 for regeneration in different liver injury models is unknown.
Method: Acute hepatocyte injury was induced by choline-deficient and ethionine-supplemented (CDE), while the 3, 5-diethoxycarbonyl-1, 4-dihydrocollidine (DDC) diet was utilized to specifically cause damage to intrahepatic bile ducts in male *Cd44*$^{-/-}$ (KO) mice and age-matched C57BL/6J control mice. As a model of a chronic liver injury, *Mdr2*$^{-/-}$; *Cd44*$^{-/-}$ mice and age-matched *Mdr2*$^{-/-}$ control mice were used. Livers were analyzed at different time points by liver immunohistopathology for expression of CD44 and the proliferation marker Ki67.
Results: In acute hepatocyte injury induced by 3 weeks of CDE diet, CD44-deficient mice comprised a significantly lower number of proliferating cells (Ki67+) in the liver (23.11% vs 14.73% p = 0.0434) with a dramatic decrease of hepatocyte proliferation (18.56% vs 6.927% p = 0.0175). Similarly, hepatocyte proliferation decreased after 2 weeks of DDC diet in CD44-deficient mice (30.51% vs 9.94% p = 0.0176). Even though CD44 in acute cholestatic liver injury (DDC diet) was highly expressed in DR, no difference in ductular proliferation was observed in *Cd44*$^{-/-}$ mice in comparison to controls. In contrast, chronic cholestatic injury in *Mdr2*$^{-/-}$ mice was associated with proliferation of DR and almost no proliferation in hepatocytes. Here, a significant difference in proliferation between *Mdr2*$^{-/-}$; *Cd44*$^{-/-}$ and *Mdr2*$^{-/-}$ was observed after 3 months (39% vs 18.20% p = 0.0421) with no difference in hepatocyte proliferation.
Conclusion: Our study utilized two well-established dietary models and a genetic model of chronic cholestasis to assess the functional role of CD44 in acute and chronic liver damage. In acute liver damage, high expression of CD44 correlates with proliferation in hepatocytes but not in DR, while CD44-deficiency in chronic cholestatic injury influences proliferation also in periportal DR. These findings highlight the cell type-specific-and possibly injury-dependent-role of CD44 in liver regeneration and further research will be needed to identify the differential cellular mechanisms mediating CD44-dependent cell proliferation.

SAT-167-YI

Generation and utilisation of an advanced iPSC-derived hepatocyte model for cholestasis modelling

Elena Garitta[1], Adam Syanda[2], Cyril Lemerle[3], James Boot[1], Jemima Burden[3], Chris Stefan[3], Richard J. Thompson[4], Kenneth Linton[1], Tamir Rashid[2]. *[1]Queen Mary University of London, London, United Kingdom; [2]Imperial College London, London, United Kingdom; [3]University College London, London, United Kingdom; [4]Kings College London, London, United Kingdom*
Email: e.garitta@qmul.ac.uk

Background and aims: Cholestasis is a pathology of the liver characterised by impaired bile formation and flow. It can be caused by genetic mutations in canalicular transporters ABCB11 (BSEP), ABCB4 or ATP8B1, or by drugs. Drug-induced cholestasis (DIC) can be life threatening and often results in clinical trial failures or withdrawal of licenced drugs. Our inability to faithfully replicate human cholestasis with current pre-clinical models limits our mechanistic understanding of this disease and accordingly restricts our ability to identify DIC-causing drugs before they reach patients. These gaps are largely due to species specific differences in composition of human and rodent bile acid pools that reduce disease penetrance in murine models and the rapid loss of bile production seen with primary human hepatocyte ex vivo culture. Patient derived iPSC -human hepatocytes (iHEPs) and advanced ex vivo culture techniques offer a potential solution to these problems. Indeed, recent advances with iHEP technology have resulted in an ability to phenocopy key features of metabolic and virally mediated pathology. To date however, there has been less success in generating iHEPs with functional bile canaliculi (BC) and canalicular transporters as is critical for modelling cholestasis. This study accordingly aimed to overcome this roadblock by developing iHEPs which are multipolar, possess functional canalicular transporters and could model DIC.
Method: iPSCs underwent an optimised 25-day hepatocyte differentiation protocol. DIC was induced with bosentan, a BSEP inhibitor, or by feeding excess chenodeoxycholic acid for 6 days. Functional, immunological and gene expression assays, along with confocal and transmission electron microscopy (TEM), were employed to validate iHEP physiology and characterise the induced cholestatic phenotype.
Results: The new differentiation cocktail in combination with an ECM sandwich-culture significantly improved the hepatocyte functionality, polarisation, and ultrastructural phenotype of iHEPs. BC expressed canalicular ABC transporters, were sealed by junctional complexes and developed a brush border, closely resembling normal liver tissue. BC functionality was confirmed by active excretion of a fluorescent MRP2 substrate into the canalicular lumen. DIC caused by BSEP inhibition and bile acid overload demonstrated changes in BC and mitochondrial morphology and ultrastructure, such as canalicular dilatation and curling of mitochondrial cristae, as seen in patient tissue samples, as well as mitochondrial dysfunction, ER stress and the secretion of inflammatory cytokines.
Conclusion: Our new iHEP model provides a more physiologically relevant platform for human cholestasis modelling, offering insights into disease mechanisms and facilitating screening of compounds that cause DIC.

SAT-170

Establishing a cholangioid library for biliary niche-on-a-chip multicellular models for the study of liver disease-associated ductular reaction

Tian Lan[1,2], Natalia Martagón Calderón[1], Guo Yin[1], Hanyang Liu[1], Queency Okechukwu[1], Milad Rezvani[1], Frank Tacke[1], Adrien Guillot[1]. *[1]Charité Universitätsmedizin Berlin, Berlin, Germany; [2]West China Hospital, Sichuan University, Chengdu, China*
Email: tian.lan@charite.de

Background and aims: Ductular reaction (DR) that includes ductular cell and macrophage accumulation is a disease progression hallmark

in virtually all chronic liver conditions. Hence, ductular cells are proposed as disease progression drivers. Yet, optimal models for functional studies of ductular cell biology are still lacking. We aim to evaluate the direct influence of ductular cells on liver macrophage activation. For this purpose, we generated a library of mouse intrahepatic cholangioids (mICO) from healthy and DR mouse models, and established a biliary niche-on-a-chip (BoC) as an in vitro perfusable multicellular system.

Method: Intrahepatic cholangiocytes were isolated from wild-type and Mdr2-deficient (KO) mice by magnetic-activated cell sorting and expanded to generate 3-dimensional mICO. Quantitative RT-PCR (qPCR) and immunostaining were performed to confirm cell identity and functionality. Dissociated WT and KO mICO were seeded into the BoC together with mouse primary hepatic stellate cells, endothelial cells, and hepatic macrophages. The BoC system was perfused with freshly isolated blood circulating immune cells.

Results: Both WT and KO mICO expressed the biliary markers CK19, CK7, and acetylated tubulin (the marker of primary cilium). KO mICO showed distinct features when compared to WT mICO, notably increased proliferation (PCNA staining) and expression of chemokines (*Cxcl1, Ccl2*), bile acid transporters and receptors (*Gpbar1, Slc10a2, Slc51a*), and bicarbonate secretion-related genes (*Cftr, Aqp1*). KO mICO also showed decreased stemness (*Sox9, Lgr5, Tpm2*), and altered chemo/osmosensing function of the primary cilium (*Trpv4, P2ry12*). mICO reversed their polarity and turned to apical-out cholangioid (AOO) when cultured in suspension, as showed by staining of polarity markers such as ZO-1 and beta-catenin. Both WT-AOO and KO-AOO exposed their apical side for potential further treatment and were more proliferative than corresponding mICOs. Mouse primary liver macrophages treated with conditioned medium from WT mICO showed increased expression of *Il1a, Il1b, Il6, Il10, Ccl2, Inos*. This effect was further enhanced when macrophages were cultured with conditioned medium from KO mICO. Cholangiocytes were successfully seeded into the BoC, and perfused immune cells were effectively recruited to the layer of liver parenchymal cells, mimicking the pathobiological processes observed in DR.

Conclusion: The mICO, AOO, and BoC are promising *in vitro* models for understanding the cell phenotype changes and cellular crosstalk within the biliary niche during DR. Our data shows drastic differences in the steady-state phenotype of WT and KO ductular cells, including their metabolic adaptability and their potential to induce immune cell response. Ongoing efforts aim at further dissecting the molecular pathways involved and to develop comparable human cell-based systems.

Advancements in liver biopsy analysis: convolutional neural networks for portal tract segmentation

Giorgio Cazzaniga[1], Vincenzo L'Imperio[1], Nicola Zucchini[1], Laura Cristoferi[2,3], Fabio Pagni[1], Pietro Invernizzi[2,3], Marco Carbone[3,4], Alessio Gerussi[2,3]. *[1]Department of Medicine and Surgery, Pathology, Fondazione IRCCS San Gerardo dei Tintori, University of Milan-Bicocca, Monza, Italy; [2]Center for Autoimmune Liver Diseases, Department of Medicine and Surgery, University of Milano-Bicocca, Monza, Italy; [3]European Reference Network on Hepatological Diseases (ERN RARE-LIVER), Division of Gastroenterology, Fondazione IRCCS San Gerardo dei Tintori, Monza, Italy; [4]Hepatology and Gastroenterology Unit, ASST Grande Ospedale Metropolitano Niguarda, Milano, Italy*
Email: giorgio9cazzaniga@gmail.com

Background and aims: Detection and evaluation of portal tracts (PT) in liver biopsy play a crucial role in the diagnostic process of liver diseases. Lack of standardized definitions and high inter-observer variability hamper current diagnostic protocols. Artificial intelligence (AI) tools can streamline the histological examination assisting pathologists in time-consuming and highly operator-dependent tasks. In our study, we investigated an AI-driven automatic identification and segmentation of PT, with the aim of automating and standardizing the process.

Method: Our study utilized a dataset of 94 hematoxylin and eosin stained liver biopsies from the European Reference Network on Hepatological Diseases (ERN RARE-LIVER) center at Fondazione IRCCS San Gerardo dei Tintori, Monza, Italy, including several liver diseases to capture a broad phenotypic landscape of liver pathology. These biopsies, collected during 2021–2022, were annotated by a pathologist using a standardized definition for PT. We trained an Attention UNet, a semantic segmentation model, for automatic identification and segmentation of PT. The training involved analyzing 256px image tiles extracted at 5×, 10×, and 20× magnifications. For the model test, we used a distinct 2023 cohort comprising 12 cases including autoimmune hepatitis (AIH), primary biliary cholangitis (PBC), primary sclerosing cholangitis (PSC), and cases of metabolic dysfunction-associated steatohepatitis (MASH). Performance metrics were recorded to evaluate their ability to binary segment classify the biopsy samples into PT and non-PT regions.

Results: The model trained with image tiles at 20x magnification, which included 1, 691 tiles for training, 188 for development, and 838 for testing, demonstrated superior performance and scalability. This was evident from key metrics on the test set, such as Intersection over Union (IoU), dice coefficient, accuracy, precision, recall, and F1 score, which were 0.87, 0.71, 0.94, 0.77, 0.70, and 0.71, respectively. These metrics outperformed those of models trained with 10× and 5× magnification tiles, which had IoUs of 0.84 and 0.56, respectively. Moreover, the ability to piece together these tiles allowed for the reconstruction of the original virtual slide, complete with annotations for all PT at the whole-slide image (WSI) level, ready for diagnostic routine use and morphometric features extraction.

Conclusion: This study demonstrates high performances in distinguishing and segmenting PT, especially when the model is fed with very close detail of liver tissue, offering a preoperative, objective evaluation of sample adequacy, enhancing workflow efficiency, and shortening diagnostic timelines. Additionally, this technique may prove highly beneficial in understanding disease mechanisms, as it efficiently extracts crucial morphometric data from histologic samples.

SAT-173-YI

TAZ and YAP play an interdependent role in biliary development and adaptation to cholestasis

Adelya Gabdulkhakova[1], Yekaterina Krutsenko[2], Satdarshan Monga[2,3], Laura Molina[2]. *[1]Heidelberg University Hospital, Heidelberg, Germany; [2]University of Pittsburgh School of Medicine, Pittsburgh, United States; [3]Pittsburgh Liver Research Center, University of Pittsburgh Medical Center, Pittsburgh, United States*
Email: adelya.gabdulkhakova@med.uni-heidelberg.de

Background and aims: Most young patients with bile duct disorders such as progressive familial intrahepatic cholestasis (PFIC), biliary atresia, Alagille syndrome, and others, will require a liver transplant. Understanding the pathogenesis of cholangiopathies and liver adaptation mechanisms to biliary injury is crucial. We previously showed that deletion of yes-associated protein 1 (YAP) in early liver development leads to Alagille syndrome-like phenotype. YAP^{KO} mice were born without intrahepatic biliary tree and exhibited severe cholestasis. A paralog of YAP, TAZ, was significantly overexpressed in YAP^{KO} hepatocytes and interacted with TEAD transcription factors, suggesting possible compensatory activity. In this study we aimed to investigate the relationship between TAZ and YAP and their role in biliary development and cholestasis.

Method: Both Yap1 and Wwtr1 (a gene encoding TAZ) were knocked out in mice during early liver development by employing the Foxa3 promoter to drive Cre expression, resulting in diverse combination of alleles. Littermates were used as wild-type controls. We analysed these mice at stages of embryos (E17.5), new-borns (postnatal days

1–2), and adults (at the age of 3 weeks and 3–4 months) by immunohistochemistry, immunoprecipitation, western blotting, serum biochemistry, bile acid profiling, and RNA sequencing.
Results: YAP/TAZ double knockout mice were not viable and embryonic lethal. Their livers appeared grossly normal but had no intrahepatic bile ducts. We observed a 50% decrease in the expected birthrate of YAP^{KO} with TAZ heterozygosity ($YAP^{KO}TAZ^{HET}$) mice. While male $YAP^{KO}TAZ^{HET}$ mice were also embryonic/perinatally lethal, $YAP^{KO}TAZ^{HET}$ females survived and exhibited pronounced cholestasis. In response, their livers adapted by bile transport reversal and changes in the composition of bile acids to enhance hydrophilicity. Liver transaminases were more elevated in $YAP^{KO}TAZ^{HET}$ mice, compared to YAP^{KO} mice, suggesting worsened hepatocyte injury. TAZ heterozygosity impacted the expression of canonical YAP targets *Ctgf* and *Cyr61*. Alterations in gene expression resulting from partial TAZ loss were found to align with immunohistochemical findings, which included enhanced inflammatory signalling, cell cycling, apoptosis, and increased macrophage infiltration.
Conclusion: Biliary development is aborted without YAP (both in presence and absence of TAZ). Our results point to the unique roles of TAZ in liver injury repair. TAZ is implicated in regulating key YAP targets and in the setting of YAP loss, TAZ contributes to hepatocyte adaptation to chronic cholestasis through promoting cell survival and dampening macrophage recruitment. Together, they play an essential, interdependent role in the development of the intrahepatic biliary system and in the liver's response to cholestatic injury.

SAT-174
Expression of inflammatory markers in cholangiocyte organoids from patients with primary sclerosing cholangitis recapitulate disease severity
Philip Puchas[1], Farzaneh Kashfi[1], Chengcheng Zhang-Hagenlocher[1], Uta Merle[1], Patrick Michl[1], Peter Sauer[1], Michael Dill[1,2]. [1]*Department of Gastroenterology, Infectious Diseases, Intoxications, Heidelberg University Hospital, Heidelberg, Germany;* [2]*German Cancer Research Center (DKFZ) Heidelberg, Research Group Experimental Hepatology, Inflammation and Cancer, Heidelberg, Germany*
Email: michael.dill@med.uni-heidelberg.de

Background and aims: Primary sclerosing cholangitis (PSC) is a rare liver disease defined by inflammation and consecutive fibrotic alterations of the bile ducts. Importantly, PSC has a highly variable clinical course and mechanisms driving interindividual progression are incompletely understood. Cholangiocytes can adapt a highly secretive phenotype and therefore facilitate PSC pathogenesis. It is unclear whether susceptibility and reactivity of cholangiocytes influences the course of the disease, but differences in cytokine expression (e.g. Interleukin-8) in bile of PSC patients has been shown. 3D culture allows for culture of primary patient-derived cholangiocytes as organoids (chol-orgs). We aimed to investigate whether chol-orgs could be used as a tool to study potential molecular differences based on interindividual PSC severity.
Method: 31 chol-org lines (controls n = 10, mild PSC = 10, severe PSC = 11) were generated from bile sampled endoscopically. Severe PSC cases were defined having evidence of advanced liver fibrosis and severe cholangiographic findings, while mild cases were selected for minor cholangiographic changes and limited fibrosis of the liver. Controls consisted of cases without evidence of chronic inflammation (i.e. choledocholithiasis, postoperative biliary leakage, papillary stenosis and polycystic liver disease). Chol-orgs were analysed at passage 4-8 for mRNA expression of selected genes and this correlated with clinicopathological parameters. Statistical analysis was performed via T-tests, linear regression and Pearson correlation. Written informed consent was obtained from all patients.
Results: mRNA expression of the genes *CCL20*, *P21*, *TFF1*, *CFTR* and *GGT* was not significantly different between all chol-org groups. However, severe PSC chol-orgs showed >2-fold upregulated mRNA expression of Interleukin-8 (IL8) compared to mild PSC chol orgs (p = 0.0139). Interestingly, IL8 expression in controls was similar compared to severe PSC chol-orgs. In PSC, IL8 expression positively correlated with disease stage as indicated by liver stiffness (p = 0.0113, r = 0.5539) and worsening of liver function in a 6-12 month-follow-up by change in labMELD score (p = 0.031, r = 0.5395). Further, IL8 expression correlated moderately with serum bilirubin and GGT across all groups (p = 0.0032, r = 0.5122 and p = 0.0091, r = 0.4609). CCL20 expression also positively correlated with worsening of liver function in PSC (p = 0.0256, r 0.5551).
Conclusion: Under regular culturing conditions, IL8 and CCL20 mRNA expression in PSC chol-orgs still correlated with worsening of liver function in PSC, indicating a rationale for more comprehensive molecular and functional analyses of chol-orgs between PSC severity subgroups. The selection of good bile controls has to be carefully considered in this setting.

SAT-175
PPAR-delta activation with seladelpar regulates cholangiocyte inflammation
Xia Wu[1], Yen-Wen Chen[2], Jiangao Song[1], Edward Cable[1], Jeff Johnson[1], Joanne Elliott[2], Francisco Caballero-Camino[3], Xin Chen[1], Robert Martin[1], Jeffrey Stebbins[1], Jesús M. Bañales[3], Charles A. McWherter[1]. [1]*CymaBay Therapeutics, Inc., Fremont, United States;* [2]*Triple Ring Technologies Inc., Newark, United States;* [3]*Biogipuzkoa Health Research Institute, San Sebastian, Spain*
Email: xwu@cymabay.com

Background and aims: Cholangiocytes, epithelial cells lining bile ducts, play a crucial role as the primary site of injury in primary biliary cholangitis (PBC). The Phase 3 RESPONSE trial in patients with PBC demonstrated that the selective PPAR-delta agonist seladelpar effectively reduced bile acid pools, improved cholestatic and liver injury markers (ALP, GGT and ALT), and decreased the pruritogenic cytokine IL-31, leading to an accompanying alleviation of patient-reported pruritus. Given the central role of cholangiocytes in PBC pathobiology, we investigated the response to seladelpar treatment of human cholangiocyte cells as a potential translational model to understand its observed clinical profile.
Method: H69 human cholangiocytes were cultured and exposed to varying concentrations and durations of seladelpar treatment. Inflammatory PBC mediators like IL-17 were used in addition to seladelpar. Gene expression changes were analyzed by bulk RNAseq and qPCR assays. Secreted cytokines in culture media were analyzed with Meso Scale Discovery (MSD) assays.
Results: Treatment of cholangiocytes cells with seladelpar (10 µM) resulted in substantial changes in gene expression. Genes pivotal in lipid pathways, particularly those involved in fatty acid beta-oxidation, exhibited significant up-regulation with seladelpar, including *ANGPTL4*, *CPT1A*, *ACADVL*, *HADHA*, *HADHB*, *ACAA2*, *ECH1*. PPAR-delta-activated genes, such as *PDK4* and *ANGPTL4*, showed increases by 4-fold and 8-fold, respectively, even at low seladelpar concentrations (10 nM). Furthermore, IL-17 incubation induced an inflammatory response in cholangiocytes, leading to the up-regulation of *CXCL10*, *CCL5*, *CXCL1, CXCL8*, and *IL-6*. MSD assays confirmed the secretion of IL-6, CXCL8, IL-1beta and TNFa cytokines induced by IL-17 in cholangiocytes. Notably, co-incubation of cholangiocytes with IL-17 and seladelpar attenuated the IL-17 induced response. Cholangiocytes co-incubated with IL-17 and seladelpar exhibited reduction in gene expression of interferon genes *IFNB1* and *IFNL1*, interferon stimulated genes (*IFIT1*, *ISG15*, *RSAD2*, *CXCL10*), chemokine genes (*CCL5*, *CXCL1*, *CXCL8*, *CCL20*), and HLA genes (*HLA-F, HLA-E, HLA-DPB1*) compared with IL-17 alone.
Conclusion: This is the first evidence on the impact of selective PPAR-delta activation in a human cholangiocyte cell line. These findings indicate that seladelpar modulates multiple inflammatory mediators and this warrants further in-depth investigation.

SAT-176

Itg-Cre/DTA mice develop the autoimmune biliary disease that serologically and pathogenically models human primary biliary cholangitis

Jiaqi Zhang[1], Mayu Ouchi[1], Ryo Nakagawa[2], Akane Kurosugi[1], Goto Chihiro[2], Ryuta Kojima[1], Tatsuya Kaneko[1], Yuki Ohta[1], Motoyasu Kan[1], Masato Nakamura[1], Shingo Nakamoto[1], Jun Kato[1], Yoshihiro Hirata[3], Naoya Kato[1]. *[1]Department of Gastroenterology, Graduate School of Medicine, Chiba University, Chiba, Japan; [2]Division of Advanced Preventive Medicine, Department of Gastroenterology, Chiba University, Chiba, Japan; [3]The Institute of Medical Science, The University of Tokyo, Tokyo, Japan*
Email: zhangjiaqi@chiba-u.jp

Background and aims: Primary biliary cholangitis (PBC) is an autoimmune liver disease that has progressive destruction of the intra-hepatic bile ducts that causes the retention of bile and other toxins. The incidence of PBC in European, North American, Asia, and Australian populations is between 0.9 and 5.8 per 100, 000 population per year, and the prevalence per 100, 000 is 1.9 to 40.2. The disease is female-predominant, and an estimated 1 in 1000 women over 40 live with PBC. Multiple murine models of PBC have been developed in recent years, which aim to provide a new idea to elucidate the pathological mechanism and design for new target drugs. However, each model had different similarities to human PBC, which cannot cover all features. In the Itg-Cre/DTA (ID) mouse model, dendritic cells (DCs) are genetically depleted, immune tolerance is disrupted, and systemic autoimmune disorders occur spontaneously. It will contribute to unraveling the mechanisms underlying PBC pathogenesis and advancing its treatment options.
Method: In this murine model, hepatobiliary changes were assessed by HE staining, immunohistochemistry (IHC-p), and flow cytometry (FCM). IFN-gamma production capacity of CD4+ T lymphocytes was analyzed by intracellular staining. Gene expression of cholangitis-related cytokines was analyzed using quantitative RT-PCR (reverse transcription PCR). Serum anti-mitochondrial antibodies (AMA) and secreted IFN-gamma were evaluated by Enzyme-Linked Immunosorbent Assay (ELISA).
Results: ID mice developed extensive portal inflammation with neutrophils, CD4+ T lymphocytes, and CD8+ T lymphocytes surrounding bile ducts and portal veins. The severity of cholangitis increased with age in weeks, with intense cholangitis from 10 to 20 weeks, and partial disappearance of bile ducts was observed over 36 weeks. In addition, the ID model mice showed the presence of serum AMA and the inflammatory cytokine IFN-gamma. Moreover, the liver injury indicator ALT was observed to be elevated. Immunohistochemistry of liver tissue revealed inflammation around the bile ducts and portal vein by neutrophils, macrophages, CD4+ T lymphocytes, and CD8+ T lymphocytes. Furthermore, there was an increase in the CD4/CD8 ratio of T lymphocytes, coupled with elevated IFN-gamma production from CD4+ T lymphocytes. Besides that, Th1-dependent cytokines such as IFN-gamma, TNF-alpha, IL-2, IL-6, and IL-12p35 showed an increased expression.
Conclusion: The deficiency of DC leads to immunologic and hepatobiliary changes that resemble human PBC, and this model is characterized by the lack of direct modification of T cells compared to existing PBC models. We expect that new ID model mice will help us elucidate PBC's pathogenesis through T cell regulation and develop new treatments for PBC.

SAT-177

Assessment of PPARdelta target engagement in mouse liver assessed by single nuclei sequencing following a single oral dose of seladelpar

Edward Cable[1], Yun-Jung Choi[1], Xia Wu[1], Jiangao Song[1], Jeff Johnson[1], Charles A. McWherter[1]. *[1]CymaBay Therapeutics, Newark, United States*
Email: ecable@cymabay.com

Background and aims: Seladelpar is a selective PPARdelta agonist that recently completed a Ph 3 trial as a second-line therapy for patients with an inadequate response, or intolerance, to ursodeoxycholic acid. The results of the trial have been previously published and demonstrated significant reductions of alkaline phosphatase and improvements in pruritus. Published data in mice demonstrate seladelpar-mediated reductions of bile acid synthesis, including reduction of *Cyp7a1*, following a single oral dose in mice as well as in PPARalpha knockout mouse hepatocytes. To investigate the molecular mechanisms of seladelpar in the various liver cell types, mice were treated with a single dose of seladelpar and single nuclei harvested and analyzed by sequencing.
Method: Male CD-1 mice, five per group, were treated with vehicle (1% CMC dosed at 5 ml/kg) or seladelpar (10 mg/kg in vehicle) and sacrificed 6 hours after dosing. Sections of liver were removed and snap frozen. Nuclei were isolated using the Parse Evercode kit. 100, 000 nuclei were used to make the Evercode library. Sequencing was performed on an Illumina NovaSeq X. Data were demultiplexed with NovaSeq X Plus DRAGEN onboard BCLConvert 4.1.7. Single cell alignment was performed with Split-Pipe 1.1.2. Single cell analysis was performed with Seurat 4.4.0. Data visualization and analyses were completed on CellxGene (1.2.0).
Results: Leiden clustering identified 30 different clusters. Hepatocytes, cholangiocytes, Kupffer cells, endothelial cells, and dendritic cells were identified and were spread over different clusters. Analysis of the expression levels of PPARalpha, gamma, and delta in the vehicle group indicate that PPARalpha is the dominant PPAR isoform expressed in the liver of mice with delta and gamma being expressed at lower levels in all cell types. As expected, the PPAR responsive genes *Pdk4* and *Angptl4* were induced, and *Cyp7a1 was reduced,* in hepatocytes following seladelpar treatment. Seladelpar changed gene expression patterns in every identified cell type. Correlation of *Pdk4* and *Angplt4* was variable indicating unexpected differences in expression patterns for two "prototypical" PPAR responsive genes.
Conclusion: Identification of changes in gene expression six hours following a single dose of seladelpar, indicate that there are PPARdelta mediated changes in all identified cell types in the mouse liver. Single-cell analyses, such as this, can provide a framework in which to understand the primary PPARdelta responsive genes following seladelpar treatment and can be used to deconvolute the gene expression patterns leading to the beneficial pharmacodynamic effects reported in either humans or mice.

SAT-178-YI

Galectin-3 and prohibitin 1 are autoantigens in IgG4-related cholangitis without clear-cut protective effects against toxic bile acids

Remco Kersten[1], David Trampert[1], Lowiek Hubers[1], Dagmar Tolenaars[1], Harmjan Vos[2], Stan van de Graaf[1], Ulrich Beuers[1]. *[1]Department of Gastroenterology and Hepatology, Tytgat Institute for Liver and Intestinal Research, Amsterdam Gastroenterology Endocrinology Metabolism (AGEM), Amsterdam University Medical Center, Amsterdam, Netherlands; [2]Oncode Institute and Molecular Cancer Research, Center for Molecular Medicine, University Medical Center Utrecht, Utrecht, Netherlands*
Email: d.c.trampert@amsterdamumc.nl

Background and aims: IgG4-related cholangitis (IRC) is the hepatobiliary manifestation of IgG4-related disease, a systemic fibroinflammatory disorder. Four autoantigens have recently been described in IgG4-RD: annexin A11, galectin-3, laminin 511-E8, and prohibitin 1. We have previously reported a protective role of annexin A11 and laminin 511-E8 in human cholangiocytes against toxic bile acids. Here, we explored the potentially protective role of galectin-3 and prohibitins 1 and 2.
Method: Anti-galectin-3, anti-prohibitin 1 and 2 autoantibody positivity was assessed by ELISA/LC-MS/MS in IRC, primary sclerosing

cholangitis (PSC) and healthy control sera. IgG's were isolated from a healthy control and an IRC patient with anti-galectin 3 and anti-prohibitin 1 autoantibodies. Human H69 cholangiocytes were subjected to short hairpin RNA knockdown targeting galectin-3 (*LGALS3*), prohibitin 1 (*PHB1*), and prohibitin 2 (*PHB2*). H69 cholangiocytes were also exposed to recombinant galectin-3, the inhibitor GB1107, recombinant prohibitin 1 and the pan-prohibitin inhibitor rocaglamide. Protection against bile acid toxicity was assessed by intracellular pH (pHi) measurements using BCECF-AM, 22, 23-^{3}H-glycochenodeoxycholic acid (^{3}H-GCDC) influx, and GCDC-induced apoptosis using Caspase-3/7 assays.

Results: Anti-galectin-3 autoantibodies were detected in 13.5% of individuals with IRC but not in PSC. Knockdown of *LGALS3* and galectin-3 inhibition with GB1107 did not affect pHi, whereas recombinant galectin-3 incubation lowered pHi. *LGALS3* knockdown increased GCDC influx but not GCDC-induced apoptosis. GB1107 reduced GCDC influx and GCDC-induced apoptosis. Recombinant galectin-3 tended to decrease GCDC influx and GCDC-induced apoptosis. Anti-prohibitin 1 autoantibodies were detected in 61.5% and 35.7% of individuals with IRC and PSC respectively. *PHB1* knockdown, combined *PHB1/2* knockdown, treatment with rocaglamide, and recombinant prohibitin 1 all lowered pHi. *PHB1*, *PHB2*, or combined *PHB1/2* knockdown did not alter GCDC influx, yet *PHB1* knockdown increased GCDC-induced apoptosis. Conversely, rocaglamide reduced GCDC influx but did not attenuate GCDC-induced apoptosis. Recombinant prohibitin 1 did not affect GCDC influx or GCDC-induced apoptosis. Finally, IRC patient-derived anti-galectin-3 and anti-prohibitin 1 autoantibody pretreatment did not lead to increased GCDC influx into H69 cholangiocytes.

Conclusion: A subset of individuals with IRC have autoantibodies against galectin-3 and prohibitin 1. Gene-specific knockdown, pharmacological inhibition and recombinant protein substitution did not clearly disclose a protective role of these autoantigens in human cholangiocytes against toxic bile acids. The involvement of these autoantibodies in processes surpassing epithelial secretion remains to be elucidated.

A DNA methylation signature associated with inflammation is found in primary sclerosing cholangitis and IgG4-related cholangitis

Alexandre Adams[1], Silvia Cabras[1], Alexandra Noble[1], Rodrigo Motta[1], Belen Moron Flores[1], Jan Nowak[2], Aleksandra Glapa-Nowak[2], Alessandra Geremia[1], Jack Satsangi[1], Emma Culver[1]. *[1]Translational Gastroenterology and Liver Unit, Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom; [2]Department of Pediatric Gastroenterology and Metabolic Diseases, Poznan University of Medical Sciences, Poznan, Poland*
Email: rodrigo.vieiramotta@ndm.ox.ac.uk

Background and aims: Primary sclerosing cholangitis (PSC) and IgG4-related cholangitis (IgG4-C) are chronic fibro-inflammatory hepatobiliary conditions, with genetic, environmental, and immunologic risk factors. We sought to study epigenetic alterations that may provide insights into pathophysiology and novel disease biomarkers.

Method: Whole blood DNA methylation profiling and genotyping was performed by MethylationEPIC and Global Screening arrays (Illumina) in a cohort of 214 individuals; 56 patients with IgG4-C, 70 patients with PSC, and 88 healthy controls (HC). Epigenome-wide methylation changes were processed with minfi and limma, genotyping analysed with PLINK and methylation quantitative trait loci (meQTL) with linear models, and Horvath's epigenetic clock was used to assess age acceleration. Genome-wide significance was defined by Holm correction.

Results: Epigenome-wide methylation changes were identified between PSC and IgG4-C cohorts. In IgG4-C, there were 13 individual CpG sites with methylation alterations, including IFNAR1 ($p = 3.19 \times 10^{-10}$) and PYY ($p = 7.8 \times 10^{-10}$). meQTL analyses identified 36 significant loci in IgG4-C, including TESPA1 ($p < 3.18 \times 10^{-13}$), which is associated with B cell function and onset of autoimmune diseases. Gene ontology showed enrichment of T-cell activation, proliferation and endosome membrane recycling pathways ($p < 0.001$). DNA methylation age acceleration was observed in IgG4-SC ($p = 0.0006$). In PSC, there were 31 individual CpG sites with methylation alterations compared with HC, including TXK ($p = 2.89 \times 10^{-9}$), CEP97 ($p = 6.66 \times 10^{-15}$) and MTRNR2L1 (1.47×10^{-10}). meQTL analyses revealed a strong HLA signal in PSC. 19/40 significant findings occurred in 5 clusters (HLA-DRB1, HLA-DPB1, BTNL2, CSNK2B, and SFTA2). PSC and IgG4-C shared 8 individual CpG sites with methylation alterations, including genes associated with inflammation (CEP97) and loci associated with mitochondrial DNA copy number (C5orf36, PYY).

Conclusion: This is the first description of the methylome in IgG4-C as compared to PSC, with alterations centred on inflammatory and immune-related pathways, and age acceleration demonstrated in IgG4-C.

Targeting neutrophil injury-pathways and fibrogenesis in non-parenchymal immune tissue-like liver organoids generated from human induced pluripotent stem cells

Susanna Quach[1], Kyle Lewis[2], Kentaro Iwasawa[2], Yuka Milton[3], Adrien Guillot[4], Yeni Ait Ahmed[4], Takanori Takebe[2,5,6], Rose Yinghan Behncke[7,8], Milad Rezvani[1,7]. *[1]Charité Universitätsmedizin Berlin, Berlin, Germany; [2]Division of Gastroenterology, Hepatology and Nutrition, Cincinnati Children's Hospital Medical Center, Cincinnati, United States; [3]Division of Gastroenterology, Hepatology and Nutrition, Cincinnati Children's Hospital Medical Center, Cincinnati, Cincinnati, United States; [4]Charite Universitätsmedizin Berlin, Department of Hepatology and Gastroenterology, Berlin, Germany; [5]Institute of Research, Tokyo Medical and Dental University, Tokyo, Japan; [6]9. Premium Research Institute for Human Metaverse Medicine (WPI-PRIMe), Osaka University, Osaka, Japan; [7]Berlin Institute of Health, Center for Regenerative Therapies, Berlin, Germany; [8]Charite, Institute of Medical Genetics and Human Genetics, Berlin, Germany*
Email: susanna.quach@charite.de

Background and aims: Hepatic non-parenchymal cells (NPCs), including hepatic stellate cells (HSCs), biliary epithelial cells (BECs), endothelial cells (ECs), and various myeloid innate leukocytes, play a critical role in liver injuries induced by lipotoxic milieus. Here, we develop human induced pluripotent stem cell (hiPSC)-derived non-parenchymal immune tissue-like liver organoids (NPC-HLOs), inclusive of syngeneic neutrophils, heterogenous monocyte and macrophage subsets, as a platform to investigate injuries involving innate immune-fibrogenic pathways and hepatocyte injury.

Method: NPC-HLOs were developed from hiPSCs by co-inducing endoderm and mesoderm, followed by cluster embedding with BMP4, FGF2, FGF4, and CHIR. From day 10, NPC-HLOs were treated with basal medium for self-organization or hematopoietic cytokines for enhanced myeloid differentiation. Cell populations were identified via anti- or nanobody based immunofluorescence and flow cytometry. For modeling steatohepatitis, NPC-HLOs were treated with a lipid mix (LM) or palmitic acid (PA) and assessed using electrochemiluminescence for cytokine secretion. Intercellular pathways were identified using single-cell RNA sequencing and CellCHAT, and modulated via CXCR1/2-blockade-using Reparixin for macrophage-to-neutrophil recruitment and Notch-mediated fibrogenesis-using DAPT.

Results: We co-developed FOXA2+/CXCR4+ endoderm and KDR +/CD235a+ mesoderm and observed without adding further growth factors spontaneous in vitro organogenesis, including a reticular CD31+ EC system, CK19+ CK7+ EPCAM+ luminal BECs, PDGFRA+ alphaSMA+ HSCs, AFP+ ALB+ ECAD+ hepatocytes and CD68+ IBA-1+ macrophages with partial polarization (CD45+ CD64low

CD163+ CD206−). Including GM-CSF completed macrophage polarization and yielded CD45+CD14-CD16+CD66b MPO+ segmented, reactive oxygen species (ROS)-releasing neutrophils. Under lipotoxicity, NPC-HLOs exhibited a 5-fold decrease in HNF4alpha expression, a 1.3-fold MPO+ expansion, low-frequency detection of neutrophil extracellular traps (NETs), and a 2-fold increase in IL8 secretion. Reparixin mitigated HNF4alpha loss to 1.8-fold. Organoid-encapsulating fibrogenesis was observed after inflammatory cytokine addition, further intensified by Notch-agonism via DLL1, resembling bridging fibrosis. In contrast, treatment with DAPT prevented fibrogenesis, maintaining a non-fibrotic state. Inferring intercellular pathways via CellChat supported Notch signaling across hepatocytes-to-NPCs, primarily HSCs and ECs, in addition to autocrine NPC-signaling.
Conclusion: NPC-HLOs recapitulate the majority of cell populations of the human liver, enabling studies of parenchymal-NPC crosstalk. Our findings highlight Notch as a key regulator in fibrogenesis involving NPCs and the druggable IL8 pathway, for recruiting tissue-injurious neutrophils.

SAT-181-YI
WTAP deficiency in mice hepatocyte induces cholestatic liver diseases by modulating nuclear receptor FXR
Chuanhui Peng[1], Xueyu Zhou[1], Guomin Ju[1]. [1]*The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China*
Email: peng_chuanhui@zju.edu.cn

Background and aims: Cholestatic liver diseases are characterized with bile accumulation, hepatocyte damages, liver fibrosis and cirrhosis. Wilms' tumor-1 associated protein (WTAP), a key regulator of N6-methyladenosine (m6A) modification, has been reported to play a crucial role in MASH and liver tumors. However, there is little known about WTAP's role and its underlying mechanism in cholestatic liver diseases.
Method: Hepatocyte conditional knockout of WTAP mice were generated by CRISPR/Cas9, and compared with wild type mice at different time points. Liver zonation, inflammation, fibrosis, metabolic and immune alternation were analyzed by histology, serology, multi-omics and single cell sequencing.
Results: Here, we have identified WT1-associated protein (WTAP) as a key regulator in cholestatic liver injury. Knocking out WTAP with Alb Cre (WTAP LKO) during the perinatal period induces liver injury and cholestasis. Metabolomics and transcriptomic analyses showed that the bile acid metabolism of WTAP LKO mice was significantly affected. Biliary duct ligation (BDL) was used to induce cholestasis in control and WTAP LKO mice. Compared with wile-type mice, WTAP LKO mice showed significantly increased inflammation and liver injury. Single cell sequencing delineated the landscape of liver architecture after WTAP deletion in hepatocyte. Deleting WTAP down-regulated nuclear receptor FXR, a key protein for bile acid transport via decreasing its transcript stability. Clinically, WTAP was associated with cholestatic liver diseases.
Conclusion: WTAP was crucial in maintaining liver homeostasis. Targeting WTAP may be a promising strategy for treating cholestatic diseases.

SAT-182
Immunokinetics of CD4+ T cells in primary sclerosing cholangitis by functional transcriptome analysis
Mayu Ouchi[1], Ryo Nakagawa[1], Jiaqi Zhang[1], Naoya Kato[1]. [1]*Chiba University, Chiba, Japan*
Email: aromarokarisuo@yahoo.co.jp

Background and aims: Primary sclerosing cholangitis (PSC) is a chronic progressive cholangiopathy of unknown cause. Since PSC recurs even after liver transplantation, it is assumed that autoimmune mechanisms play a major role in the pathogenesis of the disease. In recent years, various attempts have been made to understand the immune microenvironment of PSC, and it has been suggested that TNFα and IL-17 responses to intestinal bacteria are involved in the pathogenesis of the disease. In particular, it has been reported from Japan that intestinal bacteria specific to PSC patients induce IL-17-producing CD4+ T cells in the liver of PSC patients via systemic circulation from mesenteric lymph nodes, and this immune mechanism has attracted attention. Therefore, we analyzed the gene expression profile of its CD4+ T cells to further explore the immune mechanism in PSC patients.
Method: Gene expression in peripheral blood CD4+ T cells from PSC patients and healthy controls was analyzed using RNA sequencing and quantitative RT-PCR. In vitro analysis was performed using CD4+ T cells for functional analysis of genes that showed expression variation.
Results: Expression analysis of CD4+ T cells from PSC patients ($n = 3$) and healthy controls ($n = 3$) by RNA sequencing showed 1, 035 genes showed variation (up/down: 974/61, $p < 0.005$). Pathway analysis of expression variation genes extracted 16 pathways ($p < 0.001$). Based on the similarity of the genes they encompassed, they were classified into two clusters. Among them, we focused on the cluster consisting of NFκB signaling pathway, Cytokine-cytokine receptor interaction, and Chemokine signaling pathway. We analyzed the expression of CXCL2, CXCL3, CXCL8, CCL4L2, and NFKBIA in CD4+ T cells from PSCs ($n = 6$) and healthy controls ($n = 5$), and found that CXCL2, CXCL3, CXCL8, CXCL4L2, CXCL4L2, CXCL4L2, CXCL4L2, CXCL4L2, CXCL8, CXCL8, CXCL8, and CXCL2 are common genes in these three pathways, NFKBIA showed significantly higher expression in PSCs ($p < 0.05$). Therefore, we analyzed the regulation of CXCL8 expression in vitro. First, CXCL8 was induced by TNFα stimulation in CD4+ T cells from healthy subjects ($n = 3$). Furthermore, when we compared the expression and secretion of CXCL8 in CD4+ T cells from patients with PSC ($n = 4$) and healthy controls ($n = 4$) after TNFα stimulation, the PSC group secreted more CXCL8 than the healthy group ($p < 0.01$).
Conclusion: CD4+ T cells from PSCs showed enhanced secretion of chemokines associated with NFkB signaling activity. Since CXCL8 enhances neutrophil chemotaxis and promotes inflammation, it is possible that CXCL8 produced by CD4+ T cells may contribute to the pathogenesis of PSCs. may contribute to the pathogenesis of PSC. Gene expression analysis of CD4+ T cells in PSCs revealed some of their immune mechanisms.

SAT-183
Moderate overexpression of c-Met in hepatocytes decreases cholestatic liver injury
Carlos González-Corralejo[1,2], Juan García-Sáez[1,2], Cesáreo Roncero[1,2], María Figueroa[2], Adrián Jiménez[2], Nerea Lazcanoiturburu[2], Beatriz Pacheco[2], Almudena Porras[1,2], Flavio Maina[3], Isabel Fabregat[4,5], Blanca Herrera[1,2,5], Aránzazu Sánchez[1,2,5]. Email: carlgo17@ucm.es

Background and aims: The hepatocyte growth factor (HGF) and its receptor mesenchymal-epithelial transition factor (c-Met) signaling axis plays a critical role during liver regeneration upon chronic damage through its mitogenic, survival, and morphogenic activities on hepatocytes and hepatic progenitor cells/oval cells (HPC/OC). However, the molecular mechanisms underneath HGF/c-Met pro-regenerative effects are not fully elucidated. The aim of this study was to analyze the impact of c-Met overexpression on liver regeneration upon cholestatic injury and uncover how it affects hepatocyte and HPC/OC function.

Method: Transgenic mice with moderate overexpression of c-Met receptor in the liver (albumin-positive cells) were fed with a diet supplemented with the cholestatic agent 3, 5-diethoxycarbonyl-1, 4-dihydrocollidine (DDC). Serum biomarkers of liver function and liver histological features were analyzed. A biochemical and molecular analysis of oxidative stress and antioxidant pathways was also performed both *in vivo* and *in vitro* in hepatocytes derived from c-Met transgenic mice treated with bile acids and TGF-beta to mimic the cholestatic and fibrotic liver microenvironment.
Results: Overexpression of c-Met led to a diminished liver damage in response to DDC, evidenced by lower serum levels of bilirubin and alkaline phosphatase. Interestingly, decreased damage was associated with a decreased HPC/OC expansion and an enhanced hepatocyte proliferation. In parallel, c-Met transgenic livers displayed an enhanced upregulation of the nuclear factor erythroid 2-related factor 2 (Nrf2), together with an up-regulation of the rate-limiting enzyme of glutathione biosynthetic pathway, increased levels of reduced glutathione and decreased reactive oxygen species levels during DDC treatment, along with a decreased activation of TGF-beta-induced signaling. Consistently, c-Met transgenic hepatocytes were more resistant to the cytotoxicity induced by bile acid and TGF-beta combined treatment and presented an ameliorated oxidative stress response *in vitro*.
Conclusion: Our work evidence that a moderate overexpression of c-Met in hepatocytes is sufficient to promote a strong antioxidant response in the liver that efficiently protects against chronic cholestasis thus allowing an optimal liver regeneration.

SAT-184
Primary biliary cholangitis symptoms are reduced in liver specific Mcpip1 knock-out mice after treatment with probiotic lactobacillus rharmnosus

Katarzyna Trzos[1,2], Tomasz Hutsch[3], Gabriela Machaj[4], Guillem Ylla[4], Jolanta Jura[2], Jerzy Kotlinowski[2]. [1]*Doctoral School of Exact and Natural Sciences, Cracow, Poland;* [2]*Jagiellonian University, Faculty of Biochemistry, Biophysics and Biotechnology, Cracow, Poland;* [3]*University of Warsaw, Warsaw, Poland;* [4]*Jagiellonian University, Laboratory of Bioinformatics and Genome Biology, Cracow, Poland*
Email: kat.trzos@doctoral.uj.edu.pl

Background and aims: Primary biliary cholangitis (PBC) is a chronic autoimmune liver disease that results from slow, progressive destruction of the intrahepatic bile ducts. PBC progression leads to the development of fibrosis, cholestasis, liver cirrhosis. Mcpip1fl/flAlbCre mice, with the Zc3h12a gene (encoding Mcpip1 protein) deleted in liver epithelial cells, exhibit typical PBC symptoms (increased levels of antimitochondrial and antinuclear antibodies, elevated total bile acids, and intrahepatic bile duct hyperplasia, disruption of bile duct epithelium and fibrosis). The primary objective of this project is to elucidate PBC symptoms in these mice following the administration of first- and second-line therapies commonly employed in PBC patients. Additionally, the study incorporates the use of a probiotic (Lactobacillus rhamnosus) due to emerging evidence suggesting that gut microbiota regulates host immunity.
Method: Mcpip1fl/fl and Mcpip1fl/flAlbCre male mice at 6 weeks of age were randomly divided into five groups for drug treatment. Control group received corn oil, other groups received consecutively Lakcid (L. rhamnosus, 10^9 CFU per day) suspended in water, ursodeoxycholic acid (UDCA, 15 mg/kg body mass per day) diluted in corn oil, UDCA and Lakcid, UDCA and obeticholic acid (OCA, 10 mg/kg body mass per day) both diluted in corn oil. After 6 weeks of treatment, all mice were sacrificed, and the collected material analysed by, amongst other, detailed serum liver tests, ELISA tests for the presence of anti-PDC-E2 autoantibodies, histological stainings (HandE, PSR), qPCRs and next generation sequencing (NGS) of total RNA from livers.
Results: After 6-weeks of treatment significant proliferation of cholangiocytes and fibrosis in livers from Mcpip1 knock-out mice was detected, together with high serum level of total IgM, total bile acids and anti-PDC-E2 autoantibodies. Animals receiving Lakcid had the most significant weakening of the PBC symptoms (reduced amount of total bile acids in the serum, proliferation of cholangiocytes and fibrosis). NGS analysis revealed 1131 up-regulated and 390 down-regulated genes in control knock-out mice compared to control Mcpip1fl/fl mice. Processes such as humoral immune response, regulation of lymphocyte activation and T cell activation are significantly enriched in these mice. Comparison of Lakcid-treated and control knock-out mice revealed 178 up-regulated and 308 down-regulated genes. Most importantly, NGS revealed a significant suppression of biological processes related to T cells activation and inflammatory response.
Conclusion: Treatment of Mcpip1fl/flAlbCre mice with Lakcid has beneficial effects on PBC symptoms and suggest that the gut-liver axis and intestinal microflora can be a master-regulator of PBC progression and is an interesting therapeutical target in chronic inflammatory liver diseases.

SAT-185
Human leukocyte antigen-DRB1 expression in cholangiocytes of 'early' primary sclerosing cholangitis

Ynto de Boer[1], Frank Sun[2], Vincent de Meijer[2], Klaas Nico Faber[2], Naomi Karmi[2], Sofie de Jong[2], Joris Erdmann[1], Eleonora Festen[2], Cyriel Ponsioen[1]. [1]*Amsterdam UMC, Amsterdam, Netherlands;* [2]*University Medical Center Groningen, Groningen, Netherlands*
Email: y.deboer1@amsterdamumc.nl

Background and aims: Primary sclerosing cholangitis (PSC) is a chronic cholestatic liver disease, for which there is currently no therapy to halt disease progression. PSC is generally regarded as an immune-mediated disease, but disease etiology and pathogenesis is still largely unknown. The aim of the study was to characterize the cellular composition of the tissue in stenoses in the larger bile ducts of 'early' PSC patients, as relevant literature on pathogenesis is mostly based on explant and resection material. This is done by analysis of expression profile of affected bile duct tissue on a single cell RNA sequencing (scRNAseq) level, elucidating antigen presenting properties and senescence signaling of affected cholangiocytes.
Method: PSC patients with dominant or suspected dominant strictures and a clinical reason for biliairy drainage who underwent endoscopic retrograde cholangiography (ERC) were included in this study. Strictures were sampled using Spybite max forceps. After dissociation into single cells we performed scRNAseq to characterize the cellular composition of the biopsies. We used cluster specific genetic markers with Cell-ex to obtain cluster specific cell type expression profiles.
Results: 5 PSC patients undergoing ERC were successfully biopsied. Cell dissociation proved challenging due to adherent bile, but was successful in one patient. After Cell-ex associated clustering we performed manual annotation on each cluster based on its expression profile in combination with literature and histopathological evaluation. We identified a subset of activated cholangiocytes that express abundant *HLA-DRB1* in addition to *CK7*, which suggests a primary role in the early phase of inflammation as antigen presenting cells. The evaluated material showed a paucity of lymphocellular infiltrate, concurrent with the histopathological evaluation of this biopsy.
Conclusion: We have now successfully implemented a sampling protocol to perform scRNAseq to ascertain the variation of the cellular composition of the biliary inflammation in ERC guided biopsies of 'early' PSC patients, hence establishing a reference dataset for bile duct cell type annotation. Furthermore, this preliminary single patient dataset has revealed a potential role of a subset of activated cholangiocytes that express abundant *HLA-DRB1*, a key-factor in lymphocyte activation and a known genetic risk locus for PSC development.

Risk of extrahepatic malignancies in patients with autoimmune hepatitis: a nationwide cohort study

Sung Won Chung[1], Won-Mook Choi[1], Ye-Jee Kim[2], Sehee Kim[2], Jonggi Choi[1], Danbi Lee[1], Ju Hyun Shim[1], Kang Mo Kim[1], Young-Suk Lim[1], Han Chu Lee[1]. *[1]Department of Gastroenterology, Liver Center, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Rep. of South; [2]Department of clinical epidemiology and biostatistics, Asan Medical Center, Seoul, Korea, Rep. of South*
Email: dr.choi85@gmail.com

Background and aims: Nationwide, population-based data on the risk of extrahepatic malignancy in autoimmune hepatitis (AIH) patients in Asian countries are scarce. This study aimed to examine the risk of developing extrahepatic malignancy in a nationwide cohort of patients with AIH.
Method: Using claims data from the Korean National Health Insurance Service database between 2007 and 2020, patients with AIH (n = 7, 382) were matched in a 1:8 ratio with age- and sex-matched control population (n = 58, 320) to compare the incidence of extrahepatic malignancies. We compared the incidence rates (IRs) and hazard ratios (HRs) of overall and specific extrahepatic malignancies between the two groups, also examining the impact of immunosuppressant use.
Results: During a median follow-up period of 5.4 years, a total of 3, 713 extrahepatic malignancies were developed. The IR of extrahepatic malignancy in AIH patients (990.8 cases per 100, 000 person-years) was comparable to that in the matched controls (937.6 cases per 100, 000 person-years), with an HR of 0.93 (95% CI, 0.81–1.07; $p = 0.30$). However, a significantly higher risk of hematologic malignancies, particularly lymphoma or myeloma (HR, 2.66; 95% CI, 1.70–4.17; $p < 0.001$) was observed. The use of glucocorticoids (HR, 1.09; 95% CI, 0.87–1.38; $p = 0.44$) or azathioprine (HR, 0.92; 95% CI, 0.73–1.17; $p = 0.51$) had no impact on the risk of lymphoma or myeloma in patients with AIH.
Conclusion: In this Korean nationwide, population-based cohort, AIH was not associated with an increased risk of overall extrahepatic malignancy compared with age- and sex-matched controls. However, AIH itself increased the risk of lymphoma or myeloma, independent of immunosuppressant use.

TOP-168-YI

Urgent call to action: people living with primary sclerosing cholangitis-inflammatory bowel disease (PSC-IBD) lose 10 years of life compared to those with IBD alone

Kristel Leung[1], Wenbin Li[2], Bettina E. Hansen[3], Amanda Ricciuto[4], Eric Benchimol[4,5], Aliya Gulamhusein[1], Jennifer Flemming[6,7], Gideon M. Hirschfield[8]. *[1]Toronto Centre for Liver Disease, Toronto, Canada; [2]Institute for Clinical Evaluative Sciences (ICES), Kingston, Canada; [3]Erasmus Medical Center, Rotterdam, Netherlands; [4]The Hospital for Sick Children (SickKids), Toronto, Canada; [5]Institute for Clinical Evaluative Sciences, Toronto, Canada; [6]Queen's University, Kingston, Canada; [7]Institute of Clinical Evaluative Sciences, Kingston, Canada; [8]Toronto Centre for Liver Disease, University Health Network, University of Toronto, University Health Network, Toronto, Canada*
Email: gideon.hirschfield@uhn.ca

Background and aims: We sought to evaluate current outcomes for people living with primary sclerosing cholangitis and inflammatory bowel disease (PSC-IBD) as compared to IBD.
Method: Using linked health administrative data (population ≅15 million) with previously derived and validated PSC-IBD incidence (by PSC diagnosis) and IBD incidence cohorts in Ontario, Canada from January 1, 2002, to December 31, 2018, the number of deaths (censored December 31, 2021) and underlying cause of death (up to 2018) were ascertained. To align disease observation periods for direct comparison, a subcohort with PSC-IBD (both diagnoses) and IBD alone diagnosed from 2002 to 2018 was examined to determine liver transplant-free survival from IBD diagnosis, the number of PSC and IBD-related surgeries, and related cancer cases.
Results: Of 1046 incident PSC-IBD cases with PSC diagnosed between 2002 and 2018 (median age 45 y.o., IQR 20–61), there were 325 deaths (31%) (median age 65 y.o., IQR 49–78), of which 254 (78%) had an underlying cause of death reported. Of 55, 067 incident IBD cases with IBD diagnosed between 2002 and 2018 (median age 38 y.o., IQR 24–54), there were 4757 deaths (8.6%) (median age 74 y.o., IQR 63–84), of which 3048 (64%) had cause of death reported. Cause of death was most commonly due to liver disease in 94 (37%) PSC-IBD individuals, while cardiovascular (19%) and pulmonary (19%) disease were the most common causes of death amongst the IBD incidence cohort. Those with PSC-IBD experienced a significant burden of death due to hepatopancreatobiliary malignancy compared to those with IBD (26% vs. 3.1%), while death from gastrointestinal luminal malignancy was similar (5% for both). Amongst the subcohort, those with PSC-IBD had up to a 4.5-fold worse liver transplant-free survival compared those with IBD alone. There were 98 (21%) deaths amongst PSC-IBD (median age 63 y.o. IQR 46–80), compared to 4, 672 (8.5%) deaths amongst those with IBD alone (median age 74 y.o., IQR 63–84). People with PSC-IBD compared to IBD alone underwent significantly more liver transplants (17% vs. 0.2%), cholecystectomies (12% vs. 3.5%), pouch surgery (9.5% vs. 3.4%) and ileostomy creation (16% vs. 3.4%) (p value < 0.001 for all), but a similar number of colectomies (15% vs. 13%, p = 0.13). Those with PSC-IBD had significantly more hepatocellular carcinoma (19% vs. 0.8%), cholangiocarcinoma (4.2% vs. 0.1%), colon cancer (2.7% vs. 0.6%), and pancreatic cancer (1.4% vs. 0.2%) compared to those with IBD alone (p < 0.001 for all).
Conclusion: In contrast to people living with IBD alone, people with PSC-IBD experience significantly worse outcomes with a high burden of disease-related morbidity and earlier mortality. Those with PSC-IBD experience more hepatopancreatobiliary malignancies, colon cancer, and PSC disease-related surgeries compared to those with IBD alone. Colectomy rates are as frequent in PSC-IBD, and pouch surgery is more common.

Mason[1], Bettina Hansen[14], Aldo J Montano-Loza[1], on behalf of the Canadian Network for Autoimmune Liver Diseases (CaNAL)16. *[1]University of Alberta, Edmonton, Canada; [2]University of Toronto, Toronto, Canada; [3]University Health Network, University of Toronto, Toronto, Canada; [4]University of British Columbia, Pacific Gastroenterology Associates, Vancouver, Canada; [5]University of Calgary, Snyder Institute for Chronic Diseases, Calgary, Canada; [6]Centre hospitalier de l'Universite de Montréal (CHUM), Montréal, Canada; [7]University of Saskatchewan, Saskatoon, Canada; [8]Centre Hospitalier de l'Université de Montréal (CHUM), University of Montreal, Montreal, Canada; [9]Queen's University, Kingston Health Sciences Centre, Kingston, Canada; [10]Western University, London, Canada; [11]McGill University Health Centre, Montreal, Canada; [12]University of Sherbrooke, Sherbrooke, Canada; [13]University of Ottawa, Ottawa, Canada; [14]University Health Network, Toronto, Canada; [15]Toronto Centre for Liver Disease, Toronto, Canada; [16]Canadian Network for Autoimmune Liver Diseases (CaNAL), Edmonton, Canada*
Email: lytvyak@ualberta.ca

Background and aims: Sex and ethnicity have been shown to impact prognosis in liver diseases of different aetiologies; however, data on their impact on outcomes in people living with autoimmune hepatitis (AIH) are limited. We aimed to identify and quantify the magnitude of associations between sex, ethnicity, treatment response and clinical outcomes in a large multicentric cohort of people with AIH across Canada.
Method: A multicentre, retro- and prospective cohort study was conducted using data from the Canadian Network for Autoimmune Liver Diseases (CaNAL). Adverse events were defined as the development of decompensation, hepatocellular carcinoma (HCC), liver transplantation (LT), or death. Treatment response was defined as the normalization of ALT at 6 months after treatment initiation.
Results: Data of 1198 people living with AIH with 13443 person-years follow-up and median disease duration of 9.5 years [IQR 4.6–15.4] were analyzed. The cohort had a high female predominance (73.6%), and the vast majority were Caucasians (76.9%). Males were significantly younger at the time of AIH diagnosis compared to females (35.2 [IQR 21.9–55.5] vs. 47.9 years [IQR 31.2–59.0]; $p < 0.001$). No significant difference was observed between males and females in the frequency of cirrhosis at diagnosis (29.4% vs. 26.1%; $p = 0.249$) or during follow-up (39.0% vs. 33.3%; $p = 0.124$), decompensation at diagnosis (9.6% vs. 8.7%; $p = 0.632$) or during follow-up (21.6% vs. 17.3%; $p = 0.112$), and mortality (13.9% vs. 13.2%; $p = 0.729$). However, males had twice the frequency of HCC (4.0% vs. 1.8%; $p = 0.034$) and LT (19.3% vs. 9.1%; $p < 0.001$) compared to females as well as poorer transplant-free survival (71.2% vs. 80.5%; $p = 0.001$). Moreover, males have substantially lower biochemical treatment response compared to females (36.6% vs. 56.7%; $p < 0.001$). Compared to other ethnicities, Indigenous Canadians had the highest frequency of adverse events (44.1% vs. 27.0%; $p = 0.027$), mainly driven by twice the frequencies of development of decompensation over follow-up (34.6% vs. 18.0%; $p = 0.031$), LT (26.5% vs. 11.3%; $p = 0.007$), mortality (26.5% vs. 13.0%; $p = 0.023$) and poorer transplant-free survival (21.5% vs. 38.2%; $p = 0.020$). They also had a substantially shorter event-free survival time (4.3 [IQR 1.5–9.5] vs. 8.2 [IQR 3.8–14.2] years; $p < 0.001$). In a time-dependent Cox regression, Indigenous people have a significantly higher risk of developing adverse outcomes (HR 2.70, 95% CI 1.60–4.54; $p < 0.001$) that remained strong after adjusting for male sex, age and cirrhosis at diagnosis and lack of treatment response (HR 2.80, 95% CI 1.01–7.80; $p = 0.049$).
Conclusion: Males living with AIH have lower rates of treatment response and higher frequency of HCC and need for LT compared to females. From the ethnicity perspective, Indigenous Canadians living with AIH have a higher risk of developing adverse liver outcomes compared to other ethnic groups.

Background and aims: In primary biliary cholangitis (PBC), the prognostic significance of alkaline phosphatase, bilirubin and liver stiffness measurements (LSM), and of their variation over time, have been well established. However, the association between their change during treatment with Obeticholic acid (OCA) and the occurrence of liver-related events (LRE) has never been investigated. In a large cohort of OCA-treated PBC patients, we aimed to evaluate whether the biochemical response to OCA is associated with longitudinal changes of LSM and, ultimately, with the risk of LRE.
Method: Data were extracted from the Italian RECAPITULATE cohort, including OCA-treated PBC patients from centers belonging to the Italian PBC Registry and/or the CLEO/AIGO PBC study groups. After excluding subjects with <6 months' observation and cirrhotic patients in Child-Pugh B-C classes, biochemical response was evaluated through POISE criteria. Linear mixed models were used to describe on-treatment variations of liver enzymes and LSM, while Cox-models to assess their impact on LRE. Joint models were applied to estimate the association between changes in LSM and LRE, defined as the occurrence of hepatic decompensation, liver transplantation or liver-related death.
Results: 631 PBC subjects (median age 58, women 89%, cirrhotics 27%) were followed for a median of 30 months (19, 164 patient-months), and 29 LRE were registered. A sub-sample of 243 individuals with at least two LSMs repeated during treatment (total 656 LSMs, median interval 12 months) was also analysed. POISE response rates were 42% and 58% at 1 and 3 years, respectively. LSM progressively increased in POISE non-responders (slope +0.44 KPa/year, 95%CI 0.04, 0.85), while decreased over time in responders (slope −0.45 KPa/year 95%CI −0.75, −0.13; p interaction <0.001). Patients attaining 1year-POISE response showed a significantly reduced incidence of LRE during follow-up (HR 0.22, 95%CI 0.08, 0.59). Any increase in LSM was associated with an increased risk of LRE, with an overall HR per 10% increase in LSM/year of 1.39 (95%CI 1.18, 1.67).
Conclusion: In patients with PBC, biochemical response to OCA translates into a reduction of LSM and of LRE during follow-up, while non-response is associated with increased LSM and risk of LRE.

THU-094

Clinical benefits with maralixibat for patients with Alagille syndrome are durable through 7 years of treatment: data from the MERGE study

Binita M. Kamath[1], Emmanuel Gonzalès[2], Deirdre Kelly[3], Douglas B. Mogul[4], Will Garner[4], Pamela Vig[4], Emmanuel Jacquemin[2]
[1]The Hospital for Sick Children and the University of Toronto, Division of Gastroenterology, Hepatology and Nutrition, Toronto, Ontario, Canada; [2]Service d'Hépatologie et de Transplantation Hépatique Pédiatriques, Centre de Référence de l'Atrésie des Voies Biliaires et des Cholestases Génétiques (AVB-CG), FSMR FILFOIE, ERN RARE LIVER, Hôpital Bicêtre, AP-HP, Faculté de Médecine Paris-Saclay, Le Kremlin-Bicêtre, and Inserm U1193, Hépatinov, Université Paris-Saclay, Orsay, France; [3]Liver Unit, Birmingham Women's and Children's Hospital NHS Trust and University of Birmingham, Birmingham, United Kingdom; [4]Mirum Pharmaceuticals, Inc., Foster City, California, United States
Email: binita.kamath@sickkids.ca

Background and aims: Maralixibat (MRX), an ileal bile acid transport inhibitor (IBATi), is approved for the treatment of cholestatic pruritus in patients with Alagille Syndrome (ALGS) ≥3 months of age in the US and ≥2 months of age in Europe. Improvements in pruritus, serum bile acids (sBA), and height have been demonstrated from prior clinical trials including ICONIC (NCT02160782), which followed participants up to 4 years, as well as IMAGO/IMAGINE (NCT01903460/NCT02047318) and ITCH/IMAGINE-II (NCT02057692/NCT02117713), which reported outcomes to approximately 1.5 years. Participants from ICONIC, IMAGINE, and IMAGINE-II trials were invited to enroll in MERGE for additional long-term follow-up (LTFU) and prior long-term outcomes (e.g., liver transplant, death) for this group have been previously reported. Here we report on efficacy in participants with additional LTFU from MERGE, including some participants that have received treatment for 7 years.
Method: All participants from ICONIC, IMAGINE and IMAGINE-II were included in the analysis. Impact of MRX was assessed for pruritus [ItchRO (Obs) 0–4 scale, with a ≥1-point reduction considered clinically meaningful], sBA, height and weight z-scores, ALT, and total bilirubin (TB). Change from Baseline (CFB) was determined by comparing median (Q1, Q3) values from enrolment in the initial trial (i.e., ICONIC, IMAGO or ITCH) to data from the visit in MERGE that best aligned with an annual visit.
Results: Data were analyzed for 84 participants at Baseline, with follow-up to 1 year for 77 participants, 4 years for 40 participants, and 7 years for 26 participants. Baseline mean (SD) ItchRO (Obs) was 2.65 (0.75) and clinically meaningful reductions over time with CFB of −1.57 (−0.83, −2.14), −2.00 (−1.43, −2.56), and −2.14 (−1.43, −3.00) at 1 year, 4 years and 7 years, respectively. Likewise, Baseline sBA was 254 (207) µmol/L and decreased with CFB of −57 (−8, −150) µmol/L, −62 (−32, −152) µmol/L, and −105 (−41, −266) µmol/L at 1 year, 4 years and 7 years. Improvement was observed in height, with Baseline z-score of −1.7 (1.27) and CFB of 0.1 (−0.1, 0.3), 0.3 (0.0, 1.0), and 0.7 (0.0, 1.2) at 1 year, 4 years and 7 years while weight z-scores were largely unchanged. TB was stable with seven years of follow-up, with Baseline 5.5 (5.82) mg/dL, and CFB of 0.0 (−0.6, 0.5) mg/dL, 0.2 (−2.0, 0.2) mg/dL, and 0.0 (−0.9, 0.4) mg/dL over 1 year, 4 years, and 7 years. Changes in ALT showed modest increases with Baseline 158 (90) U/L and CFB of 23 (−2, 65) U/L, 36 (−4, 98) U/L, and 65 (−3, 87) U/L over 1 year, 4 years, and 7 years. There were no new safety signals.
Conclusion: In this unmatched cohort, the benefit of MRX in ALGS patients, including both improvements in clinical outcomes and sBA, persist through 7 years of treatment. No new safety concerns were identified in the long-term.

Novel machine learning algorithm for risk prediction of cholangiocarcinoma in primary sclerosing cholangitis

Ewa Wunsch[1], Marcin Horecki[2], Małgorzata Milkiewicz[1], Beata Kruk[3], Katarzyna Fischer[4], Agnieszka Winikajtis-Burzyńska[5], Gary Norman[6], Dirk Roggenbuck[7], Piotr Milkiewicz[1,3]. *[1]Pomeranian Medical University in Szczecin, Szczecin, Poland; [2]Pomeranian Medical University in Szczecin, Department of Infectious, Tropical Diseases and Acquired Immunodeficiency, Szczecin, Poland; [3]Medical University of Warsaw, Warsaw, Poland; [4]Pomeranian Medical University in Szczecin, Independent Laboratory of Rheumatic Diagnostics, Szczecin, Poland; [5]University Clinical Hospital 1, Szczecin, Poland; [6]Werfen, San Diego, United States; [7]Brandenburg University of Technology Cottbus-Senftenberg, Senftenberg, Germany*
Email: ewa.wunsch@gmail.com

Background and aims: Single serum biomarkers are insufficient to predict the risk of primary sclerosing cholangitis-related cholangiocarcinoma (PSC-CCA). Recently novel autoantibodies have been postulated to correlate with the risk of PSC-CCA. We aimed to construct an original PSC-CCA risk prediction model based on a combination of clinical and laboratory variables and an autoantibody profile in a large cohort of patients with PSC. Artificial intelligence (AI) and machine learning techniques were used.
Method: A total of 606 patients with PSC (age range 16–73, 66% male, 23% cirrhotic) from the Polish prospective PSC registry were enrolled between 2010–2022. During the median follow-up period of 41 months, 42 patients (7%) were diagnosed with CCA by tissue samples and radiology. Enzyme-linked immunosorbent or chemiluminescence assays were utilizing to detect anti-gliadin IgA, anti-F-actin IgA, anti-GP2 IgA, and PR3-ANCA IgG antibodies. Input data consisted of 37 variables previously shown to correlate with unfavorable outcome and CCA. The estimation algorithm was developed based on a Python Scilearn package and Pandas using built-in machine learning algorithms. Various types of estimation algorithms were evaluated, including MLP, Random Forest, Decision Tree, Gaussian Naïve Bayes, SVC, and Logistic Regression. Variables were pre-selected using the Recursive Feature Elimination with cross-validation. Eleven variables were selected for the estimation algorithm, including the presence of PR3-ANCA IgG, anti-GP2 IgA, and anti-gliadin IgA antibodies; abnormal laboratory parameters (ALP, GGT, bilirubin, albumin, INR, ALT, AST), and diagnosis of inflammatory bowel disease (IBD). Each algorithm was evaluated using C-Statistics and individual metrics were calculated. All results were cross-validated and the data were divided into 5 folds.
Results: All applied algorithms revealed C-statistics >0.7. Logistic Regression showed the highest recall score and was chosen for the final algorithm. Individual metrics for this model were: C-Statistics 0.85, Accuracy Score 0.86, Recall Score 0.83, Precision Score 0.29, F1 Score 0.42. Finally, the model was placed in a docker container and can be implemented in an easy-to-use mobile app, where users could calculate the CCA risk for individual patients after entering input parameters in an online form.
Conclusion: We identified autoantibodies, IBD, and worse liver biochemistry as CCA risk factors and constructed a novel AI algorithm to estimate the risk of developing CCA in patients with PSC. The algorithm uses easily available data and may therefore be valuable in routine medical practice. Further external validation however is needed before clinical application.

Email: b.hansen@erasmusmc.nl

Background and aims: Placebo-controlled trials in primary biliary cholangitis (PBC) assess biochemical response at 1 year. Recent European regulatory guidance proposes using trials of two years to assess safety and efficacy on clinical outcomes. The aim of this study was to determine whether it is feasible to detect a meaningful difference in event-free survival by extending a placebo-controlled trial to two years.
Method: A cohort of patients from the Global PBC Study group with similar eligibility criteria as the phase 3 RESPONSE study (EudraCT: 2020-004348-27) were selected; PBC diagnosis after 1990, age between 18 and 75 years, ursodeoxycholic acid (UDCA)-treatment for ≥12 months, or if untreated 12 months follow-up, total bilirubin (TB) <2 × ULN, and ALP > 1.67 × ULN. A random visit out of all eligible visits was selected as the index time. The RESPONSE population was used to estimate propensity scores based on: sex, age at visit, ALP, AST, ALT, TB, UDCA duration and use, and cirrhosis. These were subsequently used to calculate the IPTW-ATT weights. Weighted time-to-event analyses were conducted for transplant-free survival and event-free survival (hepatic decompensation [ascites, variceal bleeding, and hepatic encephalopathy], death, and liver transplantation). The incidence rate of events at two years was used for a power calculation based on a two-sided alpha of 0.05 with Fisher's exact test.
Results: There were 199 patients, 95% were female and 93% were UDCA-treated with a mean age at inclusion of 56 years (SD 10.3). The median year of diagnosis was 2004 (25th–75th percentile 1999–2009). Balance assessment between the RESPONSE cohort and the GLOBAL PBC cohort was successful after weighting. The incidence of death or liver transplantation after weighting in the first year was 1.0% as compared to 2.4% for two years, with a delta of 1.4% between one and two years. The incidence of hepatic decompensation, death, or liver transplantation after weighting in the first year was 3.3% as compared to 5.4% for two years, with a delta of 2.1% between one and two years. With the 5.4% incidence rate of events at two years in the control population and an estimated 2% incidence rate for the treated

group, a calculation with 80% power suggests that a total of 1050 patients would be required to detect a significant difference at 2 years based on Fisher's exact approach.
Conclusion: In a cohort of 199 PBC patients matched to a clinical trial population, the incidence of hepatic decompensation, death, and liver transplantation was 3.3% at one year and 5.4% at two years. Around 1000 patients would need to be included in a clinical trial for a significant difference to be detected between placebo and treatment at 2 years, which is unattainable in a rare disease and with a short inclusion time-frame. These findings emphasize the challenges of conducting placebo-controlled trials in PBC to inform on clinical outcomes.

THU-099-YI

Small duct primary sclerosing cholangitis is not associated with a heightened risk of colorectal cancer compared to inflammatory bowel disease alone

Sarah Al-Shakhshir[1], Nadir Abbas[2], Nasir Hussain[3], Sean Morris[1], Tariq Iqbal[4], Rachel Cooney[5], James Ferguson[6], Palak J. Trivedi[3]. *[1]NIHR Birmingham Biomedical Research Centre, Centre for Liver and Gastrointestinal Research, University of Birmingham, Liver Unit, Queen Elizabeth Hospital Birmingham, University Hospitals Birmingham National Health Service Foundation Trust, Birmingham, United Kingdom; [2]Liver Unit, Queen Elizabeth Hospital Birmingham, University Hospitals Birmingham National Health Service Foundation Trust, NIHR Birmingham Biomedical Research Centre, Centre for Liver and Gastrointestinal Research, University of Birmingham, Birmingham, United Kingdom; [3]NIHR Birmingham Biomedical Research Centre, Centre for Liver and Gastrointestinal Research, University of Birmingham, Liver Unit, Queen Elizabeth Hospital Birmingham, University Hospitals Birmingham National Health Service Foundation Trust, Birmingham, United Kingdom; [4]Department of Gastroenterology, Queen Elizabeth Hospital Birmingham, University Hospitals Birmingham National Health Service Foundation Trust, University of Birmingham Microbiome Treatment Centre, University of Birmingham, Birmingham, United Kingdom; [5]Department of Gastroenterology, Queen Elizabeth Hospital Birmingham, University Hospitals Birmingham National Health Service Foundation Trust, Birmingham, United Kingdom; [6]Liver Unit, Queen Elizabeth Hospital Birmingham, University Hospitals Birmingham National Health Service Foundation Trust, Birmingham, United Kingdom*
Email: sarah.al-shakhshir@nhs.net

Background and aims: Primary sclerosing cholangitis (PSC) confers heightened lifetime risks of colorectal cancer (CRC) in patients (pts) with inflammatory bowel disease (IBD). Small duct PSC (sdPSC) is a phenotypic variant, associated with a lower risk of developing PSC-related liver events. However, it is not known if the risks of colorectal outcomes differ in sdPSC compared to IBD alone, and whether the increased incidence of CRC is restricted to pts with large duct disease (ldPSC).
Method: We conducted an observational cohort study across a high-volume autoimmune liver and IBD programme in the UK. The overarching goal was to determine phenotypic differences in IBD between disease groups (sdPSC and ldPSC vs IBD alone) and quantify the risks of colonic high-grade dysplasia (HGD) and CRC. Pts with sdPSC were censored at the time of developing large duct changes on imaging and moved to the ldPSC group using a clock reset approach.
Results: Data was accrued from n = 494 pts diagnosed with PSC between 2000 and 2022, of whom 354 (72%) were diagnosed with colitis at some point in their lifetime (92.4% ldPSC-colitis; 7.6% sdPSC-colitis). The majority were men (66% ldPSC; 60% sdPSC), with a median age at PSC diagnosis of 40y and 41y, respectively. Of 27 sdPSC pts, 52% progressed to ldPSC at a rate of 6.6 per 100 follow-up years. Comparatively, 261 pts with colonic IBD (colitis) only, attended our program over the same timeframe. The median age at colitis diagnosis for pts with ldPSC, sdPSC and colonic IBD was 27 y, 29 y and 34 y ($p < 0.001$). Pancolitis was the predominant colonic disease distribution in the PSC group (50% ldPSC; 67% sdPSC), compared to left-sided colitis in the IBD group (41%) ($p < 0.001$). The ceiling of IBD treatment differed between groups, with at least 1 biologic agent being commenced in 26% of pts with colitis alone, compared to 22% and 14% of pts with sdPSC and ldPSC, respectively ($p < 0.001$). However, colectomy for refractory colitis was performed more often in pts with PSC (sdPSC 22%, ldPSC 22% vs colonic IBD 18% [($p < 0.001$]). In all, 34 cases of high-grade HGD or CRC were identified: 1 patient with sdPSC (4%), who later progressed to ldPSC; 25 in ldPSC (8%) and 8 in colonic IBD (3%). Kaplan Meier estimates (censored by death or colectomy), with log-rank P values comparing the cumulative incidence of HGD or CRC between groups, showed a higher incidence in the PSC-associated colitis group compared to IBD alone (log rank $p = 0.02$). However, in a sub-analysis based on PSC subtype, this trend only persisted for the ldPSC-associated colitis group (log rank $p = 0.01$). The risks of developing HGD or CRC were significantly greater in the ldPSC vs. IBD group (hazard ratio [HR] 1.52, 95% CI: 1.08–2.13, $p = 0.01$) but not for sdPSC vs. IBD (HR 0.72, 0.30–1.50, $p = 0.4$).
Conclusion: Colitis in sdPSC is of a similar distribution and activity to ldPSC, although the risks of developing colonic dysplasia and cancer are no greater than in IBD alone.

Background and aims: Fibrates are off-label second line treatment options for patients with primary biliary cholangitis (PBC). This study aimed to assess the factors associated with the biochemical response at one year of fibrate therapy in patients with PBC.

Method: All patients who initiated fibrates in the Dutch PBC Cohort Study-a nationwide retrospective study including every identifiable patient with PBC from 1990 onwards-were evaluated. Biochemical measurements before start of fibrates and those closest to 12 months (within the 9–18 month window) were used. Biochemical response was assessed continuously in change (delta [Δ]) of ALP (in the upper limit of normal [ULN]) and dichotomously according to Paris-2 (ALP and AST ≤1.5 × ULN and normal bilirubin) or normal ALP. Patients were stratified into a low, medium, and high baseline ALP group based on the 33rd (<1.84 × ULN) and 66th (≥2.93 × ULN) percentiles.
Results: In total, 317 initiated fibrates (bezafibrate in 310 [97.8%]). Excluded were 56 (17.6%) patients who discontinued therapy prior to response evaluation and 63 (19.8%) who had not yet reached nine months of treatment. Paired baseline and on-treatment ALP results were available for 153 patients, of which 144 (92.3%) were female. At baseline, median age was 54.4 years (IQR 48.5–63.1), 27 (19.6%) had cirrhosis, and median ALP was 2.27 (IQR 1.53–3.47). After one year of fibrate therapy, the median ΔALP was −1.02 (IQR −1.60 to −0.52, p < 0.001). The 12-month response rates for Paris-2 and normal ALP were 45.7% (64/140) and 34.6% (53/153), respectively. Age-adjusted multivariable logistic regression showed that cirrhosis (OR 0.28 [95%CI 0.08–0.96] p = 0.043), baseline ALP (OR 0.59 [95%CI 0.38–0.92], p = 0.021) and AST (OR 0.23 [95%CI 0.10–0.55] p < 0.001) were negatively associated with fulfilling Paris-2 response at 12 months of therapy. When stratified into a low, medium and high baseline ALP group, the median ΔALP were −0.56 (−0.80 to −0.31), −1.09 (−1.35 to −0.65), and −2.15 (−3.73 to −1.09), respectively (p < 0.001). In contrast, dichotomous response rates reduced with higher ALP at baseline: 78.7%, 48.8% and 13.5%, respectively, for Paris-2 (p < 0.001), and 68.6%, 32.0% and 3.8%, respectively, for normal ALP (p < 0.001). At 12 months, patients who did not fulfil Paris-2 had a significantly stronger ALP reduction than patients who did (ΔALP −1.17 [IQR −2.53 to −0.54] vs. ΔALP −0.85 [IQR −1.29 to −0.56], p = 0.032).
Conclusion: In this real-world study, cirrhotic PBC patients had a reduced biochemical response to fibrate therapy. While patients with higher baseline ALP levels showed strongly reduced dichotomous response rates after one year of fibrate therapy, their absolute ALP reduction was substantially larger. As a result, ALP decline was stronger in incomplete Paris-2 responders, emphasizing the importance to value the anticholestatic treatment based on the absolute reduction of ALP.

Background and aims: Non-invasive tests (NITs) to identify patients with Primary Biliary Cholangitis (PBC) and compensated Advanced Chronic Liver Disease (cACLD) who can avoid esophagogastroduodenoscopy (EGD) are lacking. Aims of this study were to evaluate the diagnostic performance of NITs to rule out high-risk esophageal varices (HRV) in patients with PBC-related cACLD and to assess the influence of cholestasis on the NITs performance.
Method: Data of patients with cACLD were captured from the "Italian PBC registry" and two UK referral centres (Oxford University Hospitals and University Hospital of Cambridge). This study included all PBC patients who performed an EGD for evaluation of signs of portal hypertension within 6 months from liver stiffness and biochemical evaluation. The cohort was split into a derivation (2010–2020) and a validation (2021–2023) dataset. Outcome was the presence of HRV at index EGD.
RESIST criteria (platelets count >120 × 109/L and serum albumin >3.6 g/dL) were compared with elastography-based criteria (Baveno VI-BVI, Expanded Baveno VI-EBVI) in patients with Alkaline Phosphatase (ALP) <or ≥ 1.5 times the upper limit of normal (ULN). Decision curve analysis (DCA) of NITs were calculated. Rate of patients fitting Baveno VII (BVII) criteria and prevalence of varices among them were also calculated.

Results: The cohort consisted of 303 patients [derivation (DC): n = 201, validation (VC): n = 102]. In the DC, at EGD, 119 patients (59.2%) had no varices, 60 (29.9%) had low-risk varices and 22 (10.9%) had HRV. In the VC, 51 (50%), 32 (31.4%) and 19 (18.6%) had no varices, low-risk and high-risk varices, respectively.
Proportion of correctly spared endoscopies for HRV was 98.2% (108/110), 92.3% (60/65), 92% (92/100) in DC and 94.1% (48/51), 85.2 (23/27), 85.4 (41/48) in VC for RESIST, BVI and EBVI respectively. RESIST criteria were associated with the lowest rate of missing HRV both in DC (1.8% vs 7.7% for BVI and 8.0% for EBVI) and VC (5.9% vs 14.8% for BVI and 14.6% for EBVI).
In both cohorts, patients with ALP ≥ 1.5 ULN (48.3% in DC and 33.3% in VC) had a high false negative rate to miss HRV for BVI (15.2% in DC and 16.7% in VC) and EBVI criteria (16.7% both in DC and VC). RESIST criteria false negative rate was lower (3.9 in DC and 6.2% in VC). DCA demonstrates the highest net benefit of RESIST criteria compared to elastography-based criteria for ruling out HRV, both in patients with ALp <or ≥ 1.5 ULN.
Overall, 9/56 (16.1%) patients who fit Baveno VII criteria (PLT >150 and TE <15 kPa) to rule out Clinically Significant Portal Hypertension (CSPH) had varices at EGD; 4/31 (12.9%) with ALp <1.5 and 5/25 (20%) with ALP ≥ 1.5 ULN.
Conclusion: Cholestasis impacts on NITs ability to rule out HRV and CSPH in patients with PBC and cACLD. Biochemical-based RESIST criteria demonstrates the highest net benefit compared to elastography-based criteria for ruling out HRV.

Email: nicky.somers@ugent.be

Background and aims: Primary Biliary Cholangitis (PBC) results in progressive liver fibrosis and eventually cirrhosis. Considering the varying pace of disease progression, accurate prognosis becomes essential for fine-tuning disease monitoring and treatment. We investigated the applicability of serum glycomic profiling for the identification of PBC patients at risk of poor transplant-free survival (TFS).
Method: We used stored serum samples of 858 PBC patients, collected prospectively by three centers of the GLOBAL PBC Study Group. Whole serum N-glycomic analysis was performed using DNA sequencer Aided-Fluorophore Assisted Carbohydrate Electrophoresis (DSA-FACE). Uni- and multivariate Cox regression analyses were conducted to develop the prognostic GlycoRiskScore, with associated Kaplan Meier survival analysis. The GLOBE score and UK-PBC risk score for prediction of TFS were calculated.
Results: Patients had a mean follow-up of 6.43 years since sample collection, with an overall 5- and 10-year TFS of 91.6% and 83.1%, respectively. Cox regression analysis revealed increased fucosylated glycans (NA2FB, NA3Fbc, NA4Fb) and decreased bi-, and tri-antennary glycans (NA2F, NA3) in patients with poor TFS, from which the GlycoRiskScore was derived with an area under the curve (AUC) of 0.82 (95% CI [0.78–0.86], $p < 0.001$) and a hazard ratio (HR) of 3.36 (95% CI [2.82–4.01], $p < 0.001$). Patients with a score above the cut-off value of −1.9 showed an increased risk of poor 5- and 10-year TFS, compared with patients with low values ($p < 0.001$). Furthermore, patients in the 'high risk' group developed more liver cirrhosis (15.5% vs 6.3%, $p < 0.001$), hepatic decompensation (41.4% vs 15.9%, $p < 0.001$), hepatocellular carcinoma (3.2% vs 0.6%, $p = 0.003$) and had a higher mortality rate (37.4% vs 6.6%, $p < 0.001$), when compared to the 'low risk' group. In addition, the precision for TFS estimation of both the GLOBE and UK-PBC risk scores at time of sample collection showed an AUC of 0.75 (95% CI [0.71–0.80], $p < 0.001$). Other risk factors for poor TFS were high total bilirubin and alkaline phosphatase levels, together with low albumin and platelet count-which are signs of severe liver disease. When the GlycoRiskScore was adjusted for these covariates in a multivariable Cox proportional hazards model, the association with poor TFS was confirmed (HR 2.05, 95% CI [1.66–2.53], $p < 0.001$).
Conclusion: The GlycoRiskScore might be a potential predictive biomarker, complementing the current UK-PBC and GLOBE risk scores for assessing the prognosis of PBC patients. It can be useful in identifying individuals at high risk of poor transplant-free survival who need closer monitoring, irrespective of the disease stage.

Email: gideonhirschfield@gmail.com

Background and aims: About one third of patients with primary biliary cholangitis (PBC) present with a suboptimal response to ursodeoxycholic acid (UDCA) and require additional second line therapy. The RDG-1/PBC trial aimed to evaluate the impact of adding the small molecule CD80 antagonist RhuDex to patients with PBC and inadequate response to UDCA.

Method: This was a double-blind, randomized, multi-center, placebo-controlled, comparative, exploratory phase II dose-finding trial. Patients were treated for 12 weeks with 50, 100 or 200 mg/day RhuDex gastro-resistant granules or placebo. The trial included patients with PBC and an inadequate response to UDCA, defined by serum alkaline phosphatase (ALP) levels between 1.5x and 10x the upper limit of normal (ULN) after at least 6 months of UDCA therapy. The primary efficacy end point was the relative change (%) in ALP from Baseline to the end of treatment. The trial was terminated early after a pre-planned interim analysis due to futility.
Results: 120 patients were screened. 82 patients were randomized, and 79 patients received at least one dose of study drug and were included in the full analysis set (FAS). Baseline data were comparable between treatment groups (mean age 55.5 years, 94% females, mean BMI 27.5, mean ALP 266 U/L, mean ALT 52 U/L, mean disease duration of 5.4 years). 58 patients completed the trial as planned and 21 patients of the FAS discontinued the trial prematurely. Mean treatment duration was 69 days and 79% of patients had a treatment compliance of ≥80%. The primary end point was not met. The mean relative change (%; [95% CI]) in ALP from Baseline to end of treatment were: Placebo (N = 19): −1.53 [−8.03;4.97]; RhuDex 50 mg/day (N = 20): 3.50 [−1.71;8.70]; RhuDex 100 mg/day (N = 21): 1.75 [−8.35;11.85]; RhuDex 200 mg/day (N = 19): 9.86 [−1.69;21.42]. Additional secondary end points including normalization of ALP, relative change in ALT, AST, GGT, ELF score and transient elastography did not reveal any clinical meaningful differences. Patient reported outcomes such as the PBC-40 questionnaire, Pruritus and Fatigue visual analogue scales showed no effect of RhuDex. No clinically relevant changes were observed for immune-activation related markers including TNF-alpha, IgM and IgG. Adverse events (AEs) occurred more frequently in the RhuDex 50, 100, and 200 mg groups (60.0%, 57.1%, and 84.2%, respectively) compared to placebo (52.6%). 28 AEs in 16 patients treated with RhuDex and 1 AE in 1 patient treated with placebo led to the premature trial discontinuation. 2 serious AEs were reported in 2 patients, both under RhuDex treatment, but considered not related to the study drug.
Conclusion: This trial did not show statistically significant or clinically relevant differences between RhuDex and placebo treatment. Higher AE frequencies were observed in the RhuDex groups. In this trial RhuDex did not contribute to potential second line therapies in PBC.

THU-104
Familial risk of biliary tract cancer and colorectal cancer in patients with primary sclerosing cholangitis

Erik von Seth[1], Aiva Båve[2], Michael Ingre[2], Caroline Nordenvall[3], Annika Bergquist[2]. [1]*Department of Medicine Huddinge, Karolinska Institutet, Sweden, Sweden;* [2]*Department of Medicine Huddinge, Karolinska Institutet, Stockholm, Sweden;* [3]*Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden*
Email: Erik.von.seth@ki.se

Background and aims: Primary sclerosing cholangitis (PSC) is a chronic liver disease associated with a high risk of biliary tract cancer (BTC) and colorectal cancer (CRC). Familial clustering of CRC is well-known in the general population and in individuals with inflammatory bowel disease (IBD). The familial clustering and cancer risk in individuals with PSC remains unclear. This study aimed to assess the familial risk of CRC and BTC in a large population with PSC.
Method: In a cohort of 1, 594 patients with PSC and 15, 940 age-, sex-, and geographically matched comparators from the general population in Sweden, we utilized national Health Registries to identify first-degree relatives and individuals with CRC and BTC across the entire study cohort. To assess the probability of BTC and CRC in individuals with a family history of CRC or BTC, we used logistic regression to calculate odds ratios (ORs) between PSC and their matched controls. In cases were ORs could not be calculated we used Fisher exact test. We also calculated relative risks (RR) in the group of PSC patients.
Results: The prevalence of a first degree relative with CRC and BTC was similar in PSC and in comparators, 6.1% and 1.9% vs. 6.4% and 1.6%. During a median follow-up time of 13.2 years (IQR 0.1–26.2), 5.0% (N = 79) and 13.6% (N = 191) of individuals with PSC were diagnosed with CRC or BTC. PSC with concomitant IBD had a higher likelihood of CRC than their healthy comparators (OR 5.1 (95% CI 3.6–7.0), but a family history of CRC was not associated with an increased risk of CRC in this group, RR 1.4 (95% CI 0.5–3.9). However, having a first-degree relative with CRC was associated with a higher likelihood of colectomy in individuals with PSC and IBD, RR 1.8 (95% CI 1.3–2.5). The odds of BTC in PSC patients was higher compared to matched controls, OR 80.2 (95% CI 54.4–123.1). The prevalence of familial BTC was low and therefore the risk was not assessed. Familial occurrence of either CRC or BTC was not associated with higher risk of BTC, RR 1.4 (95% CI 0.9–2.1). Having a first-degree relative with CRC was associated with an increased risk BTC in PSC, RR 1.6 (95% CI 1.0–2.5).
Conclusion: A family history of CRC does not seem to increase the risk of CRC among PSC patients with concomitant IBD but increases the risk of colectomy. The high risk of colectomy may be explained by increased tendency for cancer preventive surgery. Having a first-degree relative with CRC was associated with increased risk of BTC in PSC in addition to the already high risk.

THU-105
Improvement in lipid profiles with elafibranor treatment in primary biliary cholangitis during the phase III Elative® trial

Marlyn J. Mayo[1], Nuno Antunes[2], Mark Pedersen[1], Dimitar Tonev[3], Jianfen Shu[2], Christopher L. Bowlus[4], Kris V. Kowdley[5], Claudia O. Zein[2], Cynthia Levy[6]. [1]*Division of Digestive and Liver Diseases, University of Texas Southwestern Medical Center, Dallas, TX, United States;* [2]*Ipsen, Cambridge, MA, United States;* [3]*Ipsen, Boulogne-Billancourt, France;* [4]*Division of Gastroenterology and Hepatology, University of California Davis School of Medicine, Sacramento, CA, United States;* [5]*Liver Institute Northwest, Seattle, WA, United States;* [6]*Schiff Center for Liver Diseases, University of Miami, Miami, FL, United States*
Email: marlyn.mayo@utsouthwestern.edu

Background and aims: Primary biliary cholangitis (PBC) is a rare, cholestatic liver disease, commonly associated with comorbid dyslipidaemia, for which patients may receive lipid-modifying therapies. In the ELATIVE® phase III trial, elafibranor, a dual peroxisome proliferator-activated receptor (PPAR)-alpha/delta agonist, demonstrated significant efficacy in improving biomarkers of cholestasis in PBC. This secondary analysis evaluated the effect of elafibranor on the lipid profiles of patients in ELATIVE®, which were divided into subgroups by concomitant lipid therapy.
Method: In ELATIVE® (NCT04526665), patients with PBC with an inadequate response or intolerance to ursodeoxycholic acid were randomised 2:1 to receive once-daily elafibranor 80 mg or placebo. Changes from baseline to Week 52 in lipids (total cholesterol, low-density lipoprotein cholesterol [LDL-c], high-density lipoprotein cholesterol [HDL-c], very LDL-c [VLDL-c] and triglycerides) were assessed in patients who were receiving or were not receiving lipid-modifying therapy (statins, ezetimibe or evolocumab) for ≥30 days at start of study treatment. Analyses were performed using a mixed model for repeated measures, with adjustments for baseline values and study stratification factors.
Results: Of 161 randomised patients, 25 (15.5%) were receiving lipid-modifying therapy (elafibranor: n = 18; placebo: n = 7). In the group not receiving lipid therapy, greater improvements in lipids from baseline to Week 52 were observed in patients receiving elafibranor vs placebo according to least-squares mean difference (95% confidence interval): total cholesterol (−11.30 [−23.95, 1.34] mg/dL; p = 0.079), LDL-c (−6.93 [−17.06, 3.20] mg/dL; p = 0.178), VLDL-c (−4.91 [−6.88, −2.93] mg/dL; p < 0.001), and triglycerides (−23.61 [−33.46, −13.76] mg/dL; p < 0.001). Smaller improvements in lipids were also observed in the group receiving lipid therapy; elafibranor vs placebo

(least-squares mean difference [95% confidence interval]): total cholesterol (−2.99 [−45.54, 39.56] mg/dL; p = 0.884), LDL-c (−8.80 [−40.96, 23.36] mg/dL; p = 0.574), VLDL-c (−4.45 [−10.68, 1.78] mg/dL; p = 0.150), and triglycerides (−22.59 [−53.67, 8.49] mg/dL; p = 0.144). HDL-c levels remained stable across both groups.

Conclusion: Elafibranor treatment in patients with PBC was associated with an overall improvement in lipid profiles compared with placebo, particularly among patients not receiving lipid-modifying therapy. These data suggest that elafibranor is not only an effective treatment for PBC (as per the primary ELATIVE® analysis), but also has an added benefit on lipid profiles. Ongoing analyses are evaluating lipid parameters in subgroups stratified according to other patient characteristics.

Prospective european reference network registry (R-LIVER) supports improvement in bone disease care delivery at local level for patients with autoimmune liver diseases and enables detailed description of risk elements

Boglarka Bozso[1,2], Sandor Mogyorossy[2,3], David Tornai[1,2], Patricia Kovats[1,2], Boglarka Balogh[1,2], Nora Sipeki[1,2], Fruzsina Olah[1,2], Péter Antal-Szalmás[2,4], Zsuzsanna Vitalis[1,2], Istvan Tornai[1,2], Christoph Schramm[5,6], Maria Papp[1,2]. *[1]Division of Gastroenterology, Department of Internal Medicine, Faculty of Medicine, University of Debrecen, Debrecen, Hungary; [2]The European Reference Network on Hepatological Diseases (ERN RARE-, LIVER), Debrecen, Hungary; [3]Division of Reumatology, Department of Internal Medicine, Faculty of Medicine, University of Debrecen, Debrecen, Hungary; [4]Department of Laboratory Medicine, Faculty of Medicine, University of Debrecen, Debrecen, Hungary; [5]Department of Medicine, University Medical Centre Hamburg-Eppendorf (UKE), Hamburg, Germany; [6]The European Reference Network on Hepatological Diseases (ERN RARE-, LIVER), Hamburg, Germany*

Email: bozso.boglarka@mailbox.unideb.hu

Background and aims: Bone loss is a frequently observed complication in patients with autoimmune liver diseases (AILD). The exact risk of osteopenia and osteoporosis is unclear. Risk factors of bone loss require clarification. DEXA is both the screening method and guide for treatment. According to the EASL CPG currently in force, DEXA should be performed for all AILD patients at presentation and during follow-up (FUP). The outline standard is 80% assessment within 5 years.

We aimed to 1) assess bone loss at the time of diagnosis and during the FUP visits; 2) define risk factors of bone loss at the diagnosis; 3) evaluate the accomplishment of quality objectives for the diagnosis of bone loss and analyze how the R-LIVER Registry supported quality improvement in local level.

Method: In 2019, University of Debrecen (UNIDEB) joined the prospective, multicenter, quality-controlled R-LIVER Registry launched by the European Reference Network for Hepatological Diseases (ERN RARE-LIVER). A total of 209 AILD patients were included from UNIDEB. Clinical, laboratory, imaging, and DEXA data were collected prospectively at the time of diagnosis and during FUP visits yearly. A retrospective AILD patient cohort (n = 176, 2010–2016) from pre-accession period was used as a control group for monitoring guideline-adherence and clinical care standards of bone loss assessment.

Results: According to DEXA results, 55.7% of patients had some degree of bone loss and 24.5% had osteoporosis at the time of diagnosis with the highest prevalences in PBC (67.5% and 32.5%, respectively). Older age (OR:1.05), post-menopausal status (OR:4.82), vitamin D deficiency (OR:1.02) and presence of significant liver fibrosis (>9.2 kPa; OR:3.97) were risk factors for osteoporosis at diagnosis of AILD (p < 0.01 for all). mHAI value was an additional risk factor in AIH, but degree of cholestasis was not in PSC/PBC. Significantly more patients had DEXA assessment in line with the EASL CPG after joining ERN RARE-LIVER. DEXA assessment rate at diagnosis improved to 50% in the first year after accession and to 64.4% thereafter (12%, p < 0.001). In this subpopulation guideline adherence to FUP DEXA requirement improved to 75% and 81.6% (vs 41.4%, p < 0.001), respectively. The outline standard was not achieved in the period prior to accession (29.8% had DEXA in 5 yrs), but thereafter DEXA assessment was already 68% in just 2 yrs FUP (IQR: 0.75–4.1).

Conclusion: Bone loss was a frequent complication in our prospective AILD patient cohort. We identified several risk factors. Validation and evaluation off medical treatment on bone loss progression should be performed in the whole R-LIVER Registry cohort. After joining ERN RARE-LIVER program, gradual and significant improvement was observed in the diagnosis of bone loss in AILD that verifies prospective registries as important tools for implementation of complex care in the clinical practice at local level.

Short- and medium-term effects of hypnosis and psychoeducational interventions on fatigue associated with primary biliary cholangitis: a randomized controlled trial

Christophe Corpechot[1], Cécile Goffette[2], Cécile Flahault[2], Christel Vioulac[2], Anne-Claire Viret[3], Hélène Pérennès[4], David Da Rin[4], Karima Ben Belkacem[5], Gaouar Farid[5], Nathalie Bernard[5], Mehdi Kadhefi[6], Alexandra Rousseau[6], Pierre-Antoine Soret[5], Sara Lemoinne[5], Olivier Chazouillères[5], Aurélie Untas[7]. *[1]Reference Center for Inflammatory Biliary Diseases and Autoimmune Hepatitis, Saint-Antoine Hospital, Assistance Publique-Hôpitaux de Paris, Sorbonne University, Paris, France; [2]Laboratory of Psychopathology and Health Processes UR 4057, Institute of Psychology, Paris Cité University, Paris, France; [3]Paris, France; [4]Saint-Antoine Hospital, Assistance Publique-Hôpitaux de Paris, Paris, France; [5]Reference center for inflammatory biliary diseases and autoimmune hepatitis, Saint-Antoine Hospital, Assistance Publique-Hôpitaux de Paris, Sorbonne University, Paris, France; [6]Clinical Research Platform of the East of Paris, Saint-Antoine Hospital, Assistance Publique-Hôpitaux de Paris, Paris, France; [7]Laboratory of Psychopathology and Health Processes UR 4057, Psychology Institute, Paris City University, Boulogne-Billancourt, France*

Email: christophe.corpechot@aphp.fr

Background and aims: Fatigue is one of the main symptoms associated with primary biliary cholangitis (PBC). It affects quality of life and can lead to social isolation and depression. Although several disease-modifying therapies for PBC have proved effective, no therapeutic intervention has yet improved fatigue in this disease. The present study aimed to explore the efficacy of hypnosis and psychoeducational programs in improving fatigue in PBC patients.

Method: We conducted a randomized controlled trial in which women with stable, compensated PBC but clinically significant fatigue, defined by a PBC-40 fatigue score ≥33, were equally assigned to hypnosis (HY), psychoeducation (PE) (one weekly session for 4 weeks for both interventions) and standard care (SC) programs. Patients completed questionnaires at baseline, week 5 (W5), month 3 (M3) and month 6 (M6). The first 8 patients in each group took part to an interview at baseline and M3. Statistical analysis was performed on the intent-to-treat population. The primary end point was the difference in the PBC-40 fatigue score between M3 and baseline. Secondary end points were differences between M3 and baseline in fatigue dimensions, quality of life, sleep, anxiety and depression scores (MFI, SF-36, PSQI, ESS, HADS). Lexicometric analyses were performed on patients' interviews.

Results: A total of 55 patients (median age: 57 years; median fatigue score: 40) were assigned to HY (n = 18), PE (n = 19) and SC (n = 18) groups. Their characteristics at baseline were comparable. No adverse events occurred during the study. The primary end point did not differ statistically between groups, with median (interquartile range)

differences in the PBC-40 fatigue score between M3 and baseline in the SC, HY and PE groups of−3.0 (−10.0; 1.0), −6.0 (−11.5; −4.8) and −6.0 (−8.0; −4.0), respectively (p = 0.15 and p = 0.30 for comparison of SC with HY and PE, respectively). The results at W5 and M6 and those for the secondary end points were consistent with the results for the primary end point. Lexicometric analyses showed that patients in the HY and PE groups no longer spoke of their fatigue in the same way at M3 compared with the initial state, with a positive evolution in fatigue underlining the appropriation of the intervention followed.

Conclusion: Hypnosis and psychoeducational interventions did not result in a significantly greater short- and medium-term reduction in PBC-associated fatigue than standard care. However, a positive change was observed in the perception of fatigue in both intervention groups, suggesting that maintenance sessions could be beneficial in the long term. (Promoted by Assistance Publique-Hôpitaux de Paris; financially supported by Intercept France and ALBI Patient Association; PBC-HOPE ClinicalTrials.gov number, NCT03630718).

Email: r.deveer@erasmusmc.nl

Background and aims: Accurate prevalence rates of Primary Biliary Cholangitis (PBC) remain challenging to determine due to limited comprehensive population-based registries. We assessed the prevalence of PBC in the Netherlands over time through the nation-wide Dutch PBC Cohort Study (DPCS).

Method: The DPCS is a retrospective study which includes every identifiable patient with PBC in the Netherlands from 1990 onwards in all 71 Dutch hospitals. Case identification was performed through diagnosis and treatment codes, antimitochondrial antibodies test results, and locally available registries, by two medical doctors. Data on yearly adult population size (≥20 years) on January 1st and average life expectancy were extracted from Statistics Netherlands. Assessment of point prevalence of PBC was restricted to the period 2008–2018. Patients were censored at time of liver transplantation, death or when moving abroad. Patients lost to follow-up (LFU) were censored based on their average life expectancy. Prevalence Ratios (PR) were calculated using Poisson regression and analyzed among sex and age groups (20–45, 45–65, and ≥65 years) over time. Joinpoint regression was used to analyze time trends in prevalence by calculating annual percent changes (APC) and average annual percent changes (AAPC).

Results: On January 1st 2008, 1458 patients had PBC in the Netherlands. Over the study period, 2187 patients were newly diagnosed with PBC, while 46 were transplanted and 468 died. A total of 271 patients were LFU. Point prevalence of PBC increased from 11.93 per 100.000 persons in 2008 to 21.53 in 2018, with a median yearly prevalence of 17.06 (IQR 14.17–19.47) per 100.000 persons. The AAPC was 5.94% (95% CI 5.77–6.15, p < 0.05). The APC was 7.73% (95% CI 7.06–8.66, p < 0.05) between 2008–2012 and 4.77% (95% CI 4.42–5.09, p < 0.05) from 2012 to 2018. In 2018, prevalence of PBC was 37.6 per 100.000 persons for females and 4.9 for males (adjusted PR of 7.72, 95% CI 7.41–8.05, p < 0.001, females vs. males). The AAPC was comparable for men (5.53%, 95% CI 4.50–6.70, p < 0.05) and women (5.91%, 95% CI 5.73–6.11, p < 0.05). When stratified for age, point prevalence in 2018 ranged from 3.04 per 100.000 persons aged 20–45 years to 45.17 aged ≥65 years. Over time, compared to the population 20–45 years, adjusted PRs were 7.31 (95% CI 6.94–7.69, p < 0.001) and 11.32 (95% CI 10.76–11.90, p < 0.001) for those aged 45–65 years and ≥65 years, respectively. During the study period the AAPC was higher in older subgroups: 2.12% (95% CI 1.34–2.95, p < 0.05) in those aged 20–45 years up to 5.69% (95% CI 5.32–6.36, p < 0.05) in those ≥65 years.

Conclusion: This nationwide cohort study shows a continuing increase in prevalence of PBC, which remains a rare liver disease. As the proportion of PBC patients ≥65 years is becoming larger, future studies need to focus on the clinical impact of (additional) therapy in the elderly population.

THU-110

Time to initiation of the second-line therapy obeticholic acid in patients with primary biliary cholangitis

Sonal Kumar[1,2], Joanna P. MacEwan[3], Alina Levine[3], Leona Bessonova[4], Radhika Nair[4], Darren Wheeler[4], Jing Li[4], Robert S. Brown, Jr.[1]. *[1]Weill Cornell Medical College, New York, United States; [2]New York Presbyterian Hospital-Weill Cornell Medicine, New York, United States; [3]Genesis Research Group, Hoboken, United States; [4]Intercept Pharmaceuticals, Inc., Morristown, United States*
Email: sok9028@med.cornell.edu

Background and aims: Obeticholic acid (OCA) is the only approved second-line (2L) therapy for patients with primary biliary cholangitis (PBC). The objective of this study was to estimate the time from eligibility for 2L therapy to initiation of OCA treatment in patients with PBC.

Method: Patients with PBC (1 inpatient claim or ≥2 outpatient claims) eligible for 2L therapy between June 2016 and February 2022 were identified from the US Komodo Healthcare Map™. Eligibility for 2L therapy was determined based on inadequate response to ursodeoxycholic acid. The index date was defined as the first date of 2L eligibility. Patients were enrolled for ≥12 months preindex and were ≥18 years old at index. Patients were followed up until the initiation of OCA, end of insurance enrollment, long-term care admission, death, or end of study period (May 5, 2023), whichever came first. The proportion of patients initiating OCA and time to OCA initiation were described.

Results: Of 3880 patients with PBC eligible for 2L therapy, 306 (7.9%) initiated OCA, and 3, 574 (92.1%) did not. Eligible patients had a mean

(SD) age of 61.3 years (11.5), they were predominantly female (90.8%), and approximately half were White (50.5%). The mean (SD) time to OCA initiation from the time the patient was eligible for 2L therapy was 15.1 (15.1) months with a median (interquartile range) of 11.0 (3.0–19.3) months. Patients initiating OCA were slightly younger than those who did not, with a mean (SD) age of 57.4 (10.2) vs 61.7 (11.5) years, respectively. Of the patients initiating OCA, 90.8% were female, 42.2% were White. Based on the 1-year baseline period (12 months before and including index date), a higher proportion of patients initiating OCA had cirrhosis (18.3% vs 13.3% who did not initiate OCA) and were diagnosed with other autoimmune disease in addition to PBC (29.4% vs 26.2%). At the time of OCA initiation, the proportion of patients with cirrhosis almost doubled compared to when patients were first eligible for 2L therapy (18.3% to 32.0%). Patients initiating OCA had higher mean (SD) baseline alkaline phosphatase (ALP) levels (IU/L) than those who did not (256.0 [137.6] vs 184.2 [98.6], respectively). At the time of 2L eligibility 55.6% of patients initiating OCA had baseline ALP levels ≥1.67 × upper limit of normal (ULN) vs 25.2% of those that did not initiate OCA; by the time of OCA initiation, 66.3% of the patients had ALp >1.67 × ULN.

Conclusion: Among patients eligible for 2L therapy, less than 10% initiated OCA. A considerable delay in initiation was observed, indicating that patients may experience disease progression, including onset of cirrhosis, by the time 2L therapy is initiated. Demonstrated clinical benefit on long-term outcomes with OCA may be further improved with more timely initiation of OCA in appropriate patients.

Email: nadir.abbas@uhb.nhs.uk

Background and aims: One in 3 people who undergo liver transplantation (LT) for primary biliary cholangitis (PBC) develop disease recurrence (rPBC) despite treatment with ursodeoxycholic acid (UDCA). This international, multicentre study aimed to assess the safety and tolerability of available second-line treatments (SLTs) in the context of rPBC.

Method: We collected demographic, clinical and laboratory data from patients (pts) who underwent LT from 1999 to 2023 across 6 centres in Europe and North America. Eligible study pts were those with biopsy proven rPBC in the absence of biochemical dysfunction attributable to biliary strictures, vascular complications or allograft rejection, and who were treated with SLTs (obeticholic acid [OCA] or fibric acid derivatives. Biochemical trends, alongside discontinuation rates and tolerability data, were accrued over a 12-month period from the point of starting SLT.

Results: Over the course of the study, 21 individuals with rPBC were treated with SLT (10 OCA, 11 fibric acid derivatives). Fifteen pts were women, with a median age of PBC diagnosis and at time of LT of 41 (IQR 35–49) years and 46 (39–51) years, respectively. All pts were offered UDCA post-LT; however, 9 were UDCA-intolerant and discontinued prior to starting SLT. The median time from LT to rPBC was 1035 (684–1531) days; the earliest diagnosis was made at 183 days. The median transient elastography score at the time of rPBC was 8.8 (6.3–12.2) kPa, with median ALP, ALT, bilirubin, and albumin at baseline of 2.3 (1.8–2.8) × the upper limit of normal (ULN), 1.2 (0.7–1.8) × ULN, 12 (8–18) μmol/L and 41 (37–42) g/L, respectively. At 3-, 6- and 12-months follow-up, 16, 14 and 14 pts completed continued SLT. Five pts discontinued OCA due to disease progression (n = 3), drug intolerance (n = 1) or pruritus (n = 1). Comparatively, 4 discontinued fibric acid derivatives due to renal dysfunction (n = 2) or concerns over liver disease progression (n = 2). In total, 3/21 pts were referred for re-transplantation and 5 died (4 liver-related deaths). At 3, 6 and 12 months of OCA treatment, median reductions in serum ALP were 18 (12–25) %, p = 0.38; 30 (19–39) %, p = 0.22; and 4 (1–7) %, p = 0.40, median reductions in serum ALT from baseline were 8 (5–12) %, p = 0.08; 42 (32–51) %, p = 0.02; and 30 (21–45) %, p = 0.40. at 12 months. Median ALP reductions in the fibric acid group at 3, 6 and 12 months were 25 (11–37) %, p = 0.03; 35 (26–49) %, p = 0.01; and 35 (28–45) %, p = 0.05; respectively and median ALT reduction was 8 (4–12) %, p = 0.1; 16 (8–26) %, p = 0.19; and 8 (4–17) %, p = 0.65; respectively.

Conclusion: In this first, real-world study of SLT in rPBC, we find treatment with fibric acid derivatives is associated with significant reductions in serum ALP over time. However, discontinuation rates of OCA and fibric acid derivatives are high, underscoring the need for larger studies exploring novel treatment paradigms in the treatment of rPBC.

THU-112-YI

Quantitative magnetic resonance cholangiopancreatography provides additional prognostic value in prediction of transplant-free survival in primary sclerosing cholangitis

Tim Middelburg[1], Bregje Mol[1], Liam Young[2], Carlos Ferreira[3], Tom Davis[2], Karin Horsthuis[1], Ynto de Boer[4], Adriaan J. van der Meer[5], Annemarie de Vries[6], Roy Dwarkasing[6], Johannes Bogaards[1], Aart Nederveen[1], Jaap Stoker[1], Cyriel Ponsioen[1]. *[1]Amsterdam UMC, Amsterdam, Netherlands; [2]Perspectum Ltd, Oxford, United Kingdom; [3]Perspectum Ltd, Oxford, United Kingdom; [4]Amsterdam UMC, Amsterdam Gastroenterology, Endocrinology and Metabolism, Amsterdam, Netherlands; [5]Erasmus MC, Rotterdam, Netherlands; [6]Erasmus MC, Rotterdam, Netherlands*
Email: t.e.middelburg@amsterdamumc.nl

Background and aims: Magnetic resonance cholangiopancreatography (MRCP) is currently used for diagnostic and monitoring purposes in primary sclerosing cholangitis (PSC) and could also prove useful for prediction of transplant-free survival. Current qualitative assessments are limited by intra- and interobserver variability, whereas quantitative assessment could overcome these limitations. This study aimed to validate the additional prognostic value of quantitative MRCP metrics in PSC.

Method: Retrospective clinical and imaging data were collected from the Dutch EpiPSC2 registry, including data from one tertiary and one transplantation center. First available MRCP data was modelled by artificial-intelligence driven software (MRCP+, Perspectum Ltd.) and

quantitative metrics were generated. Data were randomized into a derivation and validation set at a 1:1 ratio. Prognostic factors including sex, type of PSC, inflammatory bowel disease phenotype and age and time-related variables were used as covariates. Cox regression analysis was used to develop and assess the predictive performance of a binary risk classifier for transplant-free survival. Subsequently, the derived risk classifier was applied on the validation set.

Results: In total 207 patients were included. Median transplant-free survival from MRCP onwards was 6.3 (IQR: 3.5–8.8) years and an event occurred in 65 patients. Multivariate analysis identified total number of candidate strictures, time from diagnosis to MRCP, proportion of ducts with 3–5 mm diameter and center of inclusion to be associated with transplant-free survival. The derived risk classifier showed good predictive performance (C-statistic = 0.74) for identifying patients at high risk of an event (HR = 5.4, 95% CI 2.3–12.4, p < 0.001) in the derivation set and remained consistent under 5-fold cross validation (C-statistic = 0.71). Applying the derived risk classifier on the validation set showed comparable predictive performance (C-statistic = 0.69) for risk assessment (HR = 3.5, 95% CI 1.7–6.9, p < 0.001).

Conclusion: This study confirms the additional prognostic value of MRCP+ metrics on long-term transplant-free survival in PSC and warrants further study on the incorporation of quantitative MRCP metrics into existing prognostic risk models.

Optimizing thiopurine therapy in autoimmune hepatitis (AIH): a multi-center study on monitoring metabolite profiles and co-therapy with allopurinol

Jan Philipp Weltzsch[1,2], Claudius Bartel[1], Moritz Waldmann[3], Stephanie Schulze[1,2], Ye Htun Oo[2,4,5], Maria Papp[2,6], Benedetta Terziroli[2,7], Adriana Baserga[2,7], Marcial Sebode[1,2], Ansgar W. Lohse[1,2], Christoph Schramm[1,2,8], Johannes Hartl[1,2].
[1]I. Dept. of Medicine, University Medical Center Hamburg-Eppendorf (UKE), Hamburg, Germany; [2]European Reference Network on Hepatological Diseases (ERN RARE-LIVER), Hamburg, Germany; [3]Institute of Clinical Chemistry and Laboratory Medicine, University Medical Center Hamburg-Eppendorf (UKE), Hamburg, Germany; [4]Centre for Liver and Gastro Research, Institute of Immunology and Immunotherapy, University of Birmingham, Birmingham, United Kingdom; [5]Liver Transplant and Hepato-biliary Unit, Queen Elizabeth Hospital, University Hospital Birmingham NHS Foundation Trust, Birmingham, United Kingdom; [6]Division of Gastroenterology, Department of Internal Medicine, Faculty of Medicine, University of Debrecen, Debrecen, Hungary; [7]Fondazione Epatocentro Ticino, Lugano, Switzerland; [8]Martin Zeitz Center for Rare Diseases, University Medical Center Hamburg-Eppendorf (UKE), Hamburg, Germany
Email: j.weltzsch@uke.de

Background and aims: We aimed to assess whether (i) a target range of thiopurine metabolites can be defined in autoimmune hepatitis (AIH), (ii) how modifying thiopurine dose and (iii) the addition of allopurinol to low-dose thiopurines impact metabolite levels and treatment response in AIH.

Method: Metabolite concentrations were tested in 331 individuals from four European centers (Hamburg, Lugano, Debrecen, Birmingham). A subgroup analysis was performed in patients with multiple metabolite measurements over time (N = 146). Thiopurine metabolite levels and treatment response were assessed after thiopurine dose increase in 50 patients and after combination with allopurinol in 36 patients.

Results: Thiopurine doses correlated with 6MMP, but not with 6TGN levels. In a cross-sectional analysis, 6TGN levels were similar in those with complete biochemical remission (CBR) and those without ("CBR": 196 pmol/0.2 ml, IQR 120–312 vs. "No CBR": 204 pmol/0.2 ml, IQR 142–350). However, higher 6TGN levels were observed in those with documented CBR at multiple time points (250 pmol/0.2 ml, IQR 228–344), compared to those failing to maintain CBR (181 pmol/0.2 ml, IQR 143–231, p = 0.0014) or those who never achieved CBR (153 pmol/0.2 ml, IQR 107–218, p < 0.0001), with a determined optimal cutoff of 223 pmol/0.2 ml (sensitivity: 76%, specificity: 78%). Increasing azathioprine doses by 36% led to preferential 6MMP formation (6MMP: +127% vs. 6TGN: +34%; p < 0.0001). In a difficult-to-treat cohort, adding 100 mg allopurinol to low-dose thiopurines raised 6TGN from 168 to 320 pmol/0.2 ml (p < 0.0001) and lowered 6MMP from 2309 to 183 pmol/0.2 ml (p < 0.0001), accompanied by improved serum ALT levels (70 to 32 U/L; p < 0.0001) in all patients and long-term CBR in 76%.

Conclusion: Maintaining CBR in AIH was associated with 6TGN concentrations above 223 pmol/0.2 ml upon multiple testing. This can be challenging to achieve due to preferential 6MMP formation. Co-administering allopurinol efficiently and safely improved metabolite profiles which was associated with sustained long-term CBR in a difficult to treat cohort.

THU-114

Alkaline phosphatase levels at 6 months as a predictor of response to ursodeoxycholic acid at 1 year in patients with primary biliary cholangitis

Carmen Sendra[1], María del Pilar Silva-Ruiz[2], Carlota Jimeno Mate[3], Patricia Cordero Ruiz[4], Domingo Pérez-Palacios[2], Gema Romero[5], Isabela Angulo-Mcgrath[3], Pablo Quiros-Rivero[6], Jose Miguel Rosales-Zábal[7], Jose Manuel Sousa-Martin[1]. *[1]Virgen del Rocio University Hospital, Seville, Spain; [2]Infanta Elena Hospital, Seville, Spain; [3]Virgen de Valme University Hospital, Seville, Spain; [4]Virgen Macarena Universitary Hospital, Seville, Spain; [5]Juan Ramón Jiménez University Hospital, Huelva, Spain; [6]Juan Ramón Jiménez University Hospital, Seville, Spain; [7]Costa del Sol University Hospital, Málaga, Spain*
Email: csendra.fernandez@gmail.com

Background and aims: Recently, Murillo Pérez et al. on behalf of the Global Primary Biliary Cholangitis (PBC) Study Group identified patients with PBC for second-line therapy at six-months after ursodeoxycholic acid (UDCA) initiation using an alkaline phosphatase (ALP) threshold of 1.9 × upper limit of normal (ULN). The negative predictive value (NPV) of that threshold was 90% (proportion of patients that did not achieve POISE criteria after one year of UDCA). Our aims were:
To assess the reproducibility of these results in our cohort.
To identify the threshold for ALP levels at 6 months that in our cohort achieves a negative predictive value (NPV) nearest to 90% response at 1 year.

Method: This multicenter, retrospective study included 393 patients with CBP from 6 hospitals in southern Spain (Sevilla, Huelva, Málaga) from 1998 to 2022. Two hundred patients were excluded due to incomplete data: lack of knowledge of UDCA initiation date or unavailability of ALP level at the beginning, at 6 months and/or at one year of treatment. Biochemical response at one year was assessed according to POISE criteria. The NPV of the threshold of ALp >1.9 × UNL at 6 months was calculated in our cohot, additionally evaluating its predictive capacity for response. Subsequently, the ALP cut-off point at 6 months that achieves an approximate NPV response of 90% at 1 year was identified.

Results: Data from 193 patients were analyzed, 89, 6% women, mean age of 65 years. ALP at six months was the best predictor of insufficient biochemical response at 1 year (AUROC was 0.87 for ALP, 0.72 for bilirubin, 0.83 for GGT, 0.74 for AST and 0.67 for ALT). The median ALP of those who met POISE criteria compared to those who did not was 1.14 × ULN (0, 72–1, 56) vs 2, 81 × ULN (0, 91–3, 72) at six months; p < 0, 001. Of the 34 patients with serum ALp >1.9 × ULN at six months, 76.4% (NPV) did not achieve POISE criteria after one year of UDCA. The ALP threshold at six months with a NPV of response nearest to 90% (89.5%) was 2.5 × ULN. Therefore, out of the 19 patients in our cohort who had ALp >2.5 × UNL at 6 months, 89.5% did not achieve biochemical response according to POISE at 1 year of UDCA.

Of those with insufficient response at 1 year according to POISE (n = 43, 22.3%), 17 (39.5%) had ALp >2.5 × ULN at 6 months and thus could have been identified earlier. 63 out of 174 patients (36.2%) with ALp <2.5 × ULN at 6 months achieved normal ALP at 1 year compared to none of the 19 (0%) patients with ALp >1.9 × UNL at 6 months.
Conclusion: In our cohort, the ALP threshold >2.5 × ULN at 6 months allows us to identify 90% of patients who will not respond after one year of treatment with UDCA.

THU-115-YI
Ursodeoxycholic acid treatment for primary sclerosing cholangitis
Bregje Mol[1], Kim van Munster[1], Rinse Weersma[2], Akin Inderson[3], Kirsten Boonstra[4], Joost PH Drenth[1], Suzanne van Meer[5], Elsemieke S. de Vries[6], B.W. Marcel Spanier[7], Ton Vrij[8], Tess Verlaan[9], Femke van Duijn[1], Willemijn Ponsioen[1], Ulrich Beuers[1], Marcel Dijkgraaf[1], Cyriel Ponsioen[1]. *[1]Amsterdam University Medical Center, Amsterdam, Netherlands; [2]University of Groningen and University Medical Center Groningen, Groningen, Netherlands; [3]Leiden University Medical Center, Leiden, Netherlands; [4]Radboud University Medical Center, Nijmegen, Netherlands; [5]University Medical Center Utrecht, Utrecht, Netherlands; [6]Isala Clinics, Zwolle, Netherlands; [7]Rijnstate Hospital, Arnhem, Netherlands; [8]Zorggroep Twente, Almelo, Netherlands; [9]Gelderse Vallei Hospital, Ede, Netherlands*
Email: b.mol@amsterdamumc.nl

Background and aims: Ursodeoxycholic acid (UDCA) is often prescribed for primary sclerosing cholangitis (PSC), although evidence to confirm a beneficial long-term effect of UDCA on solid clinical end points is insufficient. The aim of our study is to evaluate the efficacy of UDCA in terms of transplant-free survival in a longitudinal population-based cohort.
Method: Between January 2008 and August 2020, we conducted a retrospective and prospective study based on the Dutch population-based EpiPSC2 cohort. Data regarding medication use were collected by medical chart review, periodic questionnaires, and were retrieved from the national pharmacy prescription database. Survival analyses were performed for the following end points; 1) LT or all-cause mortality, 2) LT, PSC-related death or occurrence of hepatobiliary (HB) malignancies, 3) LT (excluding indication of HB malignancy) or death due to liver failure, and 4) occurrence of HB malignancy. The effect of UDCA use was estimated by using a Fine and Gray proportional hazards model to account for competing risks. Sex, age at diagnosis, PSC type, IBD status, transplant centre inclusion, NSAID use, thiopurine use, and biological use were considered as predictor variables. Events before or in the first three months after PSC diagnosis were censored.
Results: Of the 879 patients included, medication data was available for 739 patients. Patients with uncertain use of UDCA were excluded, resulting in a study population of 567. 64 patients were classified as never users, 67 used UDCA less than half of their disease duration and 415 used UDCA more than half of their disease duration. There were no significant differences in age, alkaline phosphatase levels or PSC type at baseline. UDCA use was significantly associated with a decreased hazard ratio (HR) for LT or all-cause mortality, with the most pronounced effect in the <50% use group (<50% HR 0.29 (0.15–0.54) and >50% HR 0.54 (0.34–0.87)). For the combined end point LT, PSC-related death, or occurrence of HB malignancy, the HR for <50% UDCA use was 0.33 (0.12–0.91), and 0.71 (0.38–1.34) for >50% use. No discernible effect of UDCA on LT or death due to liver failure was observed. The HR for HB malignancy occurrence was 0.25 (0.07–0.97) for <50% UDCA use and 0.60 (0.28–1.28) for >50%. NSAID use less than half of the disease duration was significantly associated with a decreased HR for all end points except LT or death due to liver failure.
Conclusion: UDCA treatment was associated with improved transplant-free survival, in particular when used <50% of the disease duration. This correlation seems predominantly driven by a reduced occurrence of hepatobiliary cancer, and supports the use of modest amounts of UDCA in the management of PSC.

THU-116-YI
The skin microbiome diversity differs in regard to age and gender but not presence of pruritus in patients with hepatobiliary diseases
Miriam M. Düll[1,2], Rebecca Weiß[1,2], Markus F. Neurath[1,2], Stefan Wirtz[1,2], Andreas E. Kremer[1,3]. *[1]Department of Medicine 1, Friedrich-Alexander-University Erlangen-Nürnberg, Erlangen, Germany; [2]Deutsches Zentrum Immuntherapie, DZI, Erlangen, Germany; [3]Department of Gastroenterology and Hepatology, University Hospital Zürich, University of Zürich, Zürich, Switzerland*
Email: miriam.duell@uk-erlangen.de

Background and aims: Recent data underline microbial components as potential contributors in the pathophysiology of chronic pruritus in different skin conditions. Still, there is very limited data on the influence of the skin microbiome on itch as a symptom in liver diseases. This study therefore investigated the composition of the skin microbiome in a large patient cohort with hepatobiliary disorders with and without pruritus.
Method: We conducted this study at a large tertiary hepatology department, collecting skin microbiome samples at one forearm using the cyanoacrylate glue method. Samples were flash frozen at −80°C immediately after collection, and stored until DNA extraction. Illumina-based next generation sequencing of the 16S V4 ribosomal RNA gene (16S rRNA) regions sequencing was employed, followed by bioinformatic processing using the Qiime2 pipeline and the R programming language. Patients' diagnoses were categorized as "immune-mediated and cholestatic liver diseases" (ICLD), "steatotic liver disease" (SLD, including MASLD, MetALD, ALD), "viral liver diseases" (VLD), "liver transplant recipients" (LTR), and "other liver diseases" (OLD). We assessed clinical and laboratory data, and a questionnaire containing demographic information, quality of life measures and detailed characteristics of pruritus.
Results: A total of 127 patient microbiome specimens were collected (with pruritus n = 60; without pruritus n = 67). Both patient groups were comparable in regard to age, sex, disease categories and stage of liver disease, with a two-third majority of ICLD patients in both groups. Overall, we observed a very diverse interindividual range of microbiome signatures in this patient cohort. There was no significant difference between the pruritic and non-pruritic patient group in beta diversity, while age and gender had a significant influence here ($p < 0.05$, Bray-Curtis dissimilarity). Similarly, we found no significant difference for beta diversity between disease categories or the presence of cirrhosis. The most prevalent phyla were *Firmicutes* and *Actinobacteriota*, which are common components of the human skin microbiome; but we also observed an overall high relative abundance of gram-negative alpha- and gamma Proteobacteria (28%) with Enhydrobacter and Acinetobacter as the most frequent genera. Interestingly, we observed the highest amount of alpha- and gamma Proteobacteria in either higher stage fibrotic/cirrhotic patients (38%), patients with ICLD or LTR receiving immunosuppressants (46%) or under UDCA therapy (58%).
Conclusion: The skin microbiome presented as very individually diverse in a large patient cohort with hepatobiliary diseases, with differences in regard to age and gender but not presence of pruritus. Still, relative abundance of certain taxa might present in disease subgroups or with specific medication such as immunosuppressants and UDCA.

THU-117-YI

The course of radiological features and liver stiffness measurement during long-term treatment with fibrates and UDCA in patients with Primary Sclerosing Cholangitis

Elisa Catanzaro[1,2], Matteo Peviani[1,2], Francesco Pezzato[1,2], Emanuela Bonaiuto[2], Paolo Rollo[1,2], Nicola Perin[3], Martina Gambato[2,4], Annarosa Floreani[5,6], Raffaella Motta[7,8], Nora Cazzagon[1,2]. *[1]Gastroenterology Unit, Azienda Ospedale—Università Padova, Padova, Italy; [2]Department of Surgery, Oncology and Gastroenterology, University of Padova, Padova, Italy; [3]Department of Medicine, University of Padua, Padua, Italy; [4]Multivisceral Transplant Unit, Azienda Ospedale-Università Padova, Padova, Italy; [5]University of Padova, Padova, Italy; [6]IRCCS Sacro Cuore Don Calabria, Negrar (Verona), Italy; [7]Department of Cardiac, Thoracic, Vascular Sciences and Public Health, University of Padova, Padova, Italy; [8]Radiology Unit, Azienda Ospedale—Università Padova, Padova, Italy*
Email: elisa.catanzaro95@gmail.com

Background and aims: Patients with Primary Sclerosing Cholangitis (PSC) lack an effective medical treatment to delay disease progression. According to EASL CPG 2022, ursodeoxycholic acid (UDCA) can be used in PSC since it improves liver function tests (LFTs) and bezafibrate is the 1st-line recommended treatment for pruritus in PSC. Moreover, bezafibrate is under investigation in a phase 3 clinical trial (NCT04309773) due to its beneficial effects in improving LFTs. We here aim at assessing the course of radiological findings and liver stiffness measurement (LSM) by VCTE during long-term treatment with fibrates in PSC.

Method: We conducted a retrospective analysis of PSC patients treated with fibrates (fenofibrate 200 mg/day or bezafibrate 400 mg/day) and UDCA for a minimum of 6 months. Notably, we analyzed the course of magnetic resonance imaging (MRI) prognostic scores, i.e. ANALI score with and without gadolinium (Gd) and DiStrict score from baseline to the end of follow-up alongside LSM, LFTs and pruritus.

Results: Among 27 consecutive PSC patients initiating fibrates between 2017 and 2020, the median age at diagnosis was 31 (21–35) years. Over a median treatment of 33.3 (20.8–51.2) months, fibrates led to a significant reduction of LFTs (ALP 2.6 *vs.* 1.7 × ULN, p = 0.002; ALT 2.0 *vs.* 1.4 × ULN, p = 0.038; GGT 4.3 *vs.* 3.4 × ULN, p = 0.012), Amsterdam-Oxford model (1.75 *vs.* 1.35 *p* = 0.03) and pruritus (56% *vs.* 20%, p = 0.031) but no improvement in LSM (6.6 *vs.* 7.1 KPa, p = ns) was observed. Regarding radiological scores, the percentage of patients with a high DiStrict score (value = 5–8) remain stable during follow-up (64% *vs.* 73%, p = 0.52) while there was a notable increase in the number of patients high ANALI scores with Gd (value = 2) and without Gd (value = 3–5) (39% *vs.* 70% and 61% *vs.* 87%, p = 0.04 for both). A more detailed analysis of individual items within the ANALI scores was conducted, revealing a trend toward a worsening of liver parenchymal dysmorphism (43% *vs.* 87%, p = 0.08) compared to other features over time. In particular, the number of patients with moderate to severe intrahepatic bile duct dilatations remained stable over time (69% *vs.* 78%, p = 0.35).

Conclusion: As the first experience of assessing radiological findings during treatment with fibrates in PSC, interesting results emerged from the observation of their course, suggesting the potential role of fibrates in stabilizing biliary alterations but without slowing the progression of parenchymal damage.

Email: diazg.alvaro@gmail.com

Background and aims: Corticosteroid therapy (CS) at doses >15 mg/day for >4 weeks, therapeutic cornerstone of autoimmune hepatitis (AIH) management, increases the risk of active Tuberculosis (TBCa) by 7.7 times in some autoimmune diseases (AID). Guidelines for other AID recommend screening for latent Tuberculosis infection (LTBI) and prophylaxis if appropriate. Furthermore, immunosuppression can also increase the risk of Pneumocystis Jirovecii (PJ), with prophylaxis indicated in some situations. However, there are no recommendations for AIH, probably because there are no published data on the incidence of LTBI, TBCa, nor PJ. Our aim was to evaluate the prevalence of LTBI and the incidence of TBCa and PJ.

Method: Retrospective study conducted in 20 Spanish centres, evaluating the diagnosis (dx) of LTBI, TBCa, and PJ between the years 2000 and 2023.

Results: 2893 patients with AIH and treated with CS were evaluated. In 5 centres (25%), routine pre-treatment LTBI screening was

performed. In these, 37 cases (4.9%) of LTBI were identified in 747 studied patients. 7 (19%) patients had previously received prophylaxis, 15 (40.5%) received it at the time of AIH dx –75% received isoniazid-, and 15 (40.5%) did not receive prophylaxis. 3 (20%) of the 15 patients treated presented DILI secondary to prophylaxis. Out of the 2893 patients, only 6 (0.2%) developed TBCa during follow-up (3 pulmonary/3 extrapulmonary). 83% were women with a median age of 52.3 years. 50% lived in a rural environment and had another AID. None of the patients had previously received immunosuppression. The time from the start of CS to TBCa was 13.3 years (IQR 9.6–22.3). No differences were identified between those who developed TBCa and the patients with LTBI in gender (p = 0.6), AIH presentation (acute/chronic/acute severe; p = 0.7), respiratory diseases (p = 0.8), diabetes mellitus (p = 0.6), BMI (p = 0.4), presence of other AID (p = 0.5), AIH treatment (p = 0.7), nor any other clinical or analytical characteristic. At the time of TBCa dx, 5 (83.3%) were treated with CS, 3 (50%) with AZA, and 1 (16.7%) with mycophenolate mofetil. On the other hand, no patient with a dx of LTBI who did not receive prophylaxis developed TBC during follow-up. Regarding Pneumocystis Jirovecii, 2 (10%) centres routinely perform prophylaxis. During follow-up, no patients were diagnosed with PJ infection (0/2893).

Conclusion: Screening for LTBI, TBCa prophylaxis, and PJ prophylaxis do not seem necessary in patients with AIH treated with standard regimens. The incidence of TBCa is low, much lower than reported in other AID, and the time from the start of CS and the development of TBCa is very long, so its development is probably not related to AIH treatment. Finally, isoniazid was associated with a significant rate of discontinuation due to DILI.

THU-119

Seladelpar treatment increases fatty acid beta-oxidation and serum carnitine levels in patients with primary biliary cholangitis consistent with increased expression of the carnitine transporter OCTN2 and the mitochondrial carnitine shuttle

Yun-Jung Choi[1], Jeff Johnson[1], Charles A. McWherter[1]. [1]*CymaBay Therapeutics, Inc., Fremont, United States*
Email: ychoi@cymabay.com

Background and aims: In a global serum metabolomic study of patients with primary biliary cholangitis treated with seladelpar, a selective PPAR-delta agonist, we found that an increase in carnitine was one of the most biochemically important changes. Carnitine plays an essential role in carrying out beta-oxidation of long-chain fatty acids for energy production. Carnitine is a major substrate of the plasma membrane transporter OCTN2, which is ubiquitously expressed and is involved in carnitine absorption from diet, carnitine reabsorption in the kidney and facilitates cellular uptake of carnitine. Our aim is to further examine seladelpar's effects on serum carnitine as well as expression of OCTN2 and the mitochondrial carnitine shuttle genes.

Method: Serum samples from 160 PBC patients were collected on Day 1 and after 3 months of treatment with placebo (n = 55), seladelpar 5 mg (n = 52) or 10 mg (n = 53) in a randomized phase 3 study (NCT03602560). The abundance of carnitine was examined using UHPLC-MS/MS (Metabolon, Inc). We also measured the effect of seladelpar on expression of OCTN2 and the carnitine shuttle genes in mouse tissues and human primary hepatocytes.

Results: Seladelpar treatment resulted in a significant dose-dependent increases from Day 1 in serum carnitine (p < 0.0001): placebo (1.02-fold), seladelpar 5 mg (1.18-fold) and 10 mg (1.24-fold). A substantial proportion of patients treated with seladelpar 5 mg (88%) and 10 mg (94%) increased serum carnitine levels compared to the placebo group (58%). RNASeq analysis of tissues from mice treated with seladelpar 10 mg/kg/day for 12 weeks revealed significant increases in Octn2 compared to vehicle: intestine (1.9-fold), liver (2-fold) and kidney (1.7-fold). The components of the mitochondrial carnitine shuttle were also induced by seladelpar treatment: Cpt1a (intestine, 1.7-fold; kidney, 1.3-fold; skeletal muscle, 1.7-fold); Cpt2 (intestine, 1.5-fold; liver, 1.4-fold; kidney, 2.1-fold); Crat (intestine, 1.4-fold; liver, 2.7-fold; kidney, 1.9-fold); and Cact (intestine, 1.8-fold; liver, 1.7-fold; kidney, 2.7-fold). Similar results were obtained in primary human hepatocytes treated with 10 uM seladelpar for 24 hours (OCTN2, 1.7-fold; CPT1A, 4-fold; CPT2, 1.7-fold; CACT, 1.6-fold). The rate-limiting carnitine biosynthesis enzyme BBOX1 was not significantly changed by seladelpar.

Conclusion: Seladelpar's upregulation of carnitine transporter in liver, intestine, and kidney may have contributed to the observed increase in serum carnitine levels. Increased gene expression of OCTN2 by seladelpar could result in increased intracellular levels of carnitine and fatty acid beta-oxidation. The effects of seladelpar via the carnitine transporter and carnitine shuttle are proposed to lead to enhanced fatty acid beta-oxidation and further study is needed regarding seladelpar's impact on this aspect of PBC disease pathology.

Background and aims: Ursodeoxycholic acid (UDCA) is the standard therapy for patients with Primary Biliary Cholangitis (PBC). Biochemical response to UDCA is mainly described in cohorts derived from academic centers. We assessed the biochemical response of UDCA at one year in the nationwide Dutch PBC Cohort Study (DPCS).

Method: The DPCS is a retrospective study which includes every identifiable patient with PBC in the Netherlands from 1990 onwards in all 71 Dutch hospitals. For the assessment of the biochemical response to UDCA monotherapy, available laboratory values (reported in upper limits of normal [ULN]) up to one year prior to start of UDCA and laboratory values closest to the 12 month timepoint, within the 9–18 month window, were included. Patients

were censored in case of liver transplantation, immunosuppression therapy and/or second line therapy prior to timepoint of UDCA response evaluation. Complete case analyses were performed per biochemical end point.
Results: In total, 4351 patients were included in the DPCS; 3835 (88.1%) were female, median age was 56.8 (48.5–66.5) years, 198 (4.6%) had cirrhosis at baseline, and 3619 (83.2%) were diagnosed at a secondary center. Of patients with UDCA (n = 4256, 97.8%), median ALP at baseline was 1.92 (IQR 1.30–3.25), median AST was 1.53 (IQR 1.06–2.31), median bilirubin was 0.53 (IQR 0.38–0.82), and 714/3025 (23.6%) patients already met PARIS 2 criteria (ALP and AST ≤1 .5 ULN and normal bilirubin). After one year of UDCA, median delta (Δ) ALP was −0.69 (IQR-1.61−−0.23), median Δ AST was-0.55 (IQR −1.13–0.20) and median Δ bilirubin was −0.05 (−0.18–0.06) (p < 0.001 for all). After one year of UDCA, 1443/2412 (59.8%) patients had a complete response according to PARIS 2, 1009/2576 (39.2%) patients had normal ALP, and 1651/2463 (67.0%) patients had a bilirubin ≤0 .6 × ULN. These response rates on PARIS 2, normal ALP and bilirubin ≤0.6 × ULN were 433 (89.3%), 340 (64.2%) and 382 (76.7%) versus 821 (51.6%), 499 (30.2%) and 1041 (64.2%) among patients who did and who did not fulfill the PARIS 2 criteria at baseline (p < 0.001 for all). The median Δ ALP was −0.61 (IQR −1.24–0.24) vs −0.95 (IQR −2.42–0.18, p < 0.001) and the median Δ bilirubin was −0.05 (IQR −0.15–0.06) vs −0.06 (IQR −0.24–0.10, p = 0.043) among patients who did and who did not meet the PARIS 2 criteria at one year of UDCA.
Conclusion: This nationwide study shows that 60% of patients have a complete response after one year of UDCA according to the PARIS 2 criteria. The decline of the cholestatic surrogate parameters was higher in patients with an incomplete response versus those with a complete response. Still, considering the discussion on the need of biochemical normalization, one year of UDCA leaves >60% of all PBC patients in the Netherlands with an elevated ALP.

THU-121
Harnessing synergy of 'triple' anti-cholestatic therapy in patients with primary biliary cholangitis

Guilherme Cançado[1], Bo Chen[1], Madeline Cameron[1], Inbal Houri[1], Kristel Leung[1], Aliya Gulamhusein[1], Bettina E. Hansen[1,2], Gideon M. Hirschfield[1]. *[1]Toronto Centre for Liver Disease, Division of Gastroenterology and Hepatology, Toronto General Hospital, University Health Network, Toronto, Canada; [2]Department of Gastroenterology and Hepatology, Erasmus University Medical Center, Rotterdam, Netherlands*
Email: gideon.hirschfield@uhn.ca

Background and aims: Treatment goals in primary biliary cholangitis (PBC) increasingly aim for normal serum liver tests. Currently add-on therapy to Ursodeoxycholic acid (UDCA) is with the approved Farnesoid X receptor (FXR) agonist Obeticholic acid (OCA), alongside off-label use of fibrates (PPARs). We report our experience of synergistic FXR-PPAR-UDCA combination therapy in PBC.
Method: Chart review of prevalent patients with PBC seen between July 2022 and July 2023 at the Toronto Centre for Liver Disease was performed.
Results: 470 patients with PBC were seen of which 71% were treated with UDCA only, 7% UDCA-OCA, 11.3% UDCA-fibrates and 10.6% UDCA-OCA-fibrates. Among 50 patients on triple therapy [86% female, median age at diagnosis 43.5 (IQR 14.6) years, median age at triple therapy 53.6 years (13.0), 96% AMA positive, 36% cirrhotic], 82% had OCA as the first add-on therapy. Most patients on fibrates (92%) received bezafibrate, while 8% had fenofibrate. 48 patients were included in final analysis. Median follow-up time after triple therapy was 17.4 months (16.8). Median alkaline phosphatase (ALP) was 396.5 U/L (282.5) before triple therapy and 147.5 U/L (75) at the last available, while bilirubin was 12 (9) µmol/L and 9 (4) µmol/L, respectively. Patients on triple therapy demonstrated median ALP reductions after 6 months of 31.1% (95%CI 25.4%–37.0%) and 37.8% (95%CI 31.6%–44.0%) at last follow-up. Patients with cirrhosis showed similar Results: 25.2% (95%CI 17.6%–32.8%) ALP reduction at 6 months and 31.2% (95%CI 20.6%–42.0%) at last follow-up. Bilirubin values were stable throughout the follow-up. Out of 34 patients with self-reported pruritus before triple therapy, 64.7% reported improvement, 11.8% worsened and 23.5% had no change in itching intensity. Liver stiffness as measured by Fibroscan remained stable after triple therapy initiation [median 7.6 kPa (4.6 kPa) pre; 8.0 kPa (7.6 kPa) at last follow-up].
Conclusion: In people living with at-risk PBC, we confirm FXR-PPAR-UDCA triple therapy significantly improves liver biochemistry.

Patient-reported insights on current care practices for primary biliary cholangitis, quality of life and self-management: results of the german PBC online survey

Diane Langenbacher[1], Achim Kautz[1], Christian Trautwein[2], Carsten Schwenke[3], Yuri Sankawa[4], Andreas E. Kremer[5]. *[1]Kautz5 gUG, Köln, Germany; [2]RWTH University Hospital, Aachen, Germany; [3]SCO: SSiS, Minden, Germany; [4]Dr. Sankawa GmbH, Stuttgart, Germany; [5]University Hospital Zürich, Department of Gastroenterology and Hepatology, Zürich, Switzerland*
Email: langenbacher@kautzhoch5.de

Background and aims: Primary biliary cholangitis (PBC) is a chronic immune-mediated cholestatic liver disease requiring lifelong stratified treatment and management. Building on an earlier patient survey conducted in Germany in 2017, a comprehensive online survey was carried out in 2021 to obtain representative data on the current care situation, symptom burden and management, quality of life and outcome-relevant influencing factors in PBC.
Method: After a pre-test phase between May and November 2020, the PBC online survey went online in January 2021 for one year. The survey was announced online at leberhilfe.org, pbcnews.info and in digital newsletters. The data was analyzed descriptively.
Results: A total of 1032 patients participated, with 92.6% being female. At the time of diagnosis, 652 patients had no liver fibrosis. Most patients (n = 697) were seen by a physician every 3 or 6 months. 56.5% of patients reported on elevated ALP, 23.4% on increased bilirubin levels, however only 14, 8% of patients were put on second line medication. Increased values were more commonly associated with female gender and presence of comorbidities. Female patients were more likely to suffer from comorbidities. QoL was lower in these patients. Factors associated with application of second-line therapies were young age (<30 years), a more recent diagnosis (50% were diagnosed between 2013 and 2022), higher education, and knowledge of lab values. Patients on second-line therapies had a better QoL. Presence of fibrosis was not associated with clinical factors (ALP level, bilirubin level, comorbidities, age, sex, time since diagnosis), but with socio-economic factors (school/professional qualifications, employment/pension status). Fatigue (58.5%), pruritus (37.8%), sicca syndrome (36.3%), and joint complaints (51.9%) were identified as the four most common and severely affecting symptoms. Patients affected by these symptoms had a poorer QoL, including dimensions such as professional/social life, and relationships/sexuality.
Conclusion: Compared to previous survey, no significant improvements were observed in biochemical markers of treatment response such as bilirubin and ALP. Nevertheless, only a minority of patients received additional second-line therapies. This seems to be in line with findings from the German PBC registry. Although fatigue, arthralgia and pruritus remain among the most distressing symptoms, medical and non-medical symptom management and general quality of life appear to have improved. Especially in empowered patients with adequate knowledge of their disease and of strategies to manage symptom burden and improve their overall well-being.

External validation of the international autoimmune hepatitis group response criteria in a multicentric real-world cohort

Lorenz Grossar[1], Sarah Raevens[2], Christophe Van Steenkiste[3], Isabelle Colle[4], Charlotte De Vloo[5], Hans Orlent[6], Jeoffrey Schouten[7], Marie Gallant[8], Annelien Van Driessche[9], Sander Lefere[10], Lindsey Devisscher[11], Anja Geerts[2], Hans Van Vlierberghe[2], Xavier Verhelst[2]. *[1]Department of internal medicine and paediatrics, hepatology research unit, Ghent University, Liver research centre Ghent, Ghent, Belgium; [2]Ghent University hospital, Hepatology, Ghent, Belgium; [3]AZ Maria Middelares, University hospital Antwerp, Ghent, Belgium; [4]Algemeen stedelijk ziekenhuis Aalst, Aalst, Belgium; [5]AZ Delta, Roeselare, Belgium; [6]AZ Sint-Jan, Brugge, Belgium; [7]AZ Nikolaas, Sint-Niklaas, Belgium; [8]Jan Yperman ziekenhuis, Ieper, Belgium; [9]AZ Glorieux, Ronse, Belgium; [10]Department of internal medicine and paediatrics, hepatology research unit, Ghent University, Liver research centre Ghent, Ghent, Belgium; [11]Department of internal medicine and paediatrics, hepatology research unit, Ghent University, Department of basic and applied medical sciences, gut-liver immunopharmacology unit, Ghent University, Ghent, Belgium*
Email: lorenz.grossar@ugent.be

Background and aims: The goal of treatment in autoimmune hepatitis (AIH) is induction of remission to prevent the development of liver fibrosis, cirrhosis, and its related complications. Considering the need for consistency in definitions of treatment response, the International Autoimmune Hepatitis Group (IAIHG) recently defined consensus criteria for treatment response. Validation of these criteria is necessary for correlation with hard end points to facilitate comparison between studies.
We aimed to validate the IAIHG response criteria in our cohort and establish correlations with survival end points. The primary end point was liver-related survival. Secondary end points were overall mortality and transplant-free survival.
Method: We performed a retrospective, multicentric cohort study in one tertiary and seven secondary care centres in Belgium. Included patients were at least 18 years of age at time of data collection and diagnosed with AIH by a simplified IAIHG score of at least 6. Patients with features of both AIH and primary sclerosing cholangitis (PSC) or primary biliary cholangiopathy (PBC), as defined by the Paris criteria, were excluded from the analysis. Complete biochemical response (CBR) was defined according to the IAIHG consensus criteria as normalisation of transaminases and serum immunoglobulin G (IgG) within the first six months of treatment. Time to development of mortality (all-cause and liver-specific) and liver transplantation was calculated and included in time-to-event analysis. Liver-related survival was defined as freedom from liver-related death or liver transplantation. Outcome was compared between subjects attaining CBR and those with insufficient response.
Results: Biochemical response status could be determined in 200 AIH patients. Median age at diagnosis and median follow-up were 47 years (interquartile range: 29–59) and 7.8 years (interquartile range: 4.1–13.0), respectively. There was a female predominance of 74.2% and 150 individuals (70.4%) were followed up in a tertiary centre. CBR was achieved in 128 (64.0%) individuals. Gender, acute symptoms, and IgG elevation at diagnosis did not associate with CBR status. Patients not achieving CBR presented more frequently with cirrhosis on initial histology (22.2% versus 10.9%, $p = 0.035$). Liver-related mortality or liver transplantation combined as a primary end point, occurred in 26 subjects (13.0%). Patients achieving CBR exhibited superior liver-related (HR: 0.118; 95% CI: 0.052–0.267. $p < 0.0001$) and overall survival (HR: 0.253; 95% CI: 0.111–0.572. $p = 0.0003$).
Conclusion: We externally validated the IAIHG consensus criteria for complete biochemical response and correlate them with survival end points in a multicentric, real-world cohort. AIH patients achieving CBR as an intermediate end point have significantly superior liver-related and overall survival.

THU-124

Population pharmacokinetics of elafibranor in healthy participants and patients with liver diseases: A pooled analysis of 17 clinical studies

Marion Dehez[1], Karl Brendel[1], Dimitar Tonev[2], Stijn van Beek[3], Qing Xi Ooi[3], Carol Addy[4]. *[1]Ipsen, Les Ulis, France; [2]Ipsen, Boulogne-Billancourt, France; [3]Pharmetheus, Uppsala, Sweden; [4]GENFIT Corp., Cambridge, MA, United States*
Email: marion.dehez@ipsen.com

Background and aims: Elafibranor is a dual peroxisome proliferator-activated receptor-alpha/delta agonist in development for the treatment of primary biliary cholangitis (PBC) and primary sclerosing cholangitis. Here, we characterise the pharmacokinetics (PK) of elafibranor and its main active metabolite, GFT1007, in healthy participants and patients with liver diseases, and assess population characteristics that could influence PK parameters.
Method: PK data consisting of 12, 205 elafibranor and 10, 592 GFT1007 samples were pooled from 17 clinical (13 phase I, 2 phase II, 2 phase III) studies in 894 participants receiving elafibranor. The population included 450 healthy participants and 444 patients with PBC, metabolic dysfunction-associated steatohepatitis, or renal or hepatic impairment. Doses ranged from 5 to 360 mg. Regimens included single dosing and daily dosing. Multiple dosing duration ranged from 14 days to >1 year.
Separate population PK models were developed for elafibranor and GFT1007 using nonlinear mixed effects modelling in NONMEM. Elimination half-life, area under the plasma concentration-time curve during a dosing interval at steady state ($AUC_{t,ss}$) and maximum/minimum plasma drug concentration at steady state ($C_{max,ss}/C_{min,ss}$) were derived. Effects of covariates (dose, drug formulation, age, sex, body mass index, Black/African American race, food intake prior to drug administration, bioanalytical method of measuring samples, estimated glomerular filtration rate, National Cancer Institute hepatic impairment score, PBC, levels of hepatic transaminases, albumin and bilirubin) on PK parameters were explored. Clinical significance of covariates on $AUC_{t,ss}$, $C_{max,ss}$ and $C_{min,ss}$ was assessed using Forest plots.
Results: A more than proportional decrease in elafibranor exposure with lower doses was observed, while elafibranor PK was linear between 50 and 360 mg/day. Following daily intake of elafibranor 80 mg in patients with PBC, predicted median elimination half-life (90% confidence interval) of elafibranor was longer versus GFT1007 (59.7 [52.1, 67.3] vs 10.7 [9.84, 11.9] hours). Predicted time to steady state for elafibranor and GFT1007 was 12.4 and 2.22 days, respectively. At this dose, GFT1007 exposure was higher versus elafibranor in patients with PBC: $AUC_{t,ss}$, $C_{max,ss}$ and $C_{min,ss}$ were approximately 5-, 8- and 1.5-fold higher, respectively.
Conclusion: Elafibranor and GFT1007 PK were found to be dose-proportional across a 50–360 mg dose range. As GFT1007 exposure at steady state was 5-fold higher than elafibranor, the pharmacodynamic effect is likely driven more by GFT1007 than by elafibranor under the assumption of equipotency.

Email: e.werner@erasmusmc.nl

Background and aims: The goal of this study was to create a question prompt list (QPL) for individuals living with primary biliary cholangitis (PBC), covering key topics to be asked during out-patient consultations which are most likely to improve PBC management.
Method: International PBC experts were invited to rate 43 questions related to 9 aspects of PBC care on a 7-point Likert scale (ranging from 1 = Very Unimportant to 7 = Very Important) in a digital survey. Participants had to consider *a*) the probability that the specific aspect of care is not optimally managed, and *b*) their confidence that optimizing that specific aspect of care will benefit patient outcomes. In addition, the top 3 questions within each aspect of care were ranked in order of importance. Questions rated by >70% of the respondents to be moderate/very important were considered best candidate questions (BCQs) for the QPL. Results of the survey were discussed during two in-person meetings, based on which the questions and/or QPL were amended. Hereafter, the study team ratified the final QPL in a consensus meeting.
Results: In total, 108 respondents completed the survey; 61 (56.5%) had >10 years of PBC experience, 71 (65.7%) worked in a tertiary center, and 5 (4.6%) were patient representatives. Eleven questions were rated as BCQs in 6 out of the 9 aspects of care: Symptoms, 2nd line therapy, Disease severity, Monitoring, Extra hepatic disease (s) and Other. During the in-person meetings (64 attendees), experts suggested combining the BCQs regarding symptoms addressing pruritus (rated as moderate/very important by 86.1% of the respondents) and fatigue (75.0%). With respect to treatment, although questions within the category of 1st line therapy failed to achieve the predefined rating for a BCQ (68.5%), attendees agreed there is a strong scientific basis to include the top-ranked question on the correct dosage of ursodeoxycholic acid in the QPL. Also, to avoid overlap, only 1 out of 3 BCQs related to the indication for 2nd line therapy was included in the QPL. With respect to disease severity, attendees approved the inclusion of BCQs related to risks of disease progression (74.1%) and presence of cirrhosis (76.9%), while being aware on a predefined disclaimer that the current QPL is not intended to target specific aspects of cirrhosis care. Attendees suggested rephrasing the BCQ on liver stiffness measurement (71.3%) to focus on the frequency of the measurement and agreed to include the BCQs related to bone health (73.1%) and availability of patient information and support (70.4%). The final QPL based on the survey results and discussion meetings contained 8 questions and was unanimously approved during the consensus meeting.
Conclusion: Through a Delphi method international expert consensus was reached on a QPL containing 8 key questions patients can ask their physician, which are felt to most likely impact their PBC care.

THU-126
Metabolomic signature in autoimmune hepatitis discriminates disease activity and predicts response to treatment
Kalliopi Zachou[1,2], Aikaterini Dimou[3], Christina Kostara[3], Kalliopi Azariadis[1,2], George Giannoulis[1,2], Angeliki Lyberopoulou[1,2], Eleni Bairaktari[3], George Dalekos[1,2]. *[1]Department of Medicine and Research Laboratory of Internal Medicine, National Expertise Center of Greece in Autoimmune Liver Diseases, General University Hospital of Larissa, Larissa, Greece; [2]European Reference Network on Hepatological Diseases (ERN RARE-LIVER), General University Hospital of Larissa, Larissa, Greece; [3]Laboratory of Clinical Chemistry, Faculty of Medicine, School of Health Sciences, University of Ioannina, Larissa, Greece*
Email: zachoukalliopi@gmail.com

Background and aims: Metabolomics were shown to be a useful tool for predicting treatment response or defining disease severity-related phenotypes in diverse autoimmune diseases. Autoimmune hepatitis (AIH) is characterized by altered metabolomic signature but the use of metabolomics in profiling patients according to response to treatment remains unexplored. Therefore, we investigated the ability of metabolites to discriminate disease activity state and predict response to treatment.
Method: Metabolites in plasma samples from 50 AIH patients at diagnosis and 78 AIH patients at complete response (CR) [normal alanine aminotransferase (ALT) and immunoglobuline G (IgG) levels] were determined by ^{1}H-NMR spectroscopy. For 28 patients matched samples were available. Fifty-two metabolites were quantified. Response to treatment was defined according to the recently reported response criteria by the International AIH Group.
Results: The metabolomic profile of AIH at diagnosis could be sufficiently discriminated from AIH on CR ($p < 0.001$) Eighteen metabolites differentiated AIH at diagnosis from AIH on CR with the top 6 (VIP scores >1.7) being acetoacetate, succinate, 2-aminobutyrate, myoinositol, tyrosine and malonate. Forty-three out of 50 AIH patients received treatment. At week 4 of treatment 36 patients were responders, while at month 6 and end of follow-up 33 and 40 patients, respectively, achieved CR. Treatment could be stopped in 28/43 patients, 16 of whom remained at remission for 59 (3–120) months. Lower carnitine levels at diagnosis could predict response at week 4 of treatment ($p < 0.05$; AOC 0.73), while higher 3-hydroxyisovalarate and choline at diagnosis could predict CR at month six ($p < 0.05$; AUC 0.68 and 0.7, respectively). Interestingly, lower formate and higher lactate levels at diagnosis could predict the possibility to withdraw treatment ($p < 0.05$; AUC 0.69 and 0.72, respectively), while higher formate and lower taurine levels could predict maintenance of remission after treatment withdrawal ($p < 0.05$; AUC 0.76 and 0.72, respectively).
Conclusion: Altered metabolomic profile characterize active AIH at diagnosis and AIH on CR after treatment initiation. Most importantly, NMR-based metabolomic signature can be used for the prediction of response to treatment in AIH patients.

Background and aims: Primary biliary cholangitis (PBC) is a rare autoimmune cholestatic liver disease. Due to the mosaic etiology of PBC, environmental variables most likely combine with immunogenetic and epigenetic risk to contribute to the disease's development. In this work, we investigated the role of soluble HLA-G (sHLA-G), HLA-G alleles and 3′UTR haplotypes and their potential impact on the onset and therapy response in Sardinian PBC patients. Sardinia, an Italian region, provides an excellent opportunity for research due to its genetic profile; it is considered a "genetic isolate" because of its homogenous genetic traits. With limited variables, a small sample of patients is sufficient to obtain significant results, particularly crucial for rare diseases like PBC.
Method: A cohort of 166 Sardinian PBC patients was compared to two groups, 180 healthy individuals and 205 AIH-1 patients. The HLA-G alleles and 3′UTR haplotypes of the patients and the healthy controls were analyzed. Plasma sHLA-G levels were measured, and the results were categorized based on HLA-G 3′UTR haplotypes linked to affecting HLA-G expression.
Results: Our data showed how the HLA-G UTR-1 haplotype was significantly more frequent in PBC patients, comparing them to the control population [160/332 (48.2%) vs 123/360 (34.3%) respectively; OR = 1.79 (95% CI 1.32–2.44); $p < 0.0001$; $pc = 0.0008$]. Furthermore, this study demonstrated a close correlation between sHLA-G levels and the response to therapy and disease severity (first line therapy response and ALP levels, gamma-GT levels, liver fibrosis score at the last follow-up). Indeed, sHLA-G levels in patients with an inadequate response were significantly lower than patients with a good response to therapy [25.58 (0.0–60.9) U/ml vs 15.53 (6.29–24.77) respectively; $p = 0.010$].
Conclusion: Our study suggests that in PBC, HLA-G extended haplotypes (HLA-G alleles and HLA-G 3′UTR control region) could play a role in disease onset, therapy response and disease progression through advanced fibrosis. This could be related to reduced levels of sHLA-G observed in PBC patients.

THU-128

A randomized phase II proof-of-concept study of beta-lapachone in patients with primary sclerosing cholangitis

Woo Hyun Paik[1], Joo Kyung Park[2], Moon Jae Chung[3], Gunn Huh[4], Heon Se Jeong[5], Hee Jin Kim[5], Do Hyun Park[4]. *[1]Seoul National University Hospital, Seoul, Korea, Rep. of South; [2]Samsung Medical Center, Seoul, Korea, Rep. of South; [3]Yonsei University College of Medicine, Seoul, Korea, Rep. of South; [4]Asan Medical Center, Seoul, Korea, Rep. of South; [5]Curome Biosciences, Seoul, Korea, Rep. of South*
Email: dhpark@amc.seoul.kr

Background and aims: Primary sclerosing cholangitis (PSC) is a rare, chronic and cholestatic liver disease caused by inflammation and fibrosis of the bile duct. This condition leads to biliary cirrhosis, liver failure and associated cancer. However, there is still no drug available that can alter the progression or prognosis of the disease. Beta-lapachone (HK-660S) induces an increase in intracellular NAD+, thereby improving mitochondrial function and activating the Sirtuins/AMPK pathway, resulting in anti-fibrotic and anti-inflammatory effects. Therefore, we aimed to evaluate the clinical feasibility of HK-660S in patients with PSC.
Method: A randomized, double-blind, placebo-controlled, parallel group phase 2 clinical study was conducted in four tertiary institutions in South Korea. The subjects were randomly assigned to either the active or placebo groups (2:1 ratio) and administered 100 mg of HK-660S or placebo twice a day for 12 weeks and followed up until 16 weeks. The primary outcomes were the reduction of serum alkaline phosphatase (ALP) after 12-week treatment and percentage of subjects who show improvement of severity PSC as assessed by magnetic resonance cholangiopancreatography (MRCP) with improvement defined as a decrease of –1 or more in the MRCP score (anali score). Secondary outcomes included liver stiffness on fibroscan, and any adverse events after 12-week treatment.
Results: Full analysis set (FAS) comprised 21 patients randomized to experimental (n = 15) and placebo (n = 6) group. After 12 weeks of treatment, among 18 patients who had initial ALP twice higher than upper normal limit, six patients (50.0%) in the experimental group (n = 12) showed a reduction in serum ALP of more than 20%, while none in the control group (n = 6) demonstrated statistically significant results ($p = 0.054$ by Fisher's exact test, significant at two-tailed $\alpha = 0.1$). Among the entire study population, two patients (13.3%) in the experimental group showed an improvement of biliary strictures on MRCP whereas none in the control group. Four patients (26.7%) in the experimental group showed improvement in stiffness measured by ELF score, while no patient in the control group did. There was only one severe adverse event (SAE) in the experimental group, which was bacteraemia not likely associated with HK-660S. No SAEs were reported in the control group.
Conclusion: This 12-week proof-of-concept clinical trial demonstrated that HK-660S was well-tolerated in PSC patients and had the potential to decrease serum ALP levels. Further phase 3 randomized trials with long-term follow-up are warranted to validate these promising results.
(ClinicalTrials.gov NCT05866809).

Maralixibat improves growth in patients with progressive familial intrahepatic cholestasis: data from the MARCH/MARCH-ON trials

Regino P. Gonzalez-Peralta[1], Alexander Miethke[2], Amal A. Aqul[3], Douglas B. Mogul[4], Tiago Nunes[4], Will Garner[4], Pamela Vig[4], Richard J. Thompson[5]. *[1]Pediatric Gastroenterology, Hepatology, and Liver Transplant, AdventHealth for Children and AdventHealth Transplant Institute, Orlando, Florida, United States; [2]Cincinnati Children's Hospital Medical Center, Cincinnati, Ohio, United States; [3]University of Texas Southwestern Medical Center, Dallas, Texas, United States; [4]Mirum Pharmaceuticals, Inc., Foster City, California, United States; [5]Institute of Liver Studies, King's College London, London, United Kingdom*
Email: regino.gonzalez-peralta.md@adventhealth.com

Background and aims: Progressive familial intrahepatic cholestasis (PFIC) is a group of disorders resulting in disrupted bile composition and cholestasis leading to debilitating pruritus, growth deficits, vitamin deficiency, and progressive liver damage. A Phase 2 open-label study (INDIGO) of maralixibat (MRX), an ileal bile acid transporter (IBAT) inhibitor, in patients with BSEP deficiency (PFIC2) demonstrated that patients who were serum bile acid (sBA) responders had significant improvements in growth with >5 years of MRX treatment compared to non-responders. MARCH was a 26-week, randomized, placebo-controlled (PBO), Phase 3 trial of MRX that achieved its primary and key secondary end points of pruritus and sBA reduction for individuals across the broadest range of PFIC types studied to date, using a higher dose than INDIGO. Long-term maintenance of effect for up to two years was observed in MARCH-ON, an open-label extension. We report on the long-term impact of MRX on improvements in growth across a variety of PFIC types from the MARCH/MARCH-ON trials.
Method: MARCH/MARCH-ON has been previously described. We analyzed height and weight z-scores based on a participant's sex and age at each scheduled trial visit.
Results: We analyzed 64 participants from the All-PFIC cohort (13 FIC1, 31 nt-BSEP, 9 MDR3, 7 TJP2, and 4 MYO5B). Mean baseline age, sBA, pruritus, and liver biochemistries were well balanced between MRX and PBO groups. Growth (mean [SE]) for the overall PFIC study

population was stunted at Baseline (weight z-score: −1.53 [0.16]; height z-score: −2.07 [0.17]). In MARCH, there was a significant increase in weight z-score in the MRX group vs. PBO with a mean [SE] change from Baseline (CFB) of +0.23 [0.11] (p = 0.039). There was an increase in height z-score in the MRX group (+0.08 [0.09]) and a decrease in the PBO group (−0.13 [0.09]), but relative change between these groups was not statistically significant (+0.21 [0.12]; p = 0.09). In MARCH-ON, the observed increases in weight z-scores (+0.52 [0.18]; p = 0.011) were maintained for >2 years of continued treatment with MRX and improvements in height z-scores further increased, resulting in significant improvements starting at Week 30 and maintained for >2 years (+0.4 [0.18]; p = 0.046). In those participants who were initially on PBO and then subsequently received MRX for up to 1 year, comparable significant improvements were observed in both weight (+0.32 [0.13]; p = 0.03) and height (+0.37 [0.37]; p = 0.012) z-scores.

Conclusion: These consistent trends in growth for MRX-treated PFIC patients of various types represents the first report of sustained improvements in weight, as well as improvements in height, with the use of an IBAT inhibitor indicating a potential disease-modifying effect of MRX treatment in PFIC.

THU-130

The role of transient elastography and enhanced liver fibrosis score in IgG4-hepato-pancreato-biliary related disease

Senamjit Kaur[1], Rodrigo Motta[2], Carolyn Mercer[1], Emma Culver[3].
[1]Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom; [2]Translational Gastroenterology Unit, Nuffield Department of Medicine, Oxford, United Kingdom; [3]Oxford University Hospitals NHS Foundation Trust, Translational Gastroenterology Unit, Nuffield Department of Medicine, Oxford, United Kingdom
Email: senamkaur@gmail.com

Background and aims: IgG4-related disease of the liver, pancreas, and bile ducts (IgG4-HPB) can lead to fibrosis and organ damage. Liver stiffness measurement (LSM) by vibration-controlled transient elastography (VCTE) and Enhanced liver fibrosis (ELF) score is a validated, non-invasive method for measuring liver fibrosis in other chronic liver diseases, but little is known in regard to their utility in IgG4-HPB. We aimed to assess LSM using Fibroscan® and ELF in a cohort of patients with IgG4-HPB.

Method: A retrospective observational cohort of patients with IgG4-HPB meeting the ACR/EULAR classification criteria for IgG4-Related Disease at Oxford University Hospitals. Clinical data collected included demographics, organ involvement, clinical flares, serum biomarkers and organ damage. LSM was recorded in 55 IgG4-HPB patients, and sequential LSM was recorded in 32 patients. Serum ELF was measured in 23 patients. Wilcoxon rank, Mann-Whitney U, and Fisher's exact tests were performed.

Results: Ninety-seven patients with IgG4-HPB disease were included; median age 68 years ± 19, 79% male. Established organ dysfunction and/or damage was seen in 67/97 (69%) of IgG4-HPB patients; (41/57) 72% of those with liver and biliary disease (IgG4-HB); and (26/40) 65% of those with pancreatic disease only (IgG4-AIP).

LSM was recorded in 55 patients: IgG4-HB (n = 38) had a higher mean LSM compared with IgG4-AIP (n = 17) (p = 0.04). IgG4-HB were risk-stratified by LSM: 25/38 (66%) had LSM <8 kPa, 8/38 (21%) had LSM ≥8 but <12 kPa, and 5/38 (13%) had LSM ≥12 kPa. There was a higher prevalence of metabolic associated steatotic liver disease (MASLD) and its risk factors (diabetes, hypertension, hypercholesterolemia, and ischaemic heart disease) in those with more advanced liver fibrosis (LSM≥12 kPa). There was a higher prevalence of organ damage in those with LSM ≥8 kPA and ≥12 kPA.

In longitudinal analysis, 32 patients with IgG4-HPB had serial LSM. Of those with IgG4-HB (n = 22), 23% showed an increase in LSM over a median of two years (IQR 1–4). The proportion of patients meeting criteria for MASLD increased from 20% to 25% over a median of two years. In those with paired readings during active disease and remission (n = 8), there was no discernible variation in LSM.

Patients with IgG4-HPB (n = 23) were stratified by ELF: 13/23 (56%) <9.8 and 10/23 (43%) ≥9.8. ELF accurately identified patients with more significant liver fibrosis; no patient with LSM ≥8 kPA was seen in the <9.8 group (p = 0.0021). There was no association of ELF with disease activity or serum biomarkers.

Conclusion: This is the first study assessing the role of LSM by Fibroscan® and ELF score in patients with IgG4-HPB. An increased LSM over time was associated with the accumulation of cardiometabolic risk factors, evidence of MASLD, and end-organ damage, while ELF score ruled out advanced fibrosis in this cohort concurrently.

THU-131

Rifaximin helps reduce cholestasis in patients with primary biliary cholangitis and increased fecal calprotectin

Laura Iliescu[1], Andreea Simu[2], Razvan Rababoc[2], Mircea Istrate[2], Ioana Tanasie[2], Alexandra Alina Mihaela Mihaila[2], Adriana Rusie[3], Letitia Toma[2]. *[1]Fundeni Clinical Institute, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [2]Fundeni Clinical Institute, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [3]Fundeni Clinical Institute, Carol Davila University of Medicine and Pharmacy, Bucharest*
Email: laura_ate@yahoo.com

Background and aims: Rifaximin is a nonsystemic oral antibiotic used in the prevention of hepatic encephalopathy. Its properties of modulating the gut microbiota suggest its potential use in autoimmune disorders associated with intestinal dysbiosis. We aim to determine the effect of rifaximin in patients with primary biliary cholangitis (PBC) and persistent cholestasis despite optimal treatment with ursodeoxycholic acid (UDCA).

Method: We performed a prospective trial including patients with known PBC and persistent cholestasis admitted to our clinic between January 2022 and June 2023. Diagnosis of PBC was established by presence of serum antibodies or liver biopsy in antibody-negative patients. All patients had a minimum of 6 months of optimal UDCA therapy. Patients with decompensated cirrhosis, history of malignancy or intestinal disease (including signs and symptoms of inflammatory bowel disease) were excluded from the trial. All patients continued UDCA and were given rifaximin 200 mg twice daily, 10 days per month, for a duration of 3 months. Serum transaminases (ALT, AST), gamma -glutamyl transpeptidase (GGT), direct bilirubin (dBili), alkaline phosphatase (AlkP) and fecal calprotectin (fCal) were determined before rifaximin initiation and after the last dose administration.

Results: We included 53 PBC patients (mean age 47.23 ± 12.43 years, 92.4% female). Increased transaminases was observed in 7 patients (median ALT 66 U/L, median AST 57 U/L). All patients had increased GGT (mean 115 ± 28 U/L), 60% had increased AlkP (164 ± 35 U/L) and 18.8% had increased dBiili (0.9 ± 0.4 mg/dL). Increased fCal was noted in 37 patients (69.8%) with mean values 87 +- 28 ug/g. After rifaximin therapy we noted a significant decrease in GGT, AlkP, dBili and fCal in patients with initially increased fCal (GGT: 34 U/L versus 86 U/L, p < 0.001, AlkP: 103 U/L versus 152 U/L p = 0.02, dBil: 0.2 versus 0.9 mg/dL, p = 0.04, fCal: 32 ug/g versus 91 ug/g, p < 0.001). In patients with normal fCal before therapy, we noted a decrease in serum markers but not reaching statistical significance (GGT 113U/L versus 121 U/L, AlkP 124 U/L versus 154 U/L, dBil 0.5 mg/dL versus 0.8 mg/dL).

Conclusion: Rifaximin alleviates cholestasis in PBC patients with insufficient response to ursodeoxycholic acid therapy and increased fecal calprotectin, probably by modulating gut microbiota and diminishing systemic inflammation. Therefore, it can become an important therapeutic means in patients with incomplete UDCA response. More information is necessary regarding the use of rifaximin in PBC patients with normal fecal calprotectin.

THU-132

Obeticholic acid normalizes inflammatory biomarkers in patients with primary biliary cholangitis

David E. Jones[1], Christopher L. Bowlus[2], Arash Thranian[3], Mary Erickson[3], Jing Li[3], Christopher Gasink[3], Robert G. Gish[4].
[1]*Translational and Clinical Research Institute, Newcastle University, Newcastle-upon-Tyne, United Kingdom;* [2]*University of California Davis, Sacramento, United States;* [3]*Intercept Pharmaceuticals, Inc., Morristown, United States;* [4]*Robert G. Gish Consultants, San Diego, United States*
Email: david.jones@newcastle.ac.uk

Background and aims: Primary biliary cholangitis (PBC) is an autoimmune cholestatic liver disease characterized by chronic inflammation and progressive destruction of bile ducts. Obeticholic acid (OCA) is a selective, potent farnesoid X receptor agonist that received accelerated approval based on results from POISE, a randomized, double-blind, placebo (PBO)-controlled phase 3 study. Our goal was to evaluate the impact of OCA on normalization of inflammatory and immune biomarkers in patients (pts) from POISE.
Method: Pts with PBC who could not tolerate or had an incomplete response to ursodeoxycholic acid were randomized 1:1:1 to receive PBO, OCA titration (OCA 5 mg daily for 6 months with the option to titrate to 10 mg daily after 6 months), or OCA 10 mg daily for 12 months. Biomarker levels (tumor necrosis factor alpha [TNF-alpha], high-sensitivity C-reactive protein [hsCRP], and immunoglobulin M [IgM]) were measured at baseline (BL) and Month 12. Normalization was defined as reduction to levels ≤8.1 pg/ml for TNF-alpha, ≤3 mg/L for hsCRP, and ≤2.3 g/L for IgM (with abnormal defined as greater than these values). The association between treatment and normalization was assessed using Cochran-Mantel-Haenszel test and the median difference was compared using the Wilcoxon rank-sum test.
Results: In the full intent-to-treat population, median BL levels of TNF-alpha were 11.7, 10.1, and 10.8 pg/ml for PBO, OCA titration, and OCA 10 mg, respectively, and median change from BL at Month 12 was 1.2, 0.8, and −0.2 pg/ml ($p < 0.01$ for OCA 10 mg vs PBO). Among the 79% of pts with TNF-alpha >8.1 pg/ml at BL, 3% (2/63) on PBO, 23% (10/52) on OCA titration, and 14% (7/56) on OCA 10 mg normalized at Month 12 ($p < 0.05$ for both vs PBO). Median BL hsCRP levels were 3.3, 3.3, and 3.1 mg/L for PBO, OCA titration, and OCA 10 mg, respectively, with median change from BL at Month 12 of 0.4, −0.5, and −0.6 mg/L ($p < 0.001$ for both vs PBO). Among the 53% of pts with elevated hsCRP at BL, 6% (2/38) on PBO, 19% (6/38) on OCA titration, and 39% (13/39) on OCA 10 mg attained ≤3 mg/L at Month 12 ($p = 0.1$ and $p < 0.001$ vs PBO, respectively). Median BL levels of IgM were 4.5, 3.7, and 3.5 g/L for PBO, OCA titration, and OCA 10 mg, respectively, with median change from BL at Month 12 of −0.3, −0.7, and −1.0 g/L ($p < 0.001$ for both vs PBO). Of the 77% of pts with high IgM at BL, 0% (0/60) on PBO, 15% (6/51) on OCA titration, and 27% (13/55) on OCA 10 mg normalized IgM at Month 12 ($p < 0.01$ for both vs PBO).
Conclusion: OCA significantly increased the proportion of pts with PBC who achieved normalization of the inflammatory biomarkers TNF-alpha, hsCRP, and IgM, the latter of which is associated with better clinical outcomes. These findings further support improvement of the autoimmune aspects of PBC in pts treated with OCA.

THU-133-YI

Radiomics for prognostication in primary sclerosing cholangitis: a proof-of-concept using GLRLM run entropy

Laura Cristoferi[1], Cesare Maino[2], Davide Bernasconi[3], Alberto Savino[1,4], Ilaria Ripamonti[1,4], Miki Scaravaglio[1,4], Eugenia Vittoria Pesatori[5], Daphne D'Amato[6], Alessio Gerussi[1,4], Chiara Alberzoni[2], Maria Grazie Valsecchi[3], Rocco Corso[2], Davide Ippolito[2,4], Pietro Invernizzi[1,4], Elisabetta De Bernardi[4], Marco Carbone[4,7]. Email: l.cristoferi@campus.unimib.it

Background and aims: Magnetic resonance imaging (MRI) in primary sclerosing cholangitis (PSC) risk assessment generally relies on qualitative or semi-quantitative analysis, leading to interpretation variability. Radiomics emerges as a promising field for developing quantitative radiological biomarkers for PSC monitoring and risk stratification. This study aims to identify and validate radiomic features from MRI images to identify patients at higher risk of developing poor outcome.
Method: This is a prospective, single-centre, observational study (Jan 2019–Dec-2022) recruiting 102 PSC patients undergoing routine gadoxetate disodium-enhanced MRI with standardized protocol. From PyRadiomics implemented in Python both morphological and radiomics features were extracted by five selected MRI sequences (3D T1 FS GRE (ax) during the arterial phase, 3D T1 FS GRE (THRIVE) (ax) during hepatobiliary phase (20 min), ADC map (mm2/s), In-phase/Out-of-phase (IP/OP) T1 WI (ax), Fat Saturation T2 WI-MultiVane (T2spir) (ax). Patients were categorized into high-risk groups based on the Mayo risk score (MRS)>0 and the liver stiffness measurement (LSM)>9.6 kPa. Predictive features from a training cohort of 58 patients were validated in 41 additional PSC patients, followed by survival analysis in the combined 99-patient cohort.
Results: Among 102 patients, 99 were analysed; 2 were excluded due to poor image quality resulting from respiratory artifacts. Of the 58 patients of the training cohort 15 (25.0%) and 17 (30.0%) were defined at high-risk by MRS and LSM. One-hundred and seven radiomic features were extracted from each of the 5 MRI sequences selected. GLRLM-Run Entropy in T2spir significantly correlates with estimates of clinical outcomes with an OR of 4.04 (CI 3.63–4.71, $p = 0.0002$) for MRS and 2.93 (CI 1.71–3.43, $p = 0.009$) for LSM. Its prognostic potential was confirmed on observed clinical events by univariate Cox analysis (HR per 0.1 of increase 1.478 95% CI 1.175;1.860) showing an excellent predicting performance (C-index = 0.85).
Conclusion: This study highlights the potential of a unique, quantitative radiomic feature for monitoring and risk-stratify PSC patients. GLRLM-Run Entropy measures the randomness or complexity of image voxel grey level intensity. Higher values might be indicative of inflammation, edema, and fibrosis. Its quantitative nature, and extraction using free, globally available software makes it a promising candidate in radiological biomarkers' field in PSC. Additional research with wider cohorts and longer follow-up is required to confirm these findings.

Metabolomic signature by 1H-NMR spectroscopy discriminates autoimmune hepatitis from other liver diseases

Kalliopi Zachou[1,2], Aikaterini Dimou[3], Christina Kostara[3], Kalliopi Azariadis[1,2], George Giannoulis[1,2], Angeliki Lyberopoulou[1,2], Eleni Bairaktari[3], George Dalekos[1,2]. [1]*Department of Medicine and Research Laboratory of Internal Medicine, National Expertise Center of Greece in Autoimmune Liver Diseases, General University Hospital of Larissa, Larissa, Greece;* [2]*European Reference Network on Hepatological Diseases (ERN RARE-LIVER), General University Hospital of Larissa, Larissa, Greece;* [3]*Laboratory of Clinical Chemistry, Faculty of Medicine, School of Health Sciences, University of Ioannina, Ioannina, Greece*
Email: zachoukalliopi@gmail.com

Background and aims: Altered metabolomic signature has already been reported in several diseases including autoimmune conditions. However, the metabolomic profile in autoimmune hepatitis (AIH), has not been investigated in depth. We investigated the metabolomic

signature of AIH and its ability to discriminate AIH from other liver diseases as well as to study its pathogenesis.
Method: Plasma samples from 50 AIH patients at diagnosis, 43 healthy controls (HC), 72 patients with primary biliary cholangitis (PBC), 26 patients with metabolic dysfunction-associated steatohepatitis (MASH) and 101 patients with chronic viral hepatitis (CVH) were investigated by ^{1}H-NMR spectroscopy. Fifty-two metabolites were quantified, and metabolic pathway analysis was performed.
Results: AIH could be differentiated from HC and each of the disease controls (multivariate analysis; $p < 0.001$). AIH differentiated also from disease controls as a total (PBC + CVH + MASH) (15 metabolites with 95% sensitivity and 92% specificity). Glutamine and arginine seem the main metabolites separating AIH from HC, while 2-aminobutyrate and kynurenine are the most important metabolites discriminating AIH from other liver diseases including MASH. The pathway of phenylalanine/tyrosine/tryptophan biosynthesis had the greatest impact on separating AIH from HC and other liver diseases. Ten metabolic pathways were altered in AIH compared to disease controls: the metabolic pathway of cysteine/methionine metabolism, butanoate metabolism, tyrosine metabolism, tryptophan metabolism, ketone bodies synthesis and degradation, arginine biosynthesis, arginine/proline metabolism, citrate cycle, phenylalanine/tyrosine/tryptophan biosynthesis, and phenylalanine metabolism ($p < 0.001$). Comparison for the altered metabolic pathways between the two autoimmune liver diseases (AIH and PBC) revealed that the metabolic pathway of branched-chain amino acids (BCAAs) (lower valine, leucine and isoleucine levels and their catabolic intermediates in PBC), methionine (lower methionine, 2-aminobutyrate and 2-hydroxybutyrate levels in PBC), alanine-aspartate-glutamate (lower metabolites in PBC) and that of metabolites associated with gut microbiota (lower choline, betaine and dimethylamine levels in PBC) were significantly different between AIH and PBC ($p < 0.01$).
Conclusion: The metabolomic profile of AIH is distinct and could be used to differentiate AIH from HC but most importantly from patients with other liver diseases including MASH as the panel of 15 metabolites that we detected by ^{1}H-NMR spectroscopy showed high sensitivity and specificity for AIH diagnosis. Therefore, ^{1}H-NMR could be used as an additional specific tool for AIH diagnosis and study pathogenesis, given that NMR technology does not need much sample handling, is highly reproducible and with low cost.

THU-135
Real-world study of reasons for non-utilization of second-line treatment in patients with primary biliary cholangitis

Seema T. Meloni[1], Claudia O. Zein[1], Allison R. Smither[2], Anushree Iyengar[2], Ediz S. Calay[2], Tyler E. Wagner[2], Rohit K. Yenukoti[3], Christelle Pommie[4], Olivier Gattolliat[4], Vitalii Doban[1], Brian D. Juran[5], Konstantinos N. Lazaridis[5]. *[1]Ipsen, Cambridge, MA, United States; [2]nference, Cambridge, MA, United States; [3]nference Labs, Karnataka, India; [4]Ipsen, Boulogne-Billancourt, France; [5]Division of Gastroenterology and Hepatology, Department of Internal Medicine, Mayo Clinic, Rochester, MN, United States*
Email: seema.meloni@ipsen.com

Background and aims: Primary biliary cholangitis (PBC) is a rare cholestatic liver disease characterized by autoimmune destruction of intrahepatic bile ducts. Left untreated, PBC can progress to hepatic fibrosis, cirrhosis, decompensation, and death. Ursodeoxycholic acid (UDCA) is the first line treatment for patients with PBC. Patients with inadequate response to UDCA treatment are considered for second line (2L) therapy. Despite availability of 2L treatment options, such as obeticholic acid and fenofibrate in the United States, low numbers of eligible patients have been prescribed these 2L treatments according to Mayo Clinic data. This study utilized natural language processing (NLP) algorithms to identify reasons why patients that met eligibility criteria for initiation of 2L treatment were not receiving it.
Method: This study utilized real-world data from a cohort of patients with PBC who were treated at Mayo Clinic in the United States. Patients with a PBC diagnosis and evidence of at least one year of UDCA treatment were identified using a combination of structured data (diagnosis codes, lab, and medication orders) and unstructured clinical notes processed using proprietary NLP algorithms. Patients were excluded if they did not have an order of UDCA between February 2016 and February 2023, or if they were part of any interventional clinical trial. 2L treatment eligibility was defined as having alkaline phosphatase (ALP) levels $\geq$1.67 upper limit of normal (ULN) after at least one year of UDCA treatment for PBC, or if there was explicit mention of receiving 2L treatment in clinical notes. Reasons for not initiating obeticholic acid were explored in the unstructured notes using NLP. Results are reported descriptively.
Results: In total, 2, 650 patients received UDCA after February 2016. Within that cohort, 753 patients met study criteria for eligibility for 2L treatment; of those, 202 patients (27%) initiated obeticholic acid and 152 (20%) initiated fenofibrate. Of the patients that did not receive a 2L treatment, the majority (72%) had no documentation of discussion of a 2L treatment. For patients with a mention of obeticholic acid in their clinical notes, primary reasons for not initiating obeticholic acid were: concerns were about side effects (48%), decision to wait until disease worsens (28%), and cost/issues with insurance reimbursement (17%).
Conclusion: This study revealed that only about one-quarter of patients who met eligibility criteria for initiating a 2L treatment received an approved 2L treatment. The findings of this study underscore that there remains unmet need in the 2L treatment space and that current 2L treatment options may not fully address patients' and healthcare providers' needs.

The epidemiological and prognostic burden of autoimmune liver disease: results of a nationwide population-based study over the past decade

Christophe Corpechot[1], Pierre Hornus[2], Mallory Calls[2], Pierre Rinder[2], Théo Marcille[2], Amina Malek[3], Karima Ben Belkacem[4], Gaouar Farid[4], Pierre Corret[5], Paola Squarzoni[3], Pierre-Antoine Soret[6,7], Sara Lemoinne[8], Olivier Chazouillères[8], Angela Leburgue[5]. *[1]Saint-Antoine Hospital, Assistance Publique-Hôpitaux de Paris, Sorbonne University, INSERM UMR_S938, Saint-Antoine Research Center, Sorbonne University, Paris; [2]Semeia©, Paris, France; [3]French Network for Rare Liver Disease in Children and Adults FILFOIE, Saint-Antoine Hospital, Assistance Publique-Hôpitaux de Paris, Paris, France; [4]Reference Center for Inflammatory Biliary Diseases and Autoimmune Hepatitis, Saint-Antoine Hospital, Assistance Publique-Hôpitaux de Paris, Paris, France; [5]ALBI Patient Association, Versailles, France; [6]Reference Center for Inflammatory Biliary Diseases and Autoimmune Hepatitis, Saint-Antoine Hospital, Assistance Publique-Hôpitaux de Paris, Sorbonne University, Paris, France; [7]Sorbonne University, Reference Center for Inflammatory Biliary Diseases and Autoimmune Hepatitis, European Reference Network on Hepatological Diseases (ERN Rare-Liver), Saint-Antoine Hospital, Assistance Publique-Hôpitaux de Paris, Sorbonne University, INSERM, Saint-Antoine Research Center (CRSA), Paris, France, Paris, France; [8]Reference Center for Inflammatory Biliary Diseases and Autoimmune hepatitis, Saint-Antoine Hospital, Assistance Publique-Hôpitaux de Paris, Sorbonne University, Paris, France*
Email: christophe.corpechot@aphp.fr

Background and aims: Autoimmune hepatitis (AIH), primary biliary cholangitis (PBC) and primary sclerosing cholangitis (PSC) are the main autoimmune liver diseases (AILDs). Their incidence and prognosis vary from study to study, with results that may be biased by data coming mainly from tertiary centers and from different time periods. The aim of our study was to assess the epidemiological and prognostic significance of AILDs on a national scale over the last decade.
Method: We conducted a retrospective observational study based on the French National Health Data System (SNDS) from 2009 to 2019.

Diagnoses of AILDs were based on International Classification of Diseases, 10th Revision (ICD-10) codes from health insurance and hospitalization records. In the absence of a specific diagnostic code for PSC, PSC patients were identify using the following composite criterion: 1) ICD-10 code for cholangitis, 2) ICD-10 codes for chronic inflammatory bowel diseases (Crohn disease, ulcerative colitis) and/or iterative hepatobiliary imaging, 3) ursodeoxycholic acid delivery. Patients detected before or after the study period and those who had undergone liver transplantation (LT) prior to this period were excluded. Prevalence, incidence, spatial clustering (Moran's index, MI) and standardized mortality ratio (SMR) with confidence interval (CI) were estimated for each AILD.

Results: The prevalence per 100, 000 inhabitants of AIH, PBC and PSC was 18.2 (adults 93%, children 7%; mean age 54 ± 21 years; sex ratio 0.37), 21.7 (adults 98%, children 2%; mean age 62 ± 18 years; sex ratio 0.34), and 5.2 (adults 89%, children 11%; mean age 44 ± 21 years; sex ratio 1.01), respectively. The quarterly incidence of AIH increased significantly (adults $r = 0.030$; $p < 0.01$; children $r = 0.025$; $p < 0.01$) over the study period, while that of PBC ($r = -0.024$; $p < 0.05$) and PSC ($r = -0.020$; $p < 0.01$) decreased in parallel. Prevalence varied from region to region, with strong spatial autocorrelation for patients with AIH (MI: 0.28; $p < 0.001$), PBC (0.30; $p < 0.001$), and to a lesser extent for those with PSC (0.11; $p = 0.06$). The 10-year SMRs for adults with AIH, PBC and PSC were 1.80 (95%CI: 1.68–1.94), 1.74 (1.66–1.83) and 2.59 (2.30–2.91) respectively.

Conclusion: Over the last decade, this study shows: 1) a comparable prevalence for AIH and PBC, and a prevalence 4 times lower for PSC, 2) an increasing incidence of AIH contrasting with a decreasing incidence of PBC and PSC, 3) a non-random territorial distribution of AIH and PBC, and to a lesser extend PSC, 4) the persistence of excess mortality for the 3 AILDs despite the therapeutic and management advances of recent decades.

Ulcerative colitis-associated anti-integrin αVß6 antibodies are highly prevalent in primary sclerosing cholangitis

Dominik Roth[1], Miriam M. Düll[1], Aylin Lindemann[1], Peter Dietrich[1], Ludwig J. Horst[2], Markus F. Neurath[1], Juergen Siebler[1], Christoph Schramm[2], Andreas E. Kremer[3], Moritz Leppkes[1].

Email: moritz.leppkes@uk-erlangen.de

Background and aims: Autoantibodies that target biliary epithelial cells have been identified in a large fraction of patients suffering from primary sclerosing cholangitis (PSC) yet the defining antigens remained elusive for decades. Recently, autoantibodies directed against the epithelial adhesion protein integrin alphaVbeta6 have been identified that strongly associate with ulcerative colitis (UC). To date, it remains unknown whether anti-integrin alphaVbeta6 is also present in PSC and other immune-mediated cholestatic liver diseases.

Method: Anti-integrin alphaVbeta6-directed autoantibodies were detected by an enzyme-linked immunosorbent assay in patient sera, including healthy controls (N = 46), ulcerative colitis (N = 35), Crohn's disease (CD, N = 65), PSC with concomitant IBD (84 samples from N = 42 patients), PSC without clinically manifest IBD (40 samples from N = 18 patients), primary biliary cholangitis (PBC, N = 24), autoimmune hepatitis (AIH, N = 21), metabolic dysfunction associated fatty liver disease (MASLD, N = 24). Furthermore, immunofluorescent analyses of the target antigen were performed in liver and colon tissue samples of PSC patients.

Results: In a cohort derived from a single academic care center anti-integrin alphaVbeta6 antibodies occurred in 91% of UC, 17% of CD, 74% of PSC with IBD, 39% of PSC without manifest IBD, 4% of PBC, 14% of AIH, 55% of AIH with overlap cholangitis and 0% of MASLD patients. ITGB6 was expressed by PSC cholangiocytes in intrahepatic fibrotic portal fields and periductular glands of the large bile ducts.

Conclusion: UC-associated anti-integrin alphaVbeta6 autoantibodies are highly prevalent in immune-mediated cholestatic liver diseases, especially in primary sclerosing cholangitis with concomitant inflammatory bowel disease. Integrin alphaVbeta6 may represent a major long-sought target of anti-biliary epithelial cell antibodies in primary sclerosing cholangitis. Anti-integrin alphaVbeta6 antibodies distinguish healthy controls and MASLD from primary sclerosing cholangitis, but do not differentiate UC from PSC-IBD.

Background and aims: Primary Biliary Cholangitis (PBC) predominantly affects the female population. However, the sex distribution differs among epidemiological studies. We assessed differences in sex distribution according to age categories in patients with PBC over time within the nationwide Dutch PBC Cohort Study (DPCS).

Method: The DPCS is a retrospective study which includes every identifiable patient with PBC in the Netherlands from 1990 onwards in all 71 Dutch hospitals. Case identification was performed through diagnosis and treatment codes, antimitochondrial antibodies test results, and locally available registries, by two medical doctors. Data on yearly population size (ages ≥20) at January 1st and average life expectancy were extracted from Statistics Netherlands. The assessment of the incidence and point prevalence of PBC was restricted to the period between 2008–2018. With respect to the assessment of point prevalence, patients were censored at time of death, liver transplantation or when moving abroad. Patients lost to follow-up were censored based on their average life expectancy. Incidence Rate Ratios (IRR) were calculated using a Poisson regression to analyze

rates among sex and age groups (20–45, 45–65, and ≥65 years) over time.
Results: In total, 2187 patients were diagnosed with PBC between 2008–2018, of which 1927 (88.1%) were female. The mean age at PBC diagnosis was 57.1 (SD 12.7) years. The median yearly incidence rate of PBC in the Netherlands during the study period was 2.6 per 100.000 inhabitants in females and 0.3 in males (age- and calendar year-adjusted IRR was 6.98, 95% CI 6.14–7.95, p < 0.001, for females vs. males). The male-to-female ratio was 1: 7.4 among newly diagnosed PBC patients during the study period, which differed based on age category. The ratio was 1: 14.4 in those <45 years, 1 : 9.9 in patients aged 45–65 years, and 1: 4.4 in those ≥65 years. In line, the adjusted IRR for females vs males range ranged from 14.51 (95 CI % 9.22–22.83, p < 0.001) in the population aged 20–45 years to 3.56 (95% CI 2.95–4.30 p < 0.001) in those ≥65 years. The age-dependent risk of PBC differed according to sex; as compared to those aged 20–45 years, the adjusted IRRs were 4.21 (95% CI 3.76–4.71, p < 0.001) and 6.30 (95% CI 4.18–9.51, p < 0.001) among those 45–65 years and 3.50 (95% CI 3.10–3.95, p < 0.001) and 14.41 (95% CI 9.62–21.60, p < 0.001) among those ≥65 years for females and males, respectively. In 2018, the PBC point prevalence was 37.6 per 100.000 females and 4.9 per 100.000 males. The male-to-female ratio in the DPCS was 1: 7.9, and ranged from 1: 22.0 in those <45 years to 1 : 6.1 in those ≥65 years.
Conclusion: Based on this nationwide cohort study, the male-to-female ratio among patients with PBC is lower in the older aged population. The age-dependent risk pattern of PBC differs according to sex; middle-aged females and elderly males are at highest risk of being diagnosed with PBC.

THU-151

A prospective study on the causes of notable elevation of alanine aminotransferase (ALT) as well as elevation of both ALT and alkaline phosphatase (ALP) with special emphasis on drug-induced liver injury (DILI)

Sigurdur S. Sigurdarson[1], Helgi K Bjornsson[2], Einar S. Björnsson[3].
[1]University of Iceland, Reykjavik, Iceland; [2]Sahlgrenska Academy, Reykjavik, Iceland; [3]landspitali University Hospital, Reykjavik, Iceland
Email: einarsb@landspitali.is

Background and aims: In a recent prospective study the most common causes of more than tenfold elevation of ALT were choledocholithiasis, ischemic hepatitis, viral hepatitis and drug induced liver injury (DILI). Very few prospective studies have investigated the most common causes of concomitant elevation of ALT and ALP. The aims of the study were to investigate the etiologies of patients with notably elevated ALT and/or ALT together with ALP elevation and to study the proportion of patients with DILI.
Method: This was a prospective study, in patients with (a) ALT>500 (normal <50 U/L) and (b) ALT>250 U/L and ALP > 210 U/L (normal <105) during an 18-month period from June 2022 to end of 2023. Appropriate diagnostic work-up was undertaken based on clinical features, with relevant imaging, viral and immunological investigations. DILI was identified in patients with exposure to drugs including over-the-counter drugs, herbals and dietary supplements (HDS) prior to the onset of liver injury with exclusion of competing etiologies. DILI cases were diagnosed by expert opinion and with the RUCAM causality assessment method.
Results: A total of 694 patients were identified with either ALT>500 U/L or ALT>250 and ALP > 210, A total of 6 patients were excluded due to lack of information and two cases from a non-liver source, leaving 680 patients for the analysis: 377 females (55%), median age 59 (IQR 40–72), 417 in group A and 263 in group B. The most common causes were choledocholithiasis 43% (n = 291), ischemic hepatitis 17% (n = 113), hepatobiliary cancer 8% (n = 56), DILI 8% (n = 53), viral hepatitis 6% (n = 43), other etiologies 10% (n = 68) and unknown etiology in 8% (n = 56). Among patients with DILI, amoxicillin-clavulanate (n = 11), HDS (n = 8), check point inhibitors (n = 6) and acetaminophen (n = 5) were the dominating agents. Liver related death was only observed in patients with ischemic hepatitis and cancer. One DILI patient needed an emergency liver transplantation due to acute liver failure associated with the HDS.
Conclusion: The most common causes of notably elevated ALT as well ALT together with ALP were choledocholithiasis and ischemic hepatitis. DILI was together with hepatobiliary cancer the third most common etiology, with amoxicillin-clavulanate, HDS and check point inhibitors as the most frequent causes.

THU-152-YI

Liver fibrosis in adolescents and young adults with autoimmune hepatitis: magnetic resonance elastography, transient elastography and liver fibrosis changes during transition of care

Maciej Janik[1], Kamil Janowski[2], Paulina Chodnicka[3], Wieslawa Grajkowska[4], Maciej Pronicki[4], Wojciech Janczyk[2], Joanna Łącz[1], Sylwia Chełstowska[5], Elżbieta Jurkiewicz[5], Piotr Milkiewicz[6], Piotr Socha[2]. *[1]Department of Hepatology, Transplantology and Internal Medicine, Medical University of Warsaw, Warsaw, Poland; [2]Department of Gastroenterology, Hepatology, Nutritional Disorder's and Pediatrics, Children's Memorial Health Institute, Warsaw, Poland; [3]Department of Radiology, Children's Memorial Health Institute, Warsaw, Poland, Warsaw, Poland; [4]Department of Patology, Children's Memorial Health Institute, Warsaw, Poland; [5]Department of Radiology, Children's Memorial Health Institute, Warsaw, Poland; [6]Department of Hepatology, Transplantology and Internal Medicine, Medical University of Warsaw, Translational Medicine Group, Pomeranian Medical University, Szczecin, Poland; Warsaw, Poland*
Email: mjanik24@gmail.com

Background and aims: Autoimmune hepatitis (AIH) requires an accurate assessment of its progression, particularly in adolescents and young adult (AYA) patients in the transition period from paediatric to adult care. Here, we evaluated liver fibrosis in AYA patients by magnetic resonance elastography (MRE) concerning liver biopsy (LB) and transient elastography (TE) and assessed liver fibrosis changes at the time of transition of care.
Method: Two independent groups of patients with AIH were included: (i) 34 adolescents (mean age 16 ± 2 years, 56% female) to calculate cutoffs of MRE (Avanto 1.5 T) in reference to LB (Ishak); (ii) 64 young adults (mean age 22 ± 4 years, 55% female) were recruited to validate MRE with TE (Fibroscan) and evaluated the liver fibrosis changes by TE in the mean follow-up of 9.4 ± 5.5 years.
Results: MRE cutoffs were calculated in the 34 patients (ALT 165 ± 302 IU/l, IgG 1603 ± 808 mg/dL, 79% on treatment and 59% of them with complete biochemical response (CBR)) in which 35% and 29% had stage ≥4 and ≥5 Ishak Score, respectively. The MRE cutoffs for severe fibrosis and cirrhosis were >2.77 kPa (AUROC 0.87, p < 0.001, SP: 68%, SE: 100%) and >3.65 kPa (AUROC 0.89, p < 0.001, SP:88%, SE:80%), respectively. Further, 64 patients treated for AIH >6 months (ALT 64 ± 90 IU/l, IgG 1468 ± 506 mg/dL, 9% LKM-positive and 60% CBR) were diagnosed with TE in 24% and 11% as severe fibrosis and cirrhosis, respectively. Regarding TE, the MRE revealed excellent accuracy for excluding severe fibrosis (0.84, PPV 73%, NPV 94%) and cirrhosis (0.87, PPV 53%, NPV 98%). Moreover, MRE classified more patients as severe fibrosis and cirrhosis than TE (both p < 0.001), but these patients had smaller spleen, lower FIB-4 and higher platelet count (all p < 0.05). During 9.4 ± 5.5 years of the follow-up, 15 patients (23%) had progression of liver fibrosis (i.e. increased liver fibrosis stage according to TE and compared to LB at diagnosis). Patients with liver fibrosis progression did not differ in age, type of AIH and stage of the disease in LB at the diagnosis. At the time of transfer to adult care (the first visit), the progression was linked to increased ALT (p = 0.03) but not with serum IgG or TE. Moreover, patients with CBR at the time of transfer to adult service had a lower risk of fibrosis progression (OR 0.17, 95% CI 0.04–0.69, p = 0.01). Of note, patients with liver fibrosis progression during transition had elevated ALT, AST, ALP (all p < 0.05),

and more advanced liver disease according to MRE and TE (both p < 0.01) during follow-up in the adult service.
Conclusion: The MRE revealed excellent accuracy in excluding severe fibrosis and cirrhosis in AYA patients with AIH. MRE identified a significantly higher proportion of patients with severe fibrosis or cirrhosis than TE, but no other clinical signs confirmed the correctness of these identifications. Liver fibrosis progression occurs in a quarter of AYA patients with AIH and is linked to a lack of CBR.

Email: cristina.rigamonti@uniupo.it

Background and aims: Primary biliary cholangitis (PBC) is a slowly progressive cholestatic disease that can lead to portal hypertension (PH). Recently, non-invasive assessment of clinically significant PH (CSPH) in compensated advanced chronic liver disease (cACLD) has been refined by adding spleen stiffness measurement (SSM). In PBC the combination of liver stiffness measurement (LSM) and SSM can significantly improve risk stratification by predicting liver decompensation.
Method: Multicentric and international study of 257 patients from 4 tertiary centres for liver diseases (Novara, Istanbul, Milan and Palermo). From this cohort, 66 patients with cACLD, defined as LSM ≥10 kPa were selected. All the patients underwent LSM and SSM by vibration-controlled transient elastography on the same day. Esophagogastroduodenoscopy (EGDS) was performed according to Baveno VI guidelines and in all patients with SSM >40 kPa. The Baveno VII criteria (BVII) for assessing CSPH using LSM alone [LSM ≤15 kPa + platelets (PLTs) ≥150000/mmc to rule out CSPH; LSM >25 kPa to rule in CSPH) were compared with the BVII for CSPH incorporating both LSM and SSM (at least 2 out of 3 between LS ≤15 kPa, PLTs ≥150000/mmc, SSM ≤40 kPa to rule out CSPH; at least 2 out of 3 between LS >25 kPa, PLT <150000/mmc, SSM >40 kPa to rule in CSPH) to evaluate their ability to identify patients with CSPH.
Results: Among the 66 PBC patients with cACLD (LSM ≥10 kPa), the vast majority were women (89%), on ursodesoxycholic acid monotherapy (71%), median age was 63.0 years (IQR 53.0–74.1), median disease duration 40.9 (9.9–94.9) months, median LSM 14.1 kPa (IQR 11.8–22.4), median SSM 48.8 kPa (IQR 32.1–66.9). Twenty-nine out of 57 (51%) patients with available EGDS had endoscopic signs of CSPH. Considering the BVII assessing only LSM, 25 patients (38%) belonged to rule out zone for CSPH, 15 (23%) belonged to rule in zone, 26 (39%) were in the grey zone. According to the BVII incorporating both LSM and SSM, 33 patients (51%) belonged to rule out zone for CSPH, 28 patients to rule in (42%), while 5 patients (7%) belonged to the grey zone. The latter all had endoscopic signs of CSPH and interestingly all had SSM >40 kPa. After excluding 9/66 patients without available EGDS, diagnostic performance of BVII with LSM alone was: sensitivity 83% (LR- 0.34) for ruling out CSPH and specificity 86% (LR 2.66) for ruling in CSPH. Diagnostic performance of BVII for CSPH incorporating both LSM and SSM was sensitivity 79% (LR- 0.34) for ruling out CSPH and specificity 79% (LR 3.22) for ruling in CSPH. SSM ≤40 kPa alone best identified patients without CSPH (sensitivity 89%, LR- 0.17).
Conclusion: In patients with PBC, the combined use of SSM with LSM helped in reducing the proportion of patients in the grey zone for ruling in and ruling out CSPH. Moreover, SSM ≤40 kPa confirmed its potential role in excluding CSPH in PBC patients.

Background and aims: The prevalence of metabolic disease is on the rise, and there is a lack of information regarding its impact on PBC. To assess the impact of liver steatosis and metabolic comorbidities on the response, prognosis, and progression of patients with PBC treated with ursodeoxycholic acid (UDCA).
Method: Patients with PBC included in the ColHai registry (Spanish registry for cholestatic and autoimmune liver diseases) were evaluated. Metabolic comorbidities, steatosis, response to treatment and development of cirrhosis were analysed.
Results: A total of 436 patients were included. 89% were female, with a median age of 55 years and a BMI of 25.8. At baseline, 148 (33.9%) presented with hypertension (AHT), 129 (29.6%) with dyslipidaemia, and 94 (21.6%) with DM. Steatosis (radiological and/or elastographic) was present in 126 patients (31%). 95 patients met the MASLD criteria, showing higher baseline liver stiffness (8.1 vs 6.5 kPa, p = 0.03) than those without MASLD. The latter group had higher ALP levels (173 vs 157 IU/L, p = 0.04), with no other relevant differences found. All patients received UDCA. After one year of treatment, 34% showed no response according to Paris II criteria and 24.9% presented GLOBE >0.3. Differences in liver stiffness had disappeared among patients with or without MASLD (7.6 vs 6.6, p = 0.18).
In the univariate analysis, we identified that baseline ALp >3 × ULN (OR 6.45 [3.28–12.67]), alcohol consumption (OR: 1.65 [1.04–2.92]) and <50 years of age at diagnosis (OR 13.19 [5.18–33.59]) were associated with worse prognosis. After one year on UDCA, patients with DM and AHT had a lower probability of response according to Paris II (DM: OR 1.79 [1.12–2.86]; AHT: OR 1.58 [1.04–2.39]), had worse prognosis by GLOBE (DM: OR 2.48 [1.34–4.61]; AHT: OR 3.67 [2.21–6.08]) and a higher probability of having a FIB-4 >3.25 (DM: OR 2.30 [1.28–4.14]; AHT: 2.27 [1.43–3.61]).
Data on the development of cirrhosis during the follow-up were available for 281 patients, of which 35 (12.5%) developed it during the follow-up. The presence of DM (OR 3.08 [1.09–8.76]) and alcohol consumption (OR 2.57 [1.01–6.55]) were independently associated in multivariate analysis with an increased risk of cirrhosis during the follow-up, regardless of the presence of steatosis.
Conclusion: DM and AHT, but not steatosis or other metabolic factors, were associated with a lower probability of response and poorer prognosis. Furthermore, in addition to alcohol, DM independently increases the risk of progression to cirrhosis.

Email: diazg.alvaro@gmail.com

Background and aims: Immunosuppression in autoimmune hepatitis (AIH) may predispose patients to the development of fungal and

other opportunistic infections. However, there is no information on their incidence in AIH. We aimed to evaluate the incidence of these infections in patients with AIH.
Method: Retrospective analysis conducted in 20 Spanish institutions to assess the incidence of Aspergillus infection, invasive candidiasis and other opportunistic infections spanning the years 2000–2023.
Results: A total of 2893 patients with diagnosis of AIH and treated with corticosteroids (CS) were included. Aspergillus infection was diagnosed in 16 patients (0.55%). Of these, 11 (68.7%) presented with invasive pulmonary aspergillosis, 3 (20%) had central nervous system infection and 2 (13.3%) were diagnosed with aspergilloma. 62.5% were women with a median age of 58 years. Risk factors (RF): 5 patients (31.2%) had received antibiotics and 3 (18.7%) had been admitted to the ICU. AIH was severe in 12/16 (75%): 8/12 acute-severe and 4/12 with acute liver failure. The time from AIH dx to infection was 1.5 months (IQR 0.8–25.2). At the time of Aspergillus dx, 15 (93.7%) were treated with prednisone (PDN), 8 (50%) with azathioprine (AZA), 2 (12.5%) with tacrolimus (TAC), 2 (12.5%) with mycophenolate and 1 (6.2%) with mercaptopurine (MP). All were treated with amphotericin B (37.5%), voriconazole (25%) or both (37.5%). 10 patients died during follow-up, 8 (80%) due to the infection.
On the other hand, 14 cases (0.48%) of invasive candidiasis were diagnosed: 10 (71.4%) presented as esophagitis, 2 (14.3%) involved lungs, 1 (7.1%) candidaemia, and 1 (7.1%) was nephro-urinary. 57% were women with a median age of 70 years. 9 patients (64.3%) had metabolic comorbidities, 3 (21.4%) were previously diagnosed with cancer and 2 (14.3%) HIV (CD4 >200). Other RF: 2 patients were previously treated with antibiotic, 1 parenteral nutrition, 1 neutropenia (<500) and 1 was admitted to the ICU. No patient presented with AS-AIH at onset (10 chronic, 4 acute). The time from AIH dx to infection was 20.3 months (IQR 1.5–85.8). At the time of dx, 10 (71.4%) patients were treated with CS, 9 (64.3%) with AZA and the rest with MMF, TAC, or MP. 9 patients (64.3%) received fluconazole, 1 (7.1%) isavuconazole and the rest were not treated. 5 patients died during follow-up, none related to fungal infection. Finally, other opportunistic infections included 5 cases of meningitis (2 Cryptococcus, 2 herpes simplex virus, and 1 Listeria), 2 of herpes zoster, 3 patients with CMV infection (2 pneumonia, 1 severe colitis) and 1 patient with Nocardia pleuritis.
Conclusion: Fungal infections are infrequent in patients with AIH. While Candida infection appeared late and was not associated with higher mortality, Aspergillus infection was diagnosed earlier and was more frequent in patients with severe onset of the disease, carrying an unfavourable prognosis.

THU-158
Improvements in serum bile acid levels are associated with improvements in key markers of liver health after maralixibat treatment in children with progressive familial intrahepatic cholestasis: data from the MARCH/MARCH-ON trials

Lorenzo D'Antiga[1], Alexander Miethke[2], Simon P. Horslen[3], Douglas B. Mogul[4], Tiago Nunes[4], Will Garner[4], Pamela Vig[4], Richard J. Thompson[5]. *[1]Paediatric Hepatology, Gastroenterology and Transplantation, Hospital Papa Giovanni XXIII, Bergamo, Italy; [2]Cincinnati Children's Hospital Medical Center, Cincinnati, Ohio, United States; [3]UPMC Children's Hospital of Pittsburgh, Pittsburgh, Pennsylvania, United States; [4]Mirum Pharmaceuticals, Inc., Foster City, California, United States; [5]Institute of Liver Studies, King's College London, London, United Kingdom*
Email: ldantiga@asst-pg23.it

Background and aims: Progressive Familial Intrahepatic Cholestasis (PFIC) refers to inherited disorders of abnormal bile secretion and/or formation causing pruritus, increased serum bile acid (sBA) levels, and chronic liver disease. Most PFIC patients develop ESLD before adulthood and become candidates for liver transplantation, highlighting the importance of liver health in this population. Reductions in bile acids and bilirubin after surgical biliary diversion (SBD) are the only predictors of longer native liver survival (NLS) in PFIC patients. MARCH was a 26-week, randomized, placebo-controlled (PBO), Phase 3 trial of maralixibat (MRX), an IBAT inhibitor, that achieved its primary and key secondary end points of pruritus and sBA reduction for individuals across a broad range of PFIC types. Long-term maintenance of effect for up to 2 years was observed in MARCH-ON, an open-label extension. We evaluated the impact of MRX on improvements in liver health through a sub-analysis on the correlation of sBA improvements and key liver parameters, including bilirubin, from the MARCH/MARCH-ON trials.
Method: MARCH/MARCH-ON study designs have been summarized. Spearman's (r) coefficients were determined to evaluate the relationship between sBA and key liver health parameters (AST, ALT, total bilirubin [TB], and direct bilirubin [DB]).
Results: This analysis included 64 patients from the All-PFIC cohort (13 FIC1, 31 nt-BSEP, 9 MDR3, 7 TJP2, and 4 MYO5B). Mean baseline age, sBA, pruritus, and liver biochemistries were well balanced between MRX and PBO groups. In MARCH, among MRX-treated participants, there was a positive correlation between average percent reductions in sBA and in AST (r 0.515, p = 0.004), TB (r 0.620, p = 0.0003), and DB (r 0.686, p < 0.0001); correlation between reductions in sBA and in ALT were weaker (r 0.339) and not significant (NS). In PBO participants, there was no correlation between changes in sBA and ALT (r 0.094), AST (r 0.25), TB (r 0.129), and DB (r 0.11). In MARCH-ON, for participants initially on PBO that subsequently received MRX for 26 weeks, a comparable positive correlation was observed between average percent reduction in sBA and in ALT (r 0.578, p = 0.002), AST (r 0.696, p < 0.0001), and DB (r 0.456, p = 0.02); correlation between sBA and TB was weaker (r 0.355) and NS. When analyzed for all participants receiving 26 weeks of MRX, correlations were stronger and statistically significant between reductions in sBA and in ALT (r 0.441, p = 0.0007), AST (r 0.616, p < 0.0001), DB (r 0.641, p < 0.0001) and TB (r 0.557, p < 0.0001).
Conclusion: Reductions in sBA following use of MRX, as anticipated by the drug's mechanism of action, are correlated with reductions in important biomarkers of liver disease like bilirubin, which has been shown to be associated with long-term clinical outcomes. These results demonstrate the potential for MRX to have disease-modifying effects in the treatment of PFIC.

THU-159-YI
Assessing the safety, tolerability and efficacy of rituximab in patients with difficult-to-treat autoimmune hepatitis: results from a tertiary UK liver unit

Abhishek Gairola[1], Jessica Dyson[1,2]. *[1]Newcastle upon Tyne Hospitals NHS Foundation Trust, Liver Unit, Newcastle upon Tyne, United Kingdom; [2]Translational and Clinical Research Institute, Newcastle University, Newcastle upon Tyne, United Kingdom*
Email: a.gairola@nhs.net

Background and aims: Autoimmune hepatitis (AIH) can result in chronic liver disease and liver transplant if biochemical remission is not achieved. Some patients have disease that is refractory to standard therapies or experience toxicity that precludes their use. Recent data suggest that rituximab (RTX), an anti-CD20 monoclonal antibody, may be a safe and effective steroid-sparing agent to maintain biochemical remission. We present our experience of using RTX in difficult-to-treat AIH.
Method: We conducted a retrospective electronic review of all AIH patients in our unit who received RTX between 2013–2023. Data collected included demographics, indication for RTX, baseline bloods (–4 to 0 months prior to 1st dose, median –0.5 months) up to 36 months after treatment started, and prednisolone dose changes. 6 patients also had longer follow-up data (38–96 months). Biochemical remission was defined as normal ALT and IgG. 1 patient was included in safety data but excluded from further analysis due to an adverse event during the 1st infusion.

Results: 19 patients were included: 10 (52.6%) female, median age at diagnosis 38.6years (11–76), median interval to RTX from diagnosis 4.59 years. 12 (63.2%) had 2 or more autoimmune diagnoses. The indication for RTX was refractory disease in 11 (57.9%), treatment of another condition in 7 (36.8%) and intolerance to all other therapies in 1 (5.3%). 17 patients were receiving prednisolone at baseline. At 1 year post-RTX, 12 achieved a mean 63.3% dose reduction, with 1 stopping completely. 12 patients (63.2%) had no adverse effects with RTX. 6 had infectious complications (3 minor, 2 requiring hospitalisation [at 9 and 38 months], and 1 death from COVID pneumonitis [4 months after last RTX]). All 6 were on 2 or more immunosuppressants. 1 patient had an anaphylactoid reaction to the 1st dose and was not rechallenged. 1 death, 58 months post-RTX, was likely unrelated (decompensated cirrhosis following fracture). Median follow-up for the 18 patients assessed for response was 27 months (5–36). At baseline, 83.3% of patients had active disease, compared with 38.9% at last follow-up within 36 months. 5/7 patients with ongoing disease activity had a mean 65.3% ALT reduction from baseline. For 6 patients with additional data (median follow-up 51 months [38–96]), 3 (50%) remained in remission.

Conclusion: Some AIH patients are at risk of disease progression due to 1st and 2nd line therapies being ineffective or poorly tolerated. Current data for RTX is limited but promising. Using it in very bespoke circumstances, we have found RTX to be effective and well tolerated. It enables reduced prednisolone dosing; a key patient priority. A multicentre trial should be a priority for the community to establish where RTX should sit within our treatment algorithm.

THU-160

Long-term variability of pruritus in primary sclerosing cholangitis and implications for future clinical trial design

Nasir Hussain[1], James Ferguson[1], Nadir Abbas[1], Usha Gungabissoon[2], Khushpreet Bhandal[1], Emma Burke[1], Diana Hull[1], Penelope Rogers[1], Linda Casillas[3], Sumanta Mukherjee[3], Andrea Ribeiro[4], Megan McLaughlin[3], Martine Walmsley[5], Paula Hanford[5], Palak J. Trivedi[1]. *[1]University of Birmingham, Birmingham, United Kingdom; [2]GSK, London, United Kingdom; [3]GSK, Collegeville, PA, United States; [4]GSK, Madrid, Spain; [5]PSC Support, Oxford, United Kingdom*
Email: nxh100@student.bham.ac.uk

Background and aims: Pruritus is a recognised symptom of primary sclerosing cholangitis (PSC). We conducted a prospective observational clinical trial (ISRCTN:15518794) to capture the burden of pruritus in PSC, including how the temporal variability in symptoms may be used to inform design of future interventional trials.

Method: Adults with PSC (age >16 y; non-transplant) were invited to complete health-related quality of life (QoL) assessments (CLDQ and EQ-5D-5L) alongside pruritus questionnaires (the 5D itch score with 2-week symptom recall, and the itch numerical rating scale (NRS) with 24-hour recall). Baseline factors associated with persistent pruritus were identified, and the inherent variability in symptom intensity quantified over time.

Results: Between Jul 21 and Feb 23, 200 PSC pts were recruited (median age 39y, 115 men, median MELD score 7), of whom 100 (50%) reported pruritus of any degree (median 5D itch score was 8.0, IQR 5.0–12.0), consisting of 25 taking anti-pruritic therapy. Baseline 5D itch scores negatively correlated with age ($r = -0.204$, $p = 0.004$), with low-moderate positive correlations against serum ALT ($r = 0.197$, $p = 0.005$), ALP ($r = 0.319$, $p < 0.001$), bilirubin ($r = 0.251$, $p < 0.001$) and bile acid values ($r = 0.354$, $p < 0.001$). Median baseline 5D-itch scores were greater in pts with cirrhosis vs. no cirrhosis (10.5 vs. 6.0), those with transient elastography scores >8.0 kPa vs. <8.0 kPa (9.0 vs. 5.0) or a history of recurrent acute cholangitis (11.0 vs. 6.0) (all comparisons: $p < 0.001$). Of 31 pts who reported moderate-severe pruritus at baseline (NRS ≥4), the majority (61%) reported persistent moderate-severe pruritus at 36–48 weeks. Reciprocally 39% reported improvement to no/mild pruritus (NRS ≤3). Amongst pts with an NRS ≤3 at baseline ($n = 118$), 11% reported new onset or worsening pruritus to NRS ≥4. Cirrhosis was a risk factor for pts developing *de novo* or worsening pruritus over time (OR 3.75, 95% CI 1.17–12.05). Anti-pruritic therapy did not significantly impact pruritus score from w0 to w36–48. Applying our data to inform the design of a future long-term placebo-controlled trial, using NRS ≥4 as an inclusion criterion, and a primary end point of NRS ≤3 at 48 weeks (1:1 randomisation, two-sided alpha, 80% power); treatment response rates of 60%, 70% and 80%, would require 316, 126 and 64 participants per treatment arm, respectively. Comparatively, a primary end point NRS score reduction of ≤2 would require 238, 86 and 42 patients per arm, respectively.

Conclusion: Pruritus is common in pts with PSC, is persistent over time in the era of current anti-itch treatment and reported as more intense among pts with advanced disease. Long-term treatment trials will require large pt numbers if powered using conventional, statistical study designs, which is not tenable given the rare disease nature of PSC.

Email: cristinadellacorte19@gmail.com

Background and aims: Sarcoidosis is a rare systemic granulomatous disease involving the liver in up to 20% of cases. The RNMR (National Registry of Rare Disease) reported 3311 sarcoidosis Italian patients (certification period 2017–2018), however data on hepatic sarcoidosis (HS) prevalence and management are lacking. The aim of this study is to enroll all consecutive patients with sarcoidosis followed in hepatologic centers, to describe the real-world experience in disease diagnosis and management.
Method: This cross-sectional study was conducted in 33 AISF (Associazione Italiana per lo Studio del Fegato) affiliated centers across Italy, since April 2022 until October 2023. Each center was firstly asked to answer an online survey (5 domains : localization-8 items, radiology-6 items, histology-3 items, therapy-7 items, liver transplant-2 items) and subsequently each center was prospectively interviewed regarding patient's management.
Results: Through the online survey a total of 78 HS patients were reported; of which 55 [median age 52 (range; 45–57) years, 33 (60%) female, 82% Caucasian] had complete data during a median follow-up of 21 (range 6–51) months. At diagnosis systemic symptoms were reported in 46% of cases, whereas 29% of patients were asymptomatic. Pulmonary and lymphatic involvement was present in 43% and 36%, respectively, while isolated HS was present in 11% of patients. HS diagnosis was histologically proven by liver biopsy in 39 (71%) patients. At diagnosis median ALP/γGT and GPT/GOT values were 190/168 and 41/36 × UI/ml. Males had a significantly higher level of γGT ($p = 0.02$) and bilirubin ($p < 0.01$) at presentation. Abdominal lymphadenopathy, hepatosplenomegaly and liver focal lesions were described in 21, 21 and 13 patients, respectively. Bile duct alterations, portal vein ectasia and ascites were reported in 7, 6 and 5 cases, respectively. Clinically-significant-portal-hypertension (CSPH), according to LSM ≥25 kPa or esophageal varices was detected in 15% of patients. Liver biopsy showed granulomas in all the specimens, F3/F4 Metavir scores were reported in 7 (32%) patients. Treatment choices included steroids in 26 (48%), steroid+ursodeoxycholic-acid (UDCA) in 11 (20%), UDCA in 6 (11%), combination of different agents (anti-metabolites, hydroxycloroquine) in 12 (21%). Median ALP decrease was 56% in 12 months, independently from the medical treatment used (p = ns). Seventeen (31%) patients received treatment adjustment with a second-line agent. No liver transplantations or hepatocellular carcinomas were reported. One patient died due to liver-related complications.
Conclusion: This multicentric study provides a first snapshot on the burden and experience of HS in Italy. HS has an intrinsic risk of CSPH, not always related to the presence of cirrhosis. Drug choice does not have an impact on ALP decrease, but UDCA are associated to a better GPT reduction.

THU-162-YI

Lack of association between persistently raised serum transaminase levels and hepatic steatosis/steatohepatitis in autoimmune hepatitis (AIH)

Sarah Flatley[1], Asha Dube[1], Barbara Hoeroldt[1], Laura Harrison[1], Elaine Wadland[1], Dermot Gleeson[1]. *[1]Sheffield Teaching Hospitals, Sheffield, United Kingdom*
Email: s.flatley@nhs.net

Background and aims: The aim of AIH treatment is to achieve complete biochemical and histological remission. We have reported (Flatley, JHep 2023:78:S382) that hepatic steatosis is present in 25% of patients at AIH diagnosis and worsens during steroid treatment in 34%. This can cause confusion as to whether persistent serum transaminase elevation reflects persisting AIH or metabolic dysfunction-associated steatotic liver disease (MASLD). We aimed to assess the associations between serum transaminases and steatosis/steatohepatitis in patients with AIH.
Method: Retrospective/prospective single-centre audit of patients with AIH (1999 IAIHG criteria) presenting 1981–2022. All received corticosteroids and underwent follow-up biopsy after 26 (1–258) months: usually to confirm histological remission, but sometimes for diagnosis in patients with persisting elevated serum transaminases. Necroinflammatory (NI) score (Ishak) and steatosis grade (% hepatocytes containing fat 0: <5%, 1: 5–33%, 2: 34–66%, 3: >67%) were assessed by a single histopathologist (AKD). Steatohepatitis was based on zone 3 hepatocyte ballooning and graded using Brunt criteria. Laboratory values were measured within 2 weeks of the biopsy.
Results: 209 patients (80% women, age (median (range) 53 (3–76) years). 122 patients (47%) had steatosis (Grade 1, 2 and 3: 92, 22 and 8 respectively) and 10 (4%) had steatohepatitis. In 119 (47%) AIH was in histological remission. Serum ALT was normal (cut off 41 IU/L in men and 33 IU/L in women) in 198 patients (76%). Percentage with steatosis (49% vs 39%, $p = 0.138$) or steatohepatitis (7% vs 5%, $p = 0.613$) did not differ between patients with normal and elevated ALT. Serum ALT did not differ between patients with and without steatosis (median 22.5 vs 24.0, $p = 0.463$), or those with and without steatohepatitis (22.0 vs 23.0, $p = 0.690$). On regression analysis, there was no association between steatosis and serum ALT ($p = 0.492$), AST ($p = 0.343$), IgG ($p = 0.336$) or NI score ($p = 0.318$). There was also no association between steatohepatitis and serum ALT ($p = 0.793$), AST ($p = 0.600$), IgG ($p = 0.247$) or NI score ($p = 0.888$). In contrast, serum ALT ($p < 0.001$), AST ($p < 0.001$) and IgG ($p < 0.001$) showed significant associations with NI score.
Conclusion: In patients with AIH, serum transaminases are not associated with steatosis or steatohepatitis, and elevated values are more likely to reflect failure to achieve biochemical remission.

THU-163

Single-cell RNA sequencing of autoimmune hepatitis identifies pathogenic marker MIF and reveals distinctions between CD8-Tc-PDCD1 cells in autoimmunity and cancer

Chao Cai[1], Chenyi Liu[1], Shu Li[1], Chen Chen[1], Yijing Cai[1], Lu Chen[1], Huifang Zhang[1], Bangguo Zhou[2], Mingqin Lu[1]. *[1]The First Affiliated Hospital of Wenzhou Medical University, Wenzhou, China; [2]Shanghai Tenth People's Hospital, Ultrasound Research and Education Institute, Tongji University School of Medicine, Shanghai, China*
Email: lmq0906@163.com

Background and aims: Autoimmune hepatitis (AIH) is characterized by autoimmune-mediated inflammatory liver damage, with mechanism not fully revealed. The low clinical incidence led to a scarcity of single-cell genomics studies related to AIH, leaving a gap in the exploration of new therapeutic targets. Our study aimed to characterize the distinctive immunological microenvironment at the single-cell resolution and identified potential pathogenic markers of AIH.

Method: We isolate single cells from liver biopsy tissue of 4 AIH patients and 2 controls. Expression data of 45806 cells was collected through 10 × Genomics single-cell RNA sequencing analysis. Downstream analysis was performed using R packages (Seurat, CellChat, Monocle). Multi-colour IHC staining was performed to identify PDCD1, CD68, CD163, CD86, CD8, RORC, CD69, CD103. Serum MIF was tested with MIF Elisa tool kit.
Results: Finally, 45806 cells were captured and analyzed through 10 × scRNA sequencing. Initially 19 clusters were identified into six cell types based on expression features: myeloid cells, TandNK cells, Hepatocytes, B cells, Endothelial cells, Plasma cells. To further explore the immune-pathogenesis of AIH, subtyping was performed. Seven myeloid subtypes were identified: Mac_C1QA, Mono_S100A12, Mac_CD86, Mac_CD163, DC_FLT3, Mono_CD16, Neutro_CXCR2. Pseudotime and Cellchat analysis revealed the potential upstream inflammatory factor MIF, highly correlated with AIH, validated by ELISA in serum. T cell identification disclosed distinctions in CD8-Tc-PDCD1 cells between autoimmunity and cancer. The elevated percentage in AIH, however, does not necessarily signify immune exhaustion. Cellchat analysis indicated increased interaction between CD8-Tc-PDCD1 cells and other T cells, as well as myeloid cells, in the AIH group. Additionally, we uncovered a subset of CD8-Tc17-RORc cells, with feature genes enriched in "Nod-like-receptor-signaling-pathway" and "Rig-i-like-receptor-signaling-pathway", suggesting its potential role in regulating inflammasomes, innate immunity, and inflammation pathway activation. These findings hint at the potential significance of CD8-Tc17-RORc cells in the pathogenesis of AIH. Preliminary validation through multi-color IHC staining supported our scRNA sequencing results.
Conclusion: These findings reveal that MIF, produced by monocytes/macrophages, may serve as a crucial inflammatory factor in AIH. It is likely to modulate immune cells in liver, such as CD8-Tc-PDCD1 and CD8-Tc17-RORc, through paracrine or autocrine mechanisms, reshaping the immune microenvironment and promoting disease progression. Moreover, this study provides a single-cell transcriptomic atlas of AIH, with the potential to enhance our understanding of the complexity of the AIH immune microenvironment and offer insights for the development of new therapies.

Email: jimmy.daza@medma.uni-heidelberg.de

Background and aims: Autoimmune liver diseases (AILDs) constitute a cluster of rare liver conditions requiring precise evaluation and management, often unfamiliar to many medical providers. With the emergence of chatbots, there is potential for innovative solutions to assist healthcare professionals in order to improve their clinical management. Our study aims to systematically assess the performance of four chatbots in addressing a comprehensive questionnaire as evaluated by global liver specialists, evaluating their utility as potential clinical decision support tools in the field of AILDs.
Method: We developed a questionnaire with 56 questions focusing on AILD evaluation, diagnosis, and management. Three diseases were included: Autoimmune hepatitis (AIH, 20 questions), Primary Biliary Cholangitis (PBC, 18 questions), and Primary Sclerosing Cholangitis (PSC, 18 questions). The list was introduced to four chatbots in December 2023, namely ChatGPT 3.5, Claude, Bing Chat, and Google Bard, in their free and open access subscription tiers. Responses were critically evaluated by ten liver specialists in Europe and the Americas using a standardized 1 to 10 rating scale. The comparative analysis included assessing the mean score and the number of highest rated replies of each chatbot, and identification of common shortcomings in chatbot performance.
Results: Among the evaluated chatbots, the mean rating scores from specialists were: Claude with 7.4 out of 10, ChatGPT with 7.27, Bing Chat with 6.85, and Google Bard with 6.65. Claude also demonstrated superiority with 26 best rated replies, followed by ChatGPT with 20, while Bing Chat and Google Bard lagged significantly with only 10 each. Common deficiencies were observed across all chatbots, including a tendency to list details over providing specific advice, limited practical dosing options, inaccurate information for pregnant patients, a lack of recent data, over-recommendation of CT and MRI, and insufficient discussion on off-label use and fibrates in PBC treatment. Of note, internet access of both Bing Chat and Google Bard did not show a positive impact in chatbot precision when compared to the pretrained models.
Conclusion: While chatbots show promise in AILD support, our findings highlight crucial areas for improvement. Refinement is needed in providing specific advice, accuracy, and focused and up-to-date information. Addressing these shortcomings is essential for enhancing the clinical utility of chatbots in autoimmune liver disease management, guiding their future development, and ensuring their effectiveness as clinical decision support tools.

THU-165
Risk of primary sclerosing cholangitis is increased among patients with gastritis-a nationwide cohort study

Lina Lindström[1], Isabella Ekheden[2], Marcus Thuresson[3], Jonas F Ludvigsson[4]. [1]*Department of medicine Huddinge Karolinska Institutet, Stockholm, Sweden;* [2]*Department of Laboratory Medicine, Division of Clinical Pharmacology, Karolinska Institutet, Stockholm, Sweden;* [3]*Statisticon AB, Uppsala, Sweden;* [4]*Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm, Sweden*
Email: lina.lindstrom@ki.se

Background and aims: The pathogenesis of Primary Sclerosing Cholangitis (PSC) remains largely unknown. Infection with *Helicobacter pylori* (*H. pylori*) and subsequent gastritis could hypothetically act as a triggering event of PSC in predisposed individuals, as *H. pylori* has been shown to be more prevalent in chronic liver disease. However, the risk of PSC among patients with gastritis and its precursor, *H. pylori* infection, is undetermined. Therefore, our aim was to investigate the risk of PSC in patients with gastritis or *H. pylori* infection.
Method: This is a nationwide cohort study including all Swedish patients undergoing gastroscopy with biopsy showing gastritis or *H. pylori* during 1990–2017 (n = 318 478). For each individual with gastritis/*H. pylori* we matched up to 5 controls by sex and age from the Swedish general population. Patients were followed from the index biopsy until death, emigration, end of follow-up or date of PSC

diagnosis. We calculated the hazard ratio (HR) of PSC development, adjusting for age, sex, calendar year, county, and comorbidities.
Results: Patients with a histological diagnosis of gastritis or *H. pylori* were more likely to be diagnosed with PSC during follow-up. The adjusted HR for PSC among patients with gastritis/*H. pylori* was 3.35 (95% CI 2.67–4.20) compared to the general Swedish population. The incidence rate per 100 000 person-years for PSC in patients with gastritis/*H. pylori* was 3.7 (95% CI 3.1–4.3) and for general population controls 1.2 (95% CI 1.0–1.3).
Conclusion: Patients with a gastroscopy biopsy showing gastritis or *H. pylori* have a moderately increased risk for PSC later in life.

THU-166

Portal hypertension and its prognostic implications in patients with autoimmune hepatitis

Lukas Burghart[1], Sonja Treiber[2], David Bauer[3], Emina Halilbasic[4], Benedikt Hofer[5], Mattias Mandorfer[6], Michael Gschwantler[3], Caroline Schwarz[7], Michael Trauner[6], Thomas Reiberger[6], Albert Friedrich Stättermayer[6]. *[1]Klinik Ottakring, Vienna, Austria; [2]Medical University of Vienna, Departement for Medicine III, Division for Gastroenterology and Hepatology, Vienna, Austria; [3]Klinik Ottakring, Vienna; [4]Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria, Vienna; [5]Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria, Vienna; [6]Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria, Vienna, Austria; [7]Klinik, Ottakring, Vienna, Austria*
Email: burghartlukas@gmail.com

Background and aims: Autoimmune hepatitis (AIH) is a rare autoimmune mediated liver disease that may ultimately progress to advanced chronic liver disease, and clinically significant portal hypertension (CSPH). CSPH is associated with typical features in compensated (splenomegaly, collaterals and varices) and decompensated (ascites, hepatic encephalopathy and variceal bleeding) liver disease and is considered a major driver for hepatic decompensation.
Method: Patients presenting with AIH between Q1/2005 and Q4/2023 at the Medical University of Vienna (N = 282) were identified through a retrospective database query. Patients with a confirmed diagnosis of AIH, based on liver histology and an IAIHG Score of ≥6 were included in this study. Relevant clinical information was extracted from individual medical records. Patients with acute liver failure were excluded from further analysis (N = 11).
Results: A total of 271 AIH patients (mean age: 42.5 years (SD:19.1 years), 76.4% female, median follow-up: 7.7 (IQR 2.9–12.7) years) were retrospectively assessed. Overall, 104 (38.4%) showed features of CSPH: 37 (13.7%) developed varices, 40 (14.8%) collaterals, 76 (28.0%) splenomegaly (LDM >13 cm), 50 (18.5%) ascites, 11 (4.1%) hepatic encephalopathy and 9 (3.3%) experienced acute variceal bleeding.
Overall, 16 (5.9%) patients died with 7 deaths being caused by CSPH-related complications.
In a cox proportional hazards ratio, esophageal varices (HR 6.3 CI: 2.1–19.3), portosystemic collaterals (HR 5.4 CI: 1.7–17.3) and splenomegaly (HR 6.6 CI: 2.7–15.8) were associated with a significantly increased risk of decompensation.
Overall, patients with features of CSPH showed a significantly increased risk (HR 34.4 CI: 4.6–255.1) to require liver transplantation or to progress to death during the further course of disease.
Importantly, the combination of liver stiffness <15 kPa and platelets ≥150 G/L indicated excellent prognosis (10 Y decompensation rate: 2.6%, 10Y-TFS of 93.1%), while patients with either liver stiffness ≥15 kPa or platelets <150 G/L showed an increased 10 Y decompensation rate of 12.8% (log-rank p = 0.019) and a small decrease in 10Y-transplant-free-survival (TFS) of 86.9% (log-rank p = 0.16).
Conclusion: In patients with AIH, presence of CSPH associated features as well as liver stiffness ≥15 kPa or platelets <150 G/L are important predictors for future hepatic decompensation and impaired TFS. AIH patients with decompensated liver disease show a dismal prognosis without liver transplantation. Hence, regular CSPH screening by liver stiffness and platelet count seems warranted in order to implement PH-targeted treatment in AIH patients on time.

Email: alessio.gerussi@unimib.it

Background and aims: The European Reference Network on Hepatological Diseases (ERN RARE-LIVER) is a Europe-wide network for centers of excellence in the management of rare liver diseases. The aim of this study was to leverage the registry of ERN RARE-LIVER to explore the current diagnostic and therapeutic trends of incident PBC cases.
Method: We analyzed data from PBC diagnosed in the period Jan 2017–Sep 2023 from R-LIVER, a prospective registry of incident cases from the ERN RARE-LIVER network. Patients with available follow-up at 24 months were included. Centers including more than five patients were included.
Results: 313 patients from 10 centers were included in the analysis. Median age at diagnosis was 56 years, 91% were female. Transient elastography was performed in 221 patients (71%) at diagnosis (median liver stiffness (LS) 4.8 [IQR 6.3, 8.5], whereas 64 (20%) individuals had liver biopsy. Cirrhosis was present in 25 (8%) at diagnosis, with median liver stiffness 19.35 (IQR 12.0, 27.6). Two patients died (one of sepsis, one of liver failure), and one underwent transplantation for end-stage liver disease. Three patients suffered from variceal bleeding during follow-up. At diagnosis, median values of ALP were 1.43 × ULN, GGT 4.28 × ULN, ALT 1.39 × ULN, bilirubin 0.5 × ULN. 286 patients (91%) started treatment with Ursodeoxycholic Acid (UDCA) at diagnosis. After 12 months of UDCA, 228 (80%) achieved ALP values <1.67 × ULN; ALP values <1.5 × ULN were

achieved in 212 (74%), while ALP normalization occurred in 131 cases (46%). Among 58 patients with incomplete response, 7 (12%) started Obeticholic Acid, 14 (24%) Bezafibrate and one (2%) Fenofibrate.
Conclusion: Our data from the prospective R-LIVER registry highlight diagnostic delay and limited access to second-line therapies in patients with PBC. These should assist healthcare policymakers to improve integrated care pathways in PBC.

THU-170-YI

Paris II criteria are better than Poise to predict liver-related complications after second line therapy in patients with primary biliary cholangitis

Helena Hernàndez-Èvole[1,2,3], Ignasi Olivas[1,2,3], Alvaro Giménez Manzorro[4], Margarita Sala Llinás[5], Ares Villagrasa[6], Montserrat García-Retortillo[7], Natalia Sobenko[8], Beatriz Mateos Muñoz[9], Diana Horta[10], Gabriel Mezzano[11], Inmaculada Castello[12], Alejandra Villamil[8], Magdalena Salcedo[4], María Carlota Londoño[1,2,3], Sergio Rodriguez-Tajes[1,2,3]. *[1]Liver Unit, Hospital Clínic de Barcelona, Barcelona, Spain; [2]Centro de Investigación Biomédica en Red Enfermedades Hepáticas y Digestivas, Barcelona, Spain; [3]Institut d'Investigacions Biomediques August Pi i Sunyer, Barcelona, Spain; [4]Sección Hepatología y Trasplante Hepático. Email: hernandez.ievole@gmail.com

Background and aims: Diverse criteria exist for assessing the response to UDCA in primary biliary cholangitis (PBC); however, their utility in evaluating the response to second-line therapy has not yet been demonstrated. The aim of our study was to investigate the ability of these criteria in predicting survival and liver-related event-free survival after second-line treatment.
Method: This was a retrospective analysis of 215 PBC patients receiving second line therapy at 10 referral centers. We excluded patients with <1 year of follow-up (FU) and those who received both fibrates and OCA. We assessed the efficacy of response criteria (Paris-II, POISE, and alkaline phosphatase [ALP] normalization) in predicting 1) a combined end point of mortality and liver transplantation (LT), and 2) any liver-related event (LRE, including LT, death, decompensation or hepatocellular carcinoma [HCC]).
Results: Nighty percent were women, with a median age of 57 (IQR: 50–64) years, 195 were treated with fibrates and 20 with OCA. The median FU time after second line treatment initiation was 4.7 (IQR: 2.1–10.6) years. During the FU, 16 patients developed cirrhosis, 6 died from liver-related complications, 7 underwent LT, 18 had decompensation, and 4 HCC. Response criteria were analyzed in 170 patients (79%). According to Paris II, 103 (61%) patients responded. Being a non-responder increased the risk of mortality/LT (HR 5.6; CI95% 1.2–25.9) and LRE (HR 3.5; CI95% 1.1–10.9). On using Poise criteria, 113 (65%) responded, but they were not significantly associated with mortality/LT (HR 2.2; CI95% 0.6–7.5) or LRE (HR 1.9; CI95% 0.7–5–5). Paris II had a ROC curve for predicting mortality of 0.74 (CI95% 0.66–0.8; sensitivity [Se] 0.83, specificity [Sp] 0.64), and 0.71 (CI95% 0.63–0.77, Se 0.76, Sp 0.65) for predicting LRE. On the contrary, ROC curves for Poise were the less accurate, with values of 0.67 (CI95% 0.6–0.74) and 0.63 (CI95%0.56–0.7) for mortality and LRE, respectively. According to Youden index, the best ALP cut-off for predicting mortality or LRE was 1.56 × UNL. ALP normalization did not result in improved survival compared to ALP between 1 and 1.5 × UNL. Other factors associated with both, mortality and LRE were AST normalization after 1 year of treatment (HR 0.11; CI95%0.03–0.43), FU time before second-line treatment (HR 1.1; CI95%1.02–1.19), albumin (HR 0.8, CI95% 0.71–0.9]) and, bilirubin <0.6 mg/dl (0.6–1.2: HR 7.8; CI95% 1.1–63.4 and >1.2: HR 26; CI95% 2.7–262).
Conclusion: Paris II criteria showed better performance than Poise in predicting survival and liver-related events. Normalization of ALP did not improved survival, but bilirubin (<0.6 mg/dL) and AST normalization were excellent predictors. More studies are needed to develop response criteria for second-line treatment able to better predict LT-free survival.

Email: gupseadali@gmail.com

Background and aims: Liver transplantation (LT) is the only therapeutic option for end-stage liver disease in primary sclerosing cholangitis (PSC). Unfortunately, approximately 10–25% of patients had experienced PSC recurrence after LT. Knowledge of recurrence rates and associated factors in living-donor liver transplantation (LDLT) for PSC is not well established. We aimed to investigate the prevalence and factors associated with PSC recurrence after LT in a predominantly LDLT multicentre cohort from Türkiye.
Method: In this national multicentre (8 centres) cohort study, adult patients with PSC who underwent LDLT between 2000 and 2022 were evaluated. Multivariate logistic regression analyses were used to identify factors associated with PSC recurrence.
Results: A total of 82 patients who underwent LT for PSC were analysed, among them, 63 (77%) had LDLT. The mean age of the patients at diagnosis was 35 ± 11 years, 62.2% were male, the median age at LT was 42 (18–65) years. The mean MELD score was 18 ± 7. Thirty-seven patients (45%) had inflammatory bowel disease (IBD). PSC recurrence was observed in 16 (20%) patients following LT. The median time of PSC recurrence after LT was 37 months (range: 9–252 months). PSC recurrence was slightly more prevalent in LDLT than in deceased donor LT (DDLT); (26.3% vs. 6.3%, p = 0.168). Thirteen recipients (16%) had IBD activation, and five (6%) developed de novo IBD. In the multivariate analysis, LDLT HR 14.8 (95% CI: 1.4–160.8, p = 0.027), younger age HR 0.85 (95% CI: 0.8–1.0, p = 0.007), and age at LT HR 1.2 (95% CI, 1.0–1.3; p = 0.012) were associated with the risk of PSC recurrence.
Conclusion: Based on the results of this preliminary report, LDLT may increase the risk of primary disease recurrence in patients with PSC who underwent LT.

THU-172

Investigating ACOX2 deficiency as an underlying cause of recurrent hypertransaminasemia in the Spanish population: an epidemiological study

Marta Alonso-Peña[1], Maria Menendez[2], Susana Iraola-Guzman[3], David Sordo[1], Sara Arias-Sánchez[1], Ana Álvarez-Cancelo[1], María Del Barrio[1], Álvaro Díaz-González[1], Rafael de Cid[3], Javier Crespo[1]. *[1]Valdecilla Research Institute (IDIVAL), Marqués de Valdecilla University Hospital, Santander, Spain; [2]University of Cantabria, Santander, Spain; [3]Germans Trias i Pujol Research Institute (IGTP), Badalona, Spain*
Email: martaalonsop@gmail.com

Background and aims: Elevated transaminase levels are frequently encountered. ACOX2 deficiency-associated hypertransaminasemia (ADAH) arises from an inherited disruption in bile acid synthesis, leading to recurrent hypertransaminasemia. The frequency of the ADAH-causing variant (rs150832314, c.673C>T) is globally low (0.014–0.089%), suggesting ADAH's rarity, with only five affected families documented in Spain. Our aim is to ascertain the prevalence of recurrent or persistent hypertransaminasemia in the general population and scrutinize the variant's frequency across diverse subpopulations. This exploration aims to distinguish whether ADAH qualifies as a rare disease or possibly goes undiagnosed.
Method: To assess the prevalence of recurrent or persistent hypertransaminasemia (defined as more than two determinations with ALT, AST, or GGT values exceeding normal levels, spaced at least 3 months apart), we conducted a retrospective analysis of clinical records (2018–2022) within the Cantabria Cohort. This cohort recruited individuals aged 40–70 years (n = 24852) from the general population. Employing Taqman probes (Ref. C_169947759_10), we genotyped the ACOX2 gene in 97 subjects exhibiting recurrent hypertransaminasemia (DNA supplied by Valdecilla Biobank). Minor Allele Frequency (MAF) information for the c.673C>T variant, as identified in sequencing studies (TopMed, ExAC, 1000Genomes, GO Exome Sequencing Project, Allele Frequency Aggregator, gnomAD, The PAGE Study, Medical Genome Project healthy controls from the Spanish population), was acquired from the dbSNP and Ensembl databases. Additionally, the MAF of the c.673C>T variant was scrutinized within the GCAT cohort, comprising individuals residing in Catalonia, with both genomic sequencing (n = 785) and genotyping data (n = 4988, TopMed panel).
Results: Within the Cantabria Cohort, 13% of participants exhibited recurrent or persistent hypertransaminasemia. Databases indicates that the Spanish population report the highest MAF of the c.673C>T variant (0.70%), with subsequent frequencies observed in the Dominican, Cuban, Central American, and Mexican populations. In the GCAT cohort, sequencing studies revealed a MAF = 0.51%, slightly diminishing in genotyping and imputation analyses (MAF = 0.46%). Regarding the hypertransaminasemia population in Cantabria, three heterozygous carriers of the c.673C>T variant were identified, resulting in a MAF of 1.57%.
Conclusion: According to allele frequency, an estimated prevalence of ADAH ranging from 21 to 49 cases per 10, 000 inhabitants in Spain in 2023 suggests that this condition may not be rare in our country. However, the actual prevalence is anticipated to be lower, considering the unknown penetrance and expressivity of this entity. A multi-center study is currently in progress to elucidate the precise prevalence and clinical spectrum of ADAH.

THU-173

Predicting post-partum flare in Autoimmune Hepatitis- who is at risk?

Charlotte Sewell[1], James Hodson[1], Kathryn Olsen[1], Leena Nagpal[2], Neil Rajoriya[1], Ellen Knox[2], Hsu Chong[2], James Ferguson[1], Fiona Thompson[1], Ye Htun Oo[1]. *[1]University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom; [2]Birmingham Women's Hospital, Birmingham, United Kingdom*
Email: charlottesewell@nhs.net

Background and aims: Autoimmune hepatitis (AIH) is an immune-mediated liver disease with female predominance and a young age of onset. Disease remission is often seen during pregnancy due to immune tolerance, however immune escape after delivery leads to post-partum flare. Identifying which patients are at higher risk of post-partum flare could enable closer monitoring, earlier identification and treatment of flare and therefore may improve outcomes.
Method: In this retrospective single centre study, pregnant patients with AIH were identified from archived Liver Obstetric multidisciplinary team (MDT) discussion notes (births from June 2010–April 2023). Hospital electronic records were then used to collect relevant patient demographics, information regarding the pregnancy outcome, and blood results to identify cases of post-partum flare.
Results: There was a total of 43 pregnancies in 30 patients. The majority of pregnancies were in patients of white ethnicity (61%) and with Type 1 AIH (79%), with a mean age at delivery of 31 years. Post-partum flares developed in 37% of pregnancies, with patients developing post-partum flares found to be significantly younger, with a mean age at delivery of 28 vs. 32 years (p = 0.014). In addition, post-partum flares were significantly more common in pregnancies where there were concerns about treatment compliance (73% vs. 25%, p = 0.010). Other factors that were found to have a higher rate of post-partum flare were Type 2 AIH (56% vs. 33% in type 1 AIH, p = 0.265), disease not controlled at conception (55% vs. 31%, p = 0.278), previous post-partum AIH flare (55% vs. 20%, p = 0.183) and Non-White ethnicity (50% vs 32%, p = 0.314). There was no increased risk of post- partum flare in patients with cirrhosis or in patients with SLA/LC1 antibodies.
Conclusion: Closer monitoring in patients with identified risk factors for post-partum flare may enable earlier detection and treatment. Discussion around medication compliance is important in pregnant patients with AIH, especially in younger patients. Reassurance of drug safety in pregnancy and post-partum could potentially encourage medication adherence, and reduce the risk of post-partum flare.

THU-174

Assessment of the pharmacokinetic drug-drug interaction potential of elafibranor with atorvastatin in healthy adult male participants: an open-label phase I trial

Anna Pedret-Dunn[1], Sarah Mazain[2], Richard Allan[3], Remy Hanf[4], Carol Addy[5]. *[1]Ipsen, Milton Park, United Kingdom; [2]Ipsen, Boulogne-Billancourt, France; [3]Ipsen, Slough, United Kingdom; [4]GENFIT S.A., Loos, France; [5]GENFIT Corp., Cambridge, MA, United States*
Email: anna.pedret-dunn@ipsen.com

Background and aims: Elafibranor, a dual peroxisome proliferator-activated receptor-alpha/delta agonist, is under investigation as a treatment for primary biliary cholangitis (PBC). In vitro studies demonstrated that elafibranor and its major active metabolite, GFT1007, inhibit organic anion transporter polypeptide (OATP) 1B3. A phase I trial was conducted to evaluate the drug-drug interaction (DDI) potential of elafibranor as a perpetrator with atorvastatin, an OATP1B3, OATP1B1 and cytochrome P4503A (CYP3A) clinical substrate.
Method: In this phase I, randomised, open-label trial (EudraCT: 2015-000723-88), healthy participants received single doses of atorvastatin 40 mg (Days 1 and 17) and once-daily doses of elafibranor 180 mg (Days 4–19) under fasting conditions. Pharmacokinetic (PK) parameters derived for each treatment included observed maximum

plasma concentration (C_{max}), area under the plasma concentration curve from administration up to the last quantifiable concentration at 72 hours (AUC_{0-72h}), and time to reach C_{max} (t_{max}). All adverse events (AEs) were recorded.

Results: Of 25 white male participants, 24 completed the trial; median (range) age was 32.0 (19–45) years. There was no increase in the overall exposure of atorvastatin. Compared with atorvastatin administration alone, C_{max} was 28% lower following co-administration with elafibranor, with a geometric mean ratio (GMR) of 72 (90% confidence interval [CI]: 60.1–87.2); mean (standard deviation [SD]): 19.7 (11.0) ng/ml vs 14.8 (11.4) ng/ml. Median (range) t_{max} increased from 0.67 (0.50–3.00) hours (h) to 1.00 (0.67–4.50) h. There was a small decrease of mean (SD) AUC_{0-72h} (12%) following co-administration, and the 90% CIs indicated similarity between the regimens: 81.3 (42.1) ng/ml*h vs 75.0 (51.5) ng/ml*h; GMR: 88 (90% CI: 82.2–93.3). Observed differences between the two regimens were not deemed clinically significant. A total of 16 non-serious and mild to moderate treatment-emergent AEs were reported by 11 participants; all were resolved without treatment discontinuation.

Conclusion: Co-administration of atorvastatin and elafibranor 180 mg had minimal impact on the overall exposure of atorvastatin. Therefore, co-administration of elafibranor 80 mg (clinical dose) with OATP1B1, OATP1B3 and CYP3A substrates, such as other statins, is unlikely to cause clinically significant PK DDIs. Furthermore, co-administration of atorvastatin and elafibranor was well tolerated.

THU-175-YI

Clinical outcome in patients with autoimmune hepatitis and its variant with primary sclerosing cholangitis

Karolina Wronka[1], Maciej Janik[1], Joanna Łącz[1], Joanna Raszeja-Wyszomirska[1], Piotr Milkiewicz[1,2]. *[1]Department of Hepatology, Transplantology and Internal Medicine, Medical University of Warsaw, Warsaw, Poland; [2]Translational Medicine Group, Pomeranian Medical University, Szczecin, Poland*
Email: karolina.m.wronka@gmail.com

Background and aims: People with autoimmune hepatitis (AIH), primarily a liver parenchyma disease, might present with cholestatic features, which needs to be evaluated in magnetic resonance cholangiopancreatography (MRCP). However, AIH-primary sclerosing cholangitis (PSC) variant syndrome (AIH-PSC) remains a controversial issue. Here, we evaluated the outcome in patients with the pure AIH and AIH-PSC variants.

Method: A total group of 412 adults fulfilling the criteria for diagnosing both conditions were included in the analysis. These included 306 (74%) patients with biopsy-proven AIH and 106 (26%) patients with AIH-PSC, diagnosed in all individuals with liver biopsy and magnetic resonance cholangiopancreatography (MRCP), according to EASL 2015 Guidelines. The complete biochemical response (CBR) was defined as normalization of serum transaminases and IgG. The end point was defined as liver transplantation (LT) or liver-related death. Data were presented as median (IQR) or per cent when appropriated.

Results: Patients with AIH-PSC, compared to pure AIH, were younger at the time of diagnosis (median age of 20 (12) vs 30 (32) years, $p < 0.001$), more frequently diagnosed at the paediatric age (46% vs 29%, $p = 0.013$). Female patients were more common in the pure AIH group (77% vs 36%, $p < 0.001$). In a median follow-up of 8 (10) years, the CBR was observed more frequently in AIH than in AIH-PSC (54% vs 24%, $p = 0.005$). During the 8-year follow-up, 124 patients reached the clinical end point (122 LT (30%) and two deaths (5%)). Patients with AIH-PSC required LT or had liver-related death more frequently than those with pure AIH (51% vs. 23%, $p < 0.001$). Diagnosis of AIH-PSC was an independent risk factor for LT or liver-related death HR 1.98 (95% CI 1.38–2.82, $p < 0.001$), irrespective of sex or age. Of note, hepatocellular carcinoma was diagnosed in 12 patients (3%), including nine (3%) with pure AIH and three (4%) with the AIH-PSC variant.

Conclusion: The diagnosis of AIH-PSC carries a significantly worse prognosis as compared to pure AIH population.

THU-176

Chronic pruritus presents with similar clinical features in metabolic and cholestatic liver diseases

Miriam M. Düll[1,2], Vanessa Karlen[1,2], Marcel Vetter[1,2], Peter Dietrich[1,2,3], Jörg Kupfer[4], Markus F. Neurath[1,2], Andreas E. Kremer[1,5]. *[1]Department of Medicine 1, Friedrich-Alexander-University Erlangen-Nürnberg, Erlangen, Germany; [2]Deutsches Zentrum Immuntherapie, DZI, Erlangen, Germany; [3]Institute of Biochemistry, Emil-Fischer-Zentrum, Friedrich-Alexander-University Erlangen-Nürnberg, Erlangen, Germany; [4]Institute of Medical Psychology, Justus-Liebig-University Giessen, Giessen, Germany; [5]Department of Gastroenterology and Hepatology, University Hospital Zürich, University of Zürich, Zürich, Switzerland*
Email: miriam.duell@uk-erlangen.de

Background and aims: Real-word experience underlines that pruritus is a common and sometimes difficult-to-treat symptom in various hepatobiliary diseases beyond cholestasis. This analysis aims at further characterizing clinical features of pruritus in patients with cholestatic and non-cholestatic liver diseases in a large cohort of patients.

Method: We performed a cross-sectional questionnaire-based study in a tertiary hepatological center assessing demographics, clinical data, and detailed characteristics of pruritus including quality of life (QoL) measures such as SF-12, 5-D Itch, and ItchQoL. Patients were categorized in "immune-mediated and cholestatic liver diseases" (ICLD), "steatotic liver disease" (SLD, comprising MASLD, MetALD, ALD), "viral liver diseases" (VLD) and "other liver diseases" (OLD). Statistical analyses were performed using Mann-Whitney-U-test and Spearman's rank correlation. Data are given as mean ± SEM.

Results: Of a total of 653 patients, 26.2% reported on pruritus, of whom the majority (63.7%) was female. Laboratory values of patients with and without pruritus were comparable in regard to transaminases, cholestasis parameters and liver and kidney function tests. Pruritus was present in 33.7%, 26.9%, 18.4%, and 17.1% in ICLD, SLD, VLD and OLD, respectively. Interestingly, we observed a high itch frequency of 21.4% in liver transplant recipients. Mean and worst NRS itch intensities during the last week were rated comparably high in the ICLD and SLD group at 4.1 ± 0.3 vs 3.9 ± 0.4 and 4.6 ± 0.3 vs 4.7 ± 0.5 on a NRS, respectively, but distinctly lower in patients with VLD with a mean NRS of 3.2 ± 0.6/3.0 ± 0.6 and worst NRS of 3.7 ± 0.7/3.4 ± 0.7. While 44.3% and 48.7% of patients with ICLD and SLD had at least a moderate ich intensity (NRS>3), only one third received topical (15.3%; 18.9%) and/or systemic treatment (18.9%; 13.5%). Over 80% of all pruritic patients reported on chronic itch with a duration >6 weeks. 73.9% described a stable or increasing itch level since onset of pruritus, with a majority stating a day-time dependency of worsening in the evening and night. About one third of patients with an NRS>3 reported difficulty falling asleep or sleeping through the night due to itching. The pruritus-related QoL in both ICLD and SLD correlated with mean and worst NRS itch intensity. Median SF-12 values were significantly lower for physical ($p < 0.01$) and mental scores ($p < 0.05$) in pruritic patients in both ICLD and SLD.

Conclusion: Pruritus is a frequent symptom in patients with non-cholestatic, in particular metabolic liver diseases. In these patients, pruritus exerts comparable clinical features and has similar negative impacts on QoL compared to patients with cholestatic disorders.

THU-177-YI

Patient-reported outcomes in primary sclerosing cholangitis: an australian multicentre cohort perspective

Natassia Tan[1], Christopher Zampogna[2], Rohit Sawhney[2], Stephen Bloom[2], Kate Lynch[3], Nicholas Hannah[4], Siddharth Sood[4], Kate Collins[5], Avik Majumdar[5], Andrew Coulshed[6], Ken Liu[6], John Lubel[7], William Kemp[7], Stuart Roberts[7], Ammar Majeed[7],

Amanda Nicoll[2]. [1]*Alfred Health, Monash University, Melbourne, Australia;* [2]*Eastern Health, Melbourne, Australia;* [3]*Royal Adelaide Hospital, Melbourne, Australia;* [4]*Royal Melbourne Hospital, Melbourne, Australia;* [5]*Austin Health, Melbourne, Australia;* [6]*Royal Prince Alfred Hospital, Melbourne, Australia;* [7]*Alfred Health, Melbourne, Australia*
Email: natassiapinpintan@gmail.com

Background and aims: Primary sclerosing cholangitis (PSC) is a rare, progressive cholestatic liver condition that has a significant association with inflammatory bowel disease (IBD) and certain malignancies. PSC patients often suffer from impaired health-related quality of life (HRQOL) due to symptoms such as pruritus, pain, and fatigue. We aimed to characterise and compare validated PSC and IBD patient-reported outcomes (PRO) in an Australian prospective cohort and determine if PROs correlated with severity of liver disease.
Method: We conducted a multicentre prospective cohort study enrolling all adult PSC patients with or without IBD. Patients completed a validated PSC PRO questionnaire (Younossi, 2018) and a short IBD questionnaire (SIBDQ, Irvine, 1994) at time of enrolment. Additional baseline demographic and clinical data collected as part of routine clinical care was obtained. Differences in each HRQOL domain was compared using Mann-Whitney's U test. Linear regression was used to determine association between each HRQOL domain and severity of liver disease using Mayo PSC risk score. Spearman's correlation was used to determine if there was a correlation between PSC and IBD PROs within patients.
Results: A total of 55 PSC patients were included. The majority of patients were male (58%) with a median age of 42 years (IQR 33–56), large duct phenotype (82%), and median 7.5 (IQR 3.5–10.9) years of follow-up from PSC diagnosis. Eight patients (15%) were cirrhotic and none of the patients had received a liver transplant. Forty-six (84%) patients had IBD, with the majority having Crohn's disease (61%). There was no significant difference in patient demographics, clinical characteristics, liver disease severity and PSC PRO domains between patients with and without IBD. There was a significant increase in the PSC PRO domains of chronic symptoms (17 vs 7, $p = 0.03$), impairment in activities of daily living (7.5 vs 4, $p = 0.02$) and role function (6 vs 4, $p = 0.003$) in patients with cirrhosis compared to those without, however no difference was seen with the SIBDQ domains. All domain scores except chronic symptoms were significantly associated with disease severity (Mayo risk score). Patients who experienced a higher burden of emotional impairment and symptoms related to PSC also experienced an increased burden of IBD symptoms and related emotional impact ($p < 0.001$).
Conclusion: This is the first Australian study describing PSC and IBD PROs in a well characterised prospective cohort. We have demonstrated that PSC PROs are significantly associated with liver disease severity. PSC and IBD symptoms have a significantly positive correlation which suggests that luminal and biliary disease run a similar course within patients. Further large-scale prospective studies with a more heterogenous cohort are required to further interrogate these findings.

THU-178
Understanding the experience of people living with primary biliary cholangitis (PBC): further development of an experience map

Alexander Artyomenko[1], Abi Bowden[2], Mo Christie[3], Robert Mitchell-Thain[3], Maria Morais[4], Carol Roberts[5], Marwan Sleiman[6], Sindee Weinbaum[7]. [1]*Ipsen, Slough, United Kingdom;* [2]*Health Unlimited, London, United Kingdom;* [3]*PBC Foundation, Edinburgh, United Kingdom;* [4]*Canadian PBC Society, Toronto, United Kingdom;* [5]*PBCers, Rochester, NY, United States;* [6]*Ipsen, Boulogne-Billancourt, France;* [7]*ELPA, Brussels, Belgium*
Email: alex.artyomenko@ipsen.com

Background and aims: PBC is a rare autoimmune disease of the liver.[1] The experience of living with PBC is highly variable, and current data are limited. A range of non-specific symptoms of varying severity are reported, which can impact quality of life. The degree of symptoms does not always correlate with liver biochemistry measures or disease progression.[1] This incongruence affects most of the PBC population, with 50% developing symptoms after five years and 95% by 20 years post-diagnosis.[2] To further understand the patient experience, people living with PBC were consulted to capture their thoughts, feelings, symptoms, and impact on quality of life.
Method: Reviews of publicly available literature, medical and patient organization websites, and patient stories were conducted to identify key themes. These themes guided an international steering committee meeting of patient advocates and 1:1 interviews with patients. Insights were used to co-create an experience survey to validate prior findings and ensure an accurate representation of the PBC population. An experience map was created to represent and visualize findings.
Results: The survey was distributed via a patient app for five weeks in October-November 2023 and was completed by 113 respondents. The demographics reflected the PBC population (96% female, 86% >46 years of age). People living with PBC reported fatigue as the symptom with the biggest impact on quality of life, followed by joint pain, brain fog, and pruritus. Other reported symptoms included abdominal pain, restless legs, and heartburn. Although some patients reported no symptoms (14–15%), 48% were using treatments specifically to alleviate symptoms. When rating their mental health on a scale of 1–10 (1 = worst, 10 = best) before and after their diagnosis of PBC, 25% consistently assigned a rating of 1–3. The proportion of people reporting the highest ratings of 7–10 reduced from 48% before diagnosis to 37% after diagnosis. Emotional responses were variable, with a general trend from anxiety and fear at diagnosis towards more positive emotions at the initiation of treatment. Participants reported receiving support from numerous sources, but support resources were insufficient for patients' needs.
Conclusion: A unique patient experience map for PBC has been developed and validated using insights from a range of people living with this progressive disease. Ultimately, this tool will help to align and inform healthcare approaches and treatment to address the substantial unmet needs of people living with this challenging condition.
Disclosures (funding): Conducted under a collaboration agreement between the PBC Foundation and Ipsen. Financial support was provided to Health Unlimited for project coordination and writing support by Ipsen.

THU-179
Pruritus in primary biliary cholangitis: exploring the itch phenomenon and its progression

Beata Kruk[1], Piotr Milkiewicz[1,2], Marcin Krawczyk[1,3]. [1]*Medical University of Warsaw, Warsaw, Poland;* [2]*Pomeranian Medical University in Szczecin, Szczecin, Poland;* [3]*Saarland University Medical Center, Homburg, Germany*
Email: marcin.krawczyk@uks.eu

Background and aims: Primary biliary cholangitis (PBC) is a chronic autoimmune liver disease characterized by the progressive destruction of small bile ducts within the liver. Pruritus is one of the hallmark symptoms of PBC. An observation on a decrease of pruritus in patients who progressed to cirrhosis (Sheila Sherlock NEJM 1973) has never been challenged. However, our clinical experience has seemed not to concur with this notion. Thus, here we analyze the relationship between the worsening of liver function and pruritus in a large cohort of patients with PBC.
Method: The study group comprised 616 (554 females, 269 with cirrhosis, age range 22–87 years, MELD range 6.4–38.6) adult Polish Caucasian patients with PBC. All patients were prospectively recruited between 2006 and 2023. Health-related quality of life (HRQoL), including pruritus, was assessed in all patients using PBC-

40 questionnaire at two time points: at inclusion to the cohort and retrospectively at diagnosis of PBC. Associations between markers of liver injury and itch were tested using, Mann-Whitney U, Pearson correlations or paired Student's t tests, as appropriate.
Results: According to the PBC-40 questionnaire, PBC patients with cirrhosis experienced a significantly elevated degree of pruritus ($p = 0.002$) at inclusion compared to those without cirrhosis. The median itch for patients with cirrhosis was 5.0 (range 3.0–15.0), while for patients without cirrhosis it was 3.0 (range 3.0–15.0). Notably, there was a statistically significant positive correlation between the severity of pruritus and MELD score ($R^2 = 0.59$, $p < 0.001$). Examining two distinct time points in patients who progressed to cirrhosis during our observation period ($n = 61$), we noted a consistent correlation ($p = 0.032$) between the progression of liver disease and an increase of pruritus: 6.5 (range 3.0–15.0) in non-cirrhotic PBC *vs.* 8.0 (range 3.0–15.0) in the same patients once the cirrhosis develops.
Conclusion: Our study shows a notable association between cirrhosis and increased pruritus in subjects with PBC and may suggest a potential, positive relationship between liver function and itching intensity. This reinforces the notion that pruritus may serve as an indicator or symptom associated with the progression of liver condition in PBC.

THU-180
Presence of cholestasis and its impact on survival in patients with COVID-19 associated acute respiratory distress syndrome
Mathias Schneeweiss-Gleixner[1], Katharina Krenn[2], Mathias Petter[1], Patrick Haselwanter[1], Felix Kraft[2], Lukas Adam[2], Georg Semmler[1], Lukas Hartl[1], Emina Halilbasic[1], Nina Buchtele[3], Christoph Krall[4], Thomas Staudinger[3], Christian Zauner[1], Michael Trauner[1], Albert Friedrich Stättermayer[1]. *[1]Department of Medicine III, Division of Gastroenterology and Hepatology, Medical University of Vienna, Vienna, Austria; [2]Department of Anesthesia, General Intensive Care and Pain Medicine, Medical University of Vienna, Vienna, Austria; [3]Department of Medicine I, Intensive Care Unit 13i2, Medical University of Vienna, Vienna, Austria; [4]Department of Medical Statistics, Medical University of Vienna, Vienna, Austria*
Email: mathias.schneeweiss-gleixner@meduniwien.ac.at

Background and aims: Data on the presence and clinical outcome of liver injury-particularly cholestasis and biliary injury-in patients with COVID-19 are scarce. Development of cholestasis has been associated with disease severity and worse clinical outcomes. The primary aim of this study was to evaluate the prevalence of cholestasis and factors associated with its development and outcome in critically ill patients with COVID-19 associated acute respiratory distress syndrome (ARDS).
Method: In this retrospective exploratory study, all COVID-19 patients with ARDS admitted to the intensive care unit (ICU) at the Medical University of Vienna were evaluated for the development of cholestasis, which was defined as an alkaline phosphatase level of 1.67x upper limit of normal for at least three consecutive days. Simple and multiple logistic regression analysis was used to evaluate parameters associated with development of cholestasis and survival.
Results: 225 critically ill COVID-19 patients (mean age 56.2 ± 12.1; male 68%) were included. In total, 119 patients (53%) developed cholestasis during ICU stay. Patients with cholestasis had significantly ($p < 0.001$) higher peak levels of alkaline phosphatase, gamma-glutamyl transferase, bilirubin and inflammation parameters (pro-calcitonin, interleukin-6) compared to patients without cholestasis. Patients with cholestasis had longer ICU length of stay (40 vs. 18 days; $p < 0.001$), lower PaO2/FiO2 ratio nadir (57 vs. 64; $p = 0.001$) and more often required invasive mechanical ventilation (IMV; 99% vs. 87%; $p < 0.001$) and extracorporeal membrane oxygenation (ECMO) support (78% vs. 35%; $p < 0.001$). Further, cholestatic patients more often received norepinephrine (98% vs. 87%; $p = 0.002$), ketamine (93% vs. 69%; $p < 0.001$), continuous neuromuscular blockade (73% vs. 54%; $p = 0.004$) and parenteral nutrition (76% vs. 56%; $p = 0.003$). Factors independently associated with cholestasis were invasive mechanical ventilation (OR: 1.049; CI: 1.022–1.081; $p = 0.001$), ECMO support (OR: 3.315; CI: 1.455–7.733; $p = 0.005$), ketamine use (OR: 1.106; CI: 1.046–1.174; $p = 0.001$), and disease severity as reflected by sequential organ failure assessment score on admission (OR: 1.241; CI: 1.063–1.465; $p = 0.008$). ICU and 6-month survival was 63% and 59%, respectively. Absence of cholestasis was independently associated with better ICU (OR: 0.347; CI: 0.151–0.769; $p = 0.010$) and 6-month survival (OR: 0.389; CI: 0.179–0.822; $p = 0.015$). Treatment with ursodeoxycholic acid in 73% of patients with cholestasis had no effect on ICU survival.
Conclusion: Development of cholestasis is a common complication in critically ill COVID-19 patients and represents a negative prognostic marker for survival. It is primarily associated with disease severity and specific treatment modalities of intensive care, especially ECMO and sedation with ketamine.

THU-181
Sleep disturbance due to pruritus is associated with anxiety, depression, and worse quality of life: evidence for management of pruritus and sleep in chronic liver disease
Alan Bonder[1], Amandeep Kaur[2], Digant Gupta[2], Anna Halliday[3], Gil Yosipovitch[4]. *[1]Division of Gastroenterology and Hepatology, Beth Israel Deaconess Medical Center, Boston, MA, United States; [2]Bridge Medical, London, United Kingdom; [3]GSK, London, United Kingdom; [4]Miami Itch Centre, Miller School of Medicine, University of Miami, Miami, FL, United States*
Email: anna.c.halliday@gsk.com

Background and aims: Cholestatic pruritus (itch) is common in chronic liver diseases and is even more common in cholestatic liver disease such as primary biliary cholangitis (PBC). Pruritus in PBC, especially severe pruritus, has been associated with depression, and together they have been shown to lead to poorer quality of life (QoL) in PBC. Pruritus has also been associated with sleep disturbance; severe sleep interference is common in patients with PBC and severe pruritus, and impacts QoL. In the GLIMMER study in patients with PBC, change in pruritus severity was strongly correlated (post hoc) with change in sleep interference. Here we present results from a systematic literature review and meta-analysis performed to understand the impact of pruritus-related sleep disturbance on patients' health and QoL.
Method: A systematic literature review was conducted using MEDLINE and Embase databases. Eligible literature was published in the 10 years prior to 13 December 2022 and provided data on medical conditions where pruritus was reported in adults as a specific symptom secondary to any medical condition. Screening was conducted by two independent reviewers. Random effects meta-analyses assessed correlation between sleep quality and depression, anxiety, or health-related QoL (HRQoL). Bias was assessed using a funnel plot, Egger's linear regression test, and Duval and Tweedie's trim-and-fill method.
Results: We identified 51 publications reporting pruritus data secondary to multiple underlying medical conditions including atopic dermatitis, renal impairment with dialysis-dependance and PBC, amongst others. Measures used to assess sleep disturbance/depression/anxiety/QoL were heterogeneous between publications. Lower sleep quality was moderately correlated with depression across multiple studies, with a mean correlation (95% confidence interval [CI]) of 0.392 (0.292 to 0.483; $n = 7$; $p < 0.001$). Similarly, moderate correlations between lower sleep quality and anxiety were identified, with a mean correlation (95% CI) of 0.332 (0.247 to 0.411; $n = 4$; $p < 0.001$). Lower sleep quality was associated with worse disease-specific QoL, with a mean correlation (95% CI) between sleep quality and disease-specific QoL of 0.371 (0.259 to 0.473; $n = 8$; $p < 0.001$). The risk of bias across meta-analyses was generally low.

Conclusion: Poorer sleep quality due to pruritus secondary to any medical condition is correlated with depression, anxiety and worse disease-specific QoL. Given this widespread impact of sleep disturbance on mental health and daily life, healthcare professionals should aim to explore the impact of pruritus on their patient's sleep and identify how best to manage sleep disturbance to improve depression/anxiety and QoL. Optimal management of pruritus, especially when sleep is disrupted, is important for patients with liver diseases such as PBC.
Funding: GSK (219764).

Email: donald.malino@gmail.com

Background and aims: It is unclear whether the reported rare cases of acute liver injury with autoimmune features after COVID-19 vaccination represent autoimmune hepatitis (AIH) triggered by the vaccines, requiring long-term immunosuppression, or if the liver injury is self-limiting, as observed in drug-induced autoimmune-like hepatitis (DI-ALH). We report follow-up data of our international cohort of well characterized patients aiming at understanding if the disease course is self-limiting or immunosuppression dependent.
Method: Members of the International AIH Group and of the European Reference Network on Hepatological Diseases who had contributed cases to our original cohort were asked to provide follow-up data of all their patients at 6 and 12 months after the hepatitis diagnosis and at last follow-up.
Results: 62 patients were included, median age was 56 years, 35 (56%) female. Median follow-up was 17 months. Fifty-eight patients (94%) were treated with steroids, with or without azathioprine or mycophenolate mofetil. Four patients (6%) died of non-liver related causes. Transaminase levels normalization was achieved by 74%, 85% and 88% of patients at 6 months, 12 months and at last follow-up (median 17 months). Twenty-two patients (35%) had a phenotype and clinical course similar to DI-ALH, characterized by ALT normalization with (n = 18) or without (n = 4) a short (<9 months) immunosuppressive treatment, and no relapse after treatment discontinuation; 18 patients (30%) had a course similar to AIH, characterized by relapse after immunosuppression discontinuation (n = 10), still abnormal ALT levels after 6 months (n = 5) or 12 months (n = 3) of treatment duration; for 22 patients (35%) it was not possible, based on the available data, to assign them to one of the previous groups. Risk factors for a classical AIH course were: positive anti-smooth muscle antibodies at diagnosis (p = 0.04), advanced liver fibrosis (p = 0.03), and more severe interface hepatitis (p = 0.02).
Conclusion: Most patients with acute liver injury and autoimmune features after COVID-19 vaccination appear to have DI-ALH, but a sizable subgroup with a more severe phenotype requires long-term immunosuppression, akin to classical AIH.

THU-183-YI

Immunosuppressive treatment facilitates hepatic recompensation in patients with decompensated cirrhosis due to autoimmune hepatitis-a pilot study

Benedikt Hofer[1,2,3,4], Lukas Burghart[5], Sonja Treiber[1], Emina Halilbasic[1,4], Mattias Mandorfer[1,2], Michael Trauner[1,4], Thomas Reiberger[1,2,3,4], Albert Friedrich Stättermayer[1,4]. *[1]Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria; [2]Vienna Hepatic Hemodynamic Laboratory, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria; [3]Christian Doppler Lab for Portal Hypertension and Liver Fibrosis, Medical University of Vienna, Vienna, Austria; [4]Rare Liver Diseases (RALID) center of the ERN RARE-LIVER at the Vienna General Hospital, Vienna, Austria; [5]Klinik Ottakring, Wiener Gesundheitsverbund, Vienna, Austria*
Email: benedikt.s.hofer@meduniwien.ac.at

Background and aims: Patients with autoimmune hepatitis (AIH) are at risk of progressing to cirrhosis and hepatic decompensation, and up to 30% are already cirrhotic at time of diagnosis. While a successful treatment of the underlying aetiology may enable hepatic recompensation, e.g. with viral eradication or alcohol abstinence, recompensation has not been assessed in AIH cirrhosis.
Method: We investigated the incidence and implications of recompensation in cirrhosis due to AIH (F3/F4 histology; simplified AIH score ≥6). Patients were included at index decompensation (ascites, variceal bleeding, hepatic encephalopathy [HE]). Acute liver failure

patients were excluded due to the high urgency transplantation indication. Recompensation was defined as (i) resolution of ascites/HE despite cessation of diuretic/HE therapy, (ii) absence of variceal bleeding and (iii) improvement in liver function (bilirubin, albumin, INR) to Child-Pugh A values (Baveno VII criteria). Successful aetiological control was defined as a complete biochemical response under immunosuppressive (IS) treatment (transaminase and immunoglobulin G normalisation).
Results: Twenty-one cirrhotic AIH patients (90.5% female, age: 54.6 [39.8–61.6] years, MELD at decompensation: 15 [11–18]) were included at index decompensation (85.7% ascites, 14.3% variceal bleeding) and followed for a median of 80.4 (14.6–133.0) months. Clinically, decompensation occurred in two distinct settings resulting in two subgroups: In the first (n = 10; 47.6%), the diagnosis of AIH had already been established prior to baseline and decompensation occurred despite ongoing (median: 128 [70–164] months) IS therapy, primarily due to an insufficient response. No patient within this subgroup recompensated. In the second subgroup (n = 11; 52.4%), AIH was first diagnosed at index decompensation. Within this subgroup, in 5 patients (45.5%), IS treatment was initiated >1 month after decompensation, primarily due to delayed diagnosis; none of them recompensated. In contrast, in 6 patients (54.5%), diagnosis and IS treatment were established within 1 month of decompensation and 4 patients recompensated. All recompensated patients achieved a 50% transaminase decrease after 4 weeks of treatment. With regard to prognosis, all recompensated patients survived without liver transplantation for 62.6, 101.3, 106.3 and 202.3 months, respectively. In contrast, of the 17 patients who remained decompensated, 6 (35.3%) died (all liver-related, after median 32.8 [15.1–58.5] months) and 4 (23.5%) required transplantation (after median 37.5 [15.9–57.1] months).
Conclusion: Decompensation in AIH despite ongoing IS treatment is linked to worse outcomes. In patients with decompensated cirrhosis at initial presentation, a prompt diagnosis with early treatment initiation is associated with a higher likelihood of recompensation and better survival.

THU-184
Fatigue is not influenced by chronotype and is reported to be mainly muscular in patients with primary biliary cholangitis

Erica Nicola Lynch[1,2], Pietro Rossi[1], Giulia Mengozzi[1], Tommaso Innocenti[1,2], Gabriele Dragoni[1], Maria Rosa Biagini[1], Paolo Forte[3], Andrea Galli[1]. [1]*Gastroenterology Research Unit, Department of Experimental and Clinical Biomedical Sciences "Mario Serio," University of Florence, Florence, Italy;* [2]*Department of Medical Biotechnologies, University of Siena, Siena, Italy;* [3]*Division of Clinical Gastroenterology, University Hospital "Careggi," Florence, Italy*
Email: ericanicola.lynch@unifi.it

Background and aims: Fatigue is considered one of the most frequent and debilitating symptoms in primary biliary cholangitis (PBC), affecting over 50% of PBC patients. The pathophysiology of fatigue and the role of contributing factors are still largely unknown. The aim of the study was to assess whether patient chronotype was associated with fatigue in PBC. In addition, we evaluated the impact on fatigue of environmental and liver disease characteristics, and whether fatigue was perceived by patients as mainly muscular or mental.
Method: All noncirrhotic PBC patients attending our tertiary referral centre were asked to complete the main questionnaires on fatigue, sleepiness, and chronotype (PBC-40, Fatigue Impact Scale [FIS], Epworth Sleepiness Scale [ESS], Morningness-Eveningness Questionnaire [MEQ]) between January 2023 and June 2023. Patients were also questioned on environmental factors (employment, sleep quality, nighttime light exposure) and as to whether fatigue was perceived as mainly muscular or mental. Clinical data of patients who responded was obtained from clinical records.
Results: Of a total of 125 patients, 61 agreed to participate in the study. Most patients reported mainly muscular rather than mental fatigue (69% vs 31%). Chronotype and fatigue did not appear to be related (PBC-40 Fatigue $p = 0.26$; FIS $p = 0.64$). Patients with an intermediate chronotype had slightly less daytime sleepiness vs early and late chronotypes. Nighttime light exposure significantly affected fatigue (PBC-40 $p = 0.01$; FIS $p = 0.004$). Fatigue weakly correlated with alanine-aminotransferase (FIS: $r = 0.28$, $p = 0.03$; PBC-40 Fatigue: $r = 0.34$, $p = 0.007$) and pruritus (FIS: $r = 0.37$, $p = 0.004$; PBC-40 Fatigue: $r = 0.30$, $p = 0.02$). Women were more likely to report fatigue than men (PBC-40 Fatigue: $p = 0.02$; FIS: $p = 0.01$). No other environmental factor or disease characteristic, including treatment, was found to be associated with fatigue or sleepiness.
Conclusion: Chronotype does not appear to have an impact on fatigue in patients with PBC, although nighttime light exposure significantly worsens fatigue, and therefore should be avoided. Treatment with fibrates or obeticholic acid does not affect fatigue. PBC patients report mainly muscular rather than mental fatigue.

THU-185
Second line therapy in patients with primary biliary cholangitis and inadequate response to UDCA: are we choosing the right target population for clinical trials?

Alejandra Villamil[1], Daniela de la Viña[1], Eduardo Mullen[1], Ignacio Lucero[1], Natalia Sobenko[1], Juan Carlos Bandi[1]. [1]*Hospital Italiano de Buenos Aires, CABA, Argentina*
Email: alejandra.villamil@hospitalitaliano.org.ar

Background and aims: Identification of primary biliary cholangitis (PBC) patients who could benefit from second line therapy is uncertain. Most trials rely on 12 month UDCA response status assessed by POISE criteria. Our objective is to evaluate eligible patients and identify epidemiological, clinical and histological findings of high-risk disease that may adversely influence response.
Method: Among 614 patients with established diagnosis of PBC (Jan/16 and Dec/23) 279 were unable to normalize alkaline phosphatase (ALP) and BT after 12 months of therapeutic doses of UDCA. 107/279 (38.3%) fulfilled elegibility criteria for second line trials (ALp >1.67 ULN, bilirubin <2 ULN and non significant portal hypertension) and were analyzed. Fibrosis, bile duct loss, cholangitic and hepatitis activity were obtained in 92/107 patients (Scheuer and Nakanuma scores). All samples were stained with CK 7. Elastography was done in all patients. Statistical analysis using Fisheŕs exact test and 1-way ANOVA was performed.
Results: Inadequate responders to UDCA fulfilling eligibility criteria had mean age 55.9 ± 11.8 and 87% female (n = 93). 22.4% (n = 24) <45 years. Mean ALP 366.7 ± 192.5 UI/L, GGT 366.6 ± 326.2 UI/L, ALT 64.7 ± 43.6 UI/Land BT 1.7 ± 4.6 mg/dL. Only GGT differed between women and men (326.3 vs 634.9, $p < 0.05$). Mean MELD score was 7.4 ± 1.8 and 17 patients were cirrhotic (16%). Mean MELD was higher in cirrhotics (9.0 vs 7.1, $p < 0.001$) and correlated with liver events (9.6 vs 7.0 $p < 0.001$), occurring in 14 patients during follow-up and resulting in 4 liver related deaths and 3 transplants. 43/92 patients had moderate to severe ductopenia in histological samples, and it was significantly more frequent in <45 years (66% vs 32%, p 0.008). Moderate to severe portal inflammation with interface hepatitis and lobular spilling was observed in 52/92 samples (56.5%) irrespective of age and associated with progression. No LFT predicted cirrhosis or portal inflammation. ALP was significantly higher in patients with ductopenia (437.9 ± 207.8 UI/L vs 319.2 ± 162.0 UI/L, p 0.01). Elastography correlated with cirrhosis and liver events (10.4 kPa vs 22.9 kPa, $p < 0.001$) but not with inflammation or ductopenia.
Conclusion: A significant proportion of our patients unresponsive to UDCA were not eligible for second line trials. Poise criteria eligibility was associated with the presence of ductopenia and advanced fibrosis, particularly in young patients. The presence of moderate to severe portal inflammation is suggestive of ongoing disease activity. Yet, LFT do not reflect its presence and severity. Higher ALP is linked

to the presence of ductopenia. Elastography and MELD score correlate with cirrhosis and development of liver events. Our data suggest that we are selecting for second line trials a significant proportion of patients with adverse clinical and histological prognostic factors that might impact response.

THU-186

Long term risk assessment of patients with primary sclerosing cholangitis using clinical prognosis models

Matei Mandea[1,2], Speranta Iacob[1,2], Mihaela Ghioca[1,2], Razvan Iacob[1,2], Cristian Gheorghe[1,2], Irinel Popescu[1], Liana Gheorghe[1,2]. [1]*Fundeni Clinical Institute, Bucharest, Romania;* [2]*University of Medicine and Pharmacy "Carol Davila", Bucharest, Romania*
Email: matei.mandea@drd.umfcd.ro

Background and aims: Primary sclerosing cholangitis (PSC) is a chronic progressive cholestatic disease with poor prognosis, high likelihood of dying without liver transplantation (LT) and high risk of developing cholangiocarcinoma. The assessment of prognosis is important for stratifying the high risk patients. The aim of our study was to evaluate clinical prediction models Revised Mayo Risk Score (rMRS), Amsterdam-Oxford Model (AOM), Model for End-stage Liver Disease (MELD/MELD-Na) and Primary Sclerosing Cholangitis Risk Estimate Tool (PREsTo).
Method: Our study is an observational retrospective single center study, that included 107 patients evalauted in our clinic between 2011 and 2023.
Results: From 107 patients included, 54% were female. The average age at diagnosis was 41, 11 years (16–78 years). 24/107 (22, 4%) patients had an IBD associated, 54% (10) of them suffered from Ulcerative Colitis and 46% (11) of Crohn's disease. 92/107 (85.9%) patients had a PSC that affected large bile ducts, 15/107 (14.1%) had a small-duct PSC, 10, 2% (11) had an overlap syndrome with Autoimmune hepatitis and 3.7% (4) had an overlap syndrome with Primary Biliary Cholangitis. The diagnosis was made using either MRCP or liver biopsy and after excluding other causes of cholangitis. 17.3% of the patients had high rMRS, and 42.3% high AOM score. The average PREsTo was 6.4% at 1 year and 24.5% at 5 years. There was a significantly higher PREsTo score calculated at 1 year in patients that underwent LT compared to those that did not (9.8 ± 2.7 vs 6.3 ± 1.6, $p = 0.01$), higher MELD score ($p = 0.001$) and higher MELD-Na score ($p = 0.02$). Higher AOM ($p = 0.06$) and rMRS ($p = 0.07$) reached only marginal significance. Patients with PSC that underwent LT had significant more episodes of recurrent cholangitis ($p = 0.04$) as well as antecedents of variceal hemmorhage ($p = 0.02$).
Conclusion: Management of suspected cases should be standardized and a close follow-up could prove useful since most of the patients are asymptomatic, to identify the appearance of complications such as neoplasia, liver decompensation and the optimal moment to include the patients for OLT. In Romanian patients with PSC that underwent LT the following scores can be accurately used in order to evaluate prognosis: PREsTo score in addition to MELD/MELD-Na as well as complications like recurrent cholangitis or upper digestive hemmorrhage.

THU-187

Landscape of gall bladder cancers in India: a 25 years experience at a tertiary care cancer centre

Rupal Tripathi[1], Anurag Mehta[1], Dinesh DovaL[1], K Rana[1]. [1]*Rajiv Gandhi cancer institute and research centre, DELHI, India*
Email: sinharupal@gmail.com

Background and aims: Gall bladder cancer has heterogenous etiology with the incidence rates increasing alarmingly in India and specially in the North Indian population. This has been chiefly attributable nto the cumulative effects of genetic, epigenetic and non-genetic modifiable factors. The present study aimed to assess the landscape of gall bladder cancers at a tertiary cancer care centre in India over a period of 25 years.
Method: All patients who enrolled in the Institute during the period 1996–2021 and diagnosed with gall bladder cancers were included in the study. Details of each patient related to their demographic profile, tumor characteristics and treatment information were recorded from the electronic medical records in the Institute.
Results: During the period 1996–2021, a total of 293262 patients were registered in the Institute. Of these, a total of 8625 patients were diagnosed with gall bladder cancer as the primary site of cancer. Among these, 5883 patients (68.2%) were females. Majority of the patients (2764) were in the age group of 50–59 years. The most common mode of diagnosis of disease was histology in 4271 patients. Chemotherapy or surgery alone was given in 1363 and 345 patients, respectively. Symptomatic treatment only was given in 931 cases whereas 5440 patients did not receive any kind of treatment and presented to the hospital for second opinion only.
Conclusion: The high incidence of gall bladder cancers in India and particularly in the North Indian population and mostly in the females again points to the pressing need for having cost-effective and affordable primary diagnostic tests to ease the diagnosis and management of gall bladder cancers in the rural and urban settings. Further, large scale molecular genomic studies would be required to understand the increasing incidence of this cancer, specially in the females and further explore more cost effective treatment strategies.

THU-188

Hydroxychloroquine as an adjuvant drug to immunosuppressive treatment to achieve histological remission in autoimmune hepatitis

Andreia Evangelista[1], Debora Raquel Terrabuio[1], Ana Luiza Vilar Guedes[2], Amanda Moreto[3], Eduardo Cancado[2]. [1]*Hospital das Clinicas da Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil;* [2]*Hospital das Clinicas da Faculdade de Medicina da USP, Sao Paulo, Brazil;* [3]*Hospital das Clinicas da Faculdade de Medicina da USP, Sao Paulo*
Email: andreia1179@yahoo.com.br

Background and aims: the standard treatment (ST) of AIH is the association of corticosteroids and azathioprine, however sustained remission rates occur only in 19–40%. Additionally, nearly 10% of patients experience side effects, with discontinuation of medications. These challenges highlight the need for new therapeutic options. To minimize the side effects of higher doses of immunosuppression (IS), we aimed to evaluate the role of adding hydroxychloroquine (HCQ) to the ST in AIH patients with biochemical remission and liver biopsy (LB) with persistent mild inflammatory activity.
Method: patients with AIH with normal levels of IgG, AST, ALT and liver biopsy with persistent discrete inflammatory activity. Patients were selected to add HCQ 400 mg to the ST and were non-randomly compared to historic controls in whom the IS was increased. These patients were reassessed for histological response 18–24 months after implementing this strategy.
Results: 24 patients were selected for the use of HCQ and were compared with 45 controls with standard treatment (Augmentation of IS, AIS). The rates of response were 62.5% and 64.4% ($p = 0.873$) in the HCQ and AIS group, respectively. The levels of IgG were lower in the HCQ group (1144×1335, $p = 0.029$). Four patients in the HCQ group and six patients in the IS group experienced side effects related to the use of HCQ and increased immunosuppression, respectively.
Conclusion: the addition of Hydroxychloroquine to ST, in patients with partially treated AIH, might be an effective and safety alternative to the increase of the IS.

THU-189

Optimization of treatment in patients with primary biliary cholangitis: Gamma-glutamyl transferase levels as an early prognostic marker for ursodeoxycholic acid response. Results from the ColHai registry

Flor M Fernandez-Gordón Sánchez[1], Sergio Rodriguez-Tajes[2], María Carlota Londoño[3], Álvaro Díaz-González[4], Margarita Sala Llinás[5], Manuel Romero-Gómez[6], Javier Martínez González[7], Judith Gómez- Camarero[8], Manuel Hernández Guerra[9], Mercedes Vergara[10], Tom Stephane Fournot[11], Raul J. Andrade[12], Silvia Goñi Esarte[13], Juan Turnes Vázquez[14], Montserrat García-Retortillo[15], Marina Berenguer[16], Elena Gómez-Domínguez[1]. *[1]12 de Octubre University Hospital, Madrid, Spain; [2]Clinic Hospital of Barcelona, Barcelona, Spain; [3]Clinic Hospital of Barcelona, Barcelona, Spain; [4]Marqués de Valdecilla University Hospital, Santander, Spain; [5]Dr. Josep Trueta Hospital, Girona, Spain; [6]Virgen del Rocio University Hospital, Sevilla, Spain; [7]Ramón y Cajal University Hospital, Madrid, Spain; [8]University Hospital of Burgos, Burgos, Spain; [9]University Hospital of the Canaries, La Laguna, Spain; [10]Parc Tauli University Hospital, Sabadell, Spain; [11]Hospital de la Santa Creu i Sant Pau, Barcelona, Spain; [12]Virgen de la Victoria University Hospital, Málaga, Spain; [13]University Hospital of Navarra, Pamplona, Spain; [14]Pontevedra University Hospital Complex, Pontevedra, Spain; [15]Hospital del Mar, Barcelona, Spain; [16]La Fe University and Polytechnic Hospital, Valencia, Spain*
Email: florfgs@hotmail.com

Background and aims: The early identification of non-responding patients with Primary Biliary Cholangitis (PBC) to ursodeoxycholic acid (UDCA) is crucial for prognosis. Elevated levels of gamma-glutamyl transferase (GGT) are associated with a poorer response to UDCA. Further evidence is needed to understand its predictive capacity and the impact of alcohol consumption. To analyze the predictive value of baseline, 6-month, and 1-year GGT elevation for UDCA response. Evaluate the impact of alcohol consumption on GGT levels and its predictive capacity. Establish GGT cutoff points to identify candidates for second-line therapies.
Method: A multicenter retrospective study from the ColHAI Registry with two cohorts of PBC patients treated with UDCA, classified as responders or non-responders (Paris II criteria).
Baseline, 6-month, and 1-year variables were compared. Subgroup analysis based on alcohol consumption. U-Mann-Whitney test and Youden Index for optimal cutoff points in ROC curve analysis.
Results: 617 patients included, average age 61 years. 59 responders to UDCA at 6 months and 364 at 1 year. Non-responders at both time points had significantly higher baseline GGT levels compared to responders (465 U/l vs. 53 U/l, 402 U/l vs. 136 U/l, $p < 0.01$). They also had higher GGT at 1 year (229 U/l vs. 108 U/l, $p < 0.01$), with no difference at 6 months.
In non-alcohol consumers (67.6%) who were non-responders, baseline (444 U/l vs. 132 U/l, $p < 0.01$) and follow-up GGT levels (243 U/l vs. 105.2 U/l, $p < 0.01$) were higher.
The cutoff point of baseline GGT at 124 U/l coincides in patients with follow-up at 6 months and annually (Sensitivity 71%, Specificity 43%, AUC 0.57 vs. Sensitivity 55%, Specificity 31%, AUC 0.43).
Cutoff points for GGT non-alcohol consumers (237.5 U/l baseline [Sensitivity 55%, Specificity 75%, AUC 0.65] and 58.5 U/l [Sensitivity 69%, Specificity 50%, AUC 0.60] at 6 months) and alcohol consumers (53.5 U/l [Sensitivity 100%, Specificity 33%, AUC 0.67] baseline and 40.5 U/l [Sensitivity 100%, Specificity 50%, AUC 0.75] at 6 months) to predict treatment response. No differences in predictive capacity between both groups.
Conclusion: GGT levels, regardless of alcohol consumption, are associated with a poorer response to UDCA in PBC patients. Useful baseline GGT cutoff points have been established in the early identification of non-responding patients to antiviral treatment for chronic liver diseases.

THU-190

Quantitative assessment of anti-mitochondrial antibodies in primary biliary cholangitis: a cross-sectional analysis

Lorenzo Canova[1], Elisabetta Degasperi[1], Maria Paola Anolli[1], Marta Borghi[1], Riccardo Perbellini[1], Sonia Stella[1], Pietro Lampertico[1,2]. *[1]Division of Gastroenterology and Hepatology, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]CRC "A. M. and A. Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy*
Email: pietro.lampertico@unimi.it

Background and aims: Quantitative assessment of anti-mitochondrial antibodies (AMA)-M2 is available in primary biliary cholangitis (PBC), however its clinical meaning is still unknown. Aim of the study was to analyse quantitative AMA-M2 in PBC patients and its correlation with clinical features.
Method: PBC patients from a single Italian centre with available quantitative AMA-M2 values were included in a cross-sectional analysis. PBC was diagnosed according to international recommendations. Clinical and biochemical features were collected ± 3 months from AMA assessment. AMA was tested by chemioluminescence immunoassay (CLIA) (range 0–3000 AU/ml).
Results: Overall, 92 PBC patients (87% females) were included. At AMA assessment, median age was 67 (39–93) years, ALT 30 (8–258) U/L, ALP 0.7 (0.2–4.4) ULN, 38% patients with ALP > 1.5 ULN, gGT 1.44 (0.2–14.3) ULN, IgM 237 (39–1, 037) mg/dl, liver stiffness measurement (LSM) 5.9 (3.9–38.6) kPa, 23% with advanced fibrosis (Stage III-IV Ludwig). Median PBC duration was 89 (1–433) months, 91% UDCA-treated, 19% UCDA non-responder. Overall, in the 49 (53%) patients with quantifiable AMA, median value was 319 (20–2500) AU/ml, AMA-M2 tested >3000 AU/ml in 43 (47%) patients. No statistically significant differences were observed between patients with AMA titers above *vs.* below 3000 concerning: age ($p = 0.18$), sex ($p = 0.31$), BMI ($p = 0.34$), advanced fibrosis stage ($p = 0.55$), LSM values ($p = 0.73$), disease duration ($p = 0.78$), UDCA response ($p = 0.45$), ALT ($p = 0.97$), ALP values ($p = 0.78$) and ALP ULN categories (<1.5 ULN *vs.* 1.5–2.0 ULN *vs.* >2 ULN, $p = 0.84$), gGT ($p = 0.49$) and IgM ($p = 0.84$) values. The same was true when AMA values were analyzed according to multiple thresholds (AMA <300 *vs.* 300–1000 *vs.* 1000–3000 *vs.* >3000). Conversely, in patients with AMA<3000, male sex was associated with lower AMA-M2 values (56 *vs.* 426, $p = 0.02$).
Conclusion: In UDCA-treated PBC patients, lower AMA-M2 levels were associated with male gender, while they did not correlate with other clinical or disease features.

THU-191

Impact of ursodeoxycholic acid therapy in autoimmune liver disease patients with COVID-19 and its clinical prognosis

Minghui Li[1], Weihua Cao[2], Tingting Jiang[2], Wen Deng[2], Shiyu Wang[2], Shuling Wu[2], Lu Zhang[2], Yao Lu[2], Min Chang[2], Ruyu Liu[2], Xiaoyan Ding[2], Ge Shen[2], Yuanjiao Gao[2], Hongxiao Hao[2], Xiaoxue Chen[2], Leiping Hu[2], Mengjiao Xu[2], Yuyong Jiang[2], Wei Yi[2], Yao Xie[2], Rui Song[2]. *[1]Beijing Ditan Hospital, Capital Medical University, Peking University Ditan Teaching Hospital, Beijing, China; [2]Beijing Ditan Hospital, Capital Medical University, Beijing, China*
Email: songruii@hotmail.com

Background and aims: To explore impact of ursodeoxycholic acid (UDCA) on COVID-19 infection and clinical outcomes in patients with autoimmune liver disease (AILD).
Method: Patients diagnosed with of AILD were enrolled and divided into UDCA group and non-UDCA group based on whether they received UDCA treatment. Relevant data regarding AILD diagnosis, treatment, biochemical indicators, imaging examination were collected. Incidence and prognosis were observed in COVID-19 infected patients.
Results: 1138 patients completed follow-up. Usage rate of hormone ($p = 0.003$) and immunosuppressant ($p = 0.001$) used for treating AILD in non-UDCA group was markedly lower than that in UDCA group. UDCA usage rate was markedly lower in COVID-19 infected

patients than uninfected ones (p = 0.003). The rate of COVID-19 infection in non-UDCA group was significantly higher than that in UDCA group (p = 0.018). Logistic regression analysis showed that UDCA use (p = 0.003) was correlated to a lower incidence of COVID-19, while immunosuppressant use (p = 0.017) increased the incidence. Recovery time from COVID-19 infection was markedly longer for those receiving UDCA treatment than those in the non-UDCA group (p = 0.018).
Conclusion: Using UDCA is associated with low COVID-19 incidence in AILD patients, while using immunosuppressant increases its incidence instead. Patients receiving UDCA treatment have a longer recovery time after being infected.

THU-192
Liver steatosis assessed by controlled attenuation parameter in patients with primary biliary cholangitis
Francesca Bueti[1], Maria Stella Franzè[1], Concetta Pitrone[1], Gaia Caccamo[2], Irene Cacciola[1], Roberto Filomia[2], Sergio Maimone[2], Giovanni Raimondo[1], Carlo Saitta[1]. *[1]Division of Medicine and Hepatology, Department of Clinical and Experimental Medicine, University Hospital of Messina, Messina, Italy; [2]Division of Medicine and Hepatology, University Hospital of Messina, Messina, Italy*
Email: csaitta@unime.it

Background and aims: Primary biliary cholangitis (PBC) is a chronic inflammatory autoimmune cholestatic liver disease frequently associated with hyperlipidemia. However, the impact of steatosis on the liver disease in PBC patients has not been studied so far. Aim of the study was to investigate liver steatosis [assessed by controlled attenuation parameter (CAP)] and its relationship with liver stiffness (LS) [evaluated by transient elastography (TE)] in patients with PBC.
Method: All patients with PBC admitted to the Unit of Medicine and Hepatology of the University Hospital of Messina in 2023 underwent contemporaneous LS and CAP measurements. Demographic, anthropometric, biochemical, ultrasonographic data, and treatment information were collected from all patients. The Spearman's rank test was used for analyzing the correlation between CAP values and all the recorded variables. Uni- and stepwise multivariate analyses were performed for identifying factors independently associated with higher liver stiffness values.
Results: Seventy-four patients (68 females, 6 males; mean age 61.3 ± 11.3 years) under ursodeoxycholic acid treatment for at least twelve (range 12–233) months were included in the analysis, and 14 of them (18.9%) had cirrhosis. Mean liver stiffness was 9.1 ± 6.9 kPa, mean CAP values were 228.5 ± 55.7 dB/m. Ultrasonographic signs of steatosis were present in 70/74 (94.6%) patients, mean BMI was 25.7 ± 4.2 Kg/m^2. The Spearman's rank test showed significant correlation between CAP values and BMI (p < 0.05), IgM levels (p < 0.05), and liver stiffness (p = 0.01). Multivariate analysis showed that higher gamma-globulin levels (p = 0.002, OR 4.73), larger spleen diameter (p = 0.004, OR 1.02), and higher CAP values (p = 0.02, OR 3.11) were independently associated with higher liver stiffness values.
Conclusion: Liver steatosis is highly prevalent in patients with PBC and appears to impact on liver stiffness.

Liver development and regeneration

Metabolic needs dictate the regenerative capacity of the liver
Sara Guerra[1], Dominique L. Birrer[1], Udo Ungethuem[1], Pierre A. Clavien[2], Humar Bostjan[1]. *[1]Visceral and Transplantation Surgery Laboratory, University Hospital Zurich, Zurich, Switzerland; [2]Privatklinik Bethanien, Zurich, Switzerland*
Email: Saralsabel.DaSilvaGuerra@usz.ch

Background and aims: The liver's regenerative capacity is exceptional, but not unlimited. The metabolic duties may be one key factor impeding the proliferative abilities of hepatocytes after tissue loss. To substantiate this view, we exploited a model of accelerated regeneration induced by ALPPS surgery (associating portal vein ligation with transection), a procedure that retains portally ligated lobes (LLs) *in situ*. We sought to explore whether LLs function as auxiliary livers, thereby enabling the future liver remnant to fully focus on regeneration.
Method: Mice were separated into groups undergoing either sham or ALPPS surgery. Sham liver, the future liver remnant (FLR), and the adjacent ligated right median lobe (RML) were individually subjected to omics analysis, including metabolomics, lipidomics, and transcriptomics. A functional surgery approach to test the role of LLs was devised by creating ALPPS variants with loss or gain of ligated volume. Immunochemistry was applied to validate omics data and functional surgery outcomes.
Results: Untargeted PCA metabolomics analysis at 4 h and 8 h post-surgery highlighted increased metabolic activities after ALPPS, with a clear distinction between the FLR and the RML specifically during the growth phase. The FLR and RML exhibited heightened energy demands fueled by active lipid oxidation. However, activities related to cell cycle and proliferation were upregulated explicitly in the FLR, whereas the RML was enriched with typical metabolic liver functions such as gluconeogenesis, glycogen synthesis, bile acid metabolism, bilirubin clearance, xenobiotic detoxification, and synthetic function. Functional surgery demonstrated a full dependence of the FLR's regenerative speed on the presence of ligated lobes.
Conclusion: Metabolic pressure during liver regeneration is managed differently by the ligated RML and the FLR. We find that the LLs act as an auxiliary liver in the ALPPS regeneration process. Taking over key metabolic functions, the LLs are needed to unleash the full regenerative capacity of the FLR, as is reflected in accelerated regeneration. This transient macroscopic division of tasks roots on plastic behavior of the different lobes during ALPPS regeneration and reveals how metabolic needs dictate the liver's regenerative capacity.

Trained immunity contributes to immunomodulatory plasticity of human bone marrow mesenchymal stem cells
Bingqi Li[1], Xi Liang[2], Jing Jiang[1], Jiaojiao Xin[1], Dongyan Shi[1], Shiwen Ma[1], Hui Yang[1], Xingping Zhou[1], Jiaxian Chen[1], Jun Li[1]. *[1]State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, National Clinical Research Center for Infectious Diseases, National Medical Center for Infectious Diseases, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China; [2]Precision Medicine Center, Taizhou Central Hospital (Taizhou University Hospital), Taizhou, China*
Email: lijun2009@zju.edu.cn

Background and aims: The immunoregulatory role of human bone marrow mesenchymal stem cells (hBMSCs) is crucial for addressing cytokine storms associated with severe liver diseases. However, the intricate immune microenvironment in vivo poses challenges to the survival and functions of hBMSCs. Trained immunity has been proved to improve the adaptability of immune cells and therapeutic effect. This study aims to enhance the immunoregulation of hBMSCs by trained immunity to optimize stem cell therapy strategies.
Method: Trained immunity was induced in hBMSCs (T-hBMSCs) by exposing them to pro-inflammatory cytokines IFN-γ and TNF-α as "trainers" for 24 hours, while untrained-hBMSCs (UT-hBMSCs) were treated with medium as control. Subsequently, the cells were assessed using the same "trainers" or patient serum derived from acute-on-chronic liver failure (ACLF) after 48 hours of cleaning. Flow

cytometry, qRT-PCR, and transcriptome analysis were conducted using cell samples.
Results: The surface markers of T-hBMSCs detected by flowcytometry were positive for CD73, CD166 and CD90, but negative for CD45, CD34 and CD79a, which was consist with UT-hBMSCs. Trilineage differentiation of hBMSCs after training remained unaffected. Pro-inflammatory genes (IL-1β, IL-6 and IL-8, all $p < 0.0001$) and immunosuppressive genes (PDL-1 and IDO, both $p < 0.0001$) expressed in T-hBMSCs were higher than UT-hBMSCs. After 48 hours cleaning, the expression of immunomodulatory genes especially IDO remained significantly higher, while the expression levels of inflammatory genes especially IL-1β gradually returned to baseline in T-hBMSCs. The results revealed a significant increase in IDO expression in T-hBMSCs compared to UT-hBMSCs upon restimulation with the same dosage of "trainers" or ACLF patient-derived serum (5-fold vs. 4606-fold, both $p < 0.0001$). Transcriptome analysis detected a total of 1041 genes with significantly up-regulated expression and 827 genes with significantly down-regulated expression in T-hBMSCs compared to UT-hBMSCs. Gene set enrichment analysis revealed that trained immunity activated NF-kB signaling pathway, which is associated with innate immune responses, and subsequently induced JAK-STAT pathway in T-hBMSCs causing an increase in IDO expression. The higher expression level of IDO inhibited the proliferation and activation of T lymphocytes, thereby enhancing the immunoregulatory function of T-hBMSCs.
Conclusion: Trained immunity enhances the immunoregulation function of hBMSCs and contributes to optimize stem cell therapy strategies, indicating the potential clinical applications of T-hBMSCs in the future.

FRI-547-YI
Regenerative matrix-based hydrogels repair hepatocellular damage and promote cellular proliferation in pre-clinical models of acute liver injury

Email: dineshmanitripathi@gmail.com

Background and aims: Acute liver injury is detrimental due to massive hepatocyte damage accompanied by impaired liver functions. In this study, we investigate the potential of regenerative liver extracellular matrix (LEM-PHx) to alleviate acute liver injury in experimental animal models.
Method: 70% partial hepatectomy rat models were developed and decellularized post 96hrs to obtain LEM-PHx. ECM based hydrogels were prepared by blending the matrix proteins with 3% alginate in 1:1 ratio and were characterized by FTIR. Rheological assessment, swelling properties of the hydrogels in vitro were studied. Primary hepatocytes were cultured in the hydrogels for up to 21 days. Fabricated hydrogels were transplanted into subcapsular region of liver 24 hrs post single injection of CCL_4 (Alg-LEM = control liver ECM; Alg-LEM-PHx = PHx liver ECM; Alg = Alginate only, vehicle). The efficacy of the transplanted hydrogels was assessed in serum and by histopathological staining and molecular analysis was performed.
Results: HandE staining, DAPI staining, and DNA quantification confirmed acellularity of the decell tissues. All fabricated alginate-based hydrogels showed gelation at 37°C within 10 mins in the presence of 100 mM $CaCl_2$. FTIR analysis showed specific peaks for collagen and proteoglycans only in Alg-LEM and Alg-LEM-PHx. Rheological assessment showed shear thinning behavior of Alg-LEM and Alg-LEM-PHx upon increasing stress, which is ideal for injectable hydrogels. Primary hepatic organoids in Alg-LEM-PHx showed increase in organoid diameter size ($p < 0.05$) with increased albumin secretion ($p < 0.05$) up to 21 days compared with the organoids in Alg-LEM group. Immunocompatibility of the hydrogels was assessed by blood profiling of control vs implantation group in FACS, Σ67% vs Σ62.83%T-cells; Σ13.7% vs Σ11.8% monocytes; Σ1.28% vs Σ1.25% dendritic cells. Transplanted liver lobes showed reduction in injury and oxidative damage to the hepatocytes at the centrilobular region. Liver function improved significantly post LEM-PHx transplant (AST Σ150 IU/L; ALT Σ95 IU/L; $p < 0.05$) when compared to vehicle group (AST Σ300 IU/L; ALT Σ145 IU/L). Cell cycle genes Cyclins A, E (+2fold, +4fold; $p < 0.005$) and PCNA (+3fold; $p < 0.05$) and growth factors like HGF (+1.5fold; $p < 0.05$) were significantly upregulated vs vehicle. PCNA-positive proliferating hepatocytes were increased in LEM-PHx group (35 ± 8 cells/field; $p < 0.5$ vs Veh). Proinflammatory genes Tlr4 and IL6 (−6.5fold, −2.5fold; $p < 0.05$ vs Veh) were downregulated, whereas anti-inflammatory genes IL10, SOD (+1.5fold, +2fold; $p < 0.05$ vs Veh) were upregulated in Alg-LEM-PHx.
Conclusion: Regenerative extracellular matrix incorporated alginate hydrogel developed in this study demonstrates reduction in injury and hepatocyte damage and promotes hepatocyte proliferation during acute liver injury serving as a potential adjuvant for regenerative therapy.

FRI-548
Lysosomal protease contributes to hepatocyte proliferation during liver regeneration after partial hepatectomy
Julia Cacho-Pujol[1,2], Paloma Ruiz-Blazquez[1,2,3,4], Maria Fernandez-Fernandez[1,2,3,4], Alejandro del Castillo-Cruz[5], Anna Moles[1,3,4]. *[1]Institute of Biomedical Research of Barcelona (IIBB-CSIC), Barcelona, Spain; [2]University of Barcelona, Barcelona, Spain; [3]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain; [4]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Barcelona, Spain; [5]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona*
Email: anna.moles.fernandez@gmail.com

Background and aims: Liver regeneration is a biological process essential for the restoration of liver mass, homeostasis and function after an injury. During liver regeneration, proteolytic activity is timely regulated in infiltrating and liver resident cells. Protease expression depends on the cellular demands and participates in apoptosis, proliferation and activation and repression of growth factors, amongst others. Despite our growing understanding of the roles played by lysosomal proteases during liver disease, our knowledge of their role in liver regeneration remains still very limited. Thus, the aim of this study was to analyse cathepsin D (CtsD) cell-specific role in hepatocytes during liver regeneration.
Method: We generated and validated a novel knock-out mouse strain by breeding Albumin-Cre (hepatocytes) mice with CtsD floxed mice. Partial hepatectomy (PhX) was performed for 72 hours in $CtsD^{F/F}$ and $CtsD^{\Delta Hep}$ mice. CtsD deletion was assessed by IF and RTqPCR. Liver damage was determined by serum ALT. CtsD activity was determined by an enzymatic assay. Mitotic bodies and BrdU positive cells were analysed and quantified in liver tissue sections using Fiji software. Expression of apoptotic and cell cycle markers was determined by RT-qPCR and/or WB in total liver in $CtsD^{F/F}$ and $CtsD^{\Delta Hep}$ mice at T = 0 and T = 72 h after PhX.
Results: CtsD cell-specific deletion in hepatocytes was confirmed by WB in primary isolated hepatocytes and IF in liver tissue sections from $CtsD^{\Delta Hep}$ mice. Of note, CtsD expression remained unaffected in liver non-parenchymal cells in $CtsD^{\Delta Hep}$ mice. Next, PhX was performed for 72 h in $CtsD^{F/F}$ and $CtsD^{\Delta Hep}$ mice and CtsD deletion

was confirmed by gene expression and IF in liver. Despite CtsD deletion in hepatocytes did not affect liver damaged (ALT), liver BrdU incorporation was significantly increased in CtsD$^{\Delta Hep}$ mice after PhX indicating an increase in cell proliferation. However, neither the hepatic regeneration rate nor the number of mitotic bodies was affected. Gene expression and WB analysis of PhX livers revealed a significant increase of genes involved in proliferation and cell cycle, such as FoxMB1, Cyclin B1 and NEK2, without changes in apoptotic genes (BCL2, NOXA, BAK1 and FADD) in PhX-CtsD$^{\Delta Hep}$ mice versus PhX-CtsD$^{F/F}$ ones.
Conclusion: CtsD contributes to the control of hepatocyte proliferation and cell cycle during liver regeneration after partial hepatectomy.

FRI-549-YI
Hepatic loss of the endosomal sorting complex Retromer delays postnatal liver maturation and increases hepatocellular proliferation
Markus Gregorio Barbosa[1], Dyonne Vos[1], Andries Heida[1], Mirjam Koster[1], Vincent Bloks[1], Niels Kloosterhuis[1], Marieke Smit[1], Laura Bongiovanni[2], Dicky Struik[1], Johan Jonker[1], Jan Albert Kuivenhoven[1], Bart van de Sluis[1]. Email: m.g.barbosa@umcg.nl

Background and aims: Liver cancer, and more specifically hepatocellular carcinoma (HCC), are respectively the third and sixth most common cause of cancer death worldwide. The increasing incidence of HCC in Western countries can be attributed to the growing prevalence of metabolic dysfunction-associated steatotic liver disease (MASLD). Patients with HCC have a poor prognosis due to late diagnosis and lack of effective medical treatments. Efforts to mitigate the rising prevalence of MASLD and enhance early detection strategies are critical in addressing the burden of HCC and improving patient outcomes. Recent studies have identified VPS35 as a novel oncogene. VPS35, a component of an endosomal protein sorting complex, plays a central role in the endosomal recycling of receptors and hereby it can modulate numerous signalling pathways.
Method: To study the role of VPS35 in the development of hepatocellular carcinoma (HCC), we generated a liver-specific *Vps35* knock-out mouse model using the Cre-LoxP system (*Vps35*^{HKO}). We characterized these mice at different ages. Using immunohistochemical staining we studied the level of hepatocellular proliferation. Gene expression, kinome, and western blot analyses were performed to elucidate the pathways underlying the effect of VPS35 deficiency on hepatocellular proliferation.
Results: Using the proliferating markers BrdU and Ki67 we showed that the level of hepatocellular proliferation is increased in hepatocyte VPS35-deficient mice compared to control mice. The increased expression of several proliferating markers, such as *Spp1*, *Hnf4a-p2, Sox9,* and cell cycle genes, support the increase in hepatocellular proliferation upon VPS35 ablation. Interestingly, the expression of *Albumin* (*Alb*) and *Hnf4a-p1* isoform, both markers for differentiated hepatocytes, were markedly decreased. TUNEL assay showed that the level of apoptosis is not changed between control and liver-specific VPS35-deficient mice. Kinome analysis indicated that activity of various tyrosine kinases (TK), including, EGFR and SRC, were increased in *Vps35*^{HKO} mice compared to control mice. This increase in TK activity was accompanied by higher activation of the STAT3 signalling pathway. Remarkably, at the age of 26 weeks, hepatic VPS35 ablation did not affect the level of hepatocellular proliferation.
Conclusion: In contrast to previous studies, we here show that VPS35 inhibits hepatocellular proliferation and mediates the maturation of the postnatal liver. Our data suggest that the loss of VPS35 results in hyperactivation of several TKs, including TKs that are activated in HCC. We are currently studying the effect of VPS35 ablation on carcinogen-induced HCC development in mice.

Email: sminocha@bioschool.iitd.ac.in

Background and aims: Effective liver homeostasis and regeneration require dynamic regulation of gene expression, often compromised in metabolic dysfunction-associated liver disease (MASLD). Host Cell Factor 1 (HCF-1), a conserved transcriptional co-regulator encoded by the X-chromosome linked *Hcfc1* gene, plays a crucial role in liver function. Despite its implication in various cellular processes, its impact on the epigenome remains underexplored. Our prior research demonstrated that hepatocyte-specific loss of HCF-1 induces non-alcoholic fatty liver disease (NAFLD) progression to non-alcoholic steatohepatitis (NASH) (Minocha, S. *et al. Mol. Cell. Biol.* 39, (2019).). This study aims to unravel the epigenetic changes in murine liver upon induced hepatocyte-specific loss of HCF-1, elucidating its role in hepatic metabolism and epigenetic integrity.
Method: Tamoxifen-induced hepatocyte-specific HCF-1 knockout (*Hcfc1*^{hepKO}) was validated in mice, followed by 70% partial hepatectomy (PH) to induce liver regeneration. Liver tissue collected at specific time points underwent immunostaining and immunoblotting. Chromatin immunoprecipitation and high throughput sequencing (ChIP-Seq) analysed chromatin from tamoxifen-treated mice, identifying enrichment regions with MACS2. Differential peaks were determined using HOMER and BEDTools. Gene ontology and pathway analysis interpreted ChIP-Seq results.
Results: HCF-1 levels increased post-PH in *Hcfc1*$^{lox/Y}$ mice, emphasizing its role in hepatocyte re-entry into the cell cycle for regeneration. HCF-1-negative hepatocytes lacked proliferation capacity, while HCF-1-positive cells exhibited robust regeneration. ChIP-Seq showed altered gene expression patterns, indicating disturbances in the hepatic epigenetic landscape. Dysregulated genes involved in diverse cellular processes highlighted HCF-1's impact on overall hepatic gene expression.
Conclusion: This study unveils HCF-1's role in NAFLD pathogenesis, showcasing its impact on liver damage, epigenetic modifications, and transcriptional regulation. By understanding HCF-1's role in NAFLD pathogenesis, hepatic regeneration, and epigenomic regulation, this research contributes new insights to liver health and disease mechanisms.

Email: 15779729700@163.com

Background and aims: As the only regenerative parenchymal organ, the secret of liver regeneration is interesting and far from being revealed. β-arrestin2 (ARRB2) is a ligand of G protein-coupled

receptor, which is thought to involved in a variety of physiological and pathological biological processes. In this study, we aimed to clarify the role of ARRB2 in liver regeneration after hepatectomy and investigate the underlying mechanisms.

Method: Liver samples from patients undergone associating liver partition and portal vein ligation for staged hepatectomy (ALPPS) were obtained to evaluate the correlation between ARRB2 and liver regeneration. ARRB2 knockout (*Arrb2*-/-) mice and wild type littermates were used to establish 70% partial hepatectomy model to determine the exact role of ARRB2 during liver regeneration. In addition, the underlying mechanisms and clinical translation value were further explored.

Results: ARRB2 was found positively correlates with proliferative level of hepatocytes in patients undergone ALPPS. The kinetics of changes in ARRB2 during liver regeneration after hepatectomy in mice was consistent with the trend of hepatocyte proliferation, and knockout of ARRB2 significantly inhibited but not only delayed liver regeneration. In addition, ARRB2 promoted hepatic regeneration in a YAP- dependent way. The regulation of YAP by ARRB2 is not dependent on canonical Hippo signaling, but on the remodeling of cytoskeletal F-actin. Mechanistically, ARRB2 upregulated Diaph2 by coupling RhoA to promote actin polymerization, thereby promoting YAP translocate into nucleus and initiating the transcription of involved proliferation genes. Moreover, β-receptor blocker carvedilol that up-regulates ARRB2 remarkably promoted liver regeneration after hepatectomy in mice.

Conclusion: Our results demonstrated that ARRB2 plays a key role in liver regeneration after hepatectomy, which activates YAP by regulating actin cytoskeleton polymerization to promote hepatocyte proliferation.

FRI-554

Development of in vitro human organoid models for metabolic dysfunction-associated liver disease (MASLD)

Simran Sharma[1], Ashwini Vasudevan[1], Pooja Bhadoria[2], Ajeet Bhadoria[2], Savneet Kaur[1]. *[1]Institute of Liver and Biliary Sciences, Vasant Kunj, Delhi, India; [2]All India Institute of Medical Sciences, Rishikesh, India*
Email: savykaur@gmail.com

Background and aims: Organoid systems recapitulate in-vivo organ architecture and help to model complex pathologies. The present research work aims at developing in-vitro organoid model for metabolic dysfunction associated liver disease (MASLD) using human fetal liver cells.

Method: Primary hepatocytes were isolated from aborted human fetal liver samples (n = 5). Viable primary hepatocytes were mixed with Matrigel (Corning), in a 30 µL dome (seeding density 30, 000–50, 000 cells/well). The organoid media contained a growth factor cocktail with Acetylcysteine, Gastrin, Nicotinamide and Forskolin. After 7 days of cell seeding and culture, the hepatic organoids were given free fatty acid (FFA) (4 mM palmitic acid) and sugar (25 mM sucrose) insult for 72 hrs. The study groups were designated as Gr1- PBS; Gr2- FFA only; Gr3- Sugar only; Gr4- FFA + Sugar. The developed MASLD organoids were assessed for viability with Calcein and Sytox staining and functional characteristics post insult with BODIPY-lipid staining, RT-PCRs and ELISAs.

Results: The human fetal hepatocyte organoids showed significant increase in organoid diameter (from 35.4 ± 2 µm to 112.8 ± 2 µm; $p < 0.0001$) from day 0 to day 7. After day 7, the organoids were given different types of insult and studied at 72hrs post insult. There was no significant difference in the diameter of organoids between Gr1 and Gr3. However, as compared to Gr1, in Gr4, the diameter of the organoids was significantly decreased (120.2 ± 4 µm vs ±2 µm 90.8 ± 10 µm, $p < 0.0001$) at day 3 post insult. The viability of the organoids decreased in all the groups vs Gr1 ($p < 0.05$ each). Accumulation of lipid-rich bodies were clearly observed in brightfield imaging in Gr2 and 4, Gr3 did not show much lipid accumulation. We also validated this observation with BODIPY staining, (34 ± 5 positive organoids/field in Gr4 vs 18 ± 3 positive cells/field in Gr3; $p < 0.05$). RT-PCR analysis of the organoids post insult of Gr4 vs Gr1 organoids, showed increased expression of inflammatory markers such as IL-6 (+2.5 fold, $p < 0.05$) and Serum Amyloid A4 (SAA4) (+1 fold, p = NS). Hepatic functional markers, such as Albumin (−1.5 fold, $p < 0.05$) and CYP3A4 (−0.5 fold, p = NS) reduced in Gr4 vs Gr1. This observation was also confirmed with human rat albumin specific ELISA (albumin levels from organoid conditioned media 5 ± 2 ug/ml Gr4 vs 72 ± 3 ug/ml Gr1, $p < 0.001$).

Conclusion: The study showed that a combined insult of both sugar and fat to human fetal hepatocyte organoids results in a robust model of MASLD with attributes similar to human disease including steatosis and increase in pro-inflammatory cytokine gene expression. The developed human MASLD organoids may serve as excellent models for drug screening and testing applications.

Email: maavila@unav.es

Background and aims: Liver regeneration is essential for the preservation of homeostasis and survival. Bile acids (BAs)-mediated signaling is necessary for liver regeneration, but BAs levels need to be carefully controlled to avoid hepatotoxicity. We studied the early response of the BAs-fibroblast growth factor 19 (FGF19) axis in healthy patients undergoing hepatectomy for living donor liver transplant. We also evaluated BAs synthesis in mice upon partial hepatectomy (PH) and acute inflammation, focusing on the regulation of cytochrome-7A1 (CYP7A1), the rate-limiting enzyme in BAs synthesis from cholesterol.

Method: Serum was obtained from twelve human liver donors. Mice underwent 2/3 PH or sham-operation. Acute inflammation was induced with bacterial lipopolysaccharide (LPS) in mice fed control or antoxidant-supplemented diets. BAs and 7alpha-hydroxy-4-cholesten-3-one (C4) levels were measured by HPLC-MS/MS; serum FGF19 by ELISA. Gene expression and protein levels were analyzed by RT-qPCR and western-blot.

Results: After PH, serum BAs markedly increased. In patients with higher serum BAs levels FGF19 concentrations transiently rose, while

C4 levels (a readout of liver CYP7A1 activity) dropped 2 h post-resection in all cases. Serum BAs and C4 followed the same pattern in mice 1 h after PH, but surprisingly C4 levels also dropped in sham-operated and LPS-treated animals, without marked changes in CYP7A1 protein levels. LPS-induced serum C4 decline was attenuated in mice fed antioxidant-supplemented diet.
Conclusion: In human liver regeneration, FGF19 upregulation may constitute a protective response from BAs excess. Our findings suggest the existence of post-translational mechanisms regulating CYP7A1 activity, and therefore BAs synthesis, independent from *Cyp7a1* gene transcription.

Background and aims: The absence of accurate prognostic indicators contributes to the ongoing challenge of hepatocellular carcinoma (HCC), resulting in high mortality rates and poor prediction of the recurrence and survival. There has been limited researches exploring the relationship between small nucleolar RNAs (snoRNAs) and HCC. Studies have previously demonstrated that the expression of both SNORA47 and SNORD126 has been altered or dysregulated in liver cancer tissue. In HCC, siRNA transfection suppresses SNORA47, decrease cell invasion, proliferation, and metastasis by modifying an epithelial-mesenchymal transition. Conversely, increased SNORD126 levels have been associated with HCC, contributing to increased cell division. Our aim of study is to provide a better understanding of how snoRNA expression affects patient's outcome in non-viral HCC.
Method: We analyzed HCC and non-tumor adjacent tissue from 35 patients who had undergone resection in Pilsen University hospital between 1997 and 2019. Using q-PCR, we assessed the expression levels of specific snoRNAs namely SNORA47 and SNORD126. Patients were categorized into low and high expression groups based on the median expression of SNORA47 and SNORD126. We then conducted Kaplan-Meier analysis to assess the association of SNORA47 and SNORD126 expression levels with patient outcomes: time to recurrence (TTR), disease-free survival (DFS) and overall survival (OS).
Results: SNORA47 expression was higher in tumor tissue than in non-tumor adjacent tissue. In contrary SNORD126 expression was lower in tumor tissues compared to non-tumor adjacent tissue. Low expression of SNORA47 was associated with longer TTR ($p = 0.03$) and DFS ($p = 0.04$). Whereas low expression of SNORD126 was associated with longer TTR ($p = 0.05$) but not DFS. The combination of SNORA47-SNORD126 low expression was linked to longer TTR and DFS ($p = 0.01$ and 0.02 respectively). Furthermore, there was no association seen between expression and OS. No Correlations with clinical data was observed.
Conclusion: The findings suggest that SNORA47 and SNORD126 show potential as a promising prognostic marker in non-viral HCC. The analysis revealed that the combination analysis provides better prediction than alone for assessing the prognosis of non-viral HCC patients.

Oncogenic beta-catenin is using CD155 as a molecular actor to corrupt immunosurveillance of cold HCC
Joana Gonçalves Araujo[1], Céline Pophillat[1], Angélique Gougelet[1], Stefano Caruso[2], Mathilde Cadoux[3], Jing Fang[1], Isabelle Galy-Fauroux[4], Julien Calderaro[5], Akira Shibuya[6], Severine Morizur[1], Manon Allaire[7], Jessica Zucman-Rossi[1], Chantal Desdouets[1], Jean-Pierre Couty[1]. *[1]Centre de Recherche des Cordeliers, INSERM U1138, Paris, France; [2]INSERM U955, Créteil, France; [3]Cherry Biotech, Montreuil, France; [4]Centre de Recherche des Cordeliers, INSERM U1138, Paris; [5]Henri Mondor University Hospital, Créteil, France; [6]University of Tsukuba, Tsukuba, Japan; [7]Groupe Hospitalier Pitié-Salpétrière, Paris, France*
Email: joana.araujo@inserm.fr

Background and aims: Hepatocellular carcinoma (HCC) belongs to the poor prognosis cancers and is the 3rd most common cause of cancer-related death. Therapies are very limited but immunotherapy (anti-PDL1 + anti-VEGF) is now the first-line treatment for HCC, with only 20% of responders. HCC tumors harboring CTNNB1 activating mutations (30% of all HCCs), constitute a specific entity of cold tumors that fail to respond to immunotherapy. Our team evidenced that oncogenic beta-catenin signaling in hepatocytes subverts the immune system. We found that invariant NKT (iNKT) cells, have a strong anti-tumor potential that diminishes during tumorigenesis. Our recent data also demonstrated that beta-catenin signaling corrupts immune recognition of tumor hepatocytes through the extinction of NKG2D ligand expression. We extended the analysis to other receptor-stress ligand pairs, notably the CD226/CD155 couple. CD226 expression on the surface of CD8+ and NKT cells has recently been shown to reflect the cytotoxic potential of these cells and is a prerequisite for immunotherapy in other cancers. Its ligand CD155 is expressed by tumor cells subjected to various stresses and its expression is associated with a poor patients' prognosis. However, its involvement during Ctnnb1-induced tumorigenesis is still elusive.
Method: Cohort of HCC patients (N = 500), beta-catenin-HCC mouse models: 1) preneoplastic $Apc^{Delta\text{-}Hep}$ (activation of Wnt/beta-catenin pathway in all hepatocytes) 2) spontaneous CTNNB1-mutated, Lpk-c-myc tumors. These mice were crossed with CD226-KO mice. Technologies used: RNA-Seq, FACS, IHC, RTqPCR, Western Blot, ChIp-Seq/ATAC-Seq.
Results: Our study provides molecular evidence that CD226 is an important player in HCC immunosurveillance as we show: 1) in all human HCC subgroups that transcriptional expression of CD155 is increased as its cognate receptor CD226 is downregulated, 2) CD226 expression holds per se a prognostic value for 5-year overall survival, 3) using a model of CTNNB1-mutated HCC an upregulation of CD155 ligand expression in tumors associated with a loss of CD226 expression in iNKT cells, reducing their cytotoxic potential, 4) an exacerbation of tumorigenesis in a CD226-KO mouse model with the emergence of metastasis, 5) that in a forced beta-catenin activation model, a decrease in CD226 expression on iNKTs both dependently and independently of the interaction with its ligand CD155, provoking a reduction of their cytotoxic potential, 6) through ChIP-seq/ATAC-seq analyses that CD155 is a positive target of beta-catenin signaling.
Conclusion: Altogether, our study reveals that beta-catenin drives CD155 expression to subvert CD226-mediated immunosurveillance

in iNKT through the sustained interaction of the CD155 with CD226 receptor.

Deciphering the immunological dynamics of flares following nucleos (t)ide analogue (NA) cessation in HBeAg negative chronic hepatitis B in a large, longitudinal, phase II multi-centred clinical trial (NUC-B study)

Sandra Phillips[1,2], Sameer Mistry[1,2], Nicola Harris[1,2], Dimple Zope[1,2], Celia Moore[3], Gareth Hahn[3], Michelle Rosario[3], Camilla Carr-Smith[4], Maria Cortes Carrillo[4], Lavanya Elangovan[5], Kosh Agarwal[4], James Hand[5], Chris Sivell[5], Patrick Kennedy[5], Susan Congreave[6], Mathew Barnes[6], Stephen D. Ryder[6], Mariam Habib[3], Mark R. Thursz[3], Shilpa Chokshi[1,2]. *[1]The Roger Williams Institute of Hepatology, Foundation for Liver Research, London, United Kingdom; [2]School of Immunology and Microbial Sciences King's College, London, United Kingdom; [3]St Mary Hospital Faculty of Life Sciences and Medicine Digestive Diseases Division Imperial College, London, United Kingdom; [4]Kings college hospital NHS foundation trust, London, United Kingdom; [5]Barts Health NHS trust Royal London hospital, London, United Kingdom; [6]Nottingham University Hospitals NHS trust, London, United Kingdom*
Email: s.phillips@researchinliver.org.uk

Background and aims: Nucleos (t)ide Analogues (NA) withdrawal in CHB often lead to hepatitis flares which can be beneficial or harmful. Understanding the immunological dynamics underlying these dichotomous outcomes is critical for managing finite NA strategies.
Method: Immune-surveillance was performed during the multi-centered, randomised NUC-B study that included HBeAg-negative patients who had NA-withdrawal (Stop-NA) or NA-cessation followed by a 16-week course of PEG-IFN-alpha (IFN). Flares were defined as mild (ALT>2 × ULN) or exaggerated (>20 × ULN), the latter receiving NA retreatment (NA-ReTx). Peripheral blood mononuclear cells (PBMCs) (n = 459) were collected from 23 Stop-NA and 18 IFN patients during the 3-year follow-up with additional sampling during flares. PBMCs were stimulated with 15-mer overlapping genotype-specific peptide pools and recombinant HBcAg/HBsAg. Ex-vivo frequency of HBV-specific IFN-gamma (IFN-g)-producing T-cells was assessed by GCLP-standardised ELISpot assays.
Results: A two-year cumulative incidence of 34.8% for mild and 26.1% for exaggerated flares were found in Stop-NA versus 58.8% and 5.9% in IFN groups. Over 70% of flares occurred within 17 weeks post-NA-withdrawal. Immunological analysis highlighted an elevated frequency of IFN-g-producing-HBV-specific T cells in response to HBcAg-peptides during mild flares in Stop-NA. This is in stark contrast with loss of T-cell response during exaggerated flares in NA-ReTx group ($p = 0.010$) and mild flares in IFN ($p = 0.02$). While T-cell response recovered post-flare in IFN, this was not observed in the NA-ReTx group. Wide and broad HBcAg-T-cell responses were only observed in 17% of patients experiencing exaggerated flares in NA-ReTx group (none in the IFN mild flares group) compared to 38% in Stop-NA group experiencing mild flares ($p < 0.0001$). Notably, epitope recognition significantly contracted during exaggerated flares ($p = 0.019$) and IFN groups ($p = 0.0005$). Interestingly, at baseline, a specific region of HBcAg, induced a T-cell response that was significantly associated with RTx and IFN-related flare ($p = 0.028$).
Conclusion: Immunological analysis revealed distinct T-cell response patterns during mild and exaggerated flares after NA withdrawal and loss of T-cell responses during IFN treatment, that do not recover during NA retreatment. Significant differences in the breadth and specificity of HBcAg-T-cell responses highlight a potential biomarker at baseline associated with deleterious flares post-NA cessation in HBeAg-negative CHB.

Testosterone modulates T cells in healthy individuals and women with autoimmune liver disease

Nico Will[1], Lara Henze[2], Christian Casar[2], Victor Haas[2], Jasper Meyer[2], Dakyung Lee[2], Stephanie Stein[2], Tobias Poch[2], Jenny Krause[2], Johannees Fuß[2], Alexandra E. Kulle[3,3], Paul-Mertin Holterhus[4], Samuel Huber[2], Ansgar W. Lohse[2], Dorothee Schwinge[2], Christoph Schramm[2]. *[1]University Medical Center Hamburg, Hamburg, Germany; [2]University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [3]University Medical Center Schleswig-Hollstein, Kiel, Germany; [4]University Medical Center Schleswig-Holstein, Kiel, Germany*
Email: n.will@uke.de

Background and aims: Female people are more prone to develop the autoimmune liver diseases autoimmune hepatitis (AIH) and primary biliary cholangitis (PBC). The reasons for this high female predominance are still unknown but there is mounting evidence that androgens contribute to the regulation of immune responses. Previous data of our group revealed that testosterone was effective in suppressing liver inflammation in an inducible mouse model of autoimmune cholangitis, which shows female predominance similar to PBC. Within this study, we now aimed to further unravel the influence of testosterone on T cell differentiation and function in women with autoimmune liver diseases.
Method: We combined quantitative serum hormone measurements, *ex vivo* flow cytometry immunophenotyping, *in vitro* T cell conversion assays and single cell CITE-sequencing on multiple cohorts: i) Females with PBC compared to age and sex matched controls, ii) trans men receiving gender-affirming testosterone treatment and iii) a trans man with an AIH/PSC variant syndrome receiving gender-affirming testosterone treatment.
Results: Females with PBC presented with significantly decreased serum testosterone levels compared to age and sex matched healthy controls. Furthermore, we identified elevated frequencies of pro-inflammatory T_H1 and T_H17 $CD4^+$ T cell subsets and increased *in vitro* T_H1 conversion rates of naïve $CD4^+$ T cells in females with PBC. To investigate *in vivo* effects of testosterone in humans, peripheral blood T cells from transmen receiving gender-affirming testosterone treatment were analysed before and during treatment. We observed a shift towards the regulatory T cell population upon six months of treatment with testosterone. To substantiate these findings in disease context, we analysed samples from a trans man diagnosed with autoimmune hepatitis and sclerosing cholangitis variant syndrome. Using single-cell CITE-sequencing we observed a downregulation of proinflammatory pathways and reduced T cell activation marker expression after six months of high dose testosterone treatment. Importantly, this was paralleled by an improvement of disease activity markers and a reduction of immunosuppressive drug dosage.
Conclusion: In summary, we here report a direct effect of testosterone on human $CD4^+$ T cells, shifting them towards anti-inflammatory phenotypes. This effect may contribute to sex differences observed in autoimmune liver diseases and may provide personalized treatment strategies in the future.

Distinct soluble and cellular immunological signatures in various entities of hepatitis flares

Roni Souleiman[1,2,3,4,5], Erich Freyer[1,2,3,4,5], Tijana Ristic[1], Christine Falk[3,6], Benjamin Maasoumy[1,3,5], Heiner Wedemeyer[1,3,5], Bernd Heinrich[1], Anke R.M. Kraft[1,2,3,4,5], Markus Cornberg[1,2,3,4,5]. *[1]Department of Gastroenterology, Hepatology, Infectious Diseases and Endocrinology, Hannover Medical School, Hannover, Germany; [2]TWINCORE Center of Experimental and Clinical Infection Research, Hannover, Germany; [3]German Center for Infection Research (DZIF), Hannover, Germany; [4]Center for Individualized Infection Medicine (CiiM), Hannover, Germany; [5]Cluster of Excellence Resolving Infection*

Susceptibility (RESIST; EXC 2155), Hannover Medical School, Hannover, Germany; [6]Institute for Transplant Immunology, Hannover Medical School, Hannover, Germany
Email: souleiman.roni@mh-hannover.de

Background and aims: The management of hepatitis flares characterized by significant ALT elevations is a major clinical challenge, with consequences ranging from transient liver damage to liver failure. Understanding the immunological mechanisms and identifying predictive markers can be instrumental for effective management. Recent studies indicate, for example, that "auto-aggressive" or "bystander" CXCR6+ CD8+ T cells play a critical role in the immunopathogenesis of various chronic liver diseases.
Method: A comprehensive immunologic analysis was performed by spectral flow cytometry of PBMCs isolated from blood of 73 patients with various hepatitis flares (acute viral, chronic viral and non-viral hepatitis) defined as ALT >5-fold upper limit of normal. In addition, soluble immune markers (SIM) from a sub-cohort (n = 49) were analyzed using the Luminex platform. Results were correlated with clinical data and the Hepatocyte Injury Index (HIX, MS Shearman et al., medRxiv 2022) where possible.
Results: Our results showed a strong correlation between biochemical markers of liver injury and circulating CXCR6+ PD-1+ cytotoxic lymphocytes (CTL), which exhibited increased expression of activity markers compared to all CD8+ T cells. HLA-DR on CXCR6+ PD-1+ CTLs correlated with the real-time liver injury marker HIX ($r = 0.55$, $p < 0.001$). Moreover, CXCR6+ PD-1+ CTLs show distinct granzyme (GZ) expressions in acute and chronic viral infections, with GZB in acute and GZK in chronic infections. The CXCR6+ PD-1+ CD8 T cell subset also significantly correlated with CXCL10 plasma levels ($r = 0.54$, $p < 0.0001$). Besides CXCL10, other pro-inflammatory SIM, such as IL18 and G-CSF, positively correlated with biochemical markers of liver injury, excluding IL-13, which exhibited a negative correlation with HIX ($r = 0.55$, $p < 0.01$). The G-CSF/IL-13 ratio correlated with liver disease severity.
Conclusion: Our study emphasizes the pivotal role of CXCR6+ PD-1+ CTLs in liver inflammation, suggests HLA-DR (on CXCR6+ PD-1+ CTLs) as an activity marker, and proposes the granzyme B/K ratio on CXCR6 + PD-1+ CTLs as a differentiator of acute and chronic hepatitis. In addition, the data underscores the potential of soluble immune markers for characterizing liver inflammation and predicting progression.

SAT-533

Liver immunity index: predicting immune control of chronic hepatitis B from circulating CD8 T cells

Hannah Wintersteller[1], Sainitin Donakonda[2], Miriam Bosch[1], Anna D. Knolle[1]. *[1]Institute of Molecular Immunology, Munich, Germany; [2]Institute of Molecular Immunology, Technical University of Munich, Munich, Germany; [3]Institute of Virology, Technical University of Munich, Munich, Germany; [4]Division of Animal Physiology and Immunology, School of Life Sciences Weihenstephan, Technical University of Munich, Freising, Germany; [5]Third Department of Medicine, University Hospital Freiburg, Freiburg, Germany; [6]Department of Gastroenterology, Hepatology and Endocrinology, Hannover Medical School, Hannover, Germany; [7]Liver Unit, University Hospital Clinic Barcelona, IDIBAPS, Barcelona, Spain*
Email: hannah.wintersteller@tum.de

Background and aims: Chronic hepatitis B (CHB) is characterized by a scarcity and dysfunction of virus-specific CD8 T-cells in the liver. Immunotherapies, such as therapeutic vaccination, aim to reinvigorate and expand intra-hepatic virus-specific CD8 T-cell immunity to control viral infection. This study sought to identify biomarkers on circulating virus-specific CD8 T-cells that reflect the immune response in the liver and could be used to predict immune control of CHB.
Method: Using pre-clinical models of HBV as well as CHB patient samples, we studied the dynamics of virus-specific T-cell response by flow cytometry and single-cell RNA sequencing.
Results: Single-cell transcriptomic and protein-level analysis detected the generation of virus-specific CD8 T-cells in the liver of preclinical models of persistent as opposed to resolved infection. These HBV-specific CD8 T cells had a tissue-resident phenotype characterized by several markers. During an acute-resolving infection, these CD8 T cells were potent effector cells, as shown in preclinical models, whilst tissue-resident CD8 T-cells during persistent infection were rendered dysfunctional. Strikingly, the phenotype and functionality of HBV-specific CD8 T-cells circulating in peripheral blood were identical to the intrahepatic HBV-specific CD8 in the liver and predicted immune control of infection. Notably, liver-resident HBV-specific CD8 T-cells developed solely when recognizing their antigen in the liver and not after systemic vaccination in the absence of infection or following non-hepatotropic infection.
Conclusion: Our results identify a total of five distinct markers in HBV-specific CD8 T cells that were equally present on circulating and intrahepatic CD8 T cells and predict immune control of infection. Thus, our proprietary biomarker set allows us to study intrahepatic HBV-specific CD8 T cells by targeted analysis of circulating HBV-specific CD8 T cells and use this information for monitoring of immune therapies in CHB patients.

Macrophage-derived IL-15 imprints peritoneal tissue-resident memory T cells during spontaneous bacterial peritonitis in patients with cirrhosis

Oluwatomi Ibidapo-Obe[1], Sven Stengel[2], Mick Frissen[1], Johanna Reißing[1], Karsten Große[1], Michael Rooney[3], Hector Leal-Lassalle[4], Raquel Benedé-Ubieto[4], Yulia Nevzorova[4], Christian Trautwein[5], Tony Bruns[1]. *[1]Department of Internal Medicine III, University Hospital RWTH Aachen, Aachen, Germany; [2]Department of Internal Medicine IV, University Hospital Jena, Jena, Germany; [3]Department of Internal Medicine IV, University Hospital Jena, Jena, Germany, Jena, Germany; [4]Department of Immunology, Ophthalmology and ENT, Complutense University School of Medicine, Madrid, Spain; [5]Department of Internal Medicine III, University Hospital RWTH Aachen, Aachen, Germany, Aachen, Germany*
Email: oibidapo@ukaachen.de

Background and aims: Tissue-resident memory T cells (TRM) are long-lived memory T cells residing in tissues and capable of effective immediate response upon re-infection with a familiar pathogen. We investigated whether human peritoneal CD8 T cells from patients with cirrhosis show phenotypic and functional properties of TRM and can be imprinted by inflammatory peritoneal events, such as spontaneous bacterial peritonitis (SBP).
Method: Using mass cytometry, flow cytometry, RT-qPCR, *in vitro* cultures, single-cell RNA sequencing, and ELISA, we evaluated the phenotype and function of human CD8+ T cell subsets present in ascitic fluid (AF) from patients hospitalized for decompensated cirrhosis in the absence or presence of SBP. Observed peritoneal T cell phenotypes were validated in a preclinical, precirrhotic mouse model and potential sources of TRM-activating cytokines were validated using cell-free clinical human AF samples and isolated human peritoneal macrophages.
Results: Unsupervised mass cytometry analysis and validation by flow cytometry confirmed the presence of CD45+ CD3+ CD8+ CD103+ CD69+ CXCR6+ HLADR+ memory T cells in AF, which were largely absent in blood, consistent with the phenotype of human TRM. The presence of peritoneal CD103+ CD69+ T cells in significant numbers was also confirmed in a precirrhotic mouse model of DUAL steatotic liver disease (MetALD). Human CD103+ CD69+ TRM, particularly the CD49+ cells, were potent producers of IFN-γ after T cell receptor (TCR)

ligation, which could be augmented by IL-15. In single-cell RNA sequencing, peritoneal CD8 T cells exposed to IL-15 showed increased markers of tissue residency (*RUNX3*, *PRDM1*) alongside transcriptional features of activation and exhaustion. As shown by transcriptomic analysis in absence or presence of LPS, *in vitro* infection with *E. coli* and the analysis of cell-free AF from patients with SBP, activated peritoneal macrophages were a potent source of IL-15, which was able to upregulate cytotoxic granules (Granzyme B) and co-inhibitory receptors such as PD-1 in TRM in a TCR-independent bystander fashion. Clinical serial samples confirmed the upregulation of co-inhibitory receptors on peritoneal TRM during SBP, which persisted after the resolution of infection. Despite the expression of exhaustion markers, TRM retained their effector profiles, and blocking the PD-1/PDL-1 axis *in vitro* had no impact on their cytotoxic functions.
Conclusion: A subset of peritoneal CD8 T cells in patients with cirrhosis resembles the phenotype of tissue-resident memory T cells, which can be imprinted by macrophage-derived IL-15 during bacterial infection in the longer term. Despite the expression of coinhibitory receptors peritoneal TRM from patients with cirrhosis retain potent cytotoxic and proinflammatory effector functions.

SAT-535-YI
The role of the immune checkpoint TIGIT in CD4+ T cell dysfunction in patients with decompensated cirrhosis
Joseph Delo[1], Dan Forton[2], Evangelos Triantafyllou[3], Arjuna Singanayagam[4]. *[1]Institute of Infection and Immunity, St George's University, London, United Kingdom; [2]Department of Gastroenterology and Hepatology, St George's University Hospital, London, United Kingdom; [3]Department of Metabolism, Digestion and Reproduction, Imperial College, London, United Kingdom; [4]Institute of Infection and Immunity, St George's University, London, United Kingdom*
Email: joseph.delo@gmail.com

Background and aims: Patients with decompensated cirrhosis are highly susceptible to bacterial infections. CD4+ T cells, which normally play a key role in supporting and directing anti-bacterial immune responses, are functionally impaired in cirrhosis, but the mechanisms underlying this are not fully understood. TIGIT is an immune checkpoint expressed on T cells that transmits an inhibitory signal when bound to its ligand, CD155, expressed on antigen-presenting cells. This study aimed to determine if TIGIT blockade could improve the function of CD4+ T cells from patients with decompensated cirrhosis.
Method: Patients with stable decompensated cirrhosis (SD, n = 9), acute decompensated cirrhosis (AD, n = 17) and acute-on-chronic liver failure (ACLF, n = 11) were recruited within 48 hours of admission to hospital, along with healthy controls (HC, n = 8). Mononuclear cells were isolated from peripheral blood and the expression of membrane-bound TIGIT and CD155 on immune cell subsets was assessed by flow cytometry. An anti-TIGIT monoclonal antibody (MBSA43 clone, at 10 ug/ml) was used for TIGIT functional blockade *ex vivo*. Its impact on CD4+ T cells, following CD3 stimulation, was determined by measuring T cell expression of exhaustion markers (PD-1, LAG-3, TIM-3), proliferation, and cytokine production (IFN-gamma, IL-2, and TNF-alpha).
Results: CD4+ T cells from patients with AD and ACLF expressed more TIGIT compared to those from HC (HC 15.9%, AD 26.1%, and ACLF 27.3% positive; p = 0.005). Notably, the expression of TIGIT on CD8+ T cells or NK cells, and the expression of CD155 on CD14+ monocytes, remained the same between groups. Furthermore, patients who died within 90 days had higher TIGIT expression on their CD4+ cells at baseline than those who survived (31.7 versus 21.2% positive; p = 0.002). TIGIT blockade reduced expression of the exhaustion markers LAG-3 and PD-1, and increased IFN-gamma production by CD4+ T cells from AD and ACLF, but had no impact on CD4+ T cell proliferation.
Conclusion: This study identifies a possible new mechanism for CD4 + T cell dysfunction in cirrhosis. Expression of the inhibitory immune checkpoint TIGIT is increased on CD4+ T cells in decompensated cirrhosis, in the face of preserved levels of the ligand, CD155, on monocytes. Blockade of TIGIT *ex vivo* partially reversed CD4+ T cell exhaustion and improved proinflammatory cytokine production. It could therefore serve as a novel immunomodulatory target in decompensated cirrhosis, reducing reliance of anti-microbials in the era of emerging multi-drug resistance organisms.

SAT-536
Uptake and T cell stimulation by anti-HBs monoclonal antibody BJT-778-rHBsAg immune complexes
Loghman Salimzadeh[1,2], Stuti Shah[1,2], Danie La[2], Hilario Ramos[3], Nancy Shulman[3], Hassan Javanbakht[3], Adam Gehring[1,2,4]. *[1]Schwartz-Reisman Liver Research Centre, University Health Network, Toronto, Canada; [2]Toronto Centre for Liver Disease, University Health Network, Toronto, Canada; [3]Bluejay Therapeutics, Inc., San Mateo, United States; [4]Department of Immunology, University of Toronto, Toronto, Canada*
Email: adam.gehring@uhn.ca

Background and aims: In chronic hepatitis B patients, the sustained presence of a high quantity of hepatitis B virus surface antigens (HBsAg) contributes to the exhaustion of HBV-specific T and B cell responses. BJT-778 is a fully human IgG1 monoclonal antibody targeting the antigenic loop of HBsAg currently in Phase 1 clinical development. As clearance of HBsAg via immune complex (IC) formation may be a mechanism by which therapeutic antibodies can reduce immune exhaustion, this research-based study investigated the uptake of BJT-778-HBsAg ICs by professional antigen presenting cells and the impact of IC uptake on HBsAg-specific T cell activation.
Methods: Immune complexes were generated using BJT-778 and DyLight-550-labeled recombinant HBsAg. The kinetics of IC uptake across seven distinct professional phagocytic leukocyte populations in peripheral blood samples from healthy individuals and chronic hepatitis B patients were measured using flow cytometry. Fc receptor-mediated uptake of ICs was confirmed using an FcR blocking reagent. T cell-stimulatory effects were tested by loading CD14+ cells with BJT-HBsAg ICs, or HBsAg alone, and measuring activation of a HBsAg-specific CD4+ T cell clone by assessing IFN-γ production via flow cytometry.
Results: BJT-778 significantly increased the uptake of HBsAg compared to an isotype control antibody or HBsAg alone. Within 2h of incubation, nearly all classical (97.40%) and intermediate (94%) monocytes were positive for HBsAg compared to ~50% with HBsAg alone or isotype control. Non-classical monocytes and myeloid dendritic cells (mDCs) also displayed significant increases in HBsAg with ICs compared to HBsAg alone or isotype. CD141+ DCs, plasmacytoid DCs, or B cells did not show significant enhancement of HBsAg uptake with ICs. Cell types where BJT-778 showed significantly enhanced HBsAg uptake displayed high levels of activating FcγR1 (CD64; classical and intermediate monocytes, mDCs) and FcγRIIIa (CD16; intermediate and non-classical monocytes). Fc-mediated uptake was confirmed by blocking FcRs prior to addition of ICs. Notably, classical monocytes and myeloid dendritic cells from CHB patients exhibited significantly slower uptake of ICs compared to healthy donors. Enhanced uptake of BJT-778-rHBsAg-ICs by CD14+ monocytes resulted in increased HBsAg-specific T cell activation.
Conclusion: These data identify the likely in vivo targets of BJT-778-HBsAg ICs and demonstrate that BJT-778 ICs lead to enhanced HBsAg uptake in professional antigen presenting cells. Enhanced uptake of HBsAg resulted in increased HBV-specific CD4 T cell activation, supporting a dual mechanism of action through removal of circulating HBsAg and stimulation of HBV-specific T cell immunity.

Characterization of immune cell populations in the microenvironment of mice liver during the progression of liver fibrosis to hepatocellular carcinoma

Ananya Ajith[1], Francoise Smets[1], Etienne Sokal[1], Mustapha Najimi[1].
[1]*Université Catholique de Louvain, Brussels, Belgium*
Email: ananya.ajith@uclouvain.be

Background and aims: Around 90% of hepatocellular carcinoma (HCC) cases arise in the background of chronic liver diseases (CLD). Chronic inflammation is the underlying cause of CLD and development of HCC. Thus, dysregulated functions of hepatic immune cell populations are playing important roles in CLD and development. In this study we aim to characterize the different immune cell populations dysregulated during liver fibrosis and HCC development using a combination of Diethylnitrosamine (DEN) and carbon tetrachloride (CCl4) treated mouse model.
Method: A single injection of DEN at 4 weeks of age, followed by continuous injections of CCl4 for 6 and 21 weeks were administered respectively, to induce liver fibrosis and HCC in mice. Whole liver was perfused and digested using collagenase, to isolate and characterise single-cell suspensions of the non-parenchymal cell fraction (NPF). The different immune cell populations were then identified and sorted using FACS analysis. In parallel, the tissular hepatic immune cells were identified using specific cell surface and nuclear antibody markers and their spatial localisation evaluated using multiplex immunofluorescence on formalin fixed paraffin embedded (FFPE) liver sections.
Results: Based on the FACS analysis results, it was observed that the overall leukocyte population has drastically increased as the disease progressed from liver fibrosis to HCC in comparison to non-treated livers. Among the leukocytes, myeloid cell populations decreased due to a drastic loss of the Kupffer cell (KC) population during the disease progression, while infiltrating monocyte-derived macrophages, monocytes, and granulocyte populations increased. The lymphocyte population increases which seems to be related to an overall increase of the $CD4^+$ T cell population than the one of $CD8^+$ T cells. Our multiplex immunofluorescence results suggest that all the immune cell populations were distributed near the central vein, which is the site of inflammation in fibrotic mice liver. In HCC liver, immune cells like CD8T cells and granulocytes were found more within the tumor tissue, the hepatic macrophages were distributed throughout the liver parenchyma while Tregs, were more abundant in the invasive margin of the tumor and in the remaining tissue.
Conclusion: By FACS analysis, we observed that the overall populations of different immune cells had significantly dysregulated. By multiplex fluorescence staining the majority of the immune cells were identified to be distributed at the site of inflammation in fibrosis group. In HCC livers, the different immune cell populations were heterogeneously distributed within the tumor, the invasive margin of the tumor or the remaining parts of the liver tissue based on their specific pro-inflammatory and anti-inflammatory properties.

Differential phenotypes of γδ T cells in hepatitis E virus infection: implications for disease pathogenesis

Erich Freyer[1,2,3,4,5], Roni Souleiman[1,2,3,4,5], Severin Wulf[1,2,3,4,5], Katja Steppich[1,2,3,4,5], Patrick Behrendt[1,2,3], Heiner Wedemeyer[1,3,5], Anke R.M. Kraft[1,2,3,4,5], Markus Cornberg[1,2,3,4,5]. [1]*Hannover Medical School, Department of Gastroenterology, Hepatology, Infectious Diseases and Endocrinology, Hannover, Germany;* [2]*Twincore-Centre for Experimental and Clinical Infection Research, Hannover, Germany;* [3]*German Center for Infection Research (DZIF), Hannover, Germany;* [4]*Centre for Individualised Infection Medicine (CiiM), Hannover, Germany;* [5]*Cluster of Excellence Resolving Infection Susceptibility (RESIST, EXC 2155), Hannover Medical School, Hannover, Germany*
Email: freyer.erich@mh-hannover.de

Background and aims: Hepatitis E virus (HEV) is a global health problem with diverse outcomes ranging from acute resolving infections to chronic hepatitis in immunosuppressed individuals, highlighting the role of the immune system in disease pathogenesis. Unconventional T cells such as γδ T cells, which play a key role bridging innate and adaptive immunity, have been poorly studied in this context but may play a crucial role in the pathogenesis of HEV infection. The aim of this study was to investigate γδ T cells at different stages of HEV infection, distinguishing between immunocompetent and immunosuppressed patients.
Method: A comprehensive analysis of blood γδ T cells was performed in 29 patients (11 immunocompetent, 18 immunosuppressed) with acute, chronic, or resolved HEV infection at multiple timepoints and 15 healthy controls using spectral flow cytometry with 41 parameters.
Results: No significant differences in γδ T cell frequencies were observed between HEV groups, but lower frequencies in acute HEV infection compared to healthy controls ($p < 0.05$). In immunosuppressed compared to immunocompetent HEV patients, the Vδ1/Vδ2 ratio was inversed, which was attributed to an increased number of Vδ1 T cells ($p < 0.005$). During acute HEV infection, γδ T cell phenotypes differed with lower expression of PD-1, lower CXCR6 and higher NKG2A in immunosuppressed compared to immunocompetent patients ($p < 0.05$). Also, individuals with resolved HEV infection showed distinct γδ T cell phenotypes, e.g. higher CD69 expression and TEMRA markers ($p < 0.05$) and fewer $CD8^+V\delta2^+$ T cells in immunosuppressed compared to immunocompetent patients ($p < 0.005$). Interestingly, in chronic HEV infection (exclusively immunosuppressed), Vδ1 T cell frequency correlated negatively with ALT ($p < 0.05$, $r = 0.55$), while Vδ1 subsets showed positive correlations with ALT (CD69/Vδ1, $p < 0.05$, $r = 0.54$), liver stiffness (CD69/Vδ1, $p < 0.05$, $r = 0.89$), and HEV RNA levels (CD103/Vδ1, $p < 0.005$, $r = 0.87$).
Conclusion: Pan γδ, Vδ1, and Vδ2 T cell subsets in the blood exhibit distinct phenotypes in immunocompetent and immunosuppressed patients across different stages of HEV infection. Particularly, Vδ1 T cell frequencies during chronic HEV infection, along with subset abundance and distinct phenotypes, correlate with markers of liver inflammation, fibrosis, and viral replication. These findings suggest that alterations in γδ T cells may contribute to the immunopathogenesis of HEV infection.

Email: moritz.peiseler@gmx.de

Background and aims: The liver is the body's central microbial filter preventing spread of blood-borne pathogens. Kupffer cells (KCs) are the most abundant population of tissue resident macrophages and filter >90% of disseminated bacteria within minutes from the circulation. During liver fibrosis, sinusoidal KCs dramatically change their phenotype, lose their identity and their function. In response, monocytes invade the liver to form KC-like syncytia that compensate for loss of sinusoidal KC function. Chronic liver diseases in patients are characterised by phases of disease activity and disease regression, currently not adequately addressed in rodent models. Thus, it is unclear how the KC compartment responds to injury regression.

Method: Using a mouse model of chronic hepatotoxicity with carbon tetrachloride followed by regression of hepatic injury, monocyte and macrophage linage tracing tools, intravital microscopy and multiplex flow cytometry, we investigated the liver macrophage compartment during injury regression.
Results: Liver architecture and liver damage completely resolved in regression. Surprisingly, we found sustained alterations of the macrophage compartment that included differences in KC identity molecules such as CRIg and TIM-4. Functionally, bacterial capture and survival was impaired in regression compared to control mice. Flow cytometric profiling revealed the sustained presence of monocyte-derived KCs. Lastly, we found a novel macrophage subset expressing the markers MerTK, CD68, CD86 and PD-L1.
Conclusion: Our results demonstrate sustained alteration of the liver macrophage compartment during injury regression, favouring injury repair over antimicrobial responses thus leaving the host vulnerable to infections.

SAT-540-YI
TIGIT + Tregs maintain tolerance in autoimmune hepatitis via CTLA-4 dependent suppressive mechanism
Amber Bozward[1], Grace Wootton[1], Rémi Fiancette[1], Ye Htun Oo[1,2,3]. [1]*Centre for Liver and Gastrointestinal Research, University of Birmingham, Birmingham, United Kingdom;* [2]*Liver Transplant and Hepatobiliary Unit, University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom;* [3]*European Reference Network Centre-Centre for Rare Disease, University Hospitals Birmingham NHS Foundation TRUST, Birmingham, United Kingdom*
Email: a.g.bozward@bham.ac.uk

Background and aims: Immune checkpoint inhibitor, TIGIT, is expressed on T regulatory cells (Tregs). TIGIT$^+$Tregs are reported as a highly suppressive subset of Tregs but the mechanism behind the suppressive abilities is unknown. We explore this mechanistic aspect aiming to apply TIGIT$^+$Tregs as a potential therapy in autoimmune hepatitis.
Method: Deep immune-phenotypic characterisation of TIGIT$^+$Tregs cells in peripheral blood samples (autoimmune hepatitis [AIH, N = 12], chronic immune mediated liver diseases control [N = 7], and healthy volunteers [N = 10]) was investigated with muti-colour flow cytometry. Suppressive capacity of TIGIT$^+$Tregs was assessed with expanded and cell-sorted TIGIT$^+$Tregs and TIGIT$^-$Tregs co-cultured with matched responder CD4 T cells (N = 3). Abatacept was applied to block CTLA-4 pathway of TIGIT$^+$Tregs suppressive mechanism. In addition, we examined the effect of TIGIT agonist on TIGIT$^+$Tregs proliferation and functional markers of suppression (N = 3).
Results: TIGIT expression is observed on 41.53% ± 31.88 of Tregs in AIH blood. TIGIT$^+$Tregs significantly upregulate liver sinusoidal recruitment chemokine receptor (CXCR3, $p = 0.0002$), biliary localisation chemokine receptor (CCR6, $p < 0.0001$), hepatic migration and peribiliary localisation integrin (VLA4, $p < 0.0001$) and tissue residency (CD69, $p < 0.0001$) markers compared to TIGIT$^-$Tregs. Immunohistochemistry of AIH explant liver shows that the expression of TIGIT is within the hepatic sinusoid and lobular and interphase hepatitis inflammatory infiltrates. TIGIT$^+$Tregs express significantly higher CTLA-4 ($p = 0.0246$) and FoxP3 ($p < 0.0001$) compared to TIGIT$^-$Tregs in autoimmune blood. TIGIT agonist upregulates CTLA-4 and FoxP3, on TIGIT$^+$Tregs but does not have an impact on cell proliferation. TIGIT agonist leads to plasticity of TIGIT$^+$Tregs by increasing TNFα, however, cells remain suppressive. In addition, we demonstrate that TIGIT$^+$Tregs are more suppressive than TIGIT-Tregs via a CTLA-4 dependent pathway and the use of Abatacept reduces their suppressive ability.
Conclusion: We have identified CTLA-4 as a mechanism of suppression in TIGIT$^+$Tregs. TIGIT agonist enhances expression of CTLA-4 and FoxP3 on TIGIT$^+$Tregs suggesting TIGIT agonist as a potential therapeutic option for AIH patients.

SAT-541
High-dimensional spectral flow cytometry defines changes in circulating immune cell composition and responsiveness in patients with cirrhosis-associated immune dysfunction
Malgorzata Grzelka[1], William Cambridge[1], Guiquan Jia[2], Dario Nicetto[2], Nandhini Ramamoorthi[2], Jonathan Fallowfield[1,3,4], Prakash Ramachandran[1]. [1]*Centre for Inflammation Research, The University of Edinburgh, Edinburgh, United Kingdom;* [2]*Genentech, South San Francisco, United States;* [3]*Institute for Regeneration and Repair, University of Edinburgh, Edinburgh, United Kingdom;* [4]*Institute for Regeneration and Repair, Centre for Inflammation Research, Edinburgh, United Kingdom*
Email: grzelka.m@doctors.org.uk

Background and aims: Cirrhosis-associated immune dysfunction (CAID) represents the paradigm of aberrant immune responses as chronic liver disease (CLD) progresses. Clinically, this manifests in cirrhotic patients being prone to infections, resulting in significant mortality and morbidity. Whilst alterations of individual immune cell populations have been reported in CAID, a comprehensive assessment of changes in the composition and function of all major immune cell compartments is lacking. To address this, we utilised the advances in spectral flow cytometry to perform high-parameter analysis of circulating immune cell groups at differing stages of CLD.
Method: A panel of 23 antibody-fluorophore combinations was created for application on 100 µL of whole blood and analysis on a 3-laser Cytek Aurora spectral flow cytometer. Absolute cell count per millilitre of whole blood was established for each cell type. To assess functional responses, we developed a 27-colour panel, including intracellular cytokine staining for a stimulation assay with 6 different TLR ligands. Four study groups were defined as: healthy controls, non-cirrhotic CLD (fibroscan reading <10 kPa in the absence of other signs of cirrhosis), compensated advanced CLD (cACLD, fibroscan ≥10 kPa without clinical signs of decompensation) and decompensated advanced CLD (dACLD, clinical signs of decompensation regardless of fibroscan).
Results: Samples from 13 controls, 17 non-cirrhotic CLD (9 PBC, 8 MASLD, fibroscan mean ± SEM 6.7 ± 0.3 kPa), 59 cACLD (31 MASLD, 16 ALD, 7 other, 5 PBC, 20.3 ± 1.9 kPa) and 20 dACLD (7 MASLD, 6 ALD, 6 PBC, 1 PSC) patients were analysed. We were able to identify and enumerate all major circulating immune cell populations. Quantitation of absolute cell numbers demonstrated significant reductions in CD8$^+$ (cytotoxic), CD4$^+$CD45RA$^+$ (naïve), NKT and gamma delta T cells in patients with dACLD, independent of sex and aetiology. In contrast, numbers of circulating neutrophils, B cells and monocyte subpopulations were not significantly different by CLD stage. Functionally, dACLD CD14$^+$ monocytes (n = 8) were activated at baseline compared to cACLD (n = 5) as evidenced by increased IL-1β expression ($p < 0.005$), and a trend towards increased expression of IL-6 and TNF-α. Stimulation with TLR2 or TLR7/8 agonists (but not TLR3, TLR4, TLR5 or TLR9) showed attenuated upregulation of IL-1β in dACLD monocytes, indicating impaired responsiveness to certain TLR ligands in CAID.
Conclusion: Our high-dimensional spectral flow cytometry method allows for a comprehensive assessment of circulating immune cell composition and function from small sample volumes. This approach has identified loss of multiple circulating T cell subpopulations and aberrant monocyte responses to TLR ligands as key features of CAID. Future work will focus on understanding how these features evolve longitudinally as CLD progresses.

SAT-542
Macrophage Dvl2-HSF1 axis regulates STING-mediated innate immunity and hepatocyte death in liver ischemia and reperfusion injury
Tao Yang[1], Dongwei Xu[1], Xiaoye Qu[1], Mingwei Sheng[1], Yuanbang Lin[1], Xiao Wang[1], Christopher King[1], Jun Li[2], Longfeng Jiang[2], Qiang Xia[3], Douglas Farmer[1], Bibo Ke[1]. [1]*The Dumont-UCLA Transplant Center,*

Department of Surgery, David Geffen School of Medicine at UCLA, Los Angeles, United States; [2]Department of Infectious Diseases, the First Affiliated Hospital, Nanjing Medical University, Nanjing, China; [3]Department of Liver Surgery, Renji Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China
Email: taoyang@mednet.ucla.edu

Background and aims: Dishevelled 2 (Dvl2) is a member of the Wingless/Wnt signaling pathway that regulates cell proliferation, survival, and migration. However, whether macrophage Dvl2-HSF1 signaling may regulate STING function and cell death in oxidative stress-induced liver inflammatory injury is unknown.
Method: A mouse model of hepatic ischemia/reperfusion injury (IRI), the primary hepatocytes, and bone marrow-derived macrophages were used in the myeloid-specific Dvl2 knockout ($Dvl2^{M\text{-}KO}$) and Dvl2-proficient ($Dvl2^{FL/FL}$) mice.
Results: $Dvl2^{M\text{-}KO}$ exacerbated IR stress-induced liver damage with increased serum ALT/AST levels, macrophage/neutrophil infiltration, and proinflammatory mediators compared to the $Dvl2^{FL/FL}$ controls. Notably, $Dvl2^{M\text{-}KO}$ inhibited HSF1 and promoted STING, NLRP3, caspase-1, p65 NF-κB, RIPK3, and p-MLKL, with increased IL-1β levels in IR-stressed livers compared to the $Dvl2^{FL/FL}$ controls. Interestingly, IR stress increased macrophage Dvl2 and HSF1 nuclear translocation in ischemic livers. Chromatin immunoprecipitation (ChIP) coupled with massively parallel sequencing (ChIP-Seq) revealed that macrophage Dvl2 colocalized with HSF1 and activated its target gene *eEF2*. Activation of HSF1 augmented eEF2 and inhibited STING, NLRP3, caspase-1, and NF-κB function. However, disruption of macrophage eEF2 enhanced STING, NLRP3, caspase-1, and NF-κB activity, with increased hepatocyte RIPK3 and p-MLKL expression, ROS production, and LDH release after macrophage/hepatocyte co-culture.
Conclusion: Disruption of macrophage Dvl2 activates STING and induces hepatocyte death in IR-stressed livers. The Dvl2 interacts with HSF1 and regulates HSF1 target gene *eEF2* function, which is crucial for the control of STING and RIPK3-mediated necroptotic cell death. Our findings underscore a novel role of macrophage Dvl2 in oxidative stress-induced liver inflammation and cell death, implying the potential therapeutic targets in liver inflammatory diseases.

Email: ealvaradot@santpau.cat

Background and aims: Circulating small extracellular vesicles (sEVs) represent intercellular communication where the donor cell defines the surface antigen composition. Metabolically dysfunction-associated steatotic liver disease (MASLD) and alcohol-associated liver disease (ALD) currently stand as the leading causes of hepatopathy. Characterizing the surface antigens of sEVs may reflect the primary immune mechanisms involved in the pathogenesis of liver diseases. This study aims to characterize the quantity and the surface antigen profile in two cohorts of liver diseases: MASLD vs Alcoholic Hepatitis (AH).
Method: Consecutively and prospectively, metabolically dysfunction-associated steatotic liver disease (MASLD) (Clinica Universidad de Navarra) and patients with alcoholic hepatitis (AH) (Hospital de la Santa Creu i Sant Pau) were included. Blood samples were collected for the study of small extracellular vesicles (sEVs) in plasma, through quantification by flow cytometry (FC) MQ16 (staining with CFSE, CD81-CD9), NTA (NanoSight) and CryoME. The antigen characterization was performed using conventional flow cytometry with MACSPlex kit.
Results: A total of 45 patients with MASLD and 39 patients with AH with cirrhosis were included. Patients MASLD have lower peripheral plasmatic sEVs ($27.5 \pm 18.10 \times 10^9$ particle/ml) with significantly higher expression of endothelial-epithelial-lymphocytic and monocytic origin antigens (CD133, CD19, CD20, CD326, CD14, CD24, CD69) in sEVs, unlike patients with MASLD patients with AH have significantly higher peripheral plasmatic sEVs ($78.63 \pm 33.59 \times 10^{11}$ particle/ml) with higher expression of endothelial-epithelial-monocytic and platelet origin antigens (CD133, CD326, CD14, CD49e, CD41b, CD62p, CD42a, CD31). However, despite being etiologically and clinically different, both groups share endothelial-epithelial and monocytic origin antigens (CD133, CD326, CD14). Differentially, AH has a higher expression of platelet antigens. It is possible that from the early stages of MASLD, there is damage not only to the endothelium but also to increased activation of the immune system, which is even more pronounced in different and more advanced scenarios such as AH, where platelet involvement should be further explored.
Conclusion: Circulating sEVs exhibit a distinct surface antigen pattern based on the etiology of liver disease. The characterization of surface antigens allows the identification of early endothelial and monocytic involvement in patients with MASLD, contrasting with platelet involvement in patients with AH. Characterizing the content of sEVs may elucidate the specific cargo according to etiology and open therapeutic possibilities for immune system regulation.

SAT-544

Study on the role of natural killer cells in chronic hepatitis B patients treated with intermittent interferon therapy

Xiaoyue Bi[1], Tingting Jiang[1], Shiyu Wang[1], Ziyu Zhang[1], Xinxin Li[1], Yao Xie[1,2], Minghui Li[1]. *[1]Department of Hepatology Division 2, Beijing Ditan Hospital, Capital Medical University, Beijing, China; [2]Department of Hepatology Division 2, Peking University Ditan Teaching Hospital, Beijing, China*
Email: wuhm2000@sina.com

Background and aims: To investigate the changes of phenotype, frequency and related cytokines of Natural killer (NK) cells in Chronic

hepatitis B (CHB) patients during intermittent treatment with Interferon (IFN).
Method: CHB patients were enrolled and divided into initial treatment group, HBsAg level decreased in interferon treatment group and oral nucleoside (acid) antiviral therapy group according to different conditions of antiviral therapy. After improving the baseline examination, patients in the initial treatment group were treated with IFN alpha. For patients whose HBsAg reached a plateau after IFN alpha treatment, IFN therapy was stopped and restarted after an interval of 12–24 weeks. The oral medication group continued to use the original treatment plan. For the initial treatment group, before IFN treatment, 4 weeks of treatment and 12–24 weeks of treatment; hepatitis B virus virologic, serological and biochemical data were collected when IFN was stopped, before IFN again after a 12–24 weeks interval and at 12–24 weeks after IFN again.
Results: A total of 207 patients with chronic hepatitis B were included, including 68 in the initial treatment group, 50 in the HBsAg lowering platform group and 89 in the oral administration group. At baseline, compared with patients in the initial treatment group, patients in the HBsAg decline plateau stage had lower frequency of $CD56^{dim}$ subgroup and higher frequency of $CD56^{bright}$ subgroup ($p < 0.001$). During IFN treatment, HBsAg level in the initial treatment group showed a downward trend. After 4 weeks of IFN treatment and 12–24 weeks of IFN treatment, the frequency of $CD56^{dim}$ cells decreased significantly ($p = 0.024$; $p < 0.001$), active molecule NKG2D was significantly decreased at 4 weeks of treatment ($p = 0.021$), active molecule NKG2C was significantly decreased at 12–24 weeks of treatment ($p < 0.001$), and inhibitory molecule NKG2A was significantly increased at 12–24 weeks of treatment ($p < 0.001$). The frequency of $CD56^{bright}$ subgroup was increased, and the inhibitory molecule NKG2A and activating molecule NKG2D in $CD56^{bright}$ subgroup were significantly increased ($p < 0.01$).
Conclusion: In CHB patients who have reached a plateau with IFN treatment, intermittent retreatment mode can achieve significant clinical efficacy, which is of clinical significance. During IFN treatment, the $CD56^{dim}$ subgroup responsible for killing effect of NK cells decreased, while the frequency of $CD56^{bright}$ subgroup responsible for cytokine secretion increased. However, the activity of the two subgroups were inhibited to varying degrees, which may be related to the emergence of the plateau period. In the course of IFN treatment, the immune environment, the antiviral effect of immune cells and the pathogenic effect of HBV have been dynamically changing, and the dynamic balance between the two effects may be the cause of the plateau period.

SAT-545

Th2 cell activation in chronic liver disease is driven by local IL-33 and contributes to IL-13 dependent fibrogenesis

Johanna Reißing[1], Marie-Luise Berres[1], Pavel Strnad[1], Alexander Wree[2], Christian Trautwein[3], Tony Bruns[3], Zimmermann Henning Wolfgang[3]. *[1]Department of Internal Medicine III, Aachen, Germany; [2]Department of Gastroenterology/Hepatology, Berlin, Germany; [3]Department of Internal Medicine III, University Hospital RWTH Aachen, Aachen, Germany*
Email: joreissing@ukaachen.de

Background and aims: The role of type 2 immune responses is well known for parasite infections caused liver fibrosis, but their role in other liver diseases remains unclear. This study aims to elucidate mechanisms involving Th2 T cell polarization, activation, and recruitment in human liver fibrosis and cirrhosis.
Method: Human liver tissues, cells and serum were analysed by qRT-PCR, ELISA, FISH, immunostaining, flow cytometry and in vitro functional assays. Investigations focused on cellular interactions and soluble mediators influencing T cell polarisation and recruitment, and their impact on hepatic stellate cell (HSC) activation, proliferation and extracellular matrix synthesis.
Results: Human liver fibrosis exhibited a stage-dependent increase in Th2-related transcription factors, Th2 cytokines, and GATA3-expressing T cells, peaking in cirrhotic livers. The alarmin IL-33 was elevated in cirrhotic livers and sera, acting as a chemotactic agent for Th2 cells and inducing type 2 polarization of CD4+ T cells. IL-33 originated from oval cells, liver sinusoidal endothelial cells, intrahepatic macrophages, and migrating monocytes. IL-33-activated T cells, not IL-33 alone, induced HSC activation, evidenced by Ki67 and α-SMA staining, increased COL1A1 mRNA expression, and wound healing assays. The pro-fibrotic effect was contact-independent and countered by monoclonal antibodies against IL-13.
Conclusion: In patients with chronic liver disease, the alarmin IL-33 facilitates the recruitment and activation of CD4+ T cells with Th2-like properties, triggering paracrine HSC activation in an IL-13-dependent manner, thereby promoting fibrogenesis.

SAT-546

Elevated IL18R+CD8+T cells in Autoimmune Hepatitis patients are associated with a worse therapy response

Katharina Yankouskaya[1], Ida Allabauer[1], Grace Wootton[2], Naomi Richardson[2], Amber Bozward[2], Peter Dietrich[3], Markus F. Neurath[3], Joachim Woelfle[1], André Hoerning[1], Ye Htun Oo[2]. *[1]Pediatric Gastroenterology and Hepatology, Department of Pediatrics and Adolescent Medicine, University Hospital Erlangen, Friedrich-Alexander-University Erlangen-Nuremberg, Erlangen, Germany; [2]Centre for Liver and Gastroenterology Research, Institute of Immunology and Immunotherapy, University of Birmingham, Birmingham, United Kingdom; [3]Medicine 1, University Hospital Erlangen, Friedrich-Alexander-University Erlangen-Nuremberg, Erlangen, Germany*
Email: kyankouskaya@gmail.com

Background and aims: Autoimmune hepatitis (AIH) patients who do not achieve complete biochemical remission with current first-line and second line therapy face a worse prognosis and outcome. The Interleukin 18 Receptor (IL18R) has mostly been described on T cells and has been linked to different autoimmune diseases, making it an interesting target in autoimmune liver diseases. Our aim is to investigate the pathophysiology behind therapy responders (RS) and non-responders (NRS) in AIH, focusing on the role of IL18R+CD8+ T cells.
Method: Initially, Nanostring mRNA analysis of 8 treatment naïve AIH type I patients (4 RS and 4 NRS), and 4 nonhepatitis controls was performed. Liver derived lymphocytes and peripheral mononuclear blood cells (PBMCs) were freshly isolated from human liver explant samples (with established ethics, University of Birmingham) of 4 patients (Primary Biliary Cholangitis (n = 1), Primary Sclerosing Cholangitis (n = 1), Alcohol-related Liver Disease (n = 2)), and 3 unused donor explants as well as peripheral blood samples of 5 AIH RS and 5 AIH NRS patients undergoing treatment and 5 control blood were analysed with Flow Cytometry (FC). PBMCs were either analysed immediately, stimulated overnight with CD3/CD28, or stimulated with cytokines IL18, IL12 or IL18 and IL12 for 5 days and subsequently analysed.
Results: The Nanostring data suggested increased mRNA levels of IL18R in AIH RS compared to AIH NRS ($p < 0, 05$). In the unstimulated FC analysis, there was a tendency of an increased frequency of IL18R on CD8+ T cells in AIH NRS compared to AIH RS in blood ($p = 0.051$). However, in the liver this tendency in significance was lower in disease livers compared to unused donor livers ($p = 0.057$). After CD3/CD28 stimulation, the frequency of an inflammatory CD8+ T cells subset, with IL18R and Tumor Necrosis Factor alpha (TNFa) double positive cells, was higher in NRS than RS or control patients. Also, following IL12 and combined IL12/IL18 stimulation, the frequency of IL18R on CD8 was increased in NRS rather than in RS ($p < 0.005$) and control. Similarly, the frequency of IL18R expression on CD39+CD8+, CD69+CD8+, Ki-67+CD8+, Cytotoxic T-lymphocyte-associated Protein 4 (CTLA-4) +CD8+, Interferon gamma (IFNy)+CD8+ and T cell

immunoreceptor with Ig and ITIM domains (TIGIT)+CD8+ cells was upregulated in NRS compared to RS and HFE patients (all $p < 0.01$).
Conclusion: IL18R+CD8+ T cells seem to be expanded in AIH NRS in blood and seem to display a more exhausted (CTLA-4, TIGIT, CD39) and activated (CD69) phenotype after cytokine stimulation. However, these T cells still appear to be able to secrete inflammatory cytokines such as IFNy and express high proliferative capacity (Ki-67), thus possibly being at least in part responsible for therapy nonresponse in these patients. Further research in this area is required to better understand the mechanisms behind these pathways and functions of these cells.

Mendelian randomization strengthens the crosstalk of immune traits with primary biliary cirrhosis and primary sclerosing cholangitis

Jing Xu[1], Jie Hao[2], Ning Ling[1], Ming-Li Peng[1]. [1]*Department of Infectious Diseases, Key Laboratory of Molecular Biology for Infectious Diseases (Ministry of Education), Institute for Viral Hepatitis, the Second Affiliated Hospital, Chongqing Medical University, Chongqing, China, Chongqing, China;* [2]*Department of Oncology, Southwest Hospital, Third Military Medical University (Army Medi-cal University), Chongqing, China, Chongqing, China*
Email: peng_mingli@hospital.cqmu.edu.cn

Background and aims: Immune cells play a crucial role in the onset and progression of liver diseases. However, it is unclear whether the link is merely correlative or orchestrated by causative mechanistic interactions. This study aims to investigate the causal rela-tionship between immune cells and liver diseases using genetic data and Mendelian randomization (MR).
Method: We performed two-sample bidirectional Mendelian randomization (MR) analyses to explore the causal associations between731 immunophenotypes and 4 liver diseases. Namely, primary biliary cirrhosis (PBC), primary sclerosing cholangitis (PSC), autoimmune hepatitis (AIH) and alcoholic liver disease (ALD) comprehensively sensitive analyses were followed to validate the robustness of results.
Results: After FDR correction, forward MR indicated the following associations remained significant: CD27 on CD24+ CD27+ (OR = 1.13, PFDR = 0.017), CD27 on IgD- CD38dim (OR = 1.149, PFDR = 0.007), CD27 on IgD+ CD24+ (OR = 1.209, PFDR = 0.007), CD27 on sw mem (OR = 1.147, PFDR = 0.010), CD27 on unsw mem (OR = 1.162, PFDR = 0.008) may be associated with a higher risk of PBC. CD28 on resting Treg (OR = 0.724, PFDR = 0.004) and CD20- %B cell (OR = 0.806, PFDR = 0.011) had a protective effect on PSC and ALD, respectively. Five immunophenotypes had suggestive association with AIH. In the reverse MR analysis, five immunophenotypes were genetically predicted to be down-regulated in PBC, whereas six were predicted to be up-regulated in PSC, There was no evidence of reverse causality of AIH and ALD on immunophenotype.
Conclusion: This study provide evidence for a bidirectional causal relationship of immunophenotypes with PBC and PSC, which offers a new direction for the early detection of the two diseases and the possibility of developing treatment strategies.

SAT-548

Variations in dynamic T cell response are associated with the HCC recurrence treated with anti-PD-1 immunotherapy after interventional therapy

Yonghong Zhang[1], Tingting Mei[2], Kang Li[3], Chaoran Zang[4], Wenying Qiao[4], JianJun Li[4], Wenying Qiao[4], Ling Qin[4], Caixia Hu[4], Yinghua Zhang[4], Chunwang Yuan[4], Biyu Liu[4], Yu Sun[4]. [1]*Beijing YouAn Hospital, Capital Medical University, Beijing, China;* [2]*Beijing YouAn Hospital, Capital Medical University, Beijing, China;* [3]*Beijing YouAn Hospital, Capital Medical University, Beijing, China;* [4]*Beijing YouAn Hospital, Capital Medical University, Beijing Tsinghua Changgung Hospital, School of Clinical Medicine, Tsinghua University, Beijing, China*
Email: mtt18813078830@163.com

Background and aims: Immune checkpoint inhibitors are essential to prevent the recurrence of primary liver cancer after interventional therapy, which is related to the changes in the immune status of the body. The purpose of this research is to demonstrate the association between the dynamic changes in immune response and recurrence in HCC patients who received anti-programmed cell death 1 (anti-PD-1) therapy.
Method: We selected 15 patients with a high risk of recurrence. All enrolled patients were initially treated with TACE combined with ablation and achieved complete remission, followed by anti-PD1 immunotherapy one month later. Peripheral blood samples were collected before each immunotherapy. Laboratory tests were performed on the patients once every 3W. The patients were followed up and divided into two groups according to the recurrence within one year. Then, Elispot assay was used to explore the difference of tumor-associated specific T cell responses between the two groups. Flow cytometry was used to detect the changes in T cell function.
Results: By flow cytometry and Elispot, we found that after PD1 blockade, the expression of $PD1^+CD8^+$ T lymphocytes in HCC patients was significantly reduced, and the expression of $Perforin^+CD8^+$ T lymphocytes and effector $CD8^+$ T lymphocytes was increased greatly. Meanwhile, the magnitude of AFP-specific T cell immune response was decreased, and the frequency and magnitude of SMNMS-specific immune response had an increasing trend. In terms of prognosis, compared with the recurrence group, the non-recurrence group had less $PD1^+$ $CD8^+$ T lymphocytes, effector $CD8^+$ T lymphocytes, and $PD1^+$ effector $CD8^+$ T lymphocytes, and continued to increase the expression of $Perforin^+CD8^+$ T lymphocytes. In addition, the shift of Th1/Th2 balance to Th2 is also associated with relapse.
Conclusion: This study demonstrates the important role of anti-PD1 immunotherapy in patients at high risk for recurrence of liver cancer and reveals that improvement in immune status is closely related to the prevention of recurrence.

SAT-549

Neutrophil-derived miRNA-223 modulates peritoneal immunity in patients with cirrhosis during spontaneous bacterial peritonitis

Mick Frissen[1], Johanna Reißing[1], Oluwatomi Ibidapo-Obe[1], Christian Trautwein[1], Tony Bruns[1]. [1]*University Hospital RWTH Aachen, Aachen, Germany*
Email: mfrissen@ukaachen.de

Background and aims: MicroRNAs (miRNAs) play a pivotal role in modulating inflammatory responses and cell-cell interactions during bacterial infections. This study investigates the alterations in miRNA composition in patients with spontaneous bacterial peritonitis (SBP), identifies cellular sources, and assesses the functional consequences.
Method: Paired serum and ascitic fluid samples, obtained before and during SBP, were subjected to multiplex microRNA profiling. Regulated miRNAs were further validated using LNA miRNA PCR assays. The source of miRNA was assessed by measuring intracellular and supernatant concentrations using cultured neutrophils and mononuclear cells. Functional consequences of miRNA-223 were evaluated using co-culture assays and transfection of THP-1 cells.
Results: Multiplex microRNA profiling identified five miRNAs that were differentially regulated in ascitic fluid during SBP. qPCR validation confirmed the enrichment of miR-223 during SBP. While TLR4 ligation down-regulated miR-223 in peritoneal macrophages and did not affect the release into the supernatant, neutrophils could be identified as a potent source of extracellular miR-223. Peritoneal macrophages show an increased uptake of miR-223 and an increased inflammatory gene expression when cultured with supernatant from isolated neutrophils of SBP patients compared to healthy controls or patients without SBP. The effect of miR-223 on macrophage gene

expression was tested by transfection of differentiated THP-1 cells with miR-223-mimic.
Conclusion: During SBP, miR-223 is released from infiltrating neutrophils and is enriched in ascitic fluid. Peritoneal macrophages can take up neutrophil-derived miRNA, which may affect peritoneal inflammation, limit tissue damage, and shape subsequent immune responses in the peritoneal cavity.

SAT-550
Melatonin attenuates LPS-induced acute liver injury by reducing the formation of macrophage extracellular traps through upregulated sirtuin 4 expression
Jun Zheng[1]. [1]*the Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*
Email: zhengj67@mail2.sysu.edu.cn

Background and aims: Sepsis is a life-threatening systemic inflammatory response syndrome causing multiple organ system dysfunction including liver, namely sepsis-induced acute liver injury (SALI). Macrophages play a crucial role in the pathogenesis of SALI and the modulation of macrophages response can be used to alleviate SALI. However, no effective therapeutics are currently available for clinical application.
Method: In this study, we used lipopolysaccharides (LPS)-induced SALI mouse model and murine macrophage cell lines to uncover the role of macrophages in SALI and the therapeutic potential of melatonin for this model. Moreover, RNA-Seq, detecting mitochondrial function, and adeno-associated virus vector (serotype 2, AAV2) were utilized to analyze the mechanism of melatonin in regulating macrophage extracellular traps (METs) formation.
Results: We investigated the therapeutic efficacy of melatonin in SALI and attempted to explore its underlying basis. Through in vivo and in vitro studies, we showed that melatonin attenuated SALI by modulating the inflammatory response of intrahepatic macrophages and the formation of METs. Mechanistically, we identified that melatonin directly promoted Forkhead Box M1 (FOXM1) nuclear translocation and upregulated Sirtuin 4 (Sirt4) expression in macrophages. Sirt4 could bind to mitofusin-2 (MFN2) and control its acetylation level in response to MFN2 availability. This effect triggered mitochondrial fusion for repairing the mitochondrial functions and status followed by suppressing METs formation. Notably, the downregulation of macrophagic Sirt4 expression in vivo and in vitro weakened the hepatoprotective effect and the effect of modulating MET formation of melatonin on SALI.
Conclusion: These data provide pharmacological evidence indicating that melatonin could reduce intrahepatic METs formation to treat LPS-induced SALI by promoting mitochondrial fusion and restoring mitochondrial quality of macrophages through regulating FOXM1/Sirt4 signaling pathway to affect the acetylation level of MFN2.

SAT-551
F-actin in autoimmune liver diseases: a comprehensive evaluation of diagnostic potential using a newly-developed autoimmune liver line immunoassay
Christos Liaskos[1], Tanja Seifert[2], Eleni Patrikiou[1], Marco Kai[3], Alexandra Tsirogianni[4], Christina Tsigalou[5], Dimitrios Bogdanos[1]. Email: bogdanos@uth.gr

Background and aims: Antigen-specific profiling assays simultaneously detecting the whole spectrum of AiLD-related autoantibodies in autoimmune liver diseases (AILDs) such as autoimmune hepatitis (AIH) and primary biliary cholangitis (PBC) are in urgent need, but those so far developed do not allow the comprehensive and reliable analysis of the most frequent autoantibodies in AIH-1, namely smooth muscle autoantibodies against F-actin. The aim was to develop a new line immunoassay that detects disease-specific F-actin SMA for AIH-1 in addition to (CYP2D6) LKM, (FTCD) LC1 for AIH-2, (SepSecS) SLA for AIH, (M2–3E) AMA, (Sp100/PML) MND, (RLM) gp210 for PBC and overlapping features of AIH and PBC, and disease-related SS-A, Ro-52 and (CEN A/B) ACA and to compare its performance in relation to conventional immunofluorescence.
Method: Sera from a meticulously selected cohort of 396 samples including 170 AIH type I, 17 patients with overlapping features of AIH type I/PBC, 32 AIH type II, along with control groups (71 PBC -, 20 PSC -, 32 hepatitis C patients, 50 healthy controls), were employed for a comprehensive, thorough screening using a F-actin line blot (cut off 6; borderline 6–10; pos>10 AU/ml) and ELISA as well as immunofluorescence tests (Liver Kidney Stomach (LKS)-and VSM47 cells).
Results: F-Actin antibody positivity including borderline sera was present in 82.3% (140/170) of the AIH type I cohort (range 6–136 IU, mean ± SD: 65.1 ± 28.1) and remarkably in 100% (17/17) patients with overlap features of AIH-1/PBC (range 6–69 IU, mean ± SD: 32.5 ± 22.2) while the stringiest 11 AU/ml cut off for clear positive sera revealed F-actin reactivity in 68.2% AIH type I patients and were statistically more frequent in AIH-1 compared to AIH type II ($p < 0.001$), hepatitis C ($p = 0.003$), PBC ($p < 0.001$), PSC ($p < 0.001$) and HC ($p < 0.001$ with a specificity of 87.2% versus SMA negative healthy controls). Levels of F actin abs were significant higher in AIH type I compared to all other patient groups and HCs ($p < 0.001$ for all comparisons). ELISA and immunofluorescence results supported the line blot results as concordance analysis, assessed through Cohen's kappa statistics, revealed moderate to substantial agreement between F-actin line blot and ELISA ($\kappa = 0.75$) as well as immunofluorescence tests ($\kappa = 0.57$ for VSM47 and $\kappa = 0.51$ for LKS), highlighting the reliability of F-actin as a diagnostic marker.
Conclusion: The comprehensive evaluation underscores the promising diagnostic potential of F-actin in AILDs, particularly through line blot analysis which allows simultaneous detection of the great majority of AiLDs specific and disease-related autoantibodies through the reliable detection of F-actin SMA in AIH-1 and AIH-1/PBC overlaps in isolation or in combination with indirect immunofluorescence.

SAT-554-YI
Cellular immunity changes induced by COVID-19 vaccines in patients with chronic liver disease
Carolina Palma[1], Mariana Moura Henrique[1], André Simão[1], Ana Godinho-Santos[1], Miguel Cardoso[1], Diogo Fernandes[1], Sofia Carvalhana[2], Miguel Moura[2], João Gonçalves[1], Helena Cortez-Pinto[2,3], Rui E. Castro[1]. [1]*Research Institute for Medicines (iMed.ULisboa), Faculty of Pharmacy, Universidade de Lisboa, Lisbon, Portugal;* [2]*Departamento de Gastrenterologia, Centro Hospitalar Universitário Lisboa Norte, Lisbon, Portugal;* [3]*Clínica Universitária de Gastrenterologia, Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal*
Email: carolina-palma@campus.ul.pt

Background and aims: Patients with chronic liver disease (CLD), particularly those with cirrhosis, exhibit increased risk of developing severe illness when infected with SARS-CoV-2, primarily due to their underlying immune dysfunction and coexisting conditions. As such, vaccination plays a crucial role in safeguarding this population. Here, to fully assess the efficacy and safety of COVID-19 vaccination in patients with CLD, we thoroughly characterized the cellular immune responses of these patients to COVID-19 vaccines.
Methods: Blood samples were systematically collected from patients with CLD and healthy volunteers at various intervals spanning one year after the initial administration of mRNA-1273, BNT162b2,

ChAdOx1, and Ad26.COV2.S vaccines. Peripheral blood mononuclear cells (PBMCs) were isolated and stained with a panel of 22 surface markers and a viability dye, allowing for the detection of 28 immune cell subsets. Immunophenotyping was determined by flow cytometry with acquisition on a four-laser Cytek Aurora® spectral analyzer.
Results: Prior to vaccination, patients with CLD patients were already displaying fewer T cells and an increased number of B cells, comparing to healthy subjects. Within the T cell subsets, differences were significant for CD4+ T cells and the Naïve and Central Memory CD4+ subsets. At both 6-months and 1-year after vaccination, variances between groups were no longer observed. Rather, at 1-year post-vaccination, T, CD8+ and CD4+ cells, as well as monocytes. were found increased in both groups, suggesting that the vaccination is critical for inducing a strong cellular immune response. In patients with CLD, minor variations in the percentages of gated cells across the 3 time-points were found to relate with the underlying liver disease etiology and/or the specific vaccine that was administered. Finally, regarding COVID-19 infection in patients with CLD, variations in the percentage of gated cells before and at 1-year after vaccination were similar in almost all cell sub-types except for CD8+ T cells and NK cells, which were decreased prior to vaccination in subjects who became infected.
Conclusion: COVID-19 vaccines demonstrated robust immunogenicity in the CLD cohort, despite the differences observed in some cell populations prior to vaccination. Still, additional studies should ideally be performed to determine optimal vaccine strategies; and ascertain whether disease etiology and other disease-associated factors may influence cellular immunity responses to vaccination and/or COVID-19 vaccine efficacy and safety.

SAT-555

Global and Kupffer cell specific Nlrp3 inflammsome in-/activation greatly affects the inflammatory and metabolic progression of alcohol-related liver disease

Lukas Geisler[1,2], Marlene Kohlhepp[1], Jana Knorr-Klocke[1], Theresa Holtmann[1], Cornelius Engelmann[1], Frank Tacke[1], Alexander Wree[1]. *[1]Charité-Universitätsmedizin Berlin, Department of Hepatology and Gastroenterology, Berlin, Germany, [2]Humboldt-Universität zu Berlin, Department of Biology, Berlin, Germany*
Email: lukas.geisler@charite.de

Background and aims: The NLR family pyrin domain containing 3 (Nlrp3) inflammasome, an intracellular multi-protein complex forming in the presence of a variety of in or extrinsic danger signals, is central to immune response in disease and homeostasis. While its activation is initially pro-inflammatory, it induces an anti-inflammatory cascade to balance the consecutive response. Nlrp3 deficient animal models to study liver disease have been evaluated extensively, showing that it may cause aggravation as well as improvement of induced condition, hence has a heterogeneous impact warranting further studies. Therefore, we evaluated variants of genetically altered Nlrp3, either global deficiency, as well as Kupffer cell specific over and inactivation of the Nlrp3 inflammasome to compare its global and local function in Alcohol-related liver disease (ALD).
Method: Mice carrying a global Nlrp3 deficiency ($Nlrp3^{-/-}$), Kupffer cell (KC) specific over activation $Clec4^{Nlrp3ki}$, and inactivation $Clec4f^{ASCflox}$ were fed a combined Western Diet + Alcohol (A + WD) for 10 weeks. Ongoing evaluation of liver immune cell populations was performed using flow cytometry and multiplex protocols for histology, alongside extended serum analysis as well as quantitative evaluation of gene expression (qPCR).
Results: While serum AST and ALT remained unaltered when fed chow between all genotypes, we found elevated AST in $Nlrp3^{-/-}$ and $Clec4^{Nlrp3ki}$ mice under A + WD, the latter showing a distinct lymphocytic immune cell infiltration and marked elevation of inflammatory genes e.g. IL-1ß, IL-6, TNF. $Nlrp3^{-/-}$ additionally had a marked increase of serum triglycerides. When fed A + WD $Clec4f^{ASCflox}$ mice showed an increase in weight gain and liver/bodyweight composition alongside cholesterol and histological prevalent steatosis. Under A+WD conditions Sterol regulatory element-binding transcription factor 1 and Cytochrome P450 2A1 were significantly upregulated in $Nlrp3^{-/-}$ mice, which was not found for the other genotypes. $Clec4^{Nlrp3ki}$ mice showed increased immune cell infiltration with pronounced T-cell receptor beta and lymphocyte antigen 6 family member G (Ly6G) positive cell populations, along with signs of fibrosis in Masson's trichrome staining.
Conclusion: The results of our experiments indicate the multifaceted role of the Nlrp3 inflammasome in experimental alcoholic liver disease. While $Nlrp3^{-/-}$ mice had pronounced pathology including increased serum enzymes and IL-10 gene expression, $Clec4f^{ASCflox}$ compared to wild type animals showed increased weight gain but hardly any inflammatory reaction towards A + WD. Hence, the role of Nlrp3 inflammasome in liver disease is not limited to its functionality in mediating Kupffer cell differentiation towards a pro or anti-inflammatory phenotype, but may also affect metabolic functions and the development of fibrosis.

SAT-556-YI

Altered immune responses and PD-L1 levels in children with portal hypertension

Tengfei Si[1], Bethany Tucker[2], Huihong Yu[3], Fabiola Di Dato[3], Xiaohong Huang[3], Qing Shao[3], Eirini Kyrana[4], Yun Ma[3], Tassos Grammatikopoulos[5]. *[1]Institute of Liver Studies, King's College London, London, United Kingdom; [2]King's College Hospital, Paediatric Department, London, United Kingdom; [3]Institute of Liver Studies, King's College London, London, United Kingdom; [4]King's College Hospital, King's College London, London, United Kingdom; [5]King's College Hospital, Paediatric Department, London, United Kingdom*
Email: tengfei.si@kcl.ac.uk

Background and aims: The role of immune dysregulation in children with portal hypertension (PHT) remains unclear. This study aims to delve into the altered immune responses and the immunomodulatory role of Programmed Death-Ligand 1 (PD-L1). By exploring how PHT influences the immune system in children, we seek to unravel the complexity of immune dysregulation in this condition.
Method: We studied a group of 55 children with PHT, stemming from portal vein thrombosis or chronic liver disease, and 15 healthy controls. Assays for plasma PD-L1, various cytokines, and immune biomarkers were conducted. Flow cytometry was used to assess immune cell phenotypes and functions in 33 PHT patients and 12 controls.
Results: PHT patients exhibited higher levels of plasma IFN-γ (95.62 pg/ml vs 25.28 pg/ml, $p = 0.03$), PD-L1 (6281 pg/ml vs 454.2 pg/ml, $p = 0.032$) and activation markers of M2 macrophage (CD163, 633.5 ng/ml vs 414.8 ng/ml, $p = 0.002$;VCAM, 861 ng/ml vs 397.7 ng/ml, $p < 0.0001$) compared to controls. PD-L1 levels positively correlated with pro-inflammatory (TNF-α, $R^2 = 0.8522$, $p < 0.0001$; IFN-γ, $R^2 = 0.188$, $p = 0.018$), anti-inflammatory (IL-4, $R^2 = 0.810$, $p < 0.0001$) cytokines, and liver injury marker (MMP7, $R^2 = 0.423$, $p < 0.0001$). Notably, a decrease in peripheral T cells, especially MAIT cells, and an increase in T cell exhaustion markers were observed. There was a significant reduction of $CXCR3_{pos}$ T cells (32.5% vs 42.8%, $p = 0.04$), while non-T cells showed altered PD-1 and CD38 expression. Additionally, PHT patients displayed an increase in immunosuppressive $PD\text{-}1_{pos}CD39_{pos}$ cells within $CD4_{pos}$ and $CD8_{pos}$ T cell subsets and diminished IFN-γ and IL-17 production in MAIT cells. A positive correlation was established between the count of peripheral $PD\text{-}1_{pos}$ non-T cells ($R^2 = 0.426$, $p < 0.0001$), soluble CD25 levels ($R^2 = 0.7522$, $p < 0.0001$), and PD-L1 plasma values.
Conclusion: This study unveils a distinctive pattern of immune dysregulation in pediatric PHT, characterized by T cell exhaustion and altered cytokine profiles. Elevated PD-L1 levels underscore its role in modulating the complex immune responses in PHT.

SAT-557-YI

Loss of fibronectin contribute to poor maturation of monocyte to resolving macrophages in acute and chronic liver injury

Sandeep Kumar[1], Dhananjay Kumar[1], Deepanshu Maheshwari[1], Sunidhi Diwakar[2], Nidhi Nautiyal[3], Manisha Bhardwaj[1], Shiv Kumar Sarin[1], Anupam Kumar[1]. [1]*Institute of Liver and Biliary Sciences, New Delhi, India;* [2]*Institute of Liver and Biliary Sciences, New Delhi;* [3]*Institute of Liver and Biliary Sciences, New Delhi, India*
Email: dr.anupamkumar.ilbs@gmail.com

Background and aims: Loss of liver macrophage number and their function have been shown to be associated with poor liver clearance in both acute and chronic liver injury; however, the underlying mechanism is not well defined. The extracellular matrix is a dynamic structural component of tissue and regulate cell behaviour during tissue repair and regeneration. In the current study, we aim to study the role of the liver matrix in the maturation of bone marrow derived monocytes into macrophages and their phenotypic polarisation as well as function.
Method: Human healthy (n = 4), acute liver failure (ALF; n = 5), and chronic liver disease (CLD; n = 5) decellularized liver Extracellular matrix (ECM) was used for label-free quantitative matrix proteome using LC-MS. The decellularized matrices were lyophilized and solubilized for in vitro culture of macrophages. Gelatin and human plasma fibronectin were dissolved and coated over the tissue culture plates (TCP) for monocyte-macrophage culture. Cellular parameters like maturation, phenotype, cytokine release, and functionality were studied by flow cytometry.
Results: To check whether liver ECM has any role in maturation, polarization, and functionality of macrophages, we cultured human peripheral blood monocytes over healthy, ALF, and CLD human liver ECM solution-coated and uncoated TCPs and found that cells cultured over healthy ECM has significant high expression of maturation marker (25f9; $p < 0.001$), resolving macrophage markers ($p < 0.05$; CD163, CD206), and anti-inflammatory cytokine IL-10 ($p < 0.001$), and lower expression of inflammatory cytokines TNF-alpha ($p < 0.01$) and IL-1beta ($p < 0.01$). To further identify the factors that are regulating macrophages, we did a proteomic analysis of decellularized healthy, ALF and CLD human liver ECMs and found that out of 277 shared proteins, fibronectin was downregulated in the ALF and CLD matrix proteomes. For validating the effect of fibronectin on macrophage regulation, we coated the TCP with fibronectin and cultured monocyte-macrophages over it. In-vitro culture of human macrophages over fibronectin showed significantly higher expression of 25f9 ($p < 0.001$), resolving macrophage markers CD163 ($p < 0.05$), CD206 ($p < 0.01$), and a significant increase in their phagocytosis ($p < 0.01$) and efferocytosis ($p < 0.001$) activity as compared to gelatin coated and TCP. Also, the expression of pro-inflammatory cytokines (TNF-alpha and IL-1beta, $p < 0.01$) was significantly lesser in the fibronectin group, while the expression of anti-inflammatory cytokines (IL-10) was significantly higher ($p < 0.001$) when cultured on fibronectin coated plates.
Conclusion: The loss of fibronectin in ALF and CLD may contribute to the loss of macrophage maturation and function. Providing fibronectin enriched matrix may serve as tool for macrophages polarisation for tissue engineering.

SAT-558

CD8+ effector T cells expressing low levels of CD127 upregulate GPR56 expression and reside in the hepatic autoimmune and inflammatory microenvironment

Rémi Fiancette[1], Ayma Asif[1], Ye Htun Oo[1,2]. [1]*Institute of Immunology and Immunotherapy, Centre for Liver and Gastrointestinal research, University of Birmingham, Birmingham, United Kingdom;* [2]*Liver Transplant and Hepatobiliary Unit, University Hospitals Birmingham NHS Foundation Trust, European Reference Network Centre-Centre for Rare Disease, University Hospitals Birmingham NHS Foundation trust, Birmingham, United Kingdom*
Email: r.b.fiancette@bham.ac.uk

Background and aims: In contrast to liver cancer and viral hepatitis, little is known about the pathogenic or dysfunctional effector T cells within the proinflammatory microenvironment in inflammatory and autoimmune liver diseases.
Method: Bulk RNA-sequencing and flow cytometric analyses allowed us to identify a specific subset of $CD8^+$ T cells in both blood and liver. Immunohistochemistry analysis was performed to detect cell localisation and ligand identification.
Results: We observed a $CD8^+$ T cell subset which displays a low level of CD127 and CD160 expression. This population concomitantly upregulates the immune checkpoint GPR56 (25.76% ±4.21), an adhesion G-protein-coupled receptor, whose ligand, type 3 collagen, is particularly abundant in fibrotic and cirrhotic livers. We performed multicolour flow cytometry analyses on liver-derived lymphocyte T cell populations isolated from end-stage diseased livers with different aetiologies (ALD, n = 2; MASH, n = 4; AIH, n = 1; PSC, n = 2) as compared to non-cirrhotic donor livers not suitable for transplantation (controls, n = 2). Another hallmark of this $CD127^{lo}$ $CD8^+$ T cell population is their low expression of the transcription factor TCF-1, consistent with their acquisition of effector properties, potentially sustaining persistent inflammatory processes. $GPR56^+$ $CD127^{lo}$ $CD8^+$ T cell recruitment and concentration around the portal tract regions could be facilitated by the expression of CXCR3 and CCR6. Immunohistochemistry analysis suggested that these cells reside around fibrous septa expressing collagen 3 and may create a proinflammatory niche establishing a chronic inflammatory disorder. *Ex vivo* assays with flow cytometry staining will help characterise their proinflammatory cytokine ($TNF\alpha$, $IFN\gamma$) and effector molecule (granzyme, perforin) secretion profile, alongside spatial transcriptomic analysis which will enable a deeper description of this newly discovered T cell subset.
Conclusion: We identified a new subset of $CD127^{lo}$ $CD8^+$ T cells with a pro-inflammatory cytokine profile and residency to fibrous stromal framework. These T cells may potentially be involved in the pathogenesis of autoimmune and inflammatory liver diseases.

Liver transplantation and hepatobiliary surgery – Basic

Adipose tissue as a predictor of morbidity and mortality in patients listed for liver transplantation

Maxence Lepour[1], Delorme Alicia[1], Hubert Piessevaux[1], Pierre Trefois[2], Nicolas Lanthier[1], Géraldine Dahlqvist[1]. [1]*Cliniques Universitaires Saint-Luc, Department of Hepato-Gastro-Enterology, Brussels, Belgium;* [2]*Cliniques Universitaires Saint-Luc, Department of Radiology, Brussels, Belgium*
Email: max.lepour@gmail.com

Background and aims: Body composition plays a crucial role in the prognosis of liver diseases. However, recent studies have focused mainly on muscle parameters and less is known about the adipose tissue (AT) (=subcutaneous AT (SAT) and visceral AT (VAT)) in terms of prognosis. The aims of our work are to determine the impact of body composition on the morbidity/mortality of patients listed for liver transplantation (LT) and to assess the evolution of these parameters 6 months post-LT.
Method: This single-center prospective observational study screened adult patients who were assessed for LT from June 2021 to October 2023. Clinical data including nutritional and functional status, radiological assessment of muscular compartment and AT were performed at baseline and 6 months post-LT. Measures were

performed on abdominal CT scan at the third lumbar level (L3) using the Slice-O-Matic software. The composite outcome was defined as death and/or emergency admission to hospital. Uni- and multivariate Cox proportional hazard regressions were computed to identify predictors of morbidity and mortality. T-test investigated the evolution of variables between pre- and 6-months post-LT. Spearman correlations were also performed.

Results: We included 158 patients with a mean MELD score of 16 and a mean age of 54 years. 74% were males. 124 were cirrhotic, with alcohol-related cirrhosis in 49.2 and metabolic-associated cirrhosis in 11.3%. 35.2% were listed for hepatocellular carcinoma. During the study period, 58.2% of the patients were transplanted, 63% of them being assessed at 6-month post-LT. During the follow-up, 9, 5% died while waiting for LT, all being cirrhotic. There was at least one acute admission for 28.5%. In univariate analysis, the following variables were significantly associated with the composite outcome : MELD (HR 1.15; IC 1.1–1.201; $p < 0.005$), liver frailty index (LFI) (HR 2.73; IC 1.688–4.408; $p < 0.005$)), density of SAT (HR 1.05; IC 1.028–1.072; $p < 0.05$)), density of VAT (VAT; HR 1.04; 1.011–1.072, $p = 0.007$) and muscle density (HR 0.97; 0.956–0.987; $p < 0.005$). In multivariate analysis, only MELD and LFI were associated with outcome (HR: 1.14; IC1.078–1.20; $p < 0$, 005 and HR: 2.054; IC 1.176–3.588; $p = 0.01$; respectively). Among body composition characteristics, density of SAT was the strongest predictive factor but didn't reach significance (HR 1.033, $p = 0.091$). There was a strong correlation between density of AT and the MELD score (SAT: $r = 0.598$, 95% CI 0, 4747–0, 6987, $p < 0.0001$; VAS: $r = 0.5615$, 95% CI 0, 4306–0, 6692, $p < 0.0001$). At the 6-month post-LT, density of SAT decreased significantly ($p < 0.005$), while density of muscle increased ($p = 0.019$).

Conclusion: High SAT density, compatible with tissue inflammation, is associated with complications on the LT list and improves after LT. However, the MELD score and LFI remain the most robust independent factors for morbidity/mortality.

WED-009

Cytomegalovirus specific polyfunctional t-cells control CMV reactivation, after liver transplantation

Ângela Carvalho-Gomes[1,2], Laura Martínez-Arenas[1,3,4], Iván Sahuco[1], Almudena Cubells[1], Marina Berenguer[1,3,5], F. Xavier Lopez-Labrador[6,7], Victoria Aguilera Sancho[1,3]. [1]*Hepatología y trasplante hepático, IIS La Fe, Hospital U. y P. La Fe, Valencia, Spain, Valencia, Spain;* [2]*Ciber-EHD, Instituto De Salud Carlos III, Madrid, Spain;* [3]*Ciber-EHD, Instituto De Salud Carlos III, Madrid, Spain, Madrid, Spain;* [4]*Department of Biotechnology, Universitat Politècnica de València, Valencia, Spain, Valencia;* [5]*Dep. Medicine, University of Valencia, Valencia, Valencia, Spain;* [6]*Virology Laboratory, Genomics and Health Area, FISABIO-Public Health, Generalitat Valenciana, Valencia, Valencia, Spain;* [7]*CiberESP Instituto De Salud Carlos III, Madrid, Spain, Madrid, Spain*
Email: angela.carvalho@uv.es

Background and aims: Cytomegalovirus (CMV) viral load after liver transplantation (LT) is controlled by cell mediated immune responses (CMI). Quantification of CMV-specific T-cells may allow identifying patients that achieve spontaneous CMV control. In addition, CMI could be used to measure the state of immune-competence status of the patient, and thus useful as a biomarker to predict the risk of infections/reactivations, rejection and *de novo* tumors.

Method: Prospective post-LT clinical, virologic and immunological monitoring was carried out up to 1 year in a cohort of adult LT recipients (LT-R). CMV-specific responses were characterized using flow-cytometry multiparametric analyses.

Results: We analyzed 518 samples from 104 LT-R (83.65% R+, 16.35% R−). CMV reactivation occurred in 52 patients, 36 of which (69.23%) spontaneously controlled viral replication, while 33 had severe reactivation, 78.79% of which was developed in patients at low risk of CMV reactivation (7 in R− and 26 in R+). In pre-LT samples, 48.1% and 56.7% of the patients had detectable CMV-pp65 CD8+ or CD4+ T-cell response, respectively (at least one cytokine). In contrast, only 24.0% or 16.3% had detectable CMV-specific CD8+ or CD4+ polyfunctional T-cells, respectively. Patients with CMV-specific CD4+ T-cells higher than 0.05% of total T-cells pre-LT had less CMV reactivation episodes ($p = 0.0018$), and less severe CMV events ($p = 0.0043$). Only patients with undetectable CMV-specific CMI pre-LT developed CMV infection and were diagnosed with severe CMV events. No statistically significant differences were detected between polyfunctional CMI driven by CD4+ and CD8+ T-cells in patients who developed a de novo tumor, an acute cellular rejection or other infections and those who did not.

Conclusion: While the quantitation of CMV-specific CMI, especially that driven by CD4+ T-cells, showed good diagnostic performance to predict CMV reactivation, it did not predict the development of other clinical events (other infections, *de novo* tumors and rejection). CMV-specific CMI may be a useful biomarker for spontaneous control of CMV reactivation to tailor antiviral treatment after LT.

WED-010

Functions and molecular mechanisms of metformin in ameliorating ischemia-reperfusion injury of steatosis liver by inhibiting ferroptosis

Rong Li[1]. [1]*the Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China*
Email: tsfnlr@163.com

Background and aims: Liver transplantation is the only effective treatment for end-stage liver disease. However, the shortage of donors seriously restricts the development of liver transplantation. In recent years, there has been an increasing proportion of steatosis liver in the donor pool. Compared to normal livers, steatosis livers are more susceptible to ischemia-reperfusion injury (IRI), which greatly affects the outcome of liver transplantation. Nevertheless, the underlying mechanisms and corresponding improvement strategies remain largely unexplored. Previous studies have demonstrated that metformin, a first-line drug for type 2 diabetes management, not only effectively reduces blood sugar levels but also significantly improves stroke, myocardial infarction, and renal IRI. However, limited research has been conducted on metformin's role in liver IRI. Therefore, my study aims to investigate whether metformin can mitigate IRI in steatosis livers and elucidate its associated molecular mechanisms.

Method: We utilized clinical samples collected before and after liver transplantation from donors as well as non-alcoholic fatty liver mouse models with hepatic ischemia-reperfusion injury (HIRI) and cell models of non-alcoholic fatty liver to evaluate the effects of metformin in mitigating IRI via inhibiting ferroptosis. Mass spectrometry analysis was employed alongside Chromatin Immunoprecipitation (ChIP) assays and adeno-associated virus (AAV-8) precipitation techniques to identify and validate the potential regulatory mechanisms.

Results: Steatosis liver is indeed more prone to HIRI and exhibits a higher degree of ferroptosis. Treatment with metformin can significantly alleviate the IRI of steatosis liver. Mass spectrometry showed that metformin can down-regulate the level of transcriptional coactivator P300. Corresponding mechanism studies showed that metformin promoted the degradation of P300 by activating AMPK. Further ChIP-seq results showed that P300 could bind to the promoter region of ACSL4, up-regulate its H3K27ac modification, and promote the expression of ACSL4. Overexpression of P300 or ACSL4 can significantly reverse the improvement of metformin on the steatosis liver IRI.

Conclusion: This study reveals that metformin can effectively alleviate steatosis liver IRI through AMPK/P300/ACSL4 pathway, providing an important theoretical basis for clinical use of metformin to reduce the occurrence of steatosis liver IRI and improve its utilization rate in liver transplantation.

Prognosticating hepatocellular carcinoma before and after liver transplantation with HepatoPredict

Silvia Gomes Silva[1], Judith Pérez[2,3], Laura Frazão[4], Carolina Peixoto[4], Almudena Cubells[5,6], Eva Montalvá[6,7], Antonio Figueiredo[8], Daniela Proença[4], Jose Pereira-Leal[4], Hugo Pinto Marques[9,10], Marina Berenguer[6,11,12], Joana Cardoso[13]. *[1]Hepato-Biliary-Pancreatic and Transplantation Centre, Lisbon, Portugal; [2]Pathology Service, Hospital Universitari I Politècnic La Fe, Valencia, Spain; [3]CIBERehd, Instituto de Salud Carlos III, Madrid, Spain; [4]Ophiomics-Precision Medicine, Lisbon, Portugal; [5]Hepatology Unit, Hospital Universitari I Politècnic La Fe, Valencia, Spain; [6]CIBERehd, Instituto de Salud Carlos III, Madrid, Spain; [7]Liver Transplantation and Surgery Unit, Hospital Universitari I Politècnic La Fe, Valencia, Spain; [8]Pathology Service, Hospital Curry Cabral, Centro Hospitalar de Lisboa Central, E.P.E., Lisbon, Portugal; [9]Hospital Curry Cabral, Centro Hospitalar de Lisboa Central, E. P.E., Lisbon, Portugal; [10]Centro de Estudos de Doenças Crónicas (CEDOC), NOVA Medical School, Universidade NOVA de Lisboa (NMS/UNL), Lisbon, Portugal; [11]Hepatology Unit, Hospital Universitari I Politècnic La Fe, Valencia, Spain; [12]Universidad de Valencia, Facultad de Medicina, Valencia, Spain; [13]Ophiomics- Precision Medicine, Lisbon, Portugal*
Email: jvaz@ophiomics.com

Background and aims: Liver transplantation (LT) is the best curative treatment for hepatocellular carcinoma (HCC) but is limited by the shortage of organs for transplant and by strict pre-LT criteria. Pre-LT evaluation often underestimates tumour burden which leads to cases of tumour progression while on the waiting list or post-LT. Addressing the issue of pre-LT/post-LT prognosis discrepancy is essential to better stratify patients' post-surgery. We have recently developed a gene expression signature (HepatoPredict) to support the selection of HCC patients for LT. In the current work, we test the prognostic value of HepatoPredict to support post-LT stratification of HCC patients.
Method: A retrospective cohort of patients from two main LT centres (PT and ES) with HCC listed for LT from 1998 to 2016 was collected, containing 222 patients who underwent LT. In total 46 patients relapsed and 176 remained recurrence-free at 5 years. The molecular variables measured in each tumour using the HepatoPredict kit were combined with HCC-specific histopathological variables such as tumour number, size of tumour and tumour volume. Data was split into train and test sets and the machine learning algorithms were optimized for Precision or Recall.
Results: In our cohort, 77% of the patients were within Milan criteria pre-LT. At 5 years, 79.3% of the patients remained recurrence-free, with a 5-year incidence of HCC recurrence of 18.9% (median 23 months). The post-LT HepatoPredict algorithm trained with the molecular variables plus clinical variables and presenting the best performance had 88% precision and 90% recall. Compared to other criteria, our best algorithm was the only one showing similar or superior performance for all metrics (e.g., HepatoPredict precision of 88% versus 75% MORAL very low and low scores) with a clear gain in negative predictive value (NPV) (e.g., 65% versus 44% for Milan criteria). When applied to pre-LT prognosis, using radiology-derived tumour measurements as previously described (Pinto-Marques et al.) this algorithm also presented a good performance for all metrics (82% precision, 90% recall, 61% NPV).
Conclusion: HepatoPredict was initially developed to select HCC patients for LT. We now show that using the same algorithm, the same biomarkers and clinical variables defined by radiology or histopathology can aid in the post-LT setting. HepatoPredict-mediated post-LT stratification can identify high-risk patients and improve the definition of more effective surveillance schemes and/or adjuvant therapies.

WED-016

Continuous hemodiafiltration prevents sinusoidal endothelial failure during extended ex situ normothermic perfusion of porcine livers

Jordi Vengohechea Llorens[1], Javier Muñoz[2], Marina Vendrell[3], Josep Marti Sanahuja[3], Joaquim Albiol[4], Javier Salinas[1], Aida Vaquero-Rey[1], Amelia Judith Hessheimer[1], Constantino Fondevila[1]. *[1]Department of General and Digestive Surgery, Hospital Universitario La Paz, IdiPAZ, CIBERehd, Madrid, Spain; [2]Centro de Investigación Biomédica en Red Enfermedades Hepáticas y Digestivas (CIBERehd), Madrid, Spain; [3]Anesthesiology, Reanimation, and Pain Management Service, Hospital Clinic, Barcelona, Spain; [4]Donation and Transplantation Institute, Barcelona, Spain*
Email: jordivengo@gmail.com

Background and aims: *Ex situ* normothermic machine perfusion (NMP) is a promising strategy for liver preservation. There is still no consensus on requirements for optimal preservation of graft integrity. We aim to Evaluate the impact of continuous hemodiafiltration (HDF) applied during extended liver NMP.
Method: Porcine livers (N = 16) were perfused for 24H using a blood-based perfusate. Nutrition, vitamins, and trace elements were added after 4H. Insulin and/or glucose were also given, as needed. In a subset of cases, continuous HDF was initiated after 2H (N = 5).
Perfusate was sampled serially during perfusion to analyze markers of injury, inflammation, and hepatocellular and biliary function. Liver parenchymal and biliary tissue samples were also taken at the start and end of perfusion to assess histological injury, hepatic stellate cell (HSC) activation (alpha-SMA), and endothelial cell (EC) response (eNOS, KLF2, CD31).
Results: During 24H NMP, AST and LDH levels progressively increased for the first 12H and were higher in grafts without HDF (679 ± 410 vs. 294 ± 93 u/L $p < 0.05$ and 1636 ± 529 vs. 1013 ± 26 u/L $p < 0.01$ respectively). HDF also improved glucose consumption and lactate clearance (233 ± 140 vs. 108 ± 40 mg/dL $p < 0.02$ and 15.9 ± 4.9 vs. 7.3 ± 3.6 $p < 0.02$ mmol/L), though bile production and quality and histological biliary injury did not vary.
Levels of pro-inflammatory IL-6 and IL-8 were significantly higher in grafts without HDF at 12 (7451 ± 2060 vs. 4152 ± 569 pg/ml and 41930 ± 8960 vs. 3088 ± 791 pg/ml $p < 0.001$ respectively) and 24H (7045 ± 2174 vs. 3120 ± 587 and 16890 ± 5220 vs. 677 ± 544 pg/ml $p < 0.001$ respectively). Increased gene and protein expression of alpha-SMA reflected greater HSC activation (4.7 ± 1.6 vs.1.9 ± 0.19 $p < 0.02$ and 2 ± 0.3 vs. 1.5 ± 0.2 $p < 0.01$ for gene and protein expression respectively), while decreased gene and protein expression of eNOS (1.4 ± 0.2 vs. 4 ± 0.6 $p < 0.001$ and 1 ± 0.5 vs. 2.3 ± 0.7 $p < 0.05$ respectively) and KLF2 (0.9 ± 0.4 vs. 2 ± 0.4 and 0.9 ± 0.5 vs. 2.7 ± 0.5 $p < 0.001$ for both expressions) reflected reduced vasodilatory capacity of EC in grafts undergoing NMP without HDF ($p < 0.001$ for both genes). Consequentially, increased endothelial congestion and decreased EC area were observed among non-HDF livers (22 ± 4% vs. 29 ± 1% $p = 0.006$).
Conclusion: During extended ex situ NMP, addition of continuous HDF is associated with a less inflammatory environment and maintenance of cellular mechanisms and responses necessary to maintain the normal microarchitecture and size of the sinusoidal lumen in isolated liver grafts.

WED-017-YI

Myeloid Mas-dependent macrophage efferocytosis maintains immune homeostasis in the ischemia-stressed mouse and human livers

Shuai Chen[1], Changqing Yang[1], Zhi Lu[2]. *[1]Tongji Hospital, School of Medicine, Tongji University, Shanghai, China; [2]Tsinghua University, Beijing, China*
Email: shuai_chenrj@163.com

Background and aims: Liver ischemia-reperfusion injury (LIRI) is a local sterile inflammatory response driven by the innate immunity

following liver transplantation. Mas is a master regulator of inflammation and has been implicated in both human and murine inflammatory disease models. We aimed to characterize the roles of macrophage-specific Mas in LIRI.
Method: Hepatic expression of Mas was examined in ischemia-stressed mouse and human livers. Myeloid-specific Mas1-knockout strain was generated to study the function and mechanism of macrophage Mas in a murine LIRI model. Single-cell RNA sequencing (scRNA-seq), spatial transcriptomics (ST), multiplex immunohistochemistry (mIHC), flow cytometry, intravital imaging and Mertk-knockout mice were used to describe the efferocytosis and endogenous cell interactions. RNA-seq, ChIP-qPCR, CUTandTag, luciferase reporter assay, adenovirus and mouse primary cells were used for in vitro analysis.
Results: In human specimens, macrophage Mas expression was significantly decreased in liver tissues after transplantation or hepatectomy. Interestingly, lower Mas expressions correlated with more severe liver injury postoperatively. In a mouse model, myeloid deficiency of Mas showed worse inflammation and delayed resolution than controls. scRNA-seq, ST, and intravital imaging collectively revealed that myeloid deficiency of Mas impairs macrophage efferocytosis by downregulating MerTK, leading to the accumulation of aged neutrophils. In vitro, Mas deficiency promoted innate immune activation in macrophages and downregulated the KLF4/MerTK axis through the PKA/CREB signaling pathway. CUTandTag, luciferase reporter assay and ChIP-qPCR further demonstrated KLF4 bound to the promoter region of MerTK. Importantly, Macrophage-specific overexpression of KLF4 rescued the exacerbated phenotype caused by myeloid Mas deficiency by increasing MerTK expression and macrophage efferocytosis.
Conclusion: In conclusion, macrophage Mas mediates innate pro-inflammatory responses and attenuates LIRI by regulating the KLF4/MerTK axis, which provides a therapeutic target for LIRI. These findings identify the macrophage Mas as a putative checkpoint regulator of homeostasis in response to acute hepatic stress in mouse and human livers.

JNK signaling activates autophagy of CD8+T cells to promote acute rejection after liver transplantation in rats via regulating BECN1/BCL-2 interaction
Xiaowen Wang[1], Xiaolong Chen[2], Genshu Wang[3], Haoqi Chen[1], Xuejiao Li[4], Wenfeng Zhu[1], Zhilong Liu[2], Zhiwei Chen[2]. *[1]Department of Hepatic Surgery, Liver Transplantation, The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [2]Department of Hepatobiliary Surgery, The First Affiliated Hospital of Jinan University, Guangzhou, China; [3]Department of Hepatic Surgery, Liver Transplantation, Guangdong Provincial Hospital of Chinese Medicine, Guangzhou, China; [4]Department of Hepatology lab, The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*
Email: chxl1446@126.com

Background and aims: Acute rejection (AR) after liver transplantation (LT) remains an important factor affecting the prognosis of patients. Our previous study and other researchers' work confirmed the important role of autophagy in CD8+ T cells during AR after LT. However, the underlying autophagy regulation mechanisms in CD8+ T cells during AR remain unclear.
Method: Human liver biopsy specimens of acute rejection after orthotopic liver transplantation were collected to assess the relationship between JNK and CD8+ T cells autophagy. The effect of JNK inhibition on CD8+ T cells autophagy and its role in AR were further examined in rats. Besides, the underlying mechanisms by which JNK regulates the autophagy of CD8+ T cells were further explored.
Results: The expression of JNK is positive correlated with the autophagy level of CD8+ T cells in AR patients. And similar findings were obtained in rats after LT. Further, JNK inhibitor remarkably inhibited the autophagy of CD8+ T cells in rat LT recipients. In addition, administration of JNK inhibitor significantly attenuated AR injury by promoting the apoptosis and downregulating the function of CD8+ T cells. Mechanistically, JNK activate the autophagy of CD8+ T cells through upregulating BECN1 by inhibiting the formation of Bcl-2/BECN1 complex. Moreover, the acceleration of allograft rejection in rat recipients transferred with JNK-overexpressed CD8+T cells was abrogated after BECN1 knock down.
Conclusion: JNK signalling promoted CD8+ T cells autophagy to mediate AR after LT, providing a theoretical basis for finding new drug targets for the prevention and treatment of AR after LT.

WED-021
Circulating thrombospondin-2 as a novel, highly predictive serum marker of liver fibrosis progression post liver transplant
Rambabu Surabattula[1], Sudha Rani Myneni[1], Tim Zimmermann[2], Detlef Schuppan[1,3]. *[1]Institute of Translational Immunology, University Medical Center Mainz, Mainz, Germany; [2]Department Internal Medicine and Gastroenterology, Klinikum-Worms, Worms, Germany; [3]Division of Gastroenterology, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, United States*
Email: rasuraba@uni-mainz.de

Background and aims: Liver transplantation (LTX) is the only curative treatment option for end stage liver disease. However, up to 30% of patients develop recurrent cirrhosis (RC) post LTX within 5 years. In view of emerging antifibrotic therapies, there is an urgent need of non-invasive serum biomarkers to predict RC after LTX. We established and validated novel liver fibrosis serum markers in LTX patients with no, moderate and severe fibrosis progression followed-up for up to >5 years post-transplant.
Method: A sandwich ELISA assay measuring the matricellular fibrosis marker thrombospondin-2 (TSP2) was established using combinations of recombinantly expressed protein, commercial and proprietary monoclonal/polyclonal antibodies. Sensitivity and specificity for serum or plasma showed intra- and inter assay variations below 10% and 15%, resp. 45 LTX patients were divided into super-rapid (<1 year, RC<1) and, rapid progressors (3–5 years, RC<5) to cirrhosis, and non-progressors after LTX. TSP2 was determined at 3, 6 and 12 months post-LTX in the subset of 10 patients of the RC<1 group and in 18 patients of the RC<5 group and in 17 patients of the non-progressors at 1, 2 and 3 years.
Results: Serum levels of TSP2 were significantly increased in RC<1 (mean 253 ng/ml) at 3, 6 and 12 months after LTX compared to non-progressors (mean 86.9 ng/ml) at 1, 2 and 3 years. Super-rapid progressors (RC<1) were clearly differentiated from non-progressors at 1 year after LTX with an AUROC of 0.9. Furthermore, 3 years after LTX, the level of TSP2 was significantly elevated in rapid progressors vs non-progressors (TSP2: 224 vs 90 pg/ml). The AUROC value to distinguish all progressors from non-progressors was 0.89 for TSP2, which outperformed the ELF score (0.84). The levels of TSP2 were significantly correlated with ELF after 1 -year (non-progressors and RC<1) and 3 years (RC<5) post liver transplant. In addition, levels of TSP2 at <6 years (RC<5) and <3 years (RC<1) were significantly elevated in patients who finally died vs survived.
Conclusion: The matricellular fibrosis marker TSP2 reflects fibrogenesis and predicts rapid fibrosis progression in patients post LTX. Other markers contributed to prediction at later stages post LTX. The novel markers may support early antifibrotic interventions post LTX.

De novo malignancies after liver transplantation: a twenty years long-single center experience

Stefano Fonte[1], Lucia Lapenna[1], Giulia Cusi[1], Margherita Spigaroli[1], Marco Mattana[1], Simone Di Cola[1], Gianluca Mennini[2], Massimo Rossi[2], Manuela Merli[3]. *[1]Department of Traslational and Precision Medicine, Sapienza University of Rome, Rome, Italy; [2]General Surgery and Organ Transplantation Unit-Policlinico Umberto I, Rome, Italy; [3]Department of Translational and Precision Medicine, Rome, Italy*
Email: stefanofonte08@gmail.com

Background and aims: Patients after liver transplantation (LT) require lifelong immunosuppressive therapy, exposing them to a higher risk of recurrence or de novo malignancies. The aim of this study is to describe incidence and types of tumors observed in a cohort of patients who underwent LT and were subsequently followed.
Method: We retrospectively enrolled 358 patients undergoing LT between 2000 and 2022. Patients were excluded when survival was lower than 6 months or when follow-up was incomplete. For the statistical analysis Chi squared test and T test were used.
Results: in our cohort 62 (20.9%) patients experienced the onset of malignancy after LT. Among them 8 were HCC recurrences. Among oncological and non-oncological patients no statistically significant differences were observed between the two groups for age and sex. Patients differed for: the prevalence of pre-LT HCC (15% vs 24% in the oncologic group, p value <0.0001); the kind of immunosuppressive therapy, with significantly less patients under combination therapy with tacrolimus and antimetabolites in the oncological group before diagnosis (6.5% vs 17.2%, p value 0.032); etiology of liver disease, with a higher prevalence of alcohol related liver disease in the oncological cohort (38.7% vs 22.3%, p value 0.006) and higher prevalence of viral etiology in the non-oncological group (52% vs 33.9%, p value 0.009). The most frequent non-HCC de novo solid organ malignancy were non-melanoma skin cancers (including squamous and basal cell skin cancers) with a prevalence of 3.9% of the entire cohort, followed by lung cancer with a prevalence of 2% of the entire cohort. The most frequent hematological disorder was non-Hodgkin's lymphoma (prevalence of 2.5% of the entire population.
Conclusion: patients who have undergone liver transplantation, due to their underlying pathology and prolonged immunosuppressive therapy, require careful and specific screening.

WED-027

Long-term post-transplant emergence of metabolic syndrome is associated with gut microbial metabolites in urinary metabolomics

I. Jane Cox[1,2], Adrien Le Guennec[3], Andrew Fagan[4], Mette Lauridsen[5], Mohammad Siddiqui[6], Scott Matherly[5], Amy Bartels[5], Jasmohan Bajaj[5]. *[1]The Roger Williams Institute of Hepatology, Foundation for Liver Research, London, United Kingdom; [2]Faculty of Life Sciences and Medicine, Kings College London, London, United Kingdom; [3]Centre for Biomolecular Spectroscopy, Randall Centre for Cell and Molecular Biophysics, Kings College London, London, United Kingdom; [4]Richmond VA Medical Center, Richmond, United States; [5]VCU Medical Center, Richmond, United States; [6]VCU Mediacl Center, Richmond, United States*
Email: j.cox@researchinliver.org.uk

Background and aims: Liver transplantation (LT), although life-saving, is associated with development of *de novo* metabolic syndrome (MetS) and adverse cardiovascular events in the long-term post-LT course. Gut microbiota-related products, such as trimethylamine-*N*-oxide (TMAO) and phenylacetylglutamine (PAG), have been associated with negative cardiovascular outcomes in the general population through promotion of atherogenesis. Prior studies have considered the impact of gut microbial diversity on outcome post-LT but long-term impact of LT on microbial functionality, which could modulate the adverse pro-atherogenic profile needs to be investigated. Our aims were to determine the effect of LT on ongoing gut microbial functionality in outpatients, following patients up to 9 years post-LT, focusing on urinary metabolomics using nuclear magnetic resonance spectroscopy (NMR).
Method: We enrolled 45 patients at baseline (mean age, 57 years; 36 men) with etiologies of HCV and alcohol (n = 12 each), n = 8 with MASH and n = 13 others, Model for End-Stage Liver Disease score mean (sd) 22.6 (6.2), who received LT 11 ± 6 months after enrolment. A sub-set were re-evaluated at 6 months (n = 38), 1 year (n = 19) and 2–9 years (n = 14) after LT. The remaining either died post-LT, did not return for post-LT visits, or did not provide samples. All post-LT patients were on stable calcineurin inhibitor doses. We only included those post-LT pts who did not require re-LT, were stable clinically and did not have recent rejection episodes or infections. Urinary NMR at all these timepoints were analysed and relative signal levels (to total signal intensity) of TMAO and PAG determined. The presence of metabolic syndrome was assessed at follow-up using validated definitions.
Results: An increase in mean relative urinary TMAO and PAG were detected after LT in most patients (mean (sd) TMAO baseline 0.016 (0.009) vs all timepoints post LTx 0.027 (0.021), $p < 0.05$; PAG baseline 0.0038 (0.0033) vs post LTx 0.0080 (0.0055), $p < 0.05$. *De novo* MetS post-LT was definitively present in 10 (22%) patients and absent in 18. Metabolite differences between follow-up and baseline were observed according to presence or absence of the MetS in both TMAO (increase of 0.020 in MetS vs 0.005 in absence of MetS, ≥6 mo, $p = 0.03$; increase of 0.039 in MetS vs 0.005 in absence of MetS, ≥1 yr; $p = 0.01$) and PAG (increase of 0.001 in MetS vs 0.003 in absence of MetS ≥6 mo, $p = 0.34$; increase of 0.005 in MetS vs 0.001 in absence of MetS, ≥1 yr; $p = 0.02$).
Conclusion: There is an increase in urinary TMAO and PAG during the months post-LT, which could indicate restoration of microbial diversity. However, these gut microbiota related metabolites were relatively higher in those who developed *de novo* metabolic syndrome post-LT and indicates the role of microbial modulation as a target to modulate these outcomes.

WED-028

Livers undergoing extended ex situ normothermic machine perfusion develop Glutathione- and Methionine-cycle alterations that reverse following transplantation

Aida Vaquero-Rey[1], Jordi Vengohechea Llorens[1,2,3], Javier Muñoz[3], Joaquim Albiol[4], Carlota Largo[5], Fernando Prieto[1], Javier Salinas[1], Amelia Judith Hessheimer[1,3], Constantino Fondevila[1,3]. *[1]General and Digestive Surgery Service, Hospital Universitario La Paz, IdiPAZ, Madrid, Spain; [2]Department of Surgery and Surgical Specializations, University of Barcelona, Barcelona, Spain; [3]CIBERehd, Madrid, Spain; [4]Donation and Transplantation Institute, TPM-DTI Foundation, Barcelona, Spain; [5]Experimental Surgery Service, Hospital Universitario La Paz, IdiPAZ, Madrid, Spain*
Email: aidavaquerorey@gmail.com

Background and aims: While *ex situ* normothermic machine perfusion (NMP) is a promising technique for preservation, evaluation, and treatment of livers, current protocols do not provide physiological conditions, and the metabolic state of the liver may be altered while on the device. We aim to evaluate adequacy of support provided during extended *ex situ* liver NMP by characterizing metabolic profiles pre- and post-NMP and post-transplant.
Method: Porcine livers (N = 8) were subjected to NMP during 24H performed using a blood-based perfusate. After 2H, continuous hemodiafiltration was initiated. Parenteral nutrition, vitamins, and trace elements were added after 4H. Insulin and/or glucose were also given, as needed. After 24H, grafts were transplanted into recipients, which were followed for 5D. Tissue samples were collected in the donor, at the end of NMP, post-transplant, and at the end of follow-up. Targeted metabolomic analysis was performed to evaluate 2 metabolites in the glutathione and 9 in the methionine cycles.

PERMANOVA was used to study dissimilarities among samples and univariate analyses to compare differences among times. Principal component analysis was used to identify metabolites with highest explained variance.
Results: During 24H NMP, hepatic artery and portal vein flows, bile production, and biochemical parameters were stable. Grafts functioned well upon reperfusion in their respective recipients. Metabolic profiling was able to group the samples according to time (p = 0.001), showing more similarities between baseline and 5D with respect to the end of NMP and 1H post-transplant. Metabolites with highest explained variance included GSH, GSSG, Spermidine, Choline, SAMe, SAH and Methionine.
Conclusion: *Ex situ* NMP performed for 24H with continuous hemodiafiltration and nutritional support maintains liver viability, though reversible metabolic derangements do arise. In the future, improved metabolic support is needed to reproduce physiological conditions and maintain homeostasis during extended liver NMP.

WED-029
Adipose-derived stem cell therapy enhances liver regeneration in echinococcus multilocularis infected mice through activation of the wnt/beta-catenin/nestin signaling axis
Xiaojuan Bi[1], Ning Yang[1], Renyong Lin[1]. [1]*The First Affiliated Hospital Of Xinjiang Medical University, Urumqi, China*
Email: renyonglin@xjmu.edu.cn

Background and aims: Stem cell therapy is a promising strategy for liver regeneration, however, its role in alveolar echinococcosis remains unclear. This study aims to evaluate the effect of Adipose-derived stem cells (ADSCs) transplantation on liver regeneration in E. multilocularis infected mice through the Wnt/beta-catenin/Nestin axis.
Method: Adult Nestin-cre/Rosa26-tdTomato transgenic C57BL/6 mice were infected echinococcus multilocularis for 1, 3, 5 months. The relative expression of Nestin mRNA in liver tissue was detected by real-time fluorescence quantitative PCR. Immunofluorescence staining was used to observe the relationship between Nestin expression and ALB. The expression of PCNA in the liver was detected by immunohistochemistry to analyze liver regeneration; ADSCs were injected into Em infected mice through tail vein, The underlying mechanisms of liver regeneration by which nestin affected ADSCs were explored using real time-PCR (RT-PCR), Western blot and immunohistochemistry.
Results: The expression of Nestin gradually declined with age in all organs, except for the liver where it showed little expression. However, as the infection worsens, the expression of Nestin becomes concentrated around the lesion and increases. Nestin was found to colocalize with the hepatocyte marker ALB. Through bioinformatics protein interaction (PPI) analysis, it was revealed that Nestin interacts with characteristic genes of embryonic stem cells, such as Nanog and Sox2. The positive rate of CD90 on the cell surface of Nestin+ cells is 45%, while that of CD105 is 60%. Additionally, Nestin+cells demonstrate migration ability in vitro. Furthermore, PCNA expression significantly increased at 5 months after ADSCs transplantation. The transplantation of ADSCs activates the Wnt/beta-catenin/Nestin signal axis in the livers of mice infected with E. multilocularis, thereby promoting the expression of Nestin around the lesion.
Conclusion: The high expression of Nestin around liver lesions in mice infected with alveolaris is correlated with hepatocyte proliferation. Adipose mesenchymal stem cell transplantation alleviates liver injury and promotes regeneration in E. multilocularis infected mice through Wnt/beta-catenin/Nestin signaling axis.

Liver transplantation and hepatobiliary surgery – Clinical

TOP-001
Socioeconomic deprivation is associated with worse outcomes after adult liver transplantation
Paolo De Simone[1], Juri Ducci[2], Daniela Campani[1], Piero Marchetti[1]. [1]*University of Pisa, Pisa, Italy;* [2]*University of Pisa Medical School Hospital, Pisa, Italy*
Email: paolo.desimone@unipi.it

Background and aims: Socioeconomic deprivation is a crucial factor for the best possible outcome of pediatric and adult LT. However, the mechanisms linking social deprivation to inferior outcomes are not entirely elucidated, and powered studies are still lacking.
Method: The present study analyzed retrospectively the association between socioeconomic deprivation and graft and patient survival in a cohort of 2, 568 consecutive adult recipients of a whole-size, primary liver transplant from a donor after brain death between 1996 and 2022. The primary exposure was a nationally validated socioeconomic deprivation index (DI) ranking from 1 to 5, with higher ranks indicating more significant socioeconomic deprivation.
Results: At a median (IQR) follow-up of 144.8 (204) months, more deprived patients (DI = 4–5) had a higher risk of death (RR = 1.5; p < 0.0001), hypertension (RR = 1.38; p < 0.0001), obesity (RR = 1.42; p = 0.02), diabetes mellitus (RR = 1.42; p = 0.02), graft rejection (RR = 1.8; p < 0.0001), chronic kidney dysfunction (RR = 1.9; p < 0.0001), major cardiovascular events (RR = 1.9; p < 0.0001) and de novo malignancies (RR = 1.5;p < 0.0001) than less deprived recipients (DI = 1–2). The overall patient and graft survival rates were 92% and 90.4% at 1 year, 78.4% and 72.2% at 5 years, and 58% and 56.7% at 10 years. Recipients with a DI above the median (i.e., more deprived) had 1, 5, and 10-year patient and graft survival rates of 91% and 89.5%, 70.4% and 68.4%, 48% and 46.7%, respectively, versus 92% and 90.4%, 78.4% and 72.2%, and 58% and 56.7% for less deprived patients (log-rank p < 0.001).
Conclusion: Based on our results, socioeconomic deprivation is associated with lower graft and patient survival and a higher risk of graft rejection and cardiovascular, metabolic, and neoplastic complications. Pre-transplant socioeconomic risk profiling is warranted to better tailor post-transplant care to patient's needs and expectations.

Email: ropeml@hotmail.com

Background and aims: The Gender-Equity Model for liver Allocation corrected by sodium (GEMA-Na) may save a meaningful number of lives while palliating gender disparities among liver transplant (LT) candidates (PMID 36528041). We aimed to validate its performance in Spain, where waiting time for LT is reduced.
Method: Nationwide cohort study including adult candidates for elective LT from 25 centers in Spain (2014–2021). The primary outcome was mortality or delisting for sickness with right-censoring at 90 days. The GEMA-Na score was calculated according to the published formula available at: http://gema-transplant.com/. The discrimination of GEMA-Na was assessed by the Harrel's c-statistic (Hc) and compared with MELD-Na, and MELD 3.0. This study was funded by the Instituto de Salud Carlos III (Project no. PI22/00312) and co-funded by the European Union.
Results: Among 6, 206 eligible patients (22.4% women, aged 57.8 ± 8.6 years), 5, 460 patients had sufficient data to calculate the scores and entered the study. The most frequent indications for LT were hepatocellular carcinoma (HCC) (39.4%), hepatic insufficiency (29.4%), and refractory ascites (13%). The primary outcome occurred in 254 patients (5.2% women vs. 4.5% men; p = 0.24). Median time in the waiting list was 71 days, without gender disparities (p = 0.44). In patients without HCC, women had to wait longer (67 vs. 56 days; p = 0.025). GEMA-Na obtained the highest discrimination (Hc = 0.717), followed by MELD-Na (Hc = 0.704; p = 0.039), and MELD 3.0 (Hc = 0.701; p = 0.012). Differences were more pronounced in patients without HCC: GEMA-Na Hc = 0.776, MELD-Na Hc = 0.756 (p = 0.004 vs. GEMA-Na), and MELD 3.0 Hc = 0.752 (p = 0.005 vs. GEMA-Na). GEMA-Na obtained the highest discrimination also in patients with ascites: GEMA-Na Hc = 0.745, MELD-Na Hc = 0.724 (p = 0.002 vs. GEMA-Na), and MELD 3.0 Hc = 0.724 (p = 0.011 vs. GEMA-Na). Differential prioritization between GEMA-Na and MELD-Na occurred in 8.7% of patients, with one-in-20 deaths avoided within the first 90 days (p = 0.008). Differential prioritization between GEMA-Na and MELD 3.0 occurred in 9.7% of patients, with one-in-22 deaths avoided within the first 90 days (p < 0.001).
Conclusion: GEMA-Na was successfully validated in Spain and confirmed its advantage over the MELD family scores to predict waiting list mortality or delisting for sickness in a context of waiting list shortening.

TOP-003-YI
Model for end-stage liver disease score-based liver allocation is associated with reduced survival in low donation countries-a comparative analysis between Germany and the USA
Leke Wiering[1,2], Annette Aigner[3], Marieke van Rosmalen[4], Brigitta Globke[2,5], Nathanael Raschzok[2,5], Wenzel Schöning[5], Georg Lurje[5], Münevver Demir[1], Frank Tacke[1], Johann Pratschke[5], Robert Öllinger[6], Paul Ritschl[2,5]. *[1]Charité-Universitätsmedizin Berlin, Department of Hepatology and Gastroenterology, Berlin, Germany; [2]Berlin Institute of Health at Charité-Universitätsmedizin Berlin, BIH Biomedical Innovation Academy, Berlin, Germany; [3]Charité-Universitätsmedizin Berlin, Institute of Biometry and Clinical Epidemiology, Berlin, Germany; [4]Eurotransplant International Foundation, Leiden, Netherlands; [5]Charité-Universitätsmedizin Berlin, Department of Surgery, Berlin, Germany; [6]Charité-Universitätsmedizin Berlin, Berlin, Germany*
Email: leke.wiering@charite.de

Background and aims: The allocation of donor livers based on the Model for End-Stage Liver Disease (MELD) score is the predominant practice in most countries worldwide. Favorable outcomes in waiting list mortality and survival have been described for the USA following its implementation. However, the impact of this policy in countries with low organ donation rates, such as Germany, remains uncertain and is the aim of this investigation.
Method: Waiting list survival and survival after liver transplantation Germany (2003–2016, MELD implementation 12/2006) and the USA (1999–2016, MELD implementation 02/2002) was analyzed using data from the Germany Transplant registry and UNOS registry. A comprehensive cohort of 196, 039 waiting list registrations and 108, 199 liver transplantation was used for this retrospective analysis.
Results: Waiting list mortality did not improve after the introduction of MELD-based allocation in Germany (OR 0.97, 95% CI: 0.91–1.03). Moreover, survival after transplantation deteriorated in Germany (three-year patient survival preMELD 69.3% vs. MELD 65.3%, p < 0.001; HR: 1.16, 95% CI: 1.08–1.25). Contrarily to this, an improvement in both waiting list mortality (OR: 0.73, 95% CI: 0.71–0.75) and survival after transplantation (preMELD 75.3% vs. MELD 80.5%, p < 0.001; HR 0.75, 95% CI: 0.72–0.77) was found after the implementation of MELD-based policies in the USA. Notably, the disparities between the two countries could be attributed to the significantly higher organ donor numbers in the USA as there was no significant improvement of waiting list mortality in the USA after adjustment for donor number (OR: 1.01, 95% CI: 0.97–1.06). Similarly, survival after transplantation did not show significant improvement after adjustment for donation rates in the USA (HR: 0.96, 95% CI: 0.90–1.01). In addition, a combined multivariable cox-proportional hazards regression model of the two countries showed a markedly reduced difference in patient survival after adjustment for donor number (unadjusted HR for survival in Germany compared to the USA: 2.12, 95% CI: 2.04–2.20; adjusted HR: 1.44 (95%CI: 1.30–1.59).
Conclusion: MELD-based liver allocation demonstrates improved waiting list outcomes and post-transplant survival only in countries characterized by high organ donation rates, exemplified by the USA. Consequently, there is a need for a critical re-evaluation of liver allocation policies in nations with limited organ donation rates like Germany.

Impact of MELD 3.0 on waitlist outcomes of metabolic dysfunction-associated steatohepatitis cirrhosis among liver transplant waitlist registrants
Benedix Sim[1], Wen Hui Lim[2], Darren Jun Hao Tan[2], Cheng Han Ng[2], Nicholas Syn[2], Benjamin Nah[1], Benjamin Koh[2], Jieling Xiao[2], Christen Ong[2], Jia Hong Koh[1], Daniel Tung[1], Daniel Huang[3], Mohammad Shadab Siddiqui[4], Mark Muthiah[1], Margaret Teng[5,6]. *[1]Division of Gastroenterology and Hepatology, Department of Medicine, National University Hospital, Singapore, Singapore, Singapore,*

Singapore; [2]Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore, Singapore; [3]Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore; [4]Division of Gastroenterology, Department of Internal Medicine, Hepatology and Nutrition, Virginia Commonwealth University, Virginia, United States; [5]Division of Gastroenterology and Hepatology, Department of Medicine, Alexandra Hospital, Singapore, Singapore; [6]Division of Gastroenterology and Hepatology, Department of Medicine, National University Hospital, Singapore, Singapore
Email: margaret.tenglp@gmail.com

Background and aims: Metabolic dysfunction-associated steatohepatitis (MASH) cirrhosis is rapidly growing as an indication for liver transplantation (LT). However, the impact of MELD 3.0 on waitlist outcomes of patients with MASH cirrhosis is not established. The present study aimed to assess the impact of MELD 3.0 on waitlist outcomes of patients with MASH cirrhosis using the Scientific Registry of Transplant Recipient (SRTR) database.
Methods: The study cohort consisted of patients registered on LT waitlist between 1/1/2016 to 12/31/2022. The primary outcomes included probability of LT and waitlist mortality comparing MASH (n = 12, 794) vs. non-MASH (n = 31, 254) cirrhosis.
Results: Patients with MASH cirrhosis were listed with lower Model for End-stage Liver Disease (MELD) 3.0 score despite bearing greater burden of portal hypertension (vs non-MASH). Comparing reclassification between MELDNa and MELD 3.0, more waitlist registrants with MASH cirrhosis were down-categorized (n = 1, 658, 13.0%) than up-categorized (n = 632, 4.94%). Out of 1, 410 female MASH cirrhosis decedents, a net of 14 (0.99%) patients would be correctly reclassified. However, in terms of female LT recipients, there would be a net incorrect down-categorization of 121 (3.56%) patients. The overall transplant probability in LT waitlist registrants with MASH [vs. non-MASH] cirrhosis was significantly lower at 3-months (HR 0.837, $p < 0.001$) and 12-months (HR 0.836, $p < 0.001$). Furthermore, both 3-month (HR 1.16, $p < 0.001$) and 12-month (1.25, $p < 0.001$) waitlist mortality was significantly higher in patients with MASH cirrhosis compared to non-MASH cirrhosis. Female MASH cirrhosis patients had significantly lower 90-day (HR: 0.878, $p < 0.001$) and 1-year transplantation probability (HR: 0.863, $p < 0.001$) compared to male MASH cirrhosis patients. The key contributor to MELD score was serum creatinine among LT waitlist registrants.
Conclusion: LT waitlist registrants with MASH cirrhosis are less likely to receive transplant and more likely to die on waitlist compared to patients with non-MASH cirrhosis. Serum creatinine has the largest contribution to likelihood of LT.

Email: eleonora.demartin@aphp.fr

Background and aims: The use of immune checkpoint inhibitors (ICI) after liver transplantation (LT) is still controversial considering the potential risk of rejection, that can be fatal, reported in about 40% of treated patients. However, this data come from clinical case or small heterogeneous series and risk factors for rejection haven't been clearly identified yet. The aim of the present study was to characterize patients treated with ICI after LT and clarify risk factors for rejection.
Method: This is a retrospective, multicenter study which included adult patients who received an ICI (anti-PD1, anti-PDL1 or anti-CTLA4) after LT for hepatocellular carcinoma (HCC) recurrence or a *de novo* tumor. Tumor therapy and immunosuppression (IS) management was at physician discretion. Quantitative variables were expressed as median and interquartile (IQR 1st et 3rd quartile), while qualitative variables were expressed as number and %. Utilized tests were Mann-Whitney and Fischer.
Results: Thirty-five patients were included, 27 (77%) males, median age 60.4 (51.5;64.3) years. Fourteen (40%) patients were transplanted for alcohol related cirrhosis and 8 (23%) for HCV related cirrhosis, 28 (80%) had an HCC before LT. The median interval time between LT and cancer diagnosis was 3.27 (1.28; 6.94) years. HCC recurrence was diagnosed in 20 (57%) patients. ICI used were: anti-PD1 in 13 (37%) and anti-PDL1 in 22 (63%) patients. The median interval time between LT and ICI introduction was 4.67 (2.97; 9.66) years. IS was increased a priori in 20 (57%) patients before ICI. Six (17%) patients developed acute rejection. These patients compared to the ones without rejection were less frequently on tacrolimus (33% vs 83%, $p = 0.027$) and with a trend of being on a single IS drug (67% vs 14%, $p = 0.065$). Moreover, in patients who developed a rejection, ICI treatment duration was significantly shorter ($p = 0.026$), and the number of injection lower ($p = 0.021$) (Table 1). Twenty-four (69%) patients died and among them 4 had a fatal rejection. Survival after ICI initiation was similar in patients with or without rejection (5.10 vs 2.81 months, $p = 0.12$).
Conclusion: In patients who were treated with ICI after LT, survival is low due to oncological disease progression. In this series, rejection rate is lower compared to the literature (17%), however it was fatal in the majority of the cases. Acute rejection seems to develop rapidly after ICI introduction and in particular in patients on immunosuppression monotherapy and in the absence of tacrolimus. These circumstances should be avoided.

Email: burra@unipd.it

Background and aims: sex-based disparities in liver transplantation (LT) have been recognized since several years. This disadvantage is evident to all stages of the LT cascade. Although such disparities are well established in studies from United States, less data are available from European countries. As these differences are affected by the national context, having local data is critical to define the dimensions of the problem.
Method: we performed an observational, retrospective, nationwide study promoted by the Special Interest Group of Gender in Hepatology of The Italian Association for the Study of The Liver in collaboration with the Italian National Transplant Center on LT patients waitlisted in Italy from January 1st, 2017 to December 31st, 2021, using the data entered the Italian Transplant Information System. Demographics and clinical characteristics, as well as time on the waiting-list (WL), access to LT, and reasons for removal were assessed. The probabilities of LT and mortality on WL were analyzed using the competing risk analysis and FineandGray sub-Hazard Ratio (sHR) for sex.
Results: overall, 7609 patients were considered for the analysis, 2004 (26.3%) females. Compared to the latter, males were older (58 vs 56 years, $p < 0.05$) with higher body mass index (BMI) (25.9 vs 24.1 kg/m^2, $p < 0.05$) at listing. The indication to LT was more often liver cirrhosis (LC) for females (48.2%) and hepatocellular carcinoma (HCC) for males (47%, $p < 0.001$). Among LC etiologies, alcohol-associated disease and hepatitis C virus prevalence were higher in males (42.2 vs 24%, and 22.2 vs 13.8%, respectively, both $p < 0.001$), whereas hepatitis B virus and autoimmune diseases were more prevalent in the female sex (21.8 vs 14.3%, and 25.6 vs 8.2%, respectively, both $p < 0.001$). No significant differences were observed in the HCC etiologies. Females resulted more often listed as urgent LT (5.3 vs 2.4%, $p < 0.001$). LT occurred more frequently in males than females (79.3 vs 74.2%, $p < 0.001$), who experienced more frequently delisting for death (8.7% vs 7%, $p = 0.016$). One-year competing risk analysis for LT and mortality on the WL showed that males had higher probability to receive a LT (Cumulative Incidence Function [CIF] 69.2% [95%IC 68.0–70.4] vs 61.7% [95%CI 68.0–70.4], sHR = 1.17 [95%CI 1.1–1.2], $p < 0.0001$) and lower probability of dying compared to females (CIF 8.3% [95%CI 7.6–9.0] vs 8.9% [95%CI 7.7–10.2]; sHR = 0.89 [95%CI 0.77–1.02], $p = 0.09$). This latter difference resulted significant at 30-days from listing, but not any longer.
Conclusion: in this large Italian cohort, we found that females were less likely undergoing LT and presented with higher rates of death compared with their counterparts. This could be partially explained by a more severe clinical presentation in female at the time of listing. Future studies are needed to better identify causes and ensure equity in providing LT access to the female population.

SAT-008
Significance of routinely measured direct alcohol markers in long-term care after liver transplantation

Julia M. Grottenthaler[1], Johannes Wagner[1], Michael Boettcher[2], Jannis Altekoester[1], Hannah Kraemer[1], Franziska Trauner[1], Verena Wagner[1], Silke Templin[3], Nisar P. Background and aims: Alcohol misuse after liver transplantation (LTx) can seriously impact graft and patient survival. However, to date, there is no defined standard procedure to identify patients after LTx who are at risk for alcohol-related complications. The aim of this prospective study was to analyze screening methods for alcohol (mis) use after LTx with special focus on the diagnostic value of routinely measured ethanol metabolites: blood phosphatidylethanol (PEth) and urinary ethylglucuronide (uEtG).
Method: In this prospective study, adult patients in post LTx care were consecutively included at their visit in the outpatient clinic of the Tuebingen Transplant Center from August 2022 until September 2023. In order to screen for signs of alcohol consumption, the standardized questionnaire AUDIT-C (alcohol use disorders identification test-concise) was used in combination with measurement of PEth (cutoff <20 ng/ml) and uEtG (cutoff <500 ng/ml).
Results: 351 patients were included in the study (median age 60 years [min-max 20–81 years], 59% male). 22% (n = 77) had alcohol-related liver disease (ALD) as underlying liver disease leading to LTx, 19% (n = 65) suffered from chronic viral hepatitis, 18% (n = 63) had cholestatic liver diseases, in 10% (n = 35) acute liver failure led to LTx, 5% (n = 19) had cryptogenic liver cirrhosis, in 4% (n = 14) MASLD (metabolic dysfunction-associated steatotic liver disease) was present, and 22% (n = 78) had other reasons for LTx. Median time since LTx was 8.3 years (min 6 months, max 36 years). 34% (n = 118) of the patients had at least one positive sign for alcohol use. In the AUDIT-C, 26% (n = 93) of the patients reported at least occasional alcohol use, while 5 patients met the criteria for hazardous drinking. PEth was positive in 14% (n = 48), uEtG in 10% (n = 34) of the patients. Questionnaire results and positive alcohol metabolites were significantly correlated ($p < 0.001$). However, 25 patients (7%) reported complete alcohol abstinence but presented with at least one positive alcohol metabolite; in 11 of these patients only the longer detectable PEth was positive. There was no significant correlation between ALD as underlying disease and the detection of alcohol use post LTx ($p = 0.40$). In contrast, a longer time since liver transplantation correlated significantly with the detection of alcohol consumption ($p < 0.001$).
Conclusion: Given the high percentage of patients who do not consistently abstain from alcohol after LTx, screening for alcohol use disorders is crucial in order to prevent adverse outcomes. Direct alcohol markers can play a substantial role in detecting patients at risk and closing the gap of patient interviews. In this context, the longer detectable PEth is of special interest. Importantly, with regard to the results of this present study, screening should not be limited to the group of patients transplanted for ALD, nor only to the first few years after LTx.

Background and aims: There is a widespread occurrence of obesity in the world and an increased indication for liver transplants due to metabolic dysfunction-associated steatotic liver disease (MASLD). A large global, balanced study investigating the global pattern of etiology and indication for liver transplant (LT) has not been done. The etiology of ESLD-LTs has been reviewed according to 2 time-frames (2018–19 and 2022–23) to show changes in pattern/prevalence.

Method: The IMPROVEMENT project (ClinicalTrial.gov NCT05289609) has been designed to investigate the risk factors that predict outcomes after LT. An international steering committee identified the Centers to be invited. Attention was paid to having an equal number of high-volume Centers (>65 LTs per year) and intermediate-volume Centers (=65 LTs per year) representative of transplant activity in Italy, Europe, Asia, Oceania, and the Americas. An equal number of consecutive cases was requested for each Center. The implementation of the novel multi-society terminology with stratification in metabolic dysfunction-associated steatohepatitis (MASLD), metabolic autoimmune liver disease (Met-AILD), metabolic alcohol liver disease (Met-ALD), alcohol, viral, cryptogenic and others was adopted.

Results: After excluding acute liver failure and retransplant cases, 3599 LTs were stratified in hepatocellular carcinoma (HCC, 1574) and non-HCC (2025) cases. The analysis of HCCs during 2018–19 revealed that Met-ALD was the predominant etiology in Europe, accounting for 37.3% of cases. In contrast, viral etiology was identified as the leading cause in the Asia, Americas, and Oceania. Notably, in the subsequent period of 2022–23, MASLD emerged as the primary etiology in the Americas, comprising 42.9% of cases, while Met-ALD continued to be the most prevalent etiology in Europe, increasing to 48.7%. Viral etiology remained the most frequent cause in Asia and Oceania.

Regarding non-HCC indications, during 2018–19 Met-ALD resulted the most common indication in Europe (28.2%) and the Americas (30.9%), with viral etiology being the most prevalent in Asia, and Met-AILD being the most common in Oceania (28.8). In the 2022–23 period, Met-ALD remained the leading indication in Europe (32.5%) and the Americas (33.7%), while Met-AILD became the most prevalent cause in Asia (22.2%).

Conclusion: The increase in metabolic-related liver diseases in the Americas and Europe highlights the need for integrated healthcare interventions targeting obesity, diabetes, and alcohol consumption. The consistency of viral etiologies in Asia and Oceania emphasises the continued need for effective viral hepatitis control measures, including vaccination and antiviral therapies. LT programs must adapt to the shifting etiological patterns, which may have profound implications for organ allocation policies, patient education, and long-term management.

Email: marianne.latournerie@chu-dijon.fr

Background and aims: Indications for liver transplantation (LT) are changing, with older recipients, with more comorbidities. To help in the selection of recipients who will benefit most from LT in the context of graft shortage, we aimed to develop and validate a score to predict the one-year post-LT risk of death in recipients aged 60 years and over.
Method: This cross-sectional study used data from the national transplantation database managed by French national Biomedicine Agency. Logistic regressions were used to develop the score. The population was split into a training set (70%) and a test set (30%). The predictive ability of the score was assessed using Harrell's C-statistic.
Results: 3158 patients aged 60 years and over who received their first elective LT between 2007 and 2017 were included: 38.4% aged over 65 years and 4.2% over 70 years. 90% had cirrhosis (64% alcoholic), with a median Meld score at 14, and hepatocellular carcinoma (HCC) in 56% of cases. Older patients appeared to more often have cirrhosis unrelated to alcohol consumption ($p < 0.001$). They more often have comorbidities as diabetes ($p = 0.037$) and renal insufficiency ($p = 0.023$). Their cirrhosis was less severe at transplant ($p < 0, 001$) and was more often complicated by HCC (68% in patients over 70 years vs 58% in patients between 60 and 65 years, $p < 0.001$). Time on the waiting list increased with age (352 days vs 145 days, $p < 0.001$), as did donor age (62 years vs 58 years; $p = 0.024$).
One-year mortality after LT was 13.7%. Male sex, history of portal vein thrombosis, lower glomerular filtration rate, endotracheal intubation at LT and longer cold graft ischemia were associated with a higher risk of death at one-year post LT, whereas HCC was associated with a lower risk. According to the weight of each of these 6 variables, we constructed a score to predict the risk of death at 1 year post LT and illustrated it with a nomogram. The discriminant ability of the score on the test set was of 0.61 (95%-Confidence Interval = 0.57–0.68).
Conclusion: In this real-life study, we found that careful selection of the oldest patients ensures good results after LT. However, comorbidities and organ failure have a great impact on one-year mortality in this population. This is the first one-year mortality score that can help with the decision to list potential LT recipients aged 60 years and over.

SAT-011

Everolimus and de novo malignancies after liver transplantation in a nationwide french cohort study: an emulated target trial

Ilias Kounis[1,2,3,4,4], Long Nguyen[5], Christophe Desterke[2], Nathalie Goutte[1], Didier Samuel[1,2,3,4], Daniel Azoulay[1,2,3], Eric Vibert[1,2,3,4], Audrey Coilly[1,2,3,4], Paul Landais[2], Cyrille Feray[1,2,3,4]. *[1]AP-HP Hôpital Paul-Brousse, Centre Hépato-Biliaire, Villejuif, France; [2]Inserm, Université Paris-Saclay, UMR-S 1193, Villejuif, France; [3]Université Paris-Saclay, Inserm, Physiopathogénèse et traitement des maladies du Foie, Villejuif, France; [4]France FHU Hepatinov, Villejuif, France; [5]Department of Public Health, Copenhagen, Denmark*
Email: ilias.kounis@aphp.fr

Background and aims: De novo malignancies (DNM) following liver transplantation (LT) is as a major cause of post-transplant mortality. Everolimus is an mTor inhibitor with both antitumoral and antirejection properties. We aimed to evaluate the DNM burden after LT at a nationwide level and assess, in emulated target trials, the influence of everolimus in their occurrence.
Method: The French national health data system (SNDS), linked with the national hospital database (PMSI), contains information on 99% of the French population, including ICD-10 codes, medical procedures (MP), prescribed drugs, and vital status. We identified a total of 7, 964 patients discharged after LT from 01/01/2009 to 01/01/2020. Different emulated target trials (cloning-censoring-weighting approach) comparing everolimus (n = 2, 036 (25.5%) and control were performed with grace periods of 6 months to 4-years after LT, and outcomes being overall survival (OS) and DNM free survival, 2 to 10 years after LT.
Results: The cumulative incidence of de novo malignancies was 15.1% at 5 years and 25.7% at 10 years post-LT. Head and neck cancers and skin cancers were the most common, each accounting for 5.0% of cases. The 10-year overall survival rates varied by cancer type, with gynecological cancer having the highest rate (72.4%) and head and neck cancer the lowest (24.4%). Among the entire cohort, 2, 036 (25.5%) received everolimus. In emulated trials, for grace periods <2 years the treated group showed higher DNM free survival rates with a 10-year overall survival difference up to 10%. However, for each grace period, 10y-OS was less for everolimus (up to 10%). Competitive risk (with death) analysis confirmed the favorable effect of everolimus on DNM: 28% less at 10-y.
Conclusion: We confirmed the frequence and severity of DNM after LT previously reported. Systematic screening is clearly insufficient, particularly for ORL and lung. More importantly, emulating randomized trials showed that everolimus lowered DNM free survival when prescribed within the first 2 years following LT.

Sequential normothermic regional and end-ischemic ex-situ machine perfusion allows the safe use of very old DCD donors in liver transplantation (DCDNet trial)

Caterina Martinelli[1], Davide Ghinolfi[1], Daniele Pezzati[1], Jessica Bronzoni[1], Arianna Trizzino[1], Emanuele Balzano[2], Paola Carrai[1], Gabriele Catalano[1], Stefania Petruccelli[3], Giovanni Tincani[1], Simona Palladino[1], Davide Ghinolfi[1]. *[1]University of Pisa hospital, Division of Hepatic Surgery and Liver Transplantation, Pisa, Italy; [2]University of Pisa Hospital, Pisa, Italy; [3]University of Pisa hospital, Division of Hepatic Surgery and Liver Transplantation, Pisa, Italy*
Email: piero93.vacca@gmail.com

Background and aims: In Italy, 20 minutes of continuous, flat-line electrocardiogram are required for death declaration. Despite prolonged warm ischemia time, Italian centers reported good outcomes in controlled DCD (cDCD) liver transplantation by combining normothermic regional and end-ischemic machine perfusion. This study aimed to evaluate the safety and feasibility of the use of septuagenarian and octogenarian cDCD donors with this approach.

Method: All cDCD older than 70 years were evaluated during normothermic regional perfusion (NRP) and then randomly assigned to dual hypothermic (D-HOPE) or normothermic machine perfusion (NMP).
Results: In the period from April 2021 to December 2023, 25 cDCD older than 70 years were considered. In 9 cases (36%) the graft was not considered suitable for liver transplantation: 3 on NRP parameters, 2 on histology, 1 due to hepatic artery thrombosis at procurement, 2 on NMP parameters, and 1 due to machine perfusion technical failure. Sixteen (64%) liver grafts were eventually transplanted. The median donor age was 82 years (IQR: 79–84), being 9 (56%) older than 80. The mean functional warm ischemia was 39 ± 15 minutes. Grafts were randomly assigned to D-HOPE (9 grafts) and NMP (7 grafts). There were no cases of primary non-function, one of the patients (D-HOPE LT) experienced delayed non-function, treated with retransplantation. Four cases of post-reperfusion syndrome (25%, 50% D-HOPE vs 50% NMP group) and 2 cases (12%) of early allograft dysfunction were observed. At a median follow-up of 12 months, no vascular complications were reported. Three patients experienced biliary complications: 2 anastomotic stenosis and 1 biliary fistula. No patients experienced ischemic cholangiopathy. No major differences were found in terms of post-operative hospitalization or complications based on the type of machine perfusion.
Conclusion: The implementation of sequential normothermic regional and end-ischemic machine perfusion allows the safe use of very old DCD donor grafts in liver transplantation.

Bariatric surgery post-liver transplantation: a Belgian nationwide study

Louis Onghena[1], Anja Geerts[2], Frederik Berrevoet[3], Jacques Pirenne[4], Jef Verbeek[5], Eliano Bonaccorsi[6], Géraldine Dahlqvist[7], Luisa Vonghia[8], Olivier Detry[9], Jean Delwaide[10], Sander Lefere[11], Yves Van Nieuwenhove[12]. *[1]Liver Research Center Ghent, Ghent University, Ghent University Hospital, Ghent, Belgium; [2]Hepatology Research Unit, Gent, Belgium; [3]Department of General and Hepatobiliary Surgery and Liver Transplantation, Ghent, Belgium; [4]Department for Abdominal Transplant Surgery and Coordination, Leuven, Belgium; [5]Department of Gastroenterology and Hepatology, Leuven, Belgium; [6]Abdominal Transplant Unit, Cliniques Universitaires Saint-Luc, Louvain, Belgium; [7]Department of Hepatogastroenterology and Liver Transplantation, Brussels, Belgium; [8]Division of Gastroenterology and Hepatology, Antwerp, Belgium; [9]Department of Abdominal Surgery and Transplantation, Liege, Belgium; [10]Department of Hepatogastroenterology, Liege, Belgium; [11]Hepatology Research Unit, Ghent, Belgium; [12]Department of Gastrointestinal Surgery, Ghent, Belgium*
Email: Louis.onghena@ugent.be

Background and aims: Weight gain and metabolic dysfunction-associated steatotic liver disease (MASLD) pose a rising graft concern post-liver transplantation (LT). Bariatric surgery (BS) can be considered for post-LT weight gain, although the literature is limited and the long-term outcome still uncertain. We previously reviewed the literature and concluded that timing is crucial when considering BS in a population with liver disease or transplantation. Our current aim was to describe the demographics, mortality, and effect of BS in a post-LT population.
Method: We conducted a national retrospective analysis in 5 Belgian transplant centres and included 25 patients with a liver transplantation between 1/1/2000 and 31/12/2018 followed by a bariatric procedure between 1/1/2005 and 31/12/2020. 187 LT patients without BS were included for comparison. Clinical, biochemical and outcome data were retrospectively retrieved. Statistical analysis was performed using the t-test, Mann-Whitney U, and Chi2 tests.
Results: In our nation-wide sample, 25 patients had undergone BS post-LT, at a median 3.5 (2.1, 5.6) years after LT. Twenty-one (84.0%) patients received a sleeve gastrectomy (SG), 3 (12.0%) a Roux-en-Y gastric bypass (RYGB) and 1 (4.0%) a one-anastomosis gastric bypass. All but one procedure (96.0%) were performed laparoscopically. Patients were predominantly male (72.0%), with a lower age at time of transplantation compared to non-BS population (54.5 vs 60.6, $p < 0.0001$). Transient acute kidney failure (20.0%) was the only short-term complication occurring in more than one patient, all after SG. Weight loss was significant and sustained, with a decrease in BMI from 41.0 ± 4.5 pre-BS to 32.6 ± 5.8 ($p < 0.0001$) 1 to 3 years post-BS and 31.1 ± 5.8 ($p < 0.0001$) 3 to 5 years post-BS. Post-LT pre-BS three (12.0%) patients presented with recurrent and one (4.0%) de novo MASLD, with 100% resolution post-BS ($p = 0.016$). Notable reductions were observed in ALT levels (40.5 ± 28.5 U/L to 27.1 ± 25.1 U/L post-BS, $p = 0.051$) and HbA1c levels (6.9 ± 1.6 to 6.0 ± 1.4 post-BS, $p < 0.0001$). Daily mycophenolic acid intake rose from 1000.0 ± 288.7 mg/day to 1392.8 ± 1619.3 mg/day ($p < 0.0001$), while the dose of ciclosporin decreased from 258.3 ± 91.7 mg/day to 146.0 ± 107.4 mg/day ($p = 0.137$). Three patients were re-transplanted, and eight patients died, of which five (20.0%) due to a non-hepatic malignancy and one (4.0%) due to liver failure. Given the small sample size and relatively high mortality due to competing risks, a statistical analysis of patient or transplant-free survival was not feasible.
Conclusion: SG is the favored BS post-LT and has proven to be safe and feasible in a post-LT setting. SG post-LT is a valid treatment for de novo and recurrent MASLD post-LT. Although we report on the largest cohort to date, there is still a need for larger cohorts to examine the effect of BS on graft survival.

SAT-015-YI

Screening for asymptomatic coronary artery disease in liver transplant recipients: is it time to replace stress echocardiography with coronary CT angiography in selected patients?

Chiara Manuli[1], Margherita Saracco[1], Roberta Lasco[1], Gian Paolo Caviglia[1], Bruna Lavezzo[2], Donatella Cocchis[3], Mauro Giorgi[4], Riccardo Faletti[5], Carla Guarnaccia[5], Angelo Panio[2], Antonio Ottobrelli[1], Renato Romagnoli[3], Silvia Martini[1]. *[1]Gastrohepatology Unit, AOU Città della Salute e della Scienza di Torino, Turin, Italy; [2]Anesthesia and Intensive Care Unit 2, AOU Città della Salute e della Scienza di Torino, Turin, Italy; [3]General Surgery 2U, Liver Transplantation Center, AOU Città della Salute e della Scienza di Torino, Turin, Italy; [4]Cardiology Unit, AOU Città della Salute e della Scienza di Torino, Turin, Italy; [5]Department of Imaging Diagnostics and Radiotherapy, AOU Città della Salute e della Scienza di Torino, Turin, Italy*
Email: chiara.manuli@gmail.com

Background and aims: Asymptomatic coronary artery disease (CAD) has been reported in up to 25% of liver transplant (LT) candidates. Pre-LT cardiovascular (CV) work-up is not yet standardized, but in 2022 coronary-CT angiography (c-CT) was proposed by the American Heart Association in pre-LT selected patients (pts). We aimed to compare two CV screening protocols at our large-volume transplant Centre.
Method: We enrolled all adult cirrhotic pts who underwent first-LT between 01/2019–12/2022 in our Center. In the first period (2019–2021) echostress (EchoS) was performed in the presence of 3 minor (age 60–64 years, arterial hypertension, non-insulin treated diabetes, BMI >29 Kg/m^2, CAD family history, active smoking) or 1 major CV risk factors (insulin-treated diabetes, age >64 years, peripheral vascular disease, MASLD). From 1/2022 c-CT was performed with 1 major CV risk factor, and EchoS with 3 minor CV risk factors. Coronary angiography (CATH) was performed in pts with CAD history/symptoms, positive/doubtful non-invasive test or cardiology indication. Follow-up was closed on 31/12/2023.
Results: 477 pts were included: 374 (78%) in first period and 103 (22%) in second one. First *vs* second period: CV risk factors prevalence was similar: age >64 years 26% *vs* 25% ($p = 0.9$), previous CAD 2% *vs* 2% ($p = 1$), male sex 74% *vs* 80% ($p = 0.2$), previous stroke/TIA 2% *vs* 2% ($p = 1$), diabetes 26% *vs* 32% ($p = 0.2$), MASLD 10% *vs* 9% ($p = 0.8$), BMI >29 Kg/m^2 12% *vs* 14% ($p = 0.6$), peripheral vascular disease 1% *vs* 4% ($p = 0.07$), except for CAD family history which was higher in the first

period (15% *vs* 8%, p = 0.05). Non-invasive CAD screening was performed in 196 (52%) of the pts of the first period and 55 (53%) of the second one (p = 0.9). In the second period, the use of EchoS decreased from 52% (n = 196) to 42% (n = 43) (p = 0.055) and the use of c-CT increased from 3% (13 c-CT available outside the Centre protocol) to 23% (n = 24, p < 0.001). Positive screening tests increased from 2% (n = 8) to 8% (n = 8) (p = 0.01) and the use of CATH was 6% (n = 23) in the first period and 11% (n = 11) in the second (p = 0.1). 14/477 patients (3%) underwent revascularization, 9 (2%) in the first and 5 (5%) in the second period (p = 0.2). When considering patients who underwent both CATH and non-invasive screening tests (18 EchoS + CATH and 11 c-CT + CATH), positive predictive value was 62% for EchoS and 67% for c-CT, while negative predictive value (NPV) was 60% for EchoS and 100% for c-CT. The 2-year cumulative incidence of post-LT ischemic CV events was 2.3% and it was similar in the two periods (p = 0.8). Among 10 pts with post-LT heart ischemic events within 2 years, 7/10 (70%) tested negative at pre-LT EchoS.
Conclusion: In our cohort of 477 LT candidates, 7/10 (70%) pts with 2-year post-LT heart ischemic event tested negative at pre-LT EchoS. The implementation of c-CT in the cardiac work-up decreased the risk of underdiagnosing asymptomatic CAD in LT candidates (NPV: 60% EchoS and 100% c-CT).

SAT-016

Assessment of the role of liver transplantation with or without combined kidney transplantation in polycystic liver or liver and kidney disease

Gwladys Lubuela[1], Dominique Joly[2], Federica Dondero[3], Dany Anglicheau[4], Corinne Antoine[5], Christophe Legendre[6], Olivier Roux[1], Emmanuel Weiss[7], Carmen Lefaucheur[8], Arnaud Mejean[9], Alexandre Hertig[10], Safi Dokmak[3], Mickael Lesurtel[3], Francois Durand[1], Claire Francoz[1]. *[1]Hepatology Hopital Beaujon, Clichy, France; [2]Hopital Necker, Paris, France; [3]Hepatobiliary Surgery and Liver Transplantation Hôpital Beaujon, Clichy, France; [4]Kidney Transplantation Hôpital Necker, Paris, France; [5]Nephrology, Hôpital Saint Louis, Paris, France; [6]Kidney Transplantation Hopital Necker, Paris, France; [7]Anesthesiology and LICU, Hospital Beaujon, Clichy, France; [8]Nephrology and Kidney Transplantation Hopital Saint Louis, Paris, France; [9]Urology, Hopital Pompidou, Paris, France; [10]Nephrology and Kidney Transplantation, Hopital Foch, Suresnes, France*
Email: claire.francoz@gmail.com

Background and aims: Management of severe polycystic liver, or liver and kidney disease, is not standardized. Liver transplantation (LT) could be the best curative option in patients with major disabling related to hepatomegaly or cysts with recurrent episodes of infections difficult to manage with conservative treatments. In Patients with associated end-stage kidney disease, combined liver and kidney transplantation (CLKT) could be proposed. We report here a large monocentric study evaluating the results of LT or CKLT.
Method: From 1995 to 2022, 134 patients were transplanted for polycystic liver, or liver and kidney disease, in a single transplant center, after a median waiting time of 9 months. Among them, 101 received CLKT and 33 LT alone.
Results: There were 84% females, and the median age was 52 years. Indication for LT was large hepatomegaly in 90% of patients and cysts recurrent infections in 10%. Manifestations related to hepatomegaly were abdominal pain and early satiety in most of patients, while as high as 48% had dyspnea. As expected, all had normal liver function. Only 25% of patients had previous radiological or surgical treatment (sclerotherapy = 10%, cyst fenestration = 7% and liver resection = 10%) and 12% had received somatostatin analogues. In patients who underwent CKLT, the mean glomerular filtration rate (GFR) at listing was 14 ml/min and 40% were on dialysis. Among patients who received CKLT, 14% had previous kidney transplantation, while they were 12% in those receiving LT alone. At 10 years, patients' survival was excellent, 85% in CKLT and 83% in LT alone. In CKLT, kidney graft survival was also excellent: 98% at 10 years while no patients required re LT. Whatever patients received CLKT or LT alone, a marked improvement in quality of life was always observed. However, 7 patients with polycystic liver and kidney disease (21%) who underwent LT alone, all with GFR >60 at transplantation, developed end-stage kidney disease and sequential kidney transplantation with a median interval between LT and KT of 95 months, possibly related to the combination of progression of polycystic kidney disease and calcineurine inhibitors.
Conclusion: This large series shows that a major improvement in quality of life can be achieved in patients with major hepatomegaly and that long term survival is excellent. In patients with CLKT, long-term kidney graft survival exceeds 95% at 10 years, much higher than in patients receiving kidney transplantation alone. These results argue against reluctance to perform liver transplantation in this population.

SAT-017

QuantiFERON monitor as an immune function assay predictive of clinical events in liver transplant recipients: a validation study

Tess McClure[1,2], Boris Wong[2], Fan Zhang[2], Alexander Dobrovic[2], Vijayaragavan Muralidharan[1,2], Adam Testro[1,2]. *[1]Austin Health, Heidelberg, Australia; [2]The University of Melbourne, Parkville, Australia*
Email: tess.e.mcclure@gmail.com

Background and aims: Despite the judicious use of immunosuppression, most liver transplantation (LT) recipients experience complications such as rejection and infection. There is a clear need for innovative tools to quantify recipient immune function. QuantiFERON Monitor (QFM) is an immune function assay that involves stimulating whole blood with innate and adaptive immune ligands to induce release of interferon-γ (IFNγ). Between 2012 and 2013, Austin Health pioneered the study of QFM in 75 adult LT recipients, and found that week 1 results correlated with early clinical events. A high IFNγ (>4.45 IU/ml) was associated with a risk of rejection (area under the receiver operating characteristic curve [AUROC], 0.77; p = 0.002), and a low IFNγ (<1.30 IU/ml) with a risk of infection (AUROC, 0.74; p = 0.008) within the first month post-LT. The following validation study aimed to re-examine the utility of QFM in a larger cohort of adult LT recipients.
Method: 100 adults were recruited pre-LT from 2019 to 2022 and followed up for 12 months. Additional blood for QFM testing was taken pre- and post-LT (day 1, 3, 5; week 1, 2; month 1, 2, 4, 6, 12). The primary end points were the accuracy of QFM in predicting rejection, defined as treated biopsy-proven acute rejection (tBPAR) and infection, classified as 'probable' or 'definite' as per an international sepsis forum consensus conference.
Results: In these 100 LT recipients, the median age was 55 years and 66% were males. 94% had cirrhosis and 37% had a hepatoma. The most common disease etiologies were alcohol (42%) and hepatitis C (19%). The median pre-LT Model for End Stage Liver Disease-Sodium was 21. The median donor age was 43 years. 89% of donations were after brainstem death, 19% received OrganOx support and 6% proceeded to a split LT. Post-LT, recipients routinely received weaning steroids, a calcineurin inhibitor and an antimetabolite. 75% of patients received basiliximab. 54 recipients experienced 32 episodes of tBPAR and 84 infections. The first event was tBPAR in 14% and infection in 40%. The most common time for tBPAR (10/32) and infections (14/84) was week 1 to month 1 post-LT. At the time of submission, QFM results were available for 98 patients. The median pre-LT QFM was 20.20 IU/ml. The median week 1 QFM varied significantly between patients who were well or had a clinical event (p = 0.0007) within the first month post-LT. A high IFNγ was associated with the risk of rejection (AUROC, 0.84; p = 0.0049), and low IFNγ with a risk of infection (AUROC, 0.76; p = 0.0131), as seen in the original study. Further analysis is ongoing to determine optimal clinical thresholds.
Conclusion: QFM has been shown to be predictive of early rejection and infection post-LT. In this subsequent study, our preliminary

results validate these findings in a larger cohort of adult LT recipients. Further research, in the form a multi-centre randomised trial, is required for clinical translation.

SAT-018-YI

Liver transplantation in cystic fibrosis: the evolving landscape in the United Kingdom

Georgeina L. Jarman[1], Maria Jacobs[2], Rhiannon Taylor[2], William J. H. Griffiths[1]. [1]*Cambridge Liver Unit, Addenbrooke's Hospital, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom;* [2]*Statistics and Clinical Research, NHS Blood and Transplant, Bristol, United Kingdom*
Email: georgee.jarman@nhs.net

Background and aims: Cystic fibrosis-related liver disease (CFLD) is a common extra-pulmonary manifestation of cystic fibrosis (CF) with a range of phenotypes, from asymptomatic steatosis to end-stage cirrhosis with portal hypertension. With no specific medical therapies, and exclusion from Cystic Fibrosis Transmembrane conductance Regulator (CFTR) modulator trials, patients with advanced CFLD have historically progressed towards transplantation, often encumbered by multi-morbidity. Here we aimed to review the evolving landscape of liver transplantation in CF in the United Kingdom.
Method: National data through NHS Blood and Transplant identified patients with CF who had been registered for liver transplantation (including multi-organ) between 1989 and 2023. Super-urgent registrations were excluded. Data was collected on registration and transplant numbers, outcomes, donor type and patient and graft survival.
Results: 136 of the 188 patients registered for liver transplant (including multi-organ) between 1990 and 2023 were transplanted (72.3%). Across this period, within 12 months of listing for transplantation, 19 patients died and 10 were removed from the waiting list, including 1 in 2020–2023 due to condition improvement. Most livers came following donation after brainstem death (DBD), with only 3 transplants from donation after cardiac death (DCD), all since 2010. 2 patients received split livers from living-related donors. Historically, multi-organ transplantation was more common, with 3 patients undergoing combined liver-pancreas and 2 liver-kidney transplants. 10 heart-lung-liver transplants were performed between 1991 and 2001 and 6 liver-lung transplants have been completed, though combined liver-cardiothoracic transplants had generally poor survival outcomes (5-year survival 42.9% (95% CI 17.7–66), 1989–2018). No CF patients have been registered multi-organ transplantation since 2019. 5-year survival following isolated liver transplantation remained static at 66.7% (95% CI 19.5–90.4) in 1989–1994 and 2015–2018, respectively ($p = 0.9$).
Conclusion: Liver transplantation has provided a vital therapy to those with end-stage CFLD for almost 35 years in the UK. Trends in solid-organ transplantation have evolved; with a focus on single-organ transplantation, likely in light of combined liver-cardiothoracic outcomes. We may see further shifts in the field, with advancements in machine perfusion of DCD organs helping to close the gap between transplant demand and availability. CFTR modulators may help optimise respiratory health of patients requiring liver transplantation, reducing their burden of co-morbidity, and potentially improving outcomes. With time, optimised medical therapy with CFTR modulators in childhood may help to prevent advanced CFLD and render liver transplantation in CF obsolete.

SAT-019

Recipient donor sex constellation differences in outcome after liver transplantation for hepatocellular carcinoma-an ELTR study

Christian Magyar[1], Noah Arteaga[1], Giacomo Germani[2], Vincent Karam[3], René Adam[4], Lucienne Christen[1], Federico Storni[1], Corina Kim-Fuchs[1], Anja Lachenmayer[1], Guido Beldi[1], Daniel Candinas[1], Pompilia Radu[1], Birgit Schwacha-Eipper[1], Annalisa Berzigotti[1], Vanessa Banz[1], for the European Liver and Intestine Transplant Association (ELITA)[3]. [1]*Department of Visceral Surgery and Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland;* [2]*Multivisceral Transplant Unit, Department of Surgery, Oncology and Gastroenterology, Padua University Hospital, Padua, Italy;* [3]*The European Society for Organ Transplantation, Amsterdam, Netherlands;* [4]*Department of Surgery, Centre Hepatobiliary, Hopital Paul Brousse, Paris, France*
Email: vanessa.banz@insel.ch

Background and aims: Hepatocellular carcinoma (HCC) is the third leading cause of cancer-related deaths worldwide. Liver transplantation (LT) is the mainstay of curative treatment, as approximately 90% of HCC develop in chronic liver disease. Donor and recipient sex appears to have an impact on HCC recurrence and death after LT. We describe recipient donor sex constellation (RDSC) specific oncological outcome differences in patients receiving LT.
Method: We performed a European Liver Transplant Registry (ELTR) analysis including patients from 1988 to December 2022. Patients with incomplete tumor variables on histopathology, as well as retransplantation events, were removed. According to the RDSC the following four groups are compiled: female donor female recipient (FDFR), female donor male recipient (FDMR), male donor female recipient (MDFR) and male donor male recipient (MDMR). Survival analysis was performed using Kaplan Meier and Cox regression proportional hazard models. To adjust, factors for an a priori multivariable model were selected (histopathology, number of nodules, largest lesion size and vascular invasion status). Due to design of the registry, no adjustment for comorbidities was feasible. Data was collected in accordance with the General Data Protection Regulation, the European Union legislation and the ELTR privacy policy. The data used in the study was anonymous.
Results: Of the 7601 LT for HCC, 7428 recipients (98%) had concomitant cirrhosis. The median number of HCC lesions on histopathology was 2.0 (IQR 1.0, 3.0), median lesion size 2.8 cm (2.0, 4.0), macrovascular invasion in 275 (4.4%) and in 2822 (42%) the tumor burden was classified as beyond 'Milan criteria'. In 4784 (63%) an HCC pre-transplant specific treatment was registered. Overall median follow-up was 22.6 months (5.8, 60.7) with death registered in 1905 (25%) and, as primary cause of death, HCC tumor recurrence was seen in 496 (26%) of patients. The cohort was split into the four RDSC groups: 743 FDFR, 2325 FDMR, 548 MDFR and 3985 MDMR. There was no statistically significant difference on crude survival estimates (log-rank $p = 0.66$) with 10-year overall survival (OS) of 54% in FDFR, 55% in FDMR, 59% in MDFR and 57% in MDMR. In the a priori multivariable analysis, a trend of the effect of RDSC on OS was seen (FDFR as reference): FDMR (HR 0.91, $p = 0.332$), MDFR (HR 0.78, $p = 0.058$) and MDMR (HR 0.85, $p = 0.086$). Female recipients had a significant higher risk of death with dysfunctioning graft (FDFR 39% MDFR 43%) compared to male recipients (FDMR 29%, MDMR 32%) ($p = 0.035$). Regarding overall registered causes of death, differences between RDSC groups were found in rejection ($p = 0.017$) and cardiovascular ($p = 0.046$) associated deaths.
Conclusion: Female recipients show a trend towards worse long-term oncological outcome, if they receive a sex-mismatched organ.

SAT-020

Evaluation of 18FDG-PET/CT for prediction of waitlist dropout and post transplantation recurrence in patients listed for hepatocellular carcinoma

Catherine Lamarque[1], Anna Sessa[1], Edouard Reizine[1], Sébastien Mulé[1], Julia Chalaye[1], Norbert Ngongang[1], Nadia Oubaya[1], Vincent Leroy[1], Christophe Duvoux[1]. [1]*University Hospital Henri Mondor, Créteil, France*
Email: catherine.lamarque@yahoo.fr

Background and aims: Efficacy of liver transplantation (LT) for HCC is limited by the increasing number of HCC indications and by organ shortage This results in a 15–20% dropout rate before LT, and in a 10–

15% risk of HCC recurrence after LT. To optimize intent-to-treat efficacy, prediction of dropout should be improved. ^{18}FDG- PET/CT recently showed encouraging results in predicting post-LT recurrence. Yet, whether ^{18}FDG-PET/CT may also predict waitlist dropout remains unknown. Our objectives were to investigate the value of ^{18}FDG-PET/CT in the prediction of wait-list dropout in HCC candidates, and to further analyse its role in the prediction of post-LT recurrence.

Method: Retrospective exploratory monocentric study in a cohort of patients listed for HCC between 01/2013 and 11/2018. All patients had been investigated with ^{18}FDG-PET/CT at work-up. ^{18}FDG-PET/CT was considered positive when tumor to liver SUV ratio was ≥1.15. The primary end point was the preLT risk of dropout for tumor progression or death; secondary enpoint was 5-year-postLT recurrence free survival.

Results: 105 patients were enrolled: median age 59 yo [55;64], MELD 8 [6;14], number of tumor 2 [1;2], tumor size 1.8 cm [1.2;1.5], Milan criteria in 82.9%, AFP score 0/1/2 in respectively 62%/21.9%/11.4%. Pre-LT 15-month dropout-free survival rate was 77.4%. The 15-month risk of wait-list drop-out tended to be significantly higher in patients with positive ^{18}FDG-PET/CT compared to patients with a negative one with 28.6% (95% CI: 14.00;52.8) vs 12.3%, (95% CI: 6.8;21.7), respectively (p = 0.08). By multivariate analysis, ^{18}FDG-PET/CT tumor to liver SUV ratio, and number of tumors were independent prognostic factors of waitlist dropout for tumor progression or death (OR of 2.56 (95%CI 1.28; 5.15) and 1.7 (95% CI 1.16; 2.5), respectively). Among 72 patients eventually transplanted, 5-year HCC recurrence free survival was significantly higher in patients with negative ^{18}FDG-PET/CT compared to patients with a positive one: 90.5% (95% CI: 78.6; 95.9) vs 50% (95%CI: 20.8; 73.6), respectively (p = 0.002).

Conclusion: This study a- confirms the predictive value of ^{18}FDG-PET/CT for post-LT recurrence, b- for the 1st time, suggests that ^{18}FDG-PET/CT has the potential to predict dropout from the waitlist. Subject to retrospective design and population size, this study emphasizes the crucial role that ^{18}FDG-PET/CT may play in pre-LT work up of HCC patients, to refine selection of HCC candidates and to improve prioritization of these patients. It eagerly calls for a larger multicenter prospective assessment of FDG PET/CT in HCC candidates.

Background and aims: A significant proportion of patients with variant syndromes (VS), namely AIH/PBC or AIH/PSC require liver transplantation (LT), despite treatment. The frequency of disease recurrence and the effect on graft survival is yet to be clarified. The aim of this international, multicentric, retrospective study is to evaluate risk factors associated with recurrence and the impact of the disease recurrence after LT on graft and patient survival.
Method: We evaluated 172 patients undergoing LT for VS in 33 centres in North America, South America, Europe and Asia. Clinical data before and after LT, biochemical data within the first 12 months after LT, and immunosuppression after LT were analysed to identify patients with a higher risk of recurrence of autoimmune disease based on histological and radiological diagnosis. Cumulative probabilities of graft and overall survival after LT were calculated using semi-Markov model.
Results: VS recurred after LT in 23% and 33% of patients after 5 and 10 years, respectively. An increased ALP and ALT at 12 months after LT (HR, 1.60; 95% CI, 1.13–2.25; $p < 0.01$, HR, 1.25; 95% CI, 1.01–1.53; $p = 0.03$) and acute rejection (HR 3.58; 95% CI, 1.60–7.73; $p < 0.01$) were found associated with a higher risk of VS syndrome recurrence, whilst the use of predniso (lo)ne was associated with a reduced risk (HR 0.30, 95% CI 0.14–0.64, $p < 0.01$). After adjusting for ALT and ALP at 12-months, the use of predniso (lo)ne was found to be independently and negatively associated with recurrent disease. The recurrence of VS was found significantly associated with graft loss and patients' survival at the multivariate Cox regression analysis with time-dependent covariate. The 5-, 10- year probability of graft survival was 68% and 41% in patients with recurrent VS compared to 83% and 60% in patients without recurrent disease (p value, $p = 0.01$). The overall survival was significantly reduced in patients with recurrent disease ($p = 0.01$), with event probability at 5- and 10- years of 75% and 49 no% vs 84% and 60% in patients without recurrence.
Conclusion: VS recurrence after LT is frequent and is associated with elevation of liver enzymes within the first year after LT and rejection episodes. VS recurrence negatively impacts graft and patient survival. Strategies are warrant to prevent VS recurrence or mitigate its negative effects.

SAT-022

Post-recurrence survival after liver transplantation for hepatocellular carcinoma: outcomes of an "orphan" disease

Marianna Maspero[1], Carlo Sposito[1], Marco Bongini[1], Sherrie Bhoori[1], Valentina Bellia[1], Andrea Schlegel[2], Vincenzo Mazzaferro[1].

Email: marianna.maspero@istitutotumori.mi.it

Background and aims: During the last decades, liver transplantation (LT) for hepatocellular carcinoma (HCC) has undergone profound changes regarding patient selection, transplant criteria, downstaging and bridging therapies, allocation policies and immunotherapeutic regimens. Despite this, the main driver of post-transplant mortality in these patients remains HCC recurrence. The aim of this study was to determine whether post-transplant survival has improved during the last two decades.
Method: Using the Scientific Registry of Transplant Recipients (SRTR), we included all patients who underwent LT for HCC between 2003 and 2020 in the United States and experienced HCC recurrence. We divided them into four eras (2003–2007, 2008–2012, 2013–2016, 2017–2020) according to their year of transplant and analyzed their post-recurrence survival.
Results: 26309 patients underwent LT for HCC (era 1: 4810, 18%; era 2: 7617, 29%; era 3: 7179, 27%; era 4: 6703, 25%). Unadjusted post-transplant 5-year survival was different between the eras (1: 69%, 2: 73%; 3: 80%; 4: 75%; $p < 0.001$) with better survival in more recent eras despite an increase in Milan-OUT patients (1: 3%; 2: 4%; 3: 12%; 4: 13%). Patients who experienced recurrence were 2960 (11%): 689 in era 1, 988 in era 2, 739 in era 3 and 544 in era 4. In later eras, patients with recurrence were older (median age 1: 56; 2: 58; 3: 61; 4: 63), with more MASLD (1: 14%; 2: 28%; 3: 25%; 4: 32%), were more likely to have received bridge therapies (1: 60%; 2: 76%; 3: 90%; 4: 95%) and be outside Milan (1: 4%, 2: 5; 3: 25%; 4: 21%), however had lower AFP scores (AFP score >2 1: 17%; 2: 10.5%; 3: 6%; 4: 2%). Despite these differences, median post-recurrence survival was similar: 10 (IQR 3–27) months for era 1; 12 (IQR 3–31) months for era 2; 12 (IQR 4–31) months for era 3; and 13 (IQR 4–26) for era 4 (log rank p value = 0.178). After adjusting for bridge therapy before transplant, AFP score >2 at transplant and age, post-recurrence survival remained similar.
Conclusion: Post-recurrence survival after LT for HCC has not improved during the last two decades. Research efforts for this "orphan" disease should be made to implement post-recurrence survival, particularly in light of the new available therapeutic options.

Development of a model to preoperatively predict the risk of microvascular invasion for hepatocellular carcinoma patients undergoing liver transplantation

Quirino Lai[1], Suela Ajdini[1], Jean Emond[2], Arvinder Singh Soin[3], Tomoharu Yoshizumi[4], André Viveiros[5], Maria Hoppe Lotichius[6], Takashi Ito[7], Massimo Rossi[1], Albert CY Chan[8], Chao-Long Chen[9], Umberto Cillo[10], Timothy Pawlik[11], Jan Lerut[12]. *[1]Sapienza University of Rome, Rome, Italy; [2]Columbia University, New York, United States; [3]Medanta-The Medicity, New Delhi, India; [4]Kyushu University, Fukuoka, Japan; [5]Medical University of Innsbruck, Innsbruck, Austria; [6]Universitätsmedizin Mainz, Mainz, Germany; [7]Graduate School of Medicine, Kyoto, Japan; [8]The University of Hong Kong, Hong Kong, Hong Kong; [9]Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan; [10]Padua University, Padua, Italy; [11]The Ohio State University Wexner Medical Center, Columbus, United States; [12]Universite Catholique Louvain, Brussels, Belgium*
Email: lai.quirino@libero.it

Background and aims: Microvascular invasion (MVI) represents a relevant prognostic factor in the setting of hepatocellular carcinoma (HCC). A recent study by Endo et al. proposed a model in the setting of liver resection. A refined model to predict MVI based on preoperative variables in the setting of liver transplantation (LT) is proposed in the present study.
Method: Patients undergoing LT for HCC between 2000 and 2018 were identified using a multi-institutional database. A total of 2, 170 patients were split in a Training (70%) and a Validation Set (30%). Therefore, a preoperative predictive model for MVI was built and externally validated.
Results: Among the entire cohort, MVI was observed in 586 patients (27.0%). On multivariable logistic regression analysis in the Training Set, three preoperative parameters associated with MVI were identified: α-fetoprotein (lnAFP; odds ratio [OR] = 1.19; 95% confidence interval [CI] = 1.13–1.27), imaging tumor burden score (lnTBS; OR = 1.66; 95%CI = 1.39–1.99) and living donor LT (LDLT; OR = 1.99; 95%CI = 1.56–2.53). The c-index of the Validation Set was 0.74 vs. 0.69 observed for the score by Endo (Brier Skill Score +13%). The new score presented a relevant net reclassification index (NRI), with 34.4% of correct reclassification rate for the events and 26.6% for non-events (overall NRI = 0.61). Stratifying the Validation Set in three risk strata (0–50th, 51st–75th, >75th centile of the score), a very good stratification was observed in terms of disease-free (5-year: 89.3,

75.5, and 50.7%, respectively) and overall survival rates (5-year: 79.5, 72.6, and 53.7%, respectively).
Conclusion: Preoperative assessment of MVI using the present model showed very good accuracy to predict MVI after LT.

Impact of ISO score on oncological outcomes and survival in HCC patients candidate for liver transplantation
Elisa Pinto[1], Martina Gambato[1], Filippo Pelizzaro[1], Francesco Paolo Russo[1], Victor Echavarrìa[2], Patrizia Burra[1], Enrico Gringeri[1], Alessandro Vitale[1], Umberto Cillo[1]. [1]*University of Padua, Padua, Italy;* [2]*Hospital Universitario Marqués de Valdecilla, Santander, Santander, Spain*
Email: pintoelisa93@gmail.com

Background and aims: Liver transplantation (LT) is the most efficacious curative treatment for hepatocellular carcinoma (HCC). Waiting list (WL) prioritization criteria determine patient outcomes. Since 2015, the Italian Score for Organ Allocation (ISO) has been used in Italy to prioritize patients on the WL, introducing a specific policy for HCC. In this study, we aimed to assess the impact of ISO-score on WL dropout, HCC recurrence, and patient survival in LT candidates with HCC.
Method: This retrospective study included all patients with HCC listed for LT (n = 378) at our institute between January 2013 and December 2020. We considered 2 groups: patients prioritized before (group A, 2013–2015) and after (group B, 2016–2020) ISO score implementation. We used cumulative incidence functions within a competing risk time-to-event analysis to assess and compare, between the 2 groups, the probabilities of LT, WL death and dropout. Uni- and multivariable logistic regression models were also used to identify potential risk factors associated with WL mortality.
Results: Group B patients were older than group A patients (p = 0.01), presenting more grading 3 HCC in the explanted liver (group A: 8.3%, group B: 16.8%; p = 0.04). After the implementation of ISO score, a higher rate of HCC metabolic dysfunction associated steatotic liver disease (MASLD)-related (group A: 7%, group B: 11.7%; p = 0.03) have been registered.
During a median follow-up of 49 months, 289 HCC patients underwent LT, 4 patients (13%) died before LT, and 71 patients (18%) were removed from WL for HCC progression. According to the competing risk multivariate analysis, WL dropout rate was similar in the two groups (p = 0.07). Downstaging treatments (p = 0.0001) and alpha-fetoprotein (AFP) levels (p = 0.0001) were identified as risk factors for WL dropout. HCC recurrence after LT rate was significantly lower in group B patients than group A (p = 0.03), also confirmed at multivariate analysis (p = 0.04). Group B patients showed higher overall survival (OS) than group A patients (p = 0.04), without difference in no-HCC related deaths between the two groups (p = 0.049).
Conclusion: After the introduction of ISO score, a lower HCC recurrence after LT has been observed as well as an improved overall survival after LT. These findings strongly suggest that the implementation of the ISO score has enhanced the allocation process for HCC patients, resulting in a substantial increased transplant benefit.

Email: raffaella.vigano@ospedaleniguarda.it

Background and aims: Liver transplantation (LT) is an established therapeutic option for a subgroup of highly selected patients with alcoholic-hepatitis non[1]responder to medical treatment (MT). While some patients have a rapidly progressive disease leading to an early-LT, others initially improve with MT but need to be evaluated for a standard-LT in the following months for persisting decompensation.
Aim of the study is to describe the features of early-LT versus standard-LT for severe alcoholic hepatitis.
Method: One hundred consecutive patients with severe-AH referred to our center since April 2016 were considered, with those non-responder to medical treatment being evaluated for LT.
Results: Fifty-three patients were non-responder to MT and 17 underwent early-LT within 27 days from admission. Of the 47 responder patients, 14 were subsequently listed with 13 being transplanted after a median of 166 days for persisting decompensation despite initial clinical improvement, Fig.1. Patients receiving standard-LT had lower MELD-Na scores at presentation compared to early-LT (27 vs 34; p = 0.008) and a lower prevalence of ACLF-grade 2–3 (23% vs 82.4%; p = 0.002). After multivariate analysis patients with MELD-Na ≥30 at index hospitalization were 5.88 (95%CI:2.31–16.41) times more likely to be non-responders to MT than those with a MELD-Na <30, while those with ACLF grade 2–3 were 12.56 (95% CI:4.95–35.04) times more likely to be non responders as compared to those with ACLF grade 0–1 (Fig). Overall, 15 LT recipients (50%) suffered from depression and 10 (33%) received antidepressants post-LT. Three patients in all (10%) relapsed into any alcohol consumption. Twenty-nine (97%) are currently alive after a median follow-up of 32.2 months from LT.
Conclusion: Patients with SAH have different patterns of progression. Of those transplanted, 57% received an early-LT and 43% a standard LT. Overall, the transplant benefit was huge and relapse into alcohol consumption acceptable, 10%. Treatment of psychiatric comorbidities proved valuable to mitigate the risk of relapse.

SAT-026
Liver stiffness is associated with the results of long-term protocol biopsies in liver transplant patients recipients
Pauline Bozon-Rivière[1], Stéphanie Faure[1], José Ursic Bedoya[1], Magdalena Meszaros[1], Astrid Herrero[1], Benjamin Riviere[1], Georges-Philippe Pageaux[1], Lucy Meunier[1]. [1]*Regional University Hospital Center of Montpellier, Montpellier, France*
Email: pauline.riviere@hotmail.fr

Background and aims: Survival after liver transplantation (LT) is 74% at 5 years and 63% at 10 years. Liver biopsy (LB) is the gold standard for diagnosing post-LT complications (1). However, the use of LB as a monitoring tool is limited by its invasiveness, cost and risk of sampling error. In many indications, Vibration Controlled Transient Elastography (VCTE) has replaced biopsy for assessing liver stiffness. Some preliminary studies have demonstrated the feasibility and diagnostic performance of VCTE for the detection of fibrosis and steatosis following LT (2, 3). However, no data exists concerning the value of VCTE for long-term follow-up after LT compared with a

protocol LB in asymptomatic patients. Our study aimed to compare VCTE with protocol LB in LT patients.
Method: Patients 5 to 10 years post-LT with both protocol LB and VCTE were included. VCTE was used to measure liver stiffness measurement (LSM) and steatosis via Controlled Attenuation Parameter. The primary end point was the performance of the VCTE in predicting an abnormal LB.
Results: Among the 278 patients who underwent LT between 2012 and 2017 in our center, 138 had both LB and VCTE assessment. 80 patients could be analysed. Most of this patients were men (n = 55, 69%), with a mean age of 61 ± 10.2 years. The main indications for LT were alcohol (n = 37; 46.3%) and hepatitis B or C virus (n = 17; 21.3%). The median time between LT and LB was 6 years (IQR 5–8) and between LB and VCTE was 42.5 days (IQR 22–79). Of the 80 LB performed, 40 (50%) were normal and 14 (16%) showed steatosis with no other abnormalities. 26 (32.5%) were abnormal: acute cellular rejection (n = 9), fibrosis (n = 11), recurrence of initial disease (n = 6). Mean LSM was 8.2 ± 8 kPa (range 3.1–74.5) with a mean CAP of 242 ± 55 dB/m. Patients with abnormal LB had higher elastography (12.69 (±14.64) vs 6.02 (±1.95); p < 0.001). Liver tests were more frequently abnormal in patients with high elastography: ASAT (27.62 (±14.22) vs 21.15 (±10.93); p = 0.023), ALT (24.85 (±16.32) vs 18.91 (±13.73); p = 0.046), bilirubin (12.9 (±8.23) vs 8.8 (±4.36); p = 0.011). Elastography (AUC: 0.79 (95% CI: [0.68–0.899])) had the best statistical performance in predicting an abnormal LB compared with ALT (AUC: 0.638 (95% CI: [0.503–0.773])) and bilirubin (AUC: 0.679 (95% CI: [0.555–0.803])). For elastography, the threshold with the highest Youden index was 6.6 kPa. Elastography <5.4 kPa ruled out an abnormal LB (Se 92.3%, Sp 44.4%, VPN 92.3%, VPP 44.4%) and a value above 8.5 kPa predicted an abnormal LB (Se 42.3%, Sp 94.4%, VPN 77.3%, VPP 78.6%).
Conclusion: For patients in the 5 to 10-year post-LT period, elastography becomes a valuable tool in discerning those who may benefit from a protocol biopsy (>8.5 kPa) or find it unnecessary (<5.4 kPa), particularly in the absence of biological abnormalities. These results underscore the appropriateness of employing VCTE in long-term LT recipients to determine the need for a LB.

SAT-027
Women are also disadvantaged in accessing transplant outside the United States: analysis of the spanish liver transplantation registry

Marta Tejedor[1], Fernando Neria[2], Gloria de la Rosa[3], Carolina Almohalla Alvarez[4], María Padilla[5], Andrea Bosca[6], Yilliam Fundora[7], Francisco Sánchez-Bueno[8], Miguel Ángel Gómez Bravo[9], Marina Berenguer[10]. *[1]Hospital Universitario Infanta Elena, Madrid, Spain; [2]Universidad Francisco de Vitoria, Madrid, Spain; [3]Organización Nacional de Trasplante (ONT), Madrid, Spain; [4]Hospital Universitario Rio Hortega, Valladolid, Spain; [5]Organización Nacional de Trasplantes (ONT), Madrid, Spain; [6]Hospital Universitari i Politècnic La Fe, Valencia, Spain; [7]Hospital Clinic de Barcelona, Barcelona, Spain; [8]Hospital Clínico Universitario Virgen de la Arrixaca, Murcia, Spain; [9]Hospital Universitario Virgen del Rocío, Sevilla, Spain; [10]La Fe University and Polytechnic Hospital, Valencia, Spain*
Email: marta_tejedor@hotmail.com

Background and aims: Sex inequities in liver transplantation (LT) have been documented in several mostly US-based studies. Our aim was to describe the recipient profile over time in Spain, particularly regarding potential sex-related differences in access to LT.
Method: All adult patients registered in the RETH-Spanish Liver Transplant Registry from 2000 to 2022 for LT were included. Baseline demographics, presence of hepatocellular carcinoma (HCC), cause and severity of liver disease, time on the waiting list (WL), access to transplantation, and reasons for removal from the WL were assessed.
Results: 14, 385 patients were analysed (77% men, 56.2 ± 8.7 years). Model for end-stage liver disease (MELD) score was reported for 5475 patients (38%), with a mean value of 16.6 ± 5.7. Overall, fewer women received a LT (79% vs 82%, p < 0.001) and a greater proportion were excluded (10% vs 8%, p = 0.004) from the WL compared to men. Women were less likely to receive a transplant than men (OR 0.78, 95%CI 0.63, 0.97) and more likely to be excluded for deterioration (HR 1.17, 95%CI 0.99, 1.38), despite similar liver disease severity (MELD score for women 16.6 ± 5.7 vs men 16.6 ± 5.7, N.S). Women waited longer on the WL (198.6 ± 338.9 vs 173.3 ± 285.5 daysfor men, p < 0.001). In recent years, women's risk of dropout of the WL due to deterioration or death has reduced (2000–2010: HR 1.49 [95%CI 0.99, 2.25]; 2011–2016: HR 0.93 [95%CI 0.64, 1.36]; 2017–2022: HR 0.93 [95%CI 0.57, 1.51]), concomitantly with reduced WL times (mean waiting time for women and men respectively was 473.6 ± 693.7 vs 408.4 ± 593.1 days [p = 0.078] between 2000–2010; 207.0 ± 251.0 vs 186.5 ± 223.1 days [p = 0.005] between 2011–2016; and 104.2 ± 148.2 vs 88.7 ± 118.2 days [p < 0.001] between 2017–2022). The probability of being transplanted was lower for women before 2011 (OR 0.68, 95% CI 0.49, 0.96; p = 0.026). However, recently no significant differences in access to LT were found by sex (2011–2016: OR 0.82 [95%CI 0.60, 1.13]; 2017–2022: OR 0.77 [95%CI 0.57, 1.05]). Time on the WL did not seem to influence the risk of women undergoing transplant (HR 0.95 [95%CI 0.90, 1.01]).
Conclusion: Even in countries with short waiting times, women wait longer and have a higher risk of exclusion from the WL. Policies directed at optimizing the whole LT network should be encouraged to guarantee a fair and equal access of all patients to this life saving resource.

SAT-028
The relationship between spleen stiffness and portal hypertension liver transplant patients

Kanan Nuriyev[1], Zülal İstemihan[1], Pelin Telli[1], Asim Qurbanov[1], Mehmet Akif Yağlı[1], Gizem Dağcı[1], Aynure Rüstemzade[1], Sezen Genç Uluçeçen[1], Bilger Çavuş[1], Aslı Çifcibaşı Örmeci[1], Filiz Akyuz[1], Kadir Demir[1], Fatih Beşışık[1], Sabahattin Kaymakoğlu[1]. *[1]Istanbul University, Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Gastroenterohepatology, İstanbul, Turkey*
Email: dr_bilgercavus@yahoo.com

Background and aims: In our study, we aimed to reveal the relationship between spleen stiffness and the presence of portal hypertension after post transplant patients who are non cirrhotic.
Method: Spleen and liver stiffness was measured with Fibroscan© in liver transplant patients followed up at the liver transplant outpatient clinic of a tertiary university hospital. "Independent T-test" and "Chi-square test" were calculated. AUC was calculated within the scope of ROC analysis in order to predict the cut-off value of spleen and liver stiffness in revealing the presence of esophageal varices after liver transplantation (LT).
Results: A total of 50 patients who underwent LT at least 6 months ago (mean transplant time was 117 ± 74 months)were included in the study. Patients who developed liver cirrhosis or portal vein thrombosis after LT were excluded from the study. 70% of the patients were women, the mean age was 52.5 ± 12.9 years. 37% of the patients had cadaveric transplants. 60% of the patients had post-transplant gastroscopy results and were included in the study. Gastroscopy examination, which were performed within 6 months after transplantation, were not included in the study. All patients had liver cirrhosis before LT. HBV and cryptogenic liver cirrhosis were the most common etiologies. All patients had esophageal varices before LT, and esophageal varices were detected in 12% of patients during post-transplant gastroscopy. The mean liver stiffness was determined as 6.4 ± 2.4 kPa and the mean spleen stiffness was 29.5 ± 18.7 kPa. The mean spleen size was 136 ± 33 mm. A significant positive relationship was detected between spleen size and spleen stiffness (p < 0.01). Low platelet values after LT were associated with high liver stiffness (p < 0.05). A longer period of time after LT was associated with decreased spleen stiffness (p < 0.05). Male gender, presence of shunt before LT and history of variceal bleeding were found to be associated with increased spleen stiffness (p < 0.05). ROC analysis was performed to

evaluate whether spleen and liver stiffness predicted the presence of esophageal varices after LT. It was observed that liver stiffness did not have a statistically significant difference (p > 0.05). It was observed that spleen stiffness had 79.5% discrimination (AUC) with its cut-off value of 27.95 kPa, and had a statistically significant discrimination with its sensitivity (%66, 7) and specificity (%66, 7) values (p = 0.028).
Conclusion: In patients with LT due to cirrhosis, spleen stiffness greater than 27.9 kpA on FibroScan® predicts the presence of esophageal varices. Male gender, the presence of portosystemic shunt before LT, and a history of variceal bleeding were associated with increased spleen stiffness.

Background and aims: Liver transplantation (LT) for hyperimmunized recipients with positive crossmatch or with preformed DSA pose unique challenges due to increased sensitization and risk of antibody-mediated rejection (AMR). Induction therapy, in HLA sensitized liver transplant recipients, with rabbit anti-thymocyte globulin (rATG) has been used to prevent and to treat AMR.
Method: Consecutive hyperimmunized recipients who underwent LT between 2016 and 2022 were retrospectively reviewed. Characteristics of patients, donor, immunological status, liver biopsies and outcomes were collected.
Results: Of the 44 adult recipients (mean age of 47.1 ± 14.4 years) and mean follow-up of 35.1 ± 26.3 months, 29 patients were females (65.9%) and 15 patients were males (34.1%). 36/44 patients (82.8%) had undergone first LT, and 8 (18.2%) recipients had a previous LT. The main indications for primary LT were hepatocellular carcinoma (22.7%), biliary cirrhosis (18.2%), alcoholic related cirrhosis (11.4%). At time of transplant, the mean MELD score was 21.8 ± 9.4, sensitized recipients with positive HLA antibodies I and II were 83% and 85.4% respectively. 79.5% of the recipients had positive D/R crossmatch. All the recipients received induction therapy with rATG (3 mg/kg/day at day 0, 1, 2) associated to a triple immunosuppression regimen (Methylprednisolone, MMF and tacrolimus). High dose human immunoglobulins (IVIG, 2 g/Kg) were administered to lower anti-HLA antibodies levels. Among 44 patients, 5 patients developed acute cellular rejection (11.4%), 7 patients (15.9%) developed AMR. The 1, 3-year overall survival rates were 83.3%, and 76.7%. The 1, 3 years overall survival among patients respectively with rejection and without rejection were comparable (87.1%, 87.1% and 81.1, 76.3%). 3/44 had re-transplanted due to primary non function graft (2/3) and AMR (1/3). A total of 10/44 patients (22%) died due to sepsis (n = 5), cerebral hemorrhage (n = 3), HCC recurrence (n = 2). Mean intensive care unit stay was 10.4 ± 9.8 days. No serious adverse events were related to induction.
Conclusion: Induction therapy using rATG and IVIG for 3 days for hyperimmunized liver transplant recipients minimize the incidence and impact of antibody mediated rejection on patient and graft survival.

SAT-030

A visual classification scale of biliary anastomotic strictures with per-oral cholangioscopy predicts outcomes in liver transplant recipients

Alex Bofill[1], Lesly Calixto[1], Octavi Bassegoda[1], Alejandro Fernandez-Simon[1], Oriol Sendino[1], Henry Cordova[1], Andres Cardenas[2]. *[1]Hospital Clinic, Barcelona, Spain; [2]Hospital Clinic, Barcelona, Barcelona, Spain*
Email: acardena@clinic.cat

Background and aims: Biliary anastomotic strictures (BAS) after liver transplantation (LT) are the most common biliary adverse events in LT recipients. They are mostly managed with endoscopic retrograde cholangiopancreatography (ERCP). Prior data from our group showed that per-oral cholangioscopy (POCS) identifies two distinct visual stricture patterns: type A (scarring) and type B (erythema with sloughing and/or ulceration). This study analyzed these two stricture patterns and compared treatment outcomes.
Method: Prospective single-center study at Hospital Clinic of Barcelona of LT recipients with BAS that underwent POCS over a 7-year period (2016–2022).
Results: 45 patients with suspected post-LT biliary strictures underwent POCS. Baseline characteristics (age, sex, etiology, time from LT to POCS and therapy) according to the type of stricture were similar. The main indications for POCS were evaluation of complex biliary strictures including selective guidewire placement across strictures (95.6%) and therapy of common bile duct stones above a BAS (4.4%). POCS successfully visualized the biliary tract in 93.3% of patients (42/45). In 38 LT recipients the BAS was successfully visualized, whereas in four POCS no stenosis was confirmed. Type A strictures were present 63.2% (24/38) and Type B in 36.8% (14/38) of LT recipients with BAS. During follow-up (median follow-up 28 months), stricture resolution was successfully accomplished with endoscopic treatment in 83% of type A strictures and in 50% of type B strictures (p = 0.029). Additionally, the need for alternative treatments such as percutaneous interventions or surgery was significantly higher in those with type B strictures (50%) compared to pattern A strictures (12.5%) (p = 0.011). The cumulative probability of stricture resolution was significantly higher in type A compared to type B (p = 0.045). Adverse events (all mild) occurred in 6/45 patients (13.3%): 3 cholangitis, 2 pancreatitis, 1 controlled bleeding.
Conclusion: A visual classification scale of BAS in LT recipients with POCS demonstrates that type A BAS is associated with a higher resolution compared to type B BAS. The proposed classification Barcelona Anastomotic Stricture Scale (BASS) allows to predict outcomes of therapy in LT recipients with BAS. Further validation studies are needed.

SAT-031-YI

Evolution of pre liver transplant cardiovascular risk factors and cardiac work-up: impact on post-transplant events

Margherita Saracco[1], Chiara Manuli[1], Roberta Lasco[1], Mimma Bonomo[1], Bruna Lavezzo[2], Gian Paolo Caviglia[3], Donatella Cocchis[4], Mauro Giorgi[5], Antonio Ottobrelli[1], Renato Romagnoli[4], Silvia Martini[1]. *[1]Gastrohepatology Unit, AOU Città della Salute e della Scienza di Torino, Turin, Italy; [2]Anesthesia and Intensive Care Unit 2, AOU Città della Salute e della Scienza di Torino, Turin, Italy; [3]Department of Medical Sciences, University of Turin, Turin, Italy; [4]General Surgery 2U, Liver Transplantation Center, AOU Città della Salute e della Scienza di Torino, Turin, Italy; [5]Cardiology Unit, AOU Città della Salute e della Scienza di Torino, Turin, Italy*
Email: margherita.saracco@gmail.com

Background and aims: Liver transplant (LT) demographics are changing. Pre-LT cardiac evaluation is crucial to prevent post-LT events, but there are significant differences between Centers in cardiac protocols. We aimed to evaluate the evolution of cardiovascular risk factors (CVRF) and of screening protocol and their impact on major CV post-LT events (MACE).

Method: We retrospectively included all adult patients (pts) who underwent first LT between 01/2015 and 12/2022 (I-era 2015–2018; II-era 2019–2022) in our Center. Pts with 3 minor CVRF [age 60–64 years (y), arterial hypertension, non-insulin diabetes, BMI ≥30 Kg/m^2, family history of coronary artery disease (CAD), active smoking] underwent stress test. Pts with 1 major CVRF [age ≥65 y, insulin-treated diabetes, stroke, MASLD, peripheral arterial disease (PAD)] underwent stress test until 2021 and coronary computed tomography (c-CT) since 2022. Coronary angiography (CATH) was performed in pts with CAD history, positive stress tests or cardiology indication. We collected MACE defined as ischemia, de novo arrhythmia and heart failure within 2 y from LT.
Results: 906 cirrhotic pts were included (I-era: 429, II-era: 477). Overall: median age 58 y (20% ≥65 y, 25% 60–64 y), 27% AH, 24% diabetics, 2% previous stroke, 11% BMI ≥30 kg/m^2, 15% with CAD family history. 419/906 (46.2%) underwent echostress, 42/906 (4.6%) myocardial scintigraphy, 39/906 (4.3%) c-CT. 52/906 (5.7%) finally underwent CATH (63% for positive non-invasive test, 37% for CAD history or cardiology indication): 15/52 (28.8%) needed pre-LT revascularization. II-era vs I-era: pts were older (59 vs 58 y, p < 0.01), with higher rate of diabetes (27 vs 21%, p = 0.04), hypertension (30 vs 24%, p = 0.04), alcohol cirrhosis (26 vs 20%, p 0.03) and MASLD (9.4 vs 5.6%, p = 0.03); 297/477 (62%) vs 203/429 (47%) underwent a non-invasive cardiac test (p < 0.01). Pts who underwent CATH in II-era vs I-era were more often revascularized (44 vs 0%, p < 0.01). Within 2 y post-LT: 57 MACE were reported [30 (6.3%) in II-era; 27 (6.3%) in I-era]: 63% arrhythmia, 23% ischemia, 14% heart failure. At univariate analysis, MACE were associated with previous CAD (p = 0.013), PAD (p = <0.001), age ≥65 y (p = 0.026), male sex (p = 0.003). At multivariate cox-regression analysis, PAD (OR = 5.005, p < 0.001); previous CAD (OR = 3.645, p = 0.03) and male sex (OR = 3.397, p = 0.008) remained significantly associated with MACE. 1- and 2-y patient survival was: era-I: 95% and 92%; era-II 96% and 94%, respectively (p = 0.08).
Conclusion: In our cohort of 906 LT candidates enrolled between 2015–2022 (I-era 429, II-era: 477 pts), pre-LT CVRF burden increased over time, such us use of non-invasive cardiac test and of pre-LT coronary revascularization. Nevertheless, post-LT MACE incidence and 2-y survival did not differ between the 2 eras. At multivariate analysis, pre-LT PAD, previous CAD and male sex were significantly associated with post-LT MACE.

SAT-032

Risk stratification of emergent living donor liver transplantation from a nationwide survey of the Republic of Korea

Jongman Kim[1], Sang Jin Kim[2], Dong-Hwan Jung[3]. *[1]Samsung Medical Center, Seoul, Korea, Rep. of South; [2]Korea University College of Medicine, Ansan Hospital, Ansan, Korea, Rep. of South; [3]Asan Medical Center, Seoul, Korea, Rep. of South*
Email: yjongman21@gmail.com

Background and aims: Emergent living donor liver transplantation (LDLT) is vital for acute liver failure or acute-on-chronic liver failure patients facing life-threatening scenarios. Our study aimed to assess risk factors influencing the emergency of patients awaiting LDLT and outcomes of emergent LDLT using Korean nationwide data.
Method: We included patients who applied for emergency LDLT between 2017 and 2021. Subgroups included: 1) LDLT recipients (e-LDLT), 2) deceased donor liver transplant recipients (DDLT; received while waiting), 3) patients who died before receiving LT (death on waiting, DOW), and 4) patients of who recovered without LT or delayed LT >14 d after application (emergent LDLT unnecessary group, UNN). We compared e-LDLT characteristics and survival between e-LDLT and non-emergency LDLT controls. DOW and UNN groups were compared to establish risk factors and a scoring system. Baseline characteristics, including changes in model for end-stage liver disease (ΔMELD) scores, were analyzed.
Results: Among a total of 594 applicants for emergent LDLT, the number of e-LDLT, DDLT, DOW, and UNN groups was 419, 71, 43, and 37, respectively. Adult e-LDLT 3-year survival rates were 78·3% (overall) and 90·1% (graft); 3-year survival rates of adult non-emergent LDLT patients were 89·1% (overall) and 93·7% (graft). Chronic kidney disease, ventilator use, ΔMELD scores, and re-transplantation were associated with worsened adult e-LDLT survival. Leading reasons for emergency LDLT were hepatic encephalopathy, high MELD (>35), and uncontrolled bleeding. When comparing the adult DOW and adult UNN groups, hepatitis B virus (HBV), albumin, care in intensive care unit, ventilator use, and MELD score influenced patient mortality in univariable analysis.
Conclusion: Emergent LDLT showed reasonable survival with CKD, ventilator use, re-LT, and ΔMELD score as risk factors. High baseline MELD score, ΔMELD score, ventilator use, low albumin levels, and HBV relate to pre-LT mortality, reflecting the emergency of LT.

SAT-033

Three- vs. six-monthly measurement of phosphatidylethanol (PEth) in the detection of alcohol use relapse after liver transplantation (RAULT) for alcohol-associated liver disease (ALD)

Lubomir Skladany[1], Svetlana Adamcova Selcanova[1], Natalia Kubanek[1], Daniela Žilinčanová[1], Daniel Jan Havaj[1], Karolina Sulejova[1], Michal Patarak[1], Lubos Chvala[1], Juan Pablo Arab[2], Tomáš Koller[3]. *[1]Roosevelt University Hospital, Banska Bystrica, Slovakia; [2]Department of Medicine, Division of Gastroenterology and Hepatology, University Hospital-London Health Sciences Centre, London, Canada, Ontario, Canada; [3]Comenius University Faculty of Medicine, Bratislava, Slovakia*
Email: lubomir.skladany@gmail.com

Background and aims: Alcohol-associated liver disease (ALD) is the leading cause of liver transplantation (LT). The prevalence of RAULT ranges from 7 to 95% and is usually diagnosed by the patient´s history-based cliniciańs impression in combination with indirect laboratory markers of alcohol intake. The direct marker-phosphatidylethanol (PEth) has gained popularity for its precision and its ability to retrospectively capture alcohol intake over a period of 3–4 weeks. PEth results have been shown to be able to capture an additional 30% of patients with/wo RAULT misdiagnosed by a standard combination of history and indirect markers. In this study, we aimed to investigate the difference between three- and six-monthly PEth measurements in diagnosing RAULT.
Method: A prospective study of ALD patients after LT between May 2008 and June 2023. To diagnose RAULT, we introduced PEth in July 2020 and patients were enrolled in this study until June 2023. We excluded patients with <1 month post-LT follow-up. Data included demographics, direct and indirect history of alcohol use, clinical and laboratory parameters of liver disease, indirect biomarkers of alcohol intake, and quarterly PEth. Moderate and severe RAULT were diagnosed with PEth >0.05 and >0.3 µg/l, respectively.
Results: Of 380 LTs (360 patients), 143 were analyzed, 101 (70.6%) males, aged 56 y, with median follow-up of 63.4 months (IQR 23.75–114.3). PEth measured at 3- vs. 6-monthly intervals identified any RAULT in 46 (32.2%) vs. 43 (30.1%) of patients (p = 0.075) and heavy relapse in 23 (16.1%) vs. 18 (12.6%) of patients (p = 0, 018). Time was an independent risk factor for any as well as severe RAULT (OR = 1.17, P = 0.0002; OR = 1.14, P = 0.0093).
Conclusion: To diagnose RAULT, semi-annual and quarterly PETth measurements were comparable. Whether it is cost-effective to keep quarterly intervals in order not to delay diagnosis of severe RAULT, remains to be elucidated.

SAT-034

Acute-on-chronic liver failure in severe acute alcoholic hepatitis: impact on management, prognostication, and urgency of liver transplantation

Giovanni Perricone[1], Chiara Mazzarelli[2], Raffaella Viganò[3], Paola Prandoni[4], Marcello Vangeli[5], Francesca Aprile[6], Monica Cucco[7], Chiara Becchetti[6], Rosa Stigliano[7], Lucia Cesarini[6], MIki Scaravaglio[8], Gianpaola Monti[9], Andrea Lauterio[10], Aldo Airoldi[11], Luca Saverio Belli[12]. *[1]ASST Grande Ospedale Metropolitano Niguarda, Milan, Italy; [2]ASST GOM Niguarda, Hepatology and Gastroenterology Unit, Milan, Italy; [3]ASST GOM Niguarda, Hepatology and Gastroenterology Unit, Milano, Italy; [4]ASST GOM NIguarda, Department of Mental Health and Addiction Services, Milan; [5]ASST GOM Niguarda, Hepatology and Gastroenterology Unit, Milan; [6]ASST GOM Niguarda, Hepatology and Gastroenterology Unit, Milan, Italy; [7]ASST GOM Niguarda, Hepatology and Gastroenterology Unit, Milan; [8]University of Milano-Bicocca, Division of Gastroenterology and Center for Autoimmune Liver Diseases, Monza; [9]ASST GOM Niguarda, Department of Anesthesiology, Milan, Italy; [10]ASST GOM Niguarda, Department of General Surgery and Transplantation, University of Milano-Bicocca, School of Medicine and Surgery, Milan, Italy; [11]SST GOM Niguarda, Hepatology and Gastroenterology Unit, Milan; [12]SST GOM Niguarda, Hepatology and Gastroenterology Unit, Milan, Italy*
Email: giovanni.perricone@ospedaleniguarda.it

Background and aims: A better identification of factors predicting the course, outcome, and need for urgent liver transplantation in patients with severe acute alcoholic hepatitis (SAAH) is needed. Acute-on-chronic liver failure (ACLF) can occur in SAAH, and its impact on management, prognostication, and need for urgent liver transplantation in SAAH should be clarified. Aim of the study is to describe the impact of ACLF on management, prognostication, and need for urgent liver transplantation in SAAH.
Method: Patients with SAAH referred to our center between April 2016 and May 2023 were considered, with those non-responders to medical treatment (MT) being evaluated for LT.
Results: One hundred patients were included, with a median Maddrey Discriminant Function of 72 and a median MELD-Na score of 28. At presentation, 52 patients had ACLF grade 0–1, and 48 ACLF grade 2–3 (31 grade 2, 17 grade 3) (see Figure 1). In the latter group, circulatory failure was present in 3 (6.25%), and respiratory failure in 4 (8.3%). SAAH was the only precipitant factor in 50 (96%) and 36 (75%) patients with ACLF grade 0–1 and ACLF grade 2–3, respectively, with infection being an associated factor in 1 (2%) and 8 (17%), and GI bleeding in 1 (2%) and 5 (10%), respectively. Non-response to MT was significantly higher in patients with ACLF grade 2–3 (39/48, 81%) than in those with ACLF grade 0–1 (14/52, 27%). ACLF grade 2–3 was associated with a corresponding higher need of early LT (ACLF grade 2–3: 14/48, 29% vs ACLF grade 0–1: 3/52, 5.7%; p = 0.004). ACLF status at presentation (ACLF grade 2–3 vs ACLF grade 0–1) resulted a better predictor of outcome (death or LT) than MELD-Na (≥ or).
Conclusion: ACLF is a frequent presentation of SAAH. Severe ACLF predicts non-response to MT, indicating the urgency of liver transplantation.

SAT-035

The yield of routine post-operative doppler ultrasound to detect early post-liver transplantation vascular complications

Iulia Minciuna[1], Caroline den Hoed[2], Adriaan J. van der Meer[2], Milan J. Sonneveld[2], Dave Sprengers[2], Robert J. de Knegt[2], Jeroen de Jonge[3], Raoel Maan[4], Wojciech Polak[5], Sarwa Darwish Murad[2]. *[1]University of Medicine and Pharmacy Iuliu Hatieganu, Cluj-Napoca, Romania, Erasmus MC Transplant Institute, Department of Gastroenterology and Hepatology, Erasmus MC University Medical Center Rotterdam, Rotterdam, The Netherlands, Rotterdam, Netherlands; [2]Erasmus MC Transplant Institute, Department of Gastroenterology and Hepatology, Erasmus MC University Medical Center Rotterdam, Rotterdam, The Netherlands, Rotterdam, Netherlands; [3]Erasmus MC Transplant Institute University Medical Center Rotterdam, Department of Surgery, Division of HPB and Transplant Surgery, Rotterdam, The Netherlands, Rotterdam, Netherlands; [4]Erasmus MC Transplant Institute, Department of Gastroenterology and Hepatology, Erasmus MC University Medical Center Rotterdam, Rotterdam, The Netherlands, Rotterdam, Netherlands; [5]Erasmus MC Transplant Institute University Medical Center Rotterdam, Department of Surgery, Division of HPB and Transplant Surgery, Rotterdam, The Netherlands, Rotterdam, Netherlands*
Email: Iuliabreaban@yahoo.com

Background and aims: Early detection and timely management of post liver transplantation (LT) vascular complications are of paramount importance as these early complications can lead to fulminant graft failure. Our aim was to assess if routine Doppler ultrasound (rDUS) improves the detection of hepatic artery thrombosis (HAT), portal vein thrombosis (PVT) and hepatic venous outflow obstruction (HVOO).
Method: This is a retrospective single-centre study of 708 adult patients who underwent primary LT between 2010–2022 and underwent rDUS on post-operative day (POD) 0, 1 and 7, followed by Computed Tomography (CT) if abnormal. Timing and outcomes of HAT, PVT and HVOO, number needed to diagnose one complication (NND) and positive predictive value (PPV) of rDUS was calculated.
Results: HAT developed in N = 50 (7.1%; 68% in first week), PVT in N = 58 (8.2%) and HVOO in N = 22 (3.1%). Most early complications were diagnosed on POD 0 (26.9%), 1 (17.3%) and 5 (17.3%). Of the 26 vascular events on protocol days (0, 1, 7), 21 (80.7%) were detected by rDUS. PPV of rDUS was 53.8% (21/39), detection rate 1.1% (21/1900 ultrasounds) and NND was 90.5. Median time to diagnosis was 4 days for HAT, 21 days for HVOO and 47 days for PVT. The vascular events detected by rDUS led to surgical re-intervention in 14 patients (66.7%), while 7 (33.3%) were treated by anticoagulant therapy alone. This approach preserved the graft in 57.1% patients while 28.6% proceeded to urgent re-LT and 14.3% underwent late re-LT.
Conclusion: The majority of post-LT vascular complications occur during first week. rDUS detects the majority of events, but with low PPV and a high number of ultrasounds needed. Implementing a rDUS protocol, preferably at POD 0, 1 and 5, leads to timely diagnosis and management. However, a true clinical benefit in terms of graft and patient's survival has yet to be shown.

SAT-036-YI

Impact of distance from liver transplant centre on outcomes following liver transplantation-an australian single centre study

Simone Chin[1,2], Charlotte Kench[1,2], Rena Cao[1], Christina Lee[1], Susan Virtue[1], Claire West[1], Talal Valliani[1], David Bowen[1], Simone Strasser[1], Geoff McCaughan[1], Ken Liu[1]. *[1]Royal Prince Alfred Hospital, Sydney, Australia; [2]The University of Sydney, Sydney, Australia*
Email: schin5234@gmail.com

Background and aims: Access to liver transplantation (LT) is affected by geographic disparities. Higher waitlist mortality is observed in patients residing further away from LT centres but impact of distance on post-LT outcomes is unclear. We aimed to evaluate whether the distance LT recipients reside from their LT centre impacts on graft and patient outcomes.
Method: We retrospectively studied consecutive adults who underwent deceased-donor LT from 2006 to 2021 at Royal Prince Alfred Hospital (RPAH), the only LT centre in the state of New South Wales (NSW), Australia. The state covers an area of 801, 150km^2. Those residing outside of NSW at time of transplant were excluded. Donor and recipient data were collected from a prospective LT database. Patients' regional area code (0 = least remote, 4 = most remote) and socioeconomic code (1 = relatively greater disadvantage, 5 = relative lack of disadvantage) were obtained from the Australian Bureau of Statistics. Patients were grouped based on their distance from LT centre at time of transplant (≤100 km vs. >100 km). For survival

analyses, patients were censored if they moved to a new residential address during follow-up.
Results: During the study period, 973 patients underwent LT (69.7% male, median age 55.6 years (IQR 49.0–60.6)). The median distance from patient residence to LT centre was 44.9 km (IQR 21.9–168.0). 64.2% of patients lived ≤100 km from RPAH. 77.6% of patients were from regional area code 0. The distribution of LT recipients across the five socioeconomic codes was similar (17.9–20.2%). Compared to patients living ≤100 km from RPAH, those living >100 km away were less likely to: be male (64.0% vs. 72.7%, p = 0.004); have chronic hepatitis B (3.5% vs. 12.6%, p = 0.001) or viral hepatitis (35.7% vs. 42.2%, p = 0.049) as their cause of liver disease; or have hepatocellular carcinoma as their primary indication for LT (23.3% vs. 32.1%, p = 0.004). Patients living >100 km away had higher body mass indices (27.1 vs. 26.0 kg/m^2, p = 0.01) compared to those living closer.
At a median follow-up of 47.1 months (IQR 13.5–93.7), there were 190 deaths and 42 retransplants. Living >100 km from the LT centre was associated with fewer face-to-face clinic visits in the first year after LT (10 vs. 11 visits, p < 0.001) and fewer overall readmissions to the LT centre (32.4% vs 67.6%, p < 0.001). Distance from LT centre, regional code, and socioeconomic code did not impact on long-term graft or patient survival based on Kaplan-Meier survival analysis (Log-Rank p all >0.1). There was a trend towards increased likelihood of biopsy-proven rejection in patients living >100 km away (p = 0.069).
Conclusion: In this single centre Australian study, patients living further away from their LT centre had different demographics and fewer face-to-face visits during follow-up. Despite this, distance from the LT centre was not associated with long-term inferior graft or patient survival post-LT.

SAT-037

Impact of recipient sex on long-term survival after liver transplantation in patients with high MELD

Laia Aceituno[1,2], Christian Magyar[1,3,4], Zhihao Li[1,3], Marco Claasen[3,5], Tommy Ivanics[3,6,7], Erin Winter[1], Roxana Bucur[3], Nadia Rukavina[3], Woo Jin Choi[1,3], Nazia Selzner[1], Mamatha Bhat[1], Leslie Lilly[1], Cynthia Tsien[1], Keyur Patel[1], Markus Selzner[1,3], Ian Mcgilvray[1,3], Trevor Reichman[1,3], Chaya Shwaartz[1,3], Anand Ghanekar[1,3], Mark S. Cattral[1,3], Blayne Sayed[1,3], Elmar Jaeckel[1], Gonzalo Sapisochin[1,3]. *[1]Multi-Organ Transplant Program, Ajmera Transplant Centre, University Health Network, Toronto, Canada; [2]Liver Unit, Digestive Diseases Division, Vall d'Hebron University Hospital, Barcelona, Spain; [3]University Health Network, HPB Surgical Oncology, Toronto, Canada; [4]Department of Visceral Surgery and Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland; [5]Department of Surgery, Division of HPB and Transplant Surgery, Erasmus MC Transplant Institute, University Medical Center Rotterdam, Rotterdam, Netherlands; [6]Department of Surgery, Henry Ford Hospital, Detroit, United States; [7]Department of Surgical Sciences, Akademiska Sjukhuset, Uppsala University, Uppsala, Sweden*
Email: laiaaceituno@gmail.com

Background and aims: The MELD score is used to prioritize liver transplant (LT) candidates for deceased donor organs, with a "sickest first" approach. However, it has been shown that MELD score does not accurately reflect disease severity in females. It remains controversial whether recipient sex affects long-term post-transplantation survival. This study aimed to assess the impact of sex in a high MELD cohort on (1) long-term survival post-LT, (2) and its association with underlying diseases, cause of transplant, and comorbidities.
Method: Retrospective cohort study at Toronto General Hospital, including adult LT recipients with a MELD ≥25 at transplant between January 2007 and December 2019. Patients were stratified by sex. Survival analysis was performed using a priori multivariable Cox regression and Kaplan-Meier analysis. A post hoc sex-stratified multivariable Cox regression model was performed.
Results: 478 patients with MELD ≥25 were included; 196 (40%) were females, with a median BMI of 27.4 kg/m^2 (IQR 23.7–31.2). The median follow-up post-LT was 5.7 years (IQR 2.2, 9.2) with a median waitlist of 23.5 days (IRQ 0.0, 75.5). The median listing and pre-transplant MELD scores were 28 (IQR 21–34), and 31 (IQR 26–35) respectively. Male recipients had pre-transplant higher rates of ascites (39.8% vs. 53.5%; p = 0.003) and hepatic encephalopathy (34.2% vs. 44.3%; p = 0.026). Autoimmune hepatitis as underlying disease was more prevalent among females (26.5% vs. 12.4%; p < 0.005). Conversely, viral hepatitis (8.7% vs. 24.8%; p < 0.001), alcohol-related cirrhosis (ALD) (13.3% vs. 28.7%; p < 0.001), and mixed ALD + viral cirrhosis (1.0% vs. 5.0%; p = 0.018) were more frequent in males. Females were more frequently transplanted for acute liver failure (16.8% vs. 4.6%; p < 0.001) and fewer for cancer (4.6% vs. 11.3%; p = 0.009). No statistically significant differences were observed between sex crude overall long-term survival (log-rank p = 0.681), or estimated effect (HR 0.92; p = 0.686). In the a priori multivariable analysis, sex was not significant (HR 0.94, CI 95% 0.61–1.43; p = 0.779).There were no sex differences in early post-transplant mortality (<90 days) (6.6% females vs. 9.2% males; p = 0.309; HR 0.71, p = 0.329), mortality in the 1st year (10.7% females vs. 14.5% males; p = 0.221), 5th (16.8% females vs. 18.8% males; p = 0.584) and 10th year (20.4% females vs. 22.0% males; p = 0.679). There was no difference in risk of postoperative complications. On post hoc multivariable analysis stratified by sex, re-transplantation (HR 2.80; CI 95% 1.53–5.14; p = 0.001) and ICU stay (HR 1.009; CI 95% 1.005–1.01; p < 0.001) were significant risk factors for female mortality.
Conclusion: Our findings show no sex differences in the overall survival in high MELD liver transplant recipients. Female patients with longer ICU admission, or requiring re-transplantation, were at higher risk of all-cause mortality.

SAT-039

Comparing outcomes in patients with portal vein thrombosis undergoing deceased-donor versus living-donor liver transplantation: insights from a major North American center

Zhihao Li[1], Luckshi Rajendran[1], Owen Jones[1], Laia Aceituno[1], Christian Magyar[1], Leah Aspden[1], Elmar Jaeckel[1], Mamatha Bhat[1], Cynthia Tsien[1], Leslie Lilly[1], Nazia Selzner[1], Anand Ghanekar[1], Blayne Sayed[1], Markus Selzner[1], Ian Mcgilvray[1], Chaya Shwaartz[1], Trevor Reichman[1], Mark S. Cattral[1], Gonzalo Sapisochin[1]. *[1]University Health Network, Toronto, Canada*
Email: zhihao.li@uhn.ca

Background and Aims: Portal vein thrombosis (PVT) complicates liver transplantation (LT) due to the need for portal flow restoration. While management strategies have been established, PVT remains a contraindication for living-donor liver transplantation (LDLT) at some centers. This is due to the greater technical complexities in LDLT compared to deceased-donor LT (DDLT).
Method: We retrospectively included adults who underwent LT with main PVT between 2006–2022 and excluded cases with tumor thrombi or re-LT. We employed a 1:1 nearest neighbor propensity score matching to achieve equilibrium in variables age, MELD score, Yerdel classification, cavernous transformation and reconstruction method. Our primary end point was 90-day complication rate; secondary end points were patient and graft survival, assessed via Kaplan-Meier analysis and apriori multivariable cox regression.
Results: Of 122 included patients, 96 were matched (48 in both LDLT and DDLT groups). The median age was 57 (IQR 50–63) years, predominantly male (62%) with a median MELD of 18 (IQR 12–25). Common underlying liver diseases were hepatitis C (26%) and alcohol-related liver disease (20%). 85% had Yerdel grade I/II PVT (DDLT 88%, LDLT 83%, p = 0.77) and 15% had grade III/IV (DDLT 13%, LDLT 17%, p = 0.77). Cavernous transformation was present in 17% of cases (DDLT 17%, LDLT 17%, p = 0.99). Most patients (90%) underwent anatomical portal vein reconstruction (thrombectomy and anastomosis without interposition graft), while 10% received non-anatomical reconstruction using deceased donor iliac vein graft (jump graft to pericholedochal vein n = 2, left gastric vein n = 1, superior mesenteric vein n = 7). There were no significant differences

between the DDLT and LDLT group in terms of warm ischemia time (median: 57 vs. 58 min, p = 0.3), 90-day major complication rate (Clavien-Dindo grade ≥III) (37.5 vs. 39.6%, p = 0.99) and minor complication rate (47.9 vs. 52.1%, p = 0.84), portal vein re-thrombosis (12.5 vs. 10.6%, p = 0.99), posttransplant dialysis requirement (4 vs. 8%, p = 0.65) and ascites development (25 vs. 30%, p = 0.77). Over a median follow-up of 2.9 (IQR 1.4–6.8) years, the patient survival rates at 1/3/5 years were similar between the DDLT (90/81/76%) and LDLT group (89/79/79%, log-rank p = 0.8). Likewise, graft survival rates at these intervals were comparable between DDLT (88/79/74%) and LDLT (85/75/75%, p = 0.9). Cox regression analysis revealed that neither graft type, Yerdel classification, nor reconstruction method significantly influenced graft survival. However, posttransplant anticoagulation was identified as a protective factor (hazard ratio 0.3, p = 0.02).

Conclusion: Despite the inherent technical complexities associated with LDLT in the context of PVT, the short-term and long-term outcomes at our center were comparable to those observed in DDLT. Hence, PVT should not be considered a contraindication for LDLT.

SAT-040

Is there a need to screen for ischemic heart disease in liver transplant candidates without coronary calcification on routine chest CT?

Roos Groen[1], Susan Fischer[2], Fei-lynn Barbero[3], Maarten Tushuizen[4], Jeroen Bax[5], J. Wouter Jukema[5,6], Michiel de Graaf[5], Minneke Coenraad[4]. *[1]Department of Cardiology, Leiden University Medical Center, Leiden, Netherlands; [2]Department of Gastroenterology and Hepatology, Leiden University Medical Center, Leiden, Netherlands; [3]Leiden University Medical Center, Leiden, Netherlands; [4]Department of Gastroenterology and Hepatology, Leiden University Medical Center, Leiden, Netherlands; [5]Department of Cardiology, Leiden University Medical Center, Leiden, Netherlands; [6]Netherlands Heart Institute, Utrecht, Netherlands*
Email: r.a.groen@lumc.nl

Background and aims: Coronary artery disease (CAD) plays an important role in peri-or postoperative mortality in liver transplantation (LT) candidates and recipients. Efficient cardiac pre-operative screening is therefore of utmost importance. Still, the optimal approach for patient-specific cardiac screening is currently debated on. Non-gated computed tomography (CT) of the chest-abdomen are routinely performed, as part of follow-up of patients' liver disease. Patients' coronary artery calcium (CAC) can be readily assessed on these scans, as indicator of patients CAD-burden. This study evaluated the ability of CAC assessment on these earlier acquired scans, to identify a selection of low risk patient, in whom further cardiac imaging is safely withheld.

Method: LT recipients who underwent liver transplantation between 2008–2023 with an available non-gated chest-abdomen CT, were analyzed retrospectively. CAC was scored visually on a semi-quantitative ordinal scale using an established method. This allowed for readily and rapid assessment of atherosclerosis burden. Subsequently, patients were stratified according to CAC severity. Coronary CT angiography (CCTA), stress myocardial perfusion or invasive coronary angiography (ICA) were used as golden standard. The sensitivity and specificity of CAC to exclude or predict obstructive CAD were analyzed. In addition, peri- and postoperative mortality and cardiac events up to 30 days after LT were analyzed.

Results: A total of 149 LT patients of 31–70 years old were included. Most patients (75%) had no or mild CAC. Both no calcifications or mild calcifications could rule out obstructive CAD on CCTA and ICA with 100% certainty. The threshold of mild CAC had a sensitivity of 100% for both CCTA and ICA. The specificity for mild CAC was respectively 91% and 68%. None of the patients with no or mild calcifications experienced peri- or postoperative cardiac events or died of cardiac disease. In terms of dedicated imaging allocation, in patients with severe CAC performance of stress myocardial perfusion or ICA was most optimal. In patients with no or mild CAC, dedicated cardiac imaging could safely have been withheld.

Conclusion: Visual CAC assessment on available non-gated CT can accurately and safely exclude obstructive CAD in LT recipients. Incorporation of these available data can enhance cardiac risk stratification and dedicated cardiac imaging can efficiently be withheld or allocated in LT recipients. Hereby reducing the test burden for the patient and save health care expenses.

SAT-041

Real-world evidence of magnesium isoglycyrrhizinate for perioperative protection against hepatic injury in patients undergoing hepatectomy

Changzhen Shang[1], Chuanjiang Li[2], Jinyi Zhong[1], Xuan Luo[1], Jinxing Wei[1], Yajin Chen[1]. *[1]Department of Hepatobiliary Surgery, Sun Yat-sen Memorial Hospital of Sun Yat-sen University, Guangzhou, 510120, China, Guangzhou, China; [2]Division of Hepatobiliopancreatic Surgery, Department of General Surgery, Nanfang Hospital, Southern Medical University, Guangzhou, 510515, China, Guangzhou, China*
Email: shchzh2@mail.sysu.edu.cn

Background and aims: Real-world data remain limited on magnesium isoglycyrrhizinate (MgIG) for hepatic injury in patients undergoing hepatectomy. This retrospective, real-world study aims to evaluate the prophylactic and therapeutic effectiveness of MgIG against hepatic injury in patients undergoing hepatectomy.

Method: Clinical data of these patients who underwent hepatectomy between March 2020 and March 2023 were retrospectively collected in two institutes. After propensity score matching (PSM), cohorts were balanced for age, sex, baseline alanine aminotransferase (ALT) levels and extent of resection. The primary outcome was the incidence of moderate and severe liver injury. Key secondary outcomes included changes from baseline in ALT or aspartate aminotransferase (AST), normalization rate and the proportion of patients with a 50% reduction of ALT or AST. No or mild liver injury was defined as ALT or AST <3× upper limit of normal (ULN) and moderate or severe liver injury as ALT or AST ≥3× ULN.

Results: A total of 1711 patients were enrolled in this study. On postoperative day (POD) 1, the incidence of moderate and severe liver injuries was 74.54% among 876 patients who received MgIG prophylaxis versus 79.28% for 835 patients who did not, especially among elderly patients (≥65 years) (71.71% vs. 87.75%; p < 0.001). After PSM, patients receiving prophylaxis (n = 680) had significantly less increase from baseline in ALT (171.50, IQR 71.75–328.25 vs. 185.5, IQR 93.75–362.75; p < 0.001) and AST (178.50, IQR 83.00–347.75 vs. 240, IQR 116.50–370.50; p < 0.001) than those not receiving prophylaxis (n = 680). Among patients with postoperative abnormal liver function who were treated with MgIG plus other liver protectants, those who received prophylaxis (n = 330) had a significantly greater reduction in the incidence of moderate and severe liver injuries per ALT (52.12% vs. 65.45%; p = 0.026) and AST (16.06% vs. 31.82%; p < 0.001) on POD 3 than those not receiving prophylaxis (n = 110). In addition, more patients received prophylaxis had an apparently greater reduction in ALT on POD 7 (14.24% vs. 22.73%; p = 0.046). Among patients who received no prophylaxis and had abnormal postoperative liver function, a significantly greater proportion of patients treated with MgIG plus other liver protectants (n = 110) experienced a ≥50% reduction on POD 7 from baseline in ALT (71.82% vs. 56.67%, p = 0.011) and AST (79.09% vs. 75.15%, p = 0.029) than those only treated with other liver protectants (n = 330). In addition, more patients treated with MgIG had a normal recovery in ALT (21.82% vs. 11.82%, p = 0.015) and AST (63.64% vs. 52.42%, p = 0.022).

Conclusion: This study provides real-world evidence that preoperative prophylaxis and postoperative treatment with MgIG is effective in protecting against postoperative liver injury and promoting postoperative liver function recovery.

SAT-042

A HDL-based prognostic model performs better than MELD in chronic liver failure

Rudolf E. Stauber[1], Florian Rainer[1], Vanessa Stadlbauer[1], Alexander Avian[2], Hubert Scharnagl[3], Gunther Marsche[4]. [1]*Medical University of Graz, Department of Internal Medicine, Graz, Austria;* [2]*Medical University of Graz, Institute of Medical Informatics, Statistics and Documentation, Graz, Austria;* [3]*Medical University of Graz, Clinical Institute of Medical and Chemical Laboratory Diagnostics, Graz, Austria;* [4]*Medical University of Graz, Institute of Pharmacology, Graz, Austria*
Email: rudolf.stauber@medunigraz.at

Background and aims: Chronic liver failure is associated with multiple lipidomic alterations including markedly reduced high-density lipoprotein cholesterol (HDL-C) levels. We have previously shown excellent prognostic value of HDL-C comparable to that of MELD (J Hepatol 2020;73:113–120). In the present study we aimed to develop a new prognostic model containing HDL-C and other known prognostic variables in the same cohort of patients with chronic liver failure.
Method: We studied a multinational cohort of patients with chronic liver failure of varying severity, including compensated cirrhosis (CC), AD and ACLF. Prognostic variables including bilirubin, creatinine, INR, HDL-C, WBC, CRP, and albumin were routinely determined in the Clinical Chemistry Laboratory. After checking intercorrelation of variables by variance inflation factors (VIF), multivariable competing risk analysis was performed with death as the event and liver transplantation as a competing risk to identify independent predictors of survival. Cox proportional hazards regression was used to construct a new prognostic model and its performance was compared to that of MELD using ROC analysis (DeLong test) for 3-month and 1-year survival.
Results: We included 508 patients (median age 57 years; 69% male; CC 45%/AD 34%/ACLF 21%; etiology alcohol 56%). Seventy-seven patients (15%) received liver transplantation, 149 (30%) died and 256 (51%) were censored. Multivariable analysis yielded three independent prognostic variables, i.e. HDL-C, INR, and creatinine, hence the new prognostic model was named HIC model. On ROC analysis, the prognostic performance of the HIC model was superior to that of MELD in the prediction of 3-month survival (AUROC 0.88 vs. 0.85, p = 0.031 by DeLong test) as well as 1-year survival (AUROC 0.85 vs. 0.82, p = 0.039 by DeLong test).
Conclusion: A new prognostic model including HDL-C, INR, and creatinine showed superior accuracy for prediction of 3-month and 1-year survival as compared to MELD. External validation is warranted to confirm our findings.

SAT-043

Liver transplantation for locally advanced, unresectable intrahepatic cholangiocarcinoma following neoadjuvant treatment with chemotherapy and radioembolization

Baptiste Giguet[1], Thomas Uguen[1], Heithem Jeddou[1], Pauline Houssel-Debry[1], Caroline Jezequel[1], Fabien Robin[2], Alexandre Chebaro[3], Karim Boudjema[4], Etienne Garin[5], Luc Beuzit[3], Turlin Bruno[3], Julien Edeline[5], Edouard Bardou-Jacquet[6], Florent Artru[6]. [1]*university hospital center Pontchaillou, Rennes, France;* [2]*university hospital center Pontchaillou, INSERM U1242, Chemistry Oncogenesis Stress Signaling, Rennes 1 University, Rennes, France, Rennes, France;* [3]*university hospital center Pontchaillou, Rennes, France;* [4]*university hospital center Pontchaillou, INSERM U1242, Chemistry Oncogenesis Stress Signaling, Rennes 1 University, Rennes, France, Rennes, France;* [5]*centre de lutte contre le cancer Eugène Marquis, Rennes, France;* [6]*University Hospital Center Pontchaillou, INSERM CHU Rennes, Institut NUMECAN, CIC 1414, Rennes, France, Rennes, France*
Email: baptiste.giguet@chu-rennes.fr

Background and aims: cholangiocarcinoma (CCA) is the second most common primary liver tumor and with three distincts variants (intrahepatic cholangiocarcinomas (iCCA), peri-hilar, and distal). Liver transplantation (LT) is not a standard indication for iCCA. The largest series of LT for locally advanced unresectable iCCA included 18 patients with heterogeneous neoadjuvant treatment and reported a 5-year survival of 57%. A promising neoadjuvant approach is the combination of selective internal radiotherapy (SIRT) to chemotherapy (CT). The aim of our study was to investigate whether the outcomes of LT in patients with unresectable iCCA treated with SIRT and CT before LT achieve collective utility (≥70% 5-year overall survival after LT).
Method: a single-center retrospective study including all patients who underwent LT for locally advanced unresectable iCCA, treated with SIRT and CT before LT from 2011 until now. The primary and secondary outcomes were 5-year overall and recurrence-free survivals after LT.
Results: five patients were included with a median age of 56.1 years [41.3–61.8]. The cumulative tumor size at diagnosis was 100 mm [64.5–115], and at the time of listing for LT, it was 80 mm [51.5–80]. Advanced chronic liver disease was present in 60% of patients. All 5 patients received neoadjuvant CT (including 4 patients receiving gemcitabine-cisplatin) and SIRT. Lymph node sampling was performed before listing in 4 patients (80%) without evidence of extrahepatic disease. Timeframe between iCCA diagnosis and LT was 516 days [394–866], and LT occurred in a median of 130 days [37–252] after placement on waiting list. Notably, 80% of allocated grafts were from donor with extended criteria. Donor age was 63 years [52.5–89.5], and cold ischemia time was 502 minutes [492–505]. The median follow-up after LT was 77 months [21–103], with 5-year overall and recurrence-free survival rates of 100% and 58.3%, respectively. The post-LT hospitalization length of stay was 12 days [12–16.5]. Long-term immunosuppression inlcuded everolimus in 4 patients (80%). 80% of patients exhibited biliary complications of LT with 2 anastomotic strictures, 1 ischemic cholangitis, and 1 biliary fistula. One patient experienced an arterial thrombosis. Oligometastatic tumor recurrence occurred in 2 patients (40%) at 573 and 577 days, both in the pulmonary site. Curative surgery was successfully performed in these patients with no further recurrence.
Conclusion: in our experience, the 5-year outcome of patients undergoing LT for locally advanced, unresectable iCCA treated with a combination of SIRT and CT suggests potential individual therapeutic benefit while maintaining collective utility. However, a higher-than-expected rate of biliary complications was noted. The impact of the neoadjuvant strategy, including SIRT, on these favorable outcomes warrants further investigation in a larger cohort.

SAT-044

Aging with a liver graft: analysis of very long-term survivors after liver transplantation

Paolo DeSimone[1], Jessica Bronzoni[2], Caterina Martinelli[2], Juri Ducci[2], Daniela Campani[1], Piero Marchetti[1]. [1]*University of Pisa, Pisa, Italy;* [2]*Azienda Ospedaliero Universitaria Pisana, Pisa, Italy*
Email: paolo.desimone@unipi.it

Background and aims: Little is known about the health status of very long-term survivors of a liver graft. We aimed to identify predictors of survival and investigate the prevalence of co-morbidities among long-term survivors.
Method: We conducted a hybrid-design study on a historical cohort of 359 adult recipients of a liver graft who received transplants between 1996 and 2002.
Results: The actuarial (95% CI) patient survival of the overall study cohort was 96% (94.6%–98.3%), 69% (64.2%–73.6%), 55% (49.8%–59.9%), 42.8% (37.6%–47.8%), and 34% (29.2%–38.9%) at 1, 5, 10, 15, and 20 years, respectively. The actuarial (95% CI) graft survival was 93.8% (91.6%–97.2%), 67.6% (62.2%–71.5%), 54.3% (49.6%–59.3%), 42.1% (37.3%–47.4%), and 33.8% (29.0%–38.4%) at 1, 5, 10, 15, and 20 years, respectively. The leading cause of death was hepatitis C virus recurrence (24.6%), followed by extrahepatic malignancies (16.9%), infection (14.4%), and hepatocellular carcinoma recurrence (14.4%).

The Cox proportional hazards analysis revealed that several independent factors were associated with the survival probability. These factors include younger donor and recipient ages ($p = 0.001$ and 0.004, respectively), female recipient sex ($p < 0.001$), absence of HCV ($p < 0.01$), absence of HCC ($p = 0.001$), and absence of diabetes mellitus at one year ($p < 0.01$). At the latest follow-up, the leading comorbidities in the long-term survivors were hypertension (53.6%), obesity (18.7%), diabetes mellitus (17.1%), hyperlipidemia (14.7%), chronic kidney dysfunction (14.7%), and extrahepatic malignancies (13.8%), with 73.9% of patients having more than one complication. The Kaplan-Meier probability (95% CI) of complication-free survival was 65.4% (60.2%–70.3%), 38.4% (33.4%–43.7%), 17.8% (14.1%–22.2%), 7.2% (4.8%–10.5%), and 1.94% (0.85%–4.15%) at 1, 5, 10, 15, and 20 years, respectively.
Conclusion: Aging with a liver graft is associated with an increased risk of complications and requires ongoing care to reduce the long-term attrition rate resulting from chronic immunosuppression.

SAT-045
Outcome of simultaneous heart and liver transplants with HCC: analysis of US national database
Fadl A. Zeineddine[1], Efstathia Polychronopoulou[2], Prasun Jalal[3].
[1]Houston Methodist Hospital, Houston, United States; [2]University of Texas Medical Branch, Galveston, United States; [3]Baylor College of Medicine, Houston, United States
Email: fazeineddine@houstonmethodist.org

Background and aims: Patients with HCC in presence of congestive hepatopathy due to underlying cardiac disease usually undergo combined heart and liver transplant. We aimed to study outcomes of patients with HCC and simultaneous heart and liver transplantation.
Method: We retrospectively analysed United Network for Organ Sharing (UNOS/OPTN) database for patients with simultaneous heart and liver transplants and MELD exception for HCC between April 1, 2012 and June 31, 2023. Tumor characteristics in pre-transplant radiology and explant histology were compared. Patient survival and recurrence were analysed.
Results: A total of 8 patients with MELD exception for HCC underwent simultaneous heart and liver transplant. All had confirmed HCC on explant histopathology. Median age at transplant was 54.5 years (17–67 years). All patients were transplanted due to concomitant cirrhosis with HCC. Three had congenital heart disease, three had dilated cardiomyopathy, and two had pulmonary fibrosis. 62.5% (n = 5) were HCV positive. Radiologically, five had single lesion with a median diameter of 2 cm. Median AFP level was 46.5 ng/ml (range 3–2960 ng/ml). On explant, median number of lesions was 3 and median maximal tumor size was 2.55 cm (2.5–4.2 cm). Only one patient showed microvascular invasion who also had recurrence after 118 days and expired after 231 days. 87.5% (n = 7) received locoregional treatment for HCC. Two received chemoembolization, four received thermal ablation and one had radiation microspheres. HCC recurrence occurred in 25% of patients (n = 2) after 118 and 152 days. 50% of patients (n = 4) expired after a median follow-up of 245 days (range 74–540 days).
Conclusion: Current radiological parameters used to define HCC may underestimate the size and number of lesions in presence of congestive hepatopathy. Outcome of patients with HCC receiving simultaneous heart and liver transplant remains poor. Appropriate selection process and use of locoregional treatment may improve the outcome.

SAT-046
Detection of conventional adenomas and serrated lesions during repetitive colonoscopies after orthotopic liver transplantation
Sidar Baysal[1], Katharina Willuweit[1], Benedikt Hild[1], Hartmut Schmidt[1], Christoph Schramm[1]. *[1]University Hospital Essen, Department of Gastroenterology, Hepatology and Transplantational Medicine, Essen, Germany*
Email: christoph.schramm@uk-essen.de

Background and aims: Patients with immunosuppression after orthotopic liver transplantation (OLT) are at an increased risk for malignancies. If this applies also to colorectal cancer (CRC) is controversial, especially in the absence of primary sclerosing cholangitis (PSC) and associated inflammatory bowel disease (IBD). Standardized recommendations for CRC screening in this population are not available. We aim to investigate the effect of repetitive colonoscopies on the incidences of colorectal polyps.
Method: We performed a retrospective analysis of patients who underwent screening colonoscopies after OLT at a single liver transplant center in Germany. Exclusion criteria were no post-OLT-colonoscopy, PSC prior to OLT, IBD, hereditary cancer and polyposis syndromes, and CRC prior to OLT. Only the first five post-OLT-colonoscopies per patient were analyzed. Clinically relevant serrated polyps (crSP) were defined as serrated polyps (SP) >5 mm proximal to the splenic flexure, SP ≥10 mm, and SP with high grade dysplasia. Insufficient procedure quality was defined as incomplete procedure, i.e. not reaching the cecum, and/or inadequate bowel preparation.
Results: Of 129 patients screened, 59 patients were identified according to inclusion and exclusion criteria. Median age at OLT was 62 years (interquartile range (IQR) 56–65), 2/3 were male and 1/3 were female. Indications for OLT were alcohol-associated liver disease (87%), alpha1-antitrypsin deficiency (5%), autoimmune hepatitis (7%) and Alagille syndrome (2%). A total of 142 post-OLT colonoscopies were performed with a median of 2 colonoscopies per patient (range 1–8). Interval between OLT and first post-OLT colonoscopy, and between consecutive colonoscopies was 33.5 months (IQR 14–47), 33.5 months (IQR 15–42), 23 months (IQR 14–36), 23 months (IQR 8–40), and 30 months (IQR 19–39).
Detection rates for non-advanced conventional adenomas were 18.3%, 20.6%, 19%, 15.4%, and 0% in consecutive colonoscopies. Advanced conventional adenomas were detected in 1.7% and 5.9% of the first two colonoscopies, whereas none were detected hereinafter. Likewise, no crSP was detected on any of the post-OLT colonoscopies. One patient (1.7%) developed CRC, which was detected during the first post-OLT colonoscopy. Colonoscopy prior to OLT was documented in 71%. However, it was not associated with the detection of non-advanced and advanced conventional adenomas during the first post-OLT colonoscopy. Insufficient procedure quality was present in 32%, 27%, 19%, 15%, and 40% of the procedures.
Conclusion: Effectiveness of screening colonoscopies in patients after OLT in terms of detection rates seems to decrease with repetitively performed procedures. Additionally, detection of crSP and procedure quality are suboptimal.

SAT-047
Racial disparities in the receipt of liver transplantation among african american patients with hepatocellular carcinoma in the United States: a systematic review
Nabil El Hage Chehade[1], Isabelle Nguyen[1], Nour El Hage Chehade[2], Joy-Marie Hermes[1], Adam Deising[1], Paul Pockros[1], Julio Gutierrez[1].
[1]Scripps Clinic, La Jolla, United States; [2]Cleveland Clinic Foundation, Cleveland, United States
Email: elhagechehade.nabil@scrippshealth.org

Background and aims: Hepatocellular carcinoma (HCC), a leading indication for liver transplantation (LT), is one of the fastest-rising cancers in the United States. Prior studies demonstrate that African American (AA) patients tend to have higher mortality rates as compared with white patients with HCC, despite accounting for

differences in tumor burden, etiology of liver disease, and presence of other comorbidities. Various policies, such as the 2015 MELD exception policy change and the Regional Share 35 policy, were instituted to ensure equitable access to LT for eligible patients. However, it remains unclear whether these efforts have closed the gaps in access to LT or improved post-LT outcomes among different racial groups. Our systematic review aimed to investigate potential racial disparities within LT for patients with HCC.

Method: We performed a review of the literature across major databases including PubMed/MEDLINE, Embase, and Google Scholar in December 2023. Eligible studies included adult patients with HCC who were either waitlisted for or received LT. The primary end point of our study was to assess LT rates in AA patients as compared with white patients with HCC. The secondary end point was to compare post-LT mortality among both racial groups.

Results: 11 retrospective studies involving transplant-eligible patients with HCC were included in our systematic review. 8 studies included data from large LT databases. The years of publication spanned from 2010 to 2023. Pooled results reveal AA patients were significantly less likely to receive LT than white patients with HCC. The odds ratio for AA patients with HCC receiving a LT ranged between 0.03 and 0.60 ($p < 0.05$ across all studies). AA patients had a stronger association with increased post-LT mortality compared to whites. The hazard ratio ranged between 1.03 and 1.53 across all studies ($p < 0.05$ across all but one single center study). AA patients with HCC had higher post-LT mortality rates despite the 2015 MELD exception policy change and the Regional Share 35 policy. In AA patients with HCC due to chronic hepatitis C, post-LT survival rates were mixed despite the introduction of direct acting anti-viral therapy.

Conclusion: Our study highlights a persistent disparity among AA patients with HCC, despite current policies in the United States aimed at achieving equity in liver transplant allocation. Future initiatives should focus on dismantling racial barriers in existing LT policies and providing more support for AA patients to improve access to LT.

SAT-048

Long-term mortality and risk factors associated with mortality after liver transplantation in the modern era

Background and aims: Available robust data on the long-term mortality and associated risk factors in liver transplant (LT) recipients receiving contemporary immunosuppressive agents (Tacrolimus and Mycophenolic acid) are very limited. This study aimed to assess long-term mortality, causes and risk factors of death, in a large cohort of French LT recipients.

Method: A total of 6246 adult LTs were performed between 2008 and 2013 in France. Due to incomplete data in the National Database of the Transplantation Agency, a 20% sample (1249 LTs) was obtained from each LT center to ensure representative characteristics of the total cohort. Clinical and biological data from the pre- and post-LT periods were analyzed, and causes of death were documented in both early (6 months) and late (beyond 5 years) post-transplant periods. Predictive risk factors for death were determined by univariate and multivariate regression analysis.

Results: To date, complete data from 892 LT recipients of the 20% sample (/1249, i.e. 71.4%) were analyzed. Patients' survival in the sample was similar to that of the entire population. Predominant initial liver disease was alcohol-related cirrhosis (37, 6%), with or without hepatocellular carcinoma. The cohort, mainly male (72%), had a mean age of 52.1 ± 11.5 years, and median follow-up after LT was 9.16 years. Survival rates at 5 and 10 years post-LT were 72.6% (95% CI: 69.5–75.4) and 61.7% (95% CI: 58.4–64.8), respectively. During follow-up, 384 (43%) patients died, 26.3% from hepatic causes and 73.7% from non-hepatic causes. Hepatocellular carcinoma recurrence caused liver-related death in 26 (6, 7%) of LT recipients. In the initial 6 months post-LT, 114 patients (29.6%) died, with 32.4% due to hepatic causes and 20.1% to cardiovascular causes. Late mortality (>5 years) was mostly malignancy-related (30.7%): digestive (23%), lung (17.4%) and head and neck (17, 4%). Univariate analysis identified as significant prognostic factors: pre-LT diabetes (HR 1.51 [1.12–2.06]), pre-LT smoking (1.81 [1.34–2.41]), pre-LT stroke (HR 3.18 [1.4–6.4]), pre-LT coronary artery disease (HR = 2.19 [1.51–3.19]), age>60 years at LT (1.61 [1.31–1.99]), ($p < 0.05$). Multivariate analysis identified as significant prognostic factors: age at LT (HR = 1.02 [1.0–1.03]), pre-LT diabetes (HR = 1.38 [1.05–1.82]), pre-LT coronary artery disease (HR = 1.79 [1.16–2.76]) ($p < 0.05$).

Conclusion: Early post-LT mortality was mainly related to liver or cardiovascular causes, while long-term mortality is predominantly malignancy-related. Risk factors included age at LT, pre-LT diabetes, and pre-LT coronary artery disease. These emphasize the need for cardiovascular risk assessment in LT candidates and implementing cancer screening for long-term care.

SAT-049

Everolimus and hepatocellular carcinoma recurrence post liver transplantation: insights from an emulated target trial

Ilias Kounis[1,2,3,4], Christophe Desterke[1], Long Nguyen[5], Nathalie Goutte[2], Audrey Coilly[1,2,3,4], Didier Samuel[1,2,3,4], Daniel Azoulay[1,2,3,4], Eric Vibert[1,2,3,4], Paul Landais[1], Cyrille Feray[1,2,3,4]. *[1]Inserm, Université Paris-Saclay, UMR-S 1193, Villejuif, France; [2]AP-HP Hôpital Paul-Brousse, Centre Hépato-Biliaire, Villejuif, France; [3]Université Paris-Saclay, Inserm, Physiopathogénèse et traitement des maladies du Foie, Villejuif, France; [4]France FHU Hepatinov, Villejuif, France; [5]Department of Public Health, Copenhagen, Denmark*
Email: ilias.kounis@aphp.fr

Background and aims: Hepatocellular carcinoma (HCC) is a major indication for liver transplantation (LT). the role of mTOR inhibitors to delay the recurrence is highly debated. No large randomized trials on everolimus and HCC recurrence is available. This study use emulated target trials to assess HCC recurrence.

Method: The French national health data system (SNDS), linked with the national hospital database (PMSI), contains information on 99% of the French population, including ICD-10 codes, medical procedures (MP), prescribed drugs, and vital status. We identified 3, 699 HCC patients from 01/01/2009 to 01/01/2020. Emulated target trials (cloning-censoring-weighting approach) comparing everolimus (n = 1316, 35%) and control were performed with grace periods of 6 months to 4 years after LT and outcomes being overall survival (OS) and HCC recurrence-free survival 2 to 10 years after LT.

Results: The 10-y cumulative incidence of HCC recurrence was 16.5% (CI: 12–26). Predictive factors for HCC recurrence were abdominal surgery before LT, gender (male), tobacco and HCV. After recurrence,

the 2-y OS was 25%. In emulated trials with grace periods longer than 24 months, the 10-y 0S or 10-y recurrence-free survival were not different between groups. For shorter grace period the 10-y recurrence-free survival was up to 25% lower in the everolimus group. Competitive risk analysis did not drop the main conclusions.
Conclusion: Emulated target trial approach recently described controls immortality bias and confounder baseline variables. It is useful when no prospective trials is possible and reflects the "real-life." The role of everolimus in the prevention of HCC recurrence could not demonstrated through emulated target trials in a large nationwide cohort.

SAT-050

Liver transplantation for biliary tract cancer in primary sclerosing cholangitis

Christina Villard[1], Sigurd Breder[2], Benny Wang[3], Emma Eide[2], Lise Engesæter[4], Henrik Mikael Reims[5], Espen Melum[2], Pål Dag Line[2], Kristine Wiencke[4], Trine Folseraas[6], Annika Bergquist[1]. *[1]Department of Medicine Huddinge, Karolinska Institutet, Stockholm, Sweden; [2]Institute of Clinical Medicine, Faculty of Medicine, University of Oslo, Oslo, Norway; [3]Department of Transplantation Surgery, Karolinska University Hospital, Stockholm, Sweden; [4]Department of Transplantation Medicine, Division of Surgery, Inflammatory Medicine and Transplantation, Oslo University Hospital Rikshospitalet, Oslo, Norway; [5]Department of Pathology, Oslo University Hospital, Rikshospitalet, Oslo, Norway; [6]Institute of Clinical Medicine, Faculty of Medicine, University of Oslo, Oslo*
Email: christina.villard@ki.se

Background and aims: Cholangiocarcinoma (CCA) is the most frequent cause of death in patients with primary sclerosing cholangitis (PSC). Liver transplantation (LT) with neoadjuvant chemoradiation could be considered in selected patients with unresectable perihilar CCA and without pre-treatment in patients with bile duct high-grade dysplasia (HGD). Early detection of CCA in patients with PSC is challenging and a number of CCA are incidentally detected in liver explants. This study aimed to evaluate diagnostics and outcome of PSC-CCA treated with LT.
Method: A retrospective cohort study was conducted on patients with PSC undergoing LT due to suspicion of hepatobiliary malignancy, identified by the Nordic Liver Transplant Registry. Patients with PSC, aged ≥18 years, receiving their first LT and patients without PSC treated with LT for CCA, from 1st of January 2000 to 31st December 2021 at Oslo University Hospital and Karolinska University Hospital were included. Clinicopathological data including biochemical status at time of listing, results of diagnostics, histopathological analyses of the explants and outcome were analysed by comparative analyses. Survival was assessed by the Kaplan-Meier method and Cox regression.
Results: Out of 133 PSC patients transplanted due to suspicion of malignancy, CCA was confirmed in the explants of 45 patients (33%), HGD was found in 29 patients (22%), and hepatocellular carcinoma in 16 patients (12%). CCA was known prior to LT by brush cytology in 6 patients (13%) and was an unexpected finding in the explant of 5 patients (11%). Recurrence of hepatobiliary malignancy occurred in 26 patients (60%). The cancer-free recurrence was 17 months (9–26 months) and the median overall survival following recurrence was 5 months (2–13months). The median overall survival in patients with PSC-CCA was 24 months compared with 45 months in PSC patients with HGD. Survival following LT was similar in patients with PSC-CCA and CCA without underlying PSC (9 patients), 24 months, and 20 months, respectively.
Conclusion: The limited survival in patients with PSC-CCA following treatment with LT stresses the importance of early detection of CCA and effective oncological therapy to prevent cancer recurrence.

SAT-051

The clinical relevance of prior bariatric surgery in alcohol-related liver disease in a nationwide belgian liver transplant population

Sander Lefere[1], Roberto Troisi[2], Vincent Karam[3], Constantino Fondevila[4], Frederik Nevens[5], Olivier Detry[6], Nicolas Lanthier[7,8], Matteo Serenari[9], Leke Wiering[10], Thomas Vanwolleghem[11], Christophe Moreno[12], Frederik Berrevoet[13], Anja Geerts[1]. *[1]Hepatology Research Unit, Dpt. of Internal Medicine and Pediatrics, Ghent University, Ghent, Belgium; [2]Dpt. of Clinical Medicine and Surgery, Federico II University of Naples, Naples, Italy; [3]Hepatobiliary center, AP-HP Paul Brousse Hospital, University of Paris-Sud, Paris, France; [4]Department of General and Digestive Surgery, Hospital Universitario La Paz, IdiPAZ, CIBERehd, Madrid, Spain; [5]Hepatology and Liver Transplantation, University Hospitals KU Leuven, Leuven, Belgium; [6]Dpt. of Abdominal Surgery and Transplantation, CHU Liege, Liege, Belgium; [7]Laboratory of Hepato-Gastroenterology, Institut de Recherche Expérimentale et Clinique, Université catholique de Louvain, Brussels, Belgium; [8]Service d'Hépato-gastroentérologie, Cliniques universitaires Saint-Luc, UCLouvain, Brussels, Belgium; [9]Dpt. of Medical and Surgical Sciences, University of Bologna, Bologna, Italy; [10]Dpt. of Hepatology and Gastroenterology, Charité-Universitätsmedizin Berlin, Berlin, Germany; [11]Division of Gastroenterology and Hepatology, University Hospital Antwerp, Antwerp, Belgium; [12]Dpt. of Gastroenterology, Hepatopancreatology and Digestive Oncology, CUB Hôpital Erasme, Universite libre de Bruxelles, Brussels, Belgium; [13]Dpt. of General and Hepatobiliary Surgery and Liver Transplantation, Ghent University Hospital, Ghent, Belgium*
Email: sander.lefere@ugent.be

Background and aims: Patients with a history of bariatric surgery (BS) are susceptible to developing alcohol use disorder, which can lead to alcohol-related liver disease (ALD). Notably, we have previously shown that mortality can be higher compared to non-BS patients. Our aim was to describe the demographics, disease phenotype and mortality of patients transplanted for alcohol-related liver disease, in relation to BS.
Method: In this European Liver Transplant Registry (ELTR)-endorsed study, we included adult patients who underwent a liver transplantation (LT) in Belgium between 1/1/2013 and 31/12/2022 for ALD. We captured all patients with a history of BS prior to developing ALD, and included non-BS control patients from the same cohort. Data were retrieved retrospectively at each centre and collected via REDCap.
Results: We identified 37 patients who underwent BS (83.8% Roux-en-Y gastric bypass) before developing ALD, who received a LT between 2013 and 2022, and included 328 non-BS patients with an LT for ALD as controls. The median time between BS and diagnosis of severe liver disease was 7.2 years. Confirming our previous findings, more BS patients were female, compared to non-BS patients (45.9% vs. 18.9%, $p < 0.001$), and BS patients were 8 years younger at the time of transplantation ($p < 0.001$). MELD score at listing was higher (median 20 vs. 15, $p = 0.003$), and complications including ascites, encephalopathy and bacterial infections were more prevalent in the BS group. These differences disappeared after excluding patients with hepatocellular carcinoma (HCC), which was more prevalent in the non-BS group (8.1% vs. 49.1%, $p < 0.001$). Despite the younger age, survival after a median follow-up time of 5.5 years following LT was similar, and patients with BS trended to have a lower survival after LT in Cox regression analysis (HR 1.86, $p = 0.077$). This risk became statistically significant after exclusion of patients transplanted for HCC ($p = 0.043$). Interestingly, causes of death also differed, with liver disease being listed in 70.0% vs. 14.3% of patients as the main cause of death. Twice as many BS patients experienced a relapse of alcohol use post-transplant (27.0 vs. 14.1%, $p = 0.038$), whereas the occurrence/recurrence of MASLD was similar between both groups.
Conclusion: Following BS, excessive alcohol use can progress to end-stage ALD and need for LT. These patients present at a younger age, with more signs of hepatic decompensation, and can be at a higher risk for post-LT mortality, especially liver-related death. Pre-surgery

screening for risk of excessive alcohol use and continued post-operative follow-up of these patients are warranted.

SAT-052

Artificial intelligence and liver transplantation: post-transplantation chronic kidney disease prediction

Paul Carrier[1], Veronique Loustaud-Ratti[1], Maryline Debette-Gratien[1], Pauline Maurel[2], Aurélie Prémaud[3], Annick Rousseau[4], Essig Marie[5], Céline Rigaud[2], Christine Silvain[6], Xavier Causse[7], Pierre Marquet[8], Ephrem Salamé[9], Jean-Baptiste Woillard[5]. *[1]CHU Limoges, Limoges, France; [2]CHU Limoges, Limoges, France; [3]UMR 850, Limoges, France; [4]UMR-850, Limoges, France; [5]INSERM U-850, Limoges, France; [6]CHU Poitiers, Poitiers, France; [7]CHR Orleans, Orleans, France; [8]Limoges, France; [9]CHU Tours, Tours, France*
Email: pcarrier@hotmail.fr

Background and aims: Renal failure, acute or chronic, is a major issue in the post-organ transplant period, including liver transplantation. It must be prevented and anticipated, eventually through predictive models, obtained thanks to artificial intelligence.
Method: On an available base of 160 patients, we used a Machine Learning approach, based on the xgboost algorithms, generalized linear models and SVM to predict chronic kidney disease post-liver transplantation. Data splitting was carried out to separate the data into a training group (119 patients) and an evaluation group (41 patients). The hyperparameters of the xgboost and SVM algorithms were optimized by cross-validation (10 sets). The choice of the most appropriate algorithm was made by cross-validation on the training base. Finally, the best algorithm was evaluated in the validation base and its performance in terms of AUROC, sensitivity and specificity was studied. Variable importance plots made it possible to evaluate the predictive variables.
Results: The xgboost algorithm provided the best performance in predicting chronic kidney disease post-liver transplantation in crossvalidation in the training database with AUROC = 0.73, sensitivity = 78% and specificity = 69% (vs GLM: AUC ROC = 0.71, sen = 61%, sp = 81%; and SVM: AUROC 0.73, sen = 68%, sp = 67%). The evaluation of Xgboost in the test database shows an AUROC = 0.78, sen = 25%, an sp = 93%. The three algorithms highlighted pre-transplant renal failure as the main risk factor linked to the event.
Conclusion: The predictive performances observed in this study were close to those in the literature studied for post-transplant acute kidney failure (Zhang et al., J. Translationel Med, 2021). We plan to study a larger cohort, with the aim of developing a more efficient predictive tool.

SAT-053

Liver transplantation in patients with autoimmune hepatitis: a large single-center study

Mohssen Nassiri-Toosi[1], Ali Jafarian[2], Amir Kasraianfard[2], Ali Mohammad Moradi[2]. *[1]Tehran University of Medical Sciences, Tehran, Iran; [2]TUMS, Tehran, Iran*
Email: mohsen_nasiri@yahoo.com

Background and aims: to find the characteristics and long-term outcomes of the patients who underwent liver transplantation for AIH-related end-stage liver disease at our center.
Method: Adult patients with primary deceased donor liver transplantation from January 2007 to March 2022 at Tehran University of Medical Sciences affiliated hospital, Iran, were enrolled. Exclusion criteria were secondary liver transplantation, patients with diagnosis of acute liver failure, acute on chronic liver failure, and fulminant hepatitis, and patients with age less than 15. AIH was defined by presence of autoantibodies including antinuclear antibodies, anti-smooth muscle antibodies, anti-liver-kidney microsomal type 1 antibody, or high IgG, or plasma cell interface hepatitis in histopathological examination of liver. Patients with overlapping syndromes or concomitant chronic liver disease were excluded. All patients were given triple immunosuppression drugs (Cacinurins, Cellcept, Prednisolone). Low-dose glucocorticoids (5–7.5 mg/d) were continued lifelong for patients with AIH, unlike the others in whom the glucocorticoids were discontinued within the first year post-transplantation. Recurrent autoimmune hepatitis was defined as presence of portal and periportal lymphoplasmacytic infiltrates in liver tissue in patients with sustained elevations of aminotransferases levels and in the absence of other causes of allograft dysfunction.
Results: During study period, 1107 subjects with a mean age 45.94 ± 12.43 years old (range 16–73, median 48) including 423 (38.2%) females were enrolled. AIH was the underlying cause of cirrhosis in 177 subjects. Other 930 subjects were in the non-AIH group with viral hepatitis in 250 (26.88%), primary sclerosing cholangitis in 153 (16.45%), non-alcoholic steatohepatitis in 119 (12.79%) subjects. All subjects were followed for a mean of 65.14 ± 1.21 months (range 3–187, median 60) post-transplant. Recurrence of AIH was detected in 8 (4.5%) subjects in the AIH group. One out of 8 subjects with a recurrence of AIH died 10 years after liver transplant because of pulmonary sepsis. At the end of the study, 825 subjects were alive, 131 (61.41%) subjects in the AIH group and 694 (74.62%) subjects in the non-AIH group were alive. Survival rates of the subjects at 1 month, 1 year and 3 years after liver transplant were 88%, 81%, and 78%, respectively. In the AIH group survival rate of the subjects at 1 month, 1 year and 3 years were 87%, 81% and 78%. In the non-AIH group survival rate of the subjects at 1 month, 1 year and 3 years were 88%, 81% and 78%. The survival rates were not significantly different between the two groups (p = 0.445).
Conclusion: AIH is common etiology of underlying liver disease with safe result and good outcomes after liver transplantation and a low-risk of recurrence of AIH especially the ones who experienced more episodes of acute rejection in our center.

SAT-054

Impact of lymphadenectomy for patients with clinically node-negative intrahepatic cholangiocarcinoma: a retrospective cohort study

Meng Sha[1], Jie Cao[1], Chuan Shen[1], Ying Tong[1], Jianjun Zhang[1], Qiang Xia[1]. *[1]Renji Hospital, Shanghai Jiao Tong University, School of Medicine, Shanghai, China*
Email: simonsha23@163.com

Background and aims: Lymph node status is a prominent prognostic factor for intrahepatic cholangiocarcinoma (ICC). However, the clinical value of performing lymphadenectomy (LND) in patients with clinical node-negative ICC remains controversial. The aim of this study is to determine whether lymphadenectomy improves long-term outcomes in this subgroup of patients.
Method: We retrospectively analyzed patients who underwent radical liver resection for clinically node-negative ICC from three tertiary referral centers. A propensity score matching analysis based on clinicopathological data was conducted between patients with and without lymphadenectomy. Recurrence-free survival and overall survival were compared in the matched cohort.
Results: Among 303 patients who underwent radical liver resection for ICC, a total of 159 clinically node-negative ICC patients were eligible for the study with 102 in the LND group and 57 in the non-LND group. After propensity score matching, two well-balanced group of 51 patients each were analyzed. There was no significant difference of median RFS (12.0 vs. 10.0 months, p = 0.37) and median OS (22.0 vs. 26.0 months, p = 0.47) between the LND and non-LND group. Also, LND was not identified as one of the independent risks for survivals. On the other hand, postoperative adjuvant therapy was the independent risk factor for both RFS (HR 0.623, 95%CI 0.393–0.987, p = 0.044) and OS (HR 0.585, 95%CI 0.359–0.952, p = 0.031). Furthermore, postoperative adjuvant therapy was associated with prolonged survivals of non-LND patients (p = 0.02 for RFS and p = 0.03 for OS).
Conclusion: Based on the data, we found that LND did not significantly improve the prognosis of patients with clinically node-

negative ICC. Postoperative adjuvant therapy was associated with prolonged survivals of ICC patients, especially in non-LND individuals.

SAT-055

Post-colectomy liver transplant recipients have higher rates of chronic kidney disease at 1-year

Victoria Kronsten[1], Alison Taylor[1], Varuna Aluvihare[1], Claire Kelly[1].
[1]*Institute of Liver Studies, King's College Hospital, London, United Kingdom*
Email: victoria.kronsten@nhs.net

Background and aims: Ileostomy formation predisposes to volume depletion, acute kidney injury (AKI) and subsequent chronic kidney disease (CKD). This risk persists after ileostomy reversal and formation of an ileal pouch-anal anastomosis (IPAA). CKD is common post liver transplantation (LT), approximate prevalence of 40% at 1-year, and carries significant morbidity and mortality. This study aimed to report post-LT renal function in post-colectomy LT recipients.
Method: A single-centre cohort study was performed. All patients who underwent LT at our institution from 01/09/2012 to 01/09/2022 with a history of colectomy were included. Clinical data was collected retrospectively from electronic patient records. Post-operative CKD was defined based on a sustained estimated glomerular filtration rate (eGFR) <60 ml/min/1.73 m^2 at 1-year.
Results: 34 patients with a history of colectomy (ileostomy (n = 19) and IPAA (n = 15)) were included. Median age at LT was 47 years (interquartile (IQ) range 38–54). Main indication for colectomy was ulcerative colitis (74%). 59% of patients had primary sclerosing cholangitis. Median MELD at LT was 20 (13–25). Renal sparing induction therapy with an interleukin 2 receptor antibody (IL2Ra) was employed in 26%. Median creatinine at LT was 82 μmol/L (72–100) compared to median creatinine at 1-year of 106 μmol/L (81–130) (p = 0.08). At 1-year, 52% of patients had developed CKD (28% CKD Stage 3a, 24% CKD Stage 3b). Sub-group analysis was performed comparing the ileostomy and IPAA groups. There was no difference in sex, age, creatinine or MELD at LT between the 2 groups. AKI rates were similar in both groups (37% vs 40% and 16% vs 20% at 48 hours and 7-days post-LT, respectively). At 1-year 61% of the ileostomy group were on a calcineurin inhibitor (CNI) sparing regimen with mycophenolate mofetil compared to 23% of the IPAA group (p = 0.03). At 1-year 75% of the ileostomy group had developed CKD (42% CKD Stage 3a, 33% CKD Stage 3b) compared to 31% (15% CKD Stage 3a, 15% CKD Stage 3b) of the IPAA group (p = 0.03).
Conclusion: CKD is more common (>50%) in post-colectomy LT recipients, with the highest rates observed in patients with ileostomies. Fluid replacement peri-transplant, and stoma management where indicated, should be optimised in post-colectomy LT recipients. Consideration should be given to planned renal sparing induction therapy and early use of a CNI sparing regimen in patients with ileostomies undergoing LT independent of pre-LT eGFR.

SAT-056

Long-term survival (≥20 years) after liver transplantation in Italy: a single center retrospective experience

Maria Francesca Donato[1], Clara DiBenedetto[1], Enrico Sguazzini[1], Michele Sagasta[1], Barbara Antonelli[2], Farina Elisa[1], Federica Invernizzi[1], Lucio Caccamo[2], Tullia De Feo[3], Pietro Lampertico[1,4]. M. and A. Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy*
Email: francesca.donato@policlinico.mi.it

Background and aims: Nowadays liver transplant (LT) represents the optimal strategy to manage end-stage liver diseases and the post-transplant outcome depends on a complex interaction between donor, recipient and transplant factors. The aim of the study was to retrospectively investigate the prevalence and clinic-epidemiological features of long-term survivors (LTS ≥20 years) LT recipients.
Method: *W*e enrolled consecutive adult patients transplanted in our liver transplant Center from 1983 to 2003 and followed until 2023. The primary end point was assessing factors associated with long term survival (≥20 years).
Results: Overall, 400 patients received 454 liver grafts (re-transplant rate = 12%), 66% were males with a median age of 47 years (range 18–63). Viral etiology was the main etiology of LT (overall 62%: 32% HBV and/or HDV, 30% HCV) followed by PBC/PSC/AIH (16%), alcohol (7%) and mixed etiologies (15%). The most common indication for LT was decompensated cirrhosis (72%) followed by HCC (18%), FHF (5%) and combined liver-kidney transplantation (5%). A CNI-based immunosuppression was used either in monotherapy or combined with steroids, azathioprine or mycophenolate mofetil in all patients. The median follow-up was 16 years (range 0–37). The estimated overall survival at 5–10–20–25 years was 68%, 60%, 43% and 37%, respectively. 171 LT recipients (43%) were classified LTS while 205 (51%) survived less than 20 years (no-LTS); 25 were lost to follow-up (6%). The median follow-up was 25 years (range 20–37) in LTS and 3 years in no-LTS recipients (range 0–19). By univariate analysis, LTS were more often females (40% vs 29%, p = 0.02), younger (44 vs 47 years, p = 0.05) and transplanted with HBV/HDV etiology (42% vs 23%, p = 0.0001) or AIH-PBC-PSC (21% vs 12%, p = 0.01) compared to no-LTS. Conversely, HCV and alcohol-related etiologies were more common in no-LTS compared to LTS (38% vs 20%, p = 0.0001 and 10.5% vs 3%, p = 0.004, respectively). By using liver stiffness (Fibroscan©), LTS recipients showed a good graft function at the last follow-up (median 6 kPa, range 2–58). LTS also showed a lower rate of diabetes and kidney impairment than no-LTS (26% vs 61%, p = 0.05 and 36% vs 54%, p < 0.05, respectively). At the end of study, 76% of LTS and 10% of those without LTS were alive. Deaths due to liver-related or cardio-cerebrovascular causes were more frequently observed in no-LTS recipients compared to LTS group.
Conclusion: This study covers 40 years of our liver transplant program and shows a high overall rate of long-term survivors. HBV and HDV infections together with autoimmune and cholestatic etiologies were more represented in LTS, the former having benefited from the advent, early in the nineties, of anti-HBV prophylaxis and cure by NUCs. The unfavorable outcome of HCV liver transplants observed in our study is justified by the fact that direct anti-HCV drugs became available only in recently.

SAT-057

Poor radiological-histopathological concordance in patients transplanted for hepatocellular carcinoma: a single centre experience

Mzamo Mbelle[1,2], Christopher Harlow[1], Charles Gallaher[1], Mercy Karoney[1], Abid Suddle[1], Claire Kelly[1], Rosa Miquel[1], Yoh Zen[1], Varuna Aluvihare[1], Michael Heneghan[1], Sarah Selemani[1], Praveen Peddu[1], Paul Ross[1], Krishna Menon[1], Miriam Cortes Cerisuelo[1], Parthi Srinivasan[1], David Wallace[1], Kosh Agarwal[1], Maria Guerra Veloz[1]. [1]*King's College Hospital, London, United Kingdom;* [2]*King's College Hospital, Institute of Liver Studies, London, United Kingdom*
Email: mzamo.mbelle@nhs.net

Background and aims: Hepatocellular cancer (HCC) is the most common primary liver malignancy and is a leading cause of liver-related mortality. Contrast-enhanced cross-sectional imaging is the cornerstone in the diagnosis, staging and management of HCC, including eligibility for liver transplant (LT). However, it is well known that the radiological and histopathological concordance in liver transplant setting is poor, and this could have a negative impact

in long term outcomes. We audited the radiological-histopathological concordance in our specialised tertiary cancer centre in the United Kingdom.
Method: This retrospective study included all patients who underwent LT for HCC at King's College Hospital and who had been discussed and/or followed-up at a multi-disciplinary tumour board between January 2019 and December 2023. Demographic, clinical data, laboratory parameters and type and date of the scans (dual- or triple-phased computed tomography (CT) scans ± magnetic resonance imaging (MRI)) were collected. Radiological and histological characterisation of the correlation for the number of cancer (s) and the largest lesion size at the time of diagnosis and post liver transplant were analysed using Pearson coefficient.
Results: One hundred eighteen patients were included, 92 (78%) were men, 91 (77%) were Caucasian and the mean age at transplantation was 60.1 (SD 7.5) years. The leading aetiology for liver disease was alcohol-associated cirrhosis (33%) followed by hepatitis C (24%) and metabolic dysfunction-associated steatotic liver disease (19%). The median times between the HCC diagnosis to LT and the wait-list time to LT were 12 (IQR 8–19) months and 4 (IQR 2–7) months respectively. Most of the patients (64%) were diagnosed and staged with dual cross-sectional imaging, and only 45 (38%) had liver contrast-enhanced cross-sectional imaging within 1 month of the LT. Seventy-two patients (65%) were within UK criteria on both imaging and explant. On pre-transplant imaging, the mean of number of cancers was 1.52 (SD 0.7) compared with the 3.4 (SD 2.7) on explant (correlation coefficient of 0.313; p = 0.001). The median of the largest cancer size was 28 (20–38.5) mm in the pre-transplant imaging compared 6 (21–35) mm in the explant (correlation coefficient of 0.391; p = 0.001).
Conclusion: Despite the poor radiological -histopathological concordance between the number of cancer (s) and the largest lesion size, only one in three patients were outside our national criteria. Staging HCC based on dual cross-sectional imaging did not improve the concordance in our cohort. New AI based imaging techniques may help to improve concordance rate.

SAT-058
The survival benefit of liver transplantation for metabolic dysfunction associated steatotic liver disease: an Italian liver transplant registry study

Alessandro Vitale[1], Silvia Trapani[2], Francesco Paolo Russo[1], Massimo Cardillo[2], Umberto Cillo[1]. [1]*Padua University, Padua, Italy;* [2]*Centro nazionale trapianti, Istituto superiore di sanita', Rome, Italy*
Email: alessandro.vitale@unipd.it

Background and aims: A recent international consensus, achieved through the Delphi method, has introduced a new definition of Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD). Our objective was to analyse past and future epidemiological trends, prognostic features, and transplant survival benefits of MASLD and non-MASLD patients waiting for liver transplantation (LT) in Italy.
Method: Utilizing the Italian Liver Transplant Registry database, we analysed data from adult patients listed for primary liver transplantation due to end-stage chronic liver disease between January 2012 and December 2022. Independent multivariable waiting lists and post-transplant survival models were developed for patients with and without hepatocellular carcinoma (HCC). A Monte Carlo simulation was employed to create 5-year transplant benefit distributions based on the presence of MASLD, HCC, and MELD-sodium values.
Results: A total sample of 16, 215 patients was considered, of whom 3, 073 were excluded due to positivity for one or more exclusion criteria. A significant increase in the prevalence of MASLD as an indication for liver transplantation was observed from 2012 to 2022, both for HCC and non-HCC cohorts. Projections suggest that, as early as next year, MASLD will overcome HCV as the second most common indication for transplantation after alcoholic liver disease in Italy. According to univariate and multivariate analyses, MASLD aetiology was not an independent predictive factor for patient survival after transplantation. However, it increased the risk of death for patients on the waiting list without HCC. Consequently, the survival benefit of transplantation in patients with MASLD without HCC was significantly larger than that of other candidates.
Conclusion: The results of this study, if externally validated, could lead to modifications in allocation policies, prioritising MASLD patients over other transplant candidates.

Retrospective population study of liver transplantation in Iceland-An update

Bjarki Leó Snorrason[1], Sigurdur Olafsson[2], Einar S. Björnsson[3]. [1]*University of Iceland, Reykjavík, Iceland;* [2]*Landspitali University Hospital, Reykavík, Iceland;* [3]*Landspitali University Hospital, University of Iceland, Reykjavík, Iceland*
Email: Bls8@Hi.Is

Background and aims: Historically, the incidence of liver cirrhosis in Iceland has been low but has increased in the past two decades due to rising alcohol consumption, obesity and hepatitis C virus (HCV) infections. Since the inception of liver transplantations in Iceland in 1984 up until 2012, the most common underlying liver disease was primary biliary cholangitis (PBC), accounting for 20% of cases. In this study we sought to explore the evolving indications of liver transplantation in Iceland over the last decade.
Method: In this retrospective nationwide study, we systematically collected data pertaining to the indications for adult liver transplantations from 2013 to 2023. A chart review was undertaken, and our findings were compared with data from a previous study to understand the changes in the frequency of liver transplantations.
Results: During the study period a total of 52 liver transplantation (4 re-transplantations) were performed in 48 patients, of whom 30 (63%) were males. The mean age of the cohort was 54 ranging from 24 to 73. The average incidence of liver transplantation in the Icelandic population was 13.1 per million inhabitants per year, representing an increase from the period 2007–2012 (8.9 per million). The most common primary indication for transplantation were cirrhosis (60.4%), cirrhosis with hepatocellular carcinoma (23%). Other indications included acute hepatic failure (4.2%), tumors beyond hepatocellular carcinoma (2.1%) and a combination of various causes (10.4%). The leading etiology for liver transplantation was metabolic-associated steatotic liver disease (MASLD) accounting for 23% of cases with an incidence of 3.03 cases per 1.000.000 person-years annually, compared to an incidence of 0.12 per million inhabitants in the period 1984–2012, a 25-fold increase. The second most common indication was alcohol related cirrhosis (21%). Other indications comprised PBC (8.3%), primary sclerosing cholangitis (8.3%), Hepatitis C (8.3%), drug-induced liver injury (DILI) 4.2%, and a combination of various other causes accounting for 27%.
Conclusion: There has been a significant increase in liver transplantations compared to previously studied periods, particularly driven by MASLD as the leading cause. Notably, alcohol related liver disease surpassed PBC as a leading etiology. These changes underscore the dynamic nature of liver disease etiology, prompting a closer examination of these trends to enhance clinical management and enable the development of targeted public health strategies.

Needle tract seeding of hepatocellular carcinoma after liver transplantation: a single center experience

Chiara Sicuro[1], Gabriella Frassanito[1], Lorenza Di Marco[2], Alessandra Pivetti[1], Roberta Odorizzi[3], Cristiano Guidetti[3], Paolo Magistri[3], Stefano Di Sandro[3], Fabrizio Di Benedetto[3], Antonio Colecchia[1], Nicola De Maria[1]. [1]*Gastroenterology Department-AOU Policlinico di Modena, Modena, Italy;* [2]*Oncology and Hematology Department-AOU Policlinico di Modena, Modena, Italy;* [3]*Onco-Hepato-*

Biliary-Pancreatic Surgery and Transplantation Unit-AOU Policlinico di Modena, Modena, Italy
Email: chiarasicuro44@gmail.com

Background and aims: Hepatocellular carcinoma (HCC) is one of the leading causes of liver transplantation (LT) worldwide. Most of the patients transplanted for HCC undergo local percutaneous procedures before LT to diagnose/downstage the tumor, to include liver biopsy (LB), thermal ablation (PTA), and ethanol injection (PEI). Needle track seeding (NTS) can occur after such procedures. According to the literature, NTS occurs in 0.01–5% of cases after an LB, 1.4% of cases after a PEI, and 0.95% of cases after a PTA. The incidence of NTS in the setting of LT is poorly investigated, only few studies and case reports about NTS after LT have been published. Aims of our study were: to determine the incidence of NTS following LB or percutaneous treatment in patients with HCC who underwent LT; to assess the impact of NTS on HCC recurrence and patients' survival.
Method: All LTs for HCC performed at our Institution between Jan 2010 and Dec 2022 were considered in this retrospective study. We recorded all percutaneous procedures as well as all HCC treatments performed prior to LT, including liver resection (LR) and trans-arterial chemoembolization (TACE). Radiological imaging of all pts was reviewed.
Results: A total of 347 pts underwent LT for HCC; 137 underwent a percutaneous procedure before LT: 54 underwent LB alone, 19 had an LB followed by a percutaneous treatment, 64 underwent PTA and/or PEI without a previous LB. NTS occurred in 6 pts (4.38%): Pt 1 had LB + TACE (G2 HCC). Peritoneal NTS appeared 13 mo after LT, 23 mo after LB; Pt 2 had LB and no treatment before LT (G3 HCC). NTS in the right rectus abdominis muscle appeared 45 mo after LT, 61 mo after LB; Pt 3 had no LB and underwent TACE + RFA + PEI (G3 HCC). Peritoneal NTS appeared 51 mo after LT, 61 mo after PEI; Pt 4 had LB and then TACE + RFA (G3 HCC). Diaphragmatic NTS appeared 53 mo after LT, 101 mo after LB; Pt 5 had LB and then TACE (G3 HCC). NTS in the right rectus abdominis muscle appeared 22 mo after LT, 34 mo after LB; Pt 6 had LB and then LR + TACE + systemic therapy (G2 HCC). Subcutaneous NTS in the epigastric region appeared 10 mo after LT, 23 mo after LB. The median time of NTS recurrence was 30 mo from PT, 17, 5 mo from LT. Patients 2, 3 and 4 underwent a successful surgical removal of the seeding lesions. No recurrence of HCC has been reported after 27, 14 and 2 mo respectively. Patient 1 is currently awaiting surgical treatment. Patients 5 and 6 underwent surgery with removal of the seeding but had evidence of HCC recurrence respectively 25 mo and 23 mo after LT. They both were Milan out before liver transplantation.
Conclusion: In our experience: 1) NTS is an uncommon but not negligible complication of liver percutaneous procedure for HCC; 2) the occurrence of NTS may not always impact patients' prognosis in terms of HCC recurrence or overall survival. In our small series 3 out of 6 patients had a successful removal of the neoplasm, without recurrence of HCC at least after a short period of follow-up.

Liver tumours – Clinical aspects except therapy

TOP-509-YI
Validation and improvement of the IMbrave050 criteria for high-risk of HCC-recurrence as an indication to adjuvant treatment: results from a 4-year retrospective competitive-risk study

Matteo Serenari[1], Matteo Cescon[1], Chiara Bonatti[1], Bernardo Stefanini[1], Sofia Penazza[1], Edoardo Prosperi[1], Elton Dajti[1], Francesco Tovoli[1], Matteo Ravaioli[1], Fabio Piscaglia[1], Federico Ravaioli[1]. [1]*Department of Medical and Surgical Sciences, University of Bologna, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, (IT), Bologna, Italy*
Email: f.ravaioli@unibo.it

Background and aims: The IMbrave050 study found that adjuvant treatment with atezolizumab and bevacizumab improved recurrence-free and overall survival in high-risk HCC recurrence (HCC-r) patients after curative-intent liver resection (LR). High-risk criteria for HCC-r are based on the number, dimension, vascular invasion, and HCC differentiation. Authors suggested integrating liver stiffness measurement (LSM) into the risk-stratification algorithm after LR. We aimed to validate the IMbrave050 criteria and improve the criteria for better stratification of patients who would benefit from adjuvant treatment.
Method: We conducted a retrospective analysis on patients with HCC who had undergone curative LR. We followed the patients according to guidelines and assessed the occurrence of HCC-r events. We performed a competing-risks regression analysis to account for liver transplantation or death as competitive events. We stratified the patients as high/low risk for HCC-r events based on the IMbrave050 criteria.
Results: 166 out of 197 HCC patients who underwent LR between 2010–2020 reached oncological radicality (R0) and included in the study. According to IMbrave050 criteria, 105 (63.3%) patients were classified as high-risk for HCC-r, potentially benefitting from adjuvant therapy. During the mean follow-up of 43.5 months, 60.8% of the patients developed HCC-r with an incidence rate of 16.8%/year [95%CI 13.8–20.4] during a follow-up time to HCC-r of 20.7 mo (7.2–43.4). 13.3% of the patients developed competitive events. Kaplan-Meier analysis showed significant stratification of HCC-r risk based on IMbrave050 criteria ($p = 0.0009$). The high-risk group had 71 out of 105 (63.2%) HCC-r, with an incidence rate of 22.5%/y [17.8–28.4]. This was significantly higher ($p = 0.0003$) than in the low-risk group, which had 30 out of 61 (49.1%) HCC-r, with an incidence rate of 10.5%/y [7.3–15]. Based on competitive-risk analysis, LSM ≥15 kPa was significantly ($p = 0.007$) associated with HCC-r with a sub-distribution hazard ratio (SHR) of 1.694 [1.155–2.486]. The incidence rate of HCC-r was significantly different ($p = 0.0019$) between patients with LSM <15 kPa (13%/y [9.9–17]) and LSM ≥15 kPa (24.3%/y [18.4–32.2]). When we applied LSM-based risk stratification in the low-risk HCC-r cohort according to IMbrave050 criteria, we separated the subgroup with LSM ≥15 kPa with a significantly higher incidence of HCC-r (17.5%/y [10.7–28.5]) compared with those with LSM <15 kPa (7.2%/y [4.2–12.1]) ($p = 0.017$).
Conclusion: The study validated the IMbrave050 criteria in radically resected patients to identify high-risk HCC-r patients who need adjuvant therapy We found that adding LSM ≥15 kPa to the IMbrave050 low HCC-r risk identifies patients at higher risk, which could similarly be considered for adjuvant therapy after radical treatment.

Incomplete thermal ablation plus programmed cell death protein 1 monoclonal antibodies increase the incidence of hyperprogressive disease in hepatocellular carcinoma

Yuzhe Cao[1,2,3], Guanglei Zheng[1], Mengxuan Zuo[1,2,3], Wang Li[1,2,3], Fei Gao[1,2,3]. [1]*Sun Yat-sen University Cancer Center, Guangzhou, China;* [2]*State Key Laboratory of Oncology in South China, Guangzhou, China;* [3]*Guangdong Provincial Clinical Research Center for Cancer, Guangzhou, China*
Email: gaof@sysucc.org.cn

Background and aims: Hepatocellular carcinoma (HCC) is the most common type of liver cancer. Programmed cell death protein 1 (PD1) monoclonal antibodies (mabs) are now standard of care for HCC management. However, reports of hyperprogressive disease (HPD) following immunotherapy triggered clinical concern. Though mechanism still not clear, HPD was hypothesized related to interaction between the fragment crystalline (Fc) of PD1 mabs and Fc γ receptors (FcγR) on macrophages. Thermal ablation is recommended as the first-line choice for early-stage patients. However, incomplete ablation (IA) is not rare when the tumors are large, multiple or

adjacent to vessels. To deal with metastases or residual lesions, a regimen consisting of ablation and PD1 mabs has raised concern due to synergy between PD1 mabs and tumor-related antigen release caused by ablation. Nonetheless, ablation could induce macrophage infiltration, which may interact with Fc of PD1 mabs and result in HPD. We conducted a retrospective clinical study to explore whether IA plus PD1 mabs increase the incidence of HPD than PD1 mabs in HCC patients. An animal experiment was also performed to validate the clinical findings, study the underlying mechanism of HPD and explore the potential precautions.

Method: This study retrospectively enrolled immunotherapy-naive HCC patients with Child-Pugh score ≤7 who underwent IA plus PD1 mabs (IAP) or PD1 mabs alone (P) from January 2018 to December 2022. Each patient had at least 2 times image data available for baseline tumor growth rate (TGR) assessment before administration of PD1 mabs. The diagnostic criteria of HPD was: 1) Time to progression <2 months; 2) ≥50% increase of sum of target lesions major diameters; 3) Two-fold increase in TGR or at least 10 new lesions after treatment. C57/BL6 mice with subcutaneous tumor were randomly assigned to P (sham ablation + PD1 mab, n = 4), IAP (IA + PD1 mab, n = 3) and IAMP (IA + modified PD1 mab with D265A mutation on Fc, n = 3). Fc with D265A mutation is unrecognized for FcγR. The tumor volume is calculated according to the modified ellipsoidal volume formula. And the TGR is the ratio between logarithm of tumor volume and interval time. The difference between pre- and post-treatment TGR was recorded as ΔTGR.

Results: In total, 55 patients met the criteria and were included in the present study (IAP: n = 12, P: n = 43), the incidence of HPD in the IAP group was significantly higher than that in the P group (58.3% vs. 20.9%, p = 0.028). The animal study verified that IAP could accelerate the tumor growth (ΔTGR: IAP vs. P, 0.047 ± 0.0030 vs. −0.0031 ± 0.0080, p < 0.001), and suggested that the blocking the interaction between Fc and FcγR receptors could interfere with the phenomenon (ΔTGR: IAMP vs. P, −0.0033 ± 0.0068 vs. −0.0031 ± 0.0080, p = 0.96).

Conclusion: IAP is likely to induce the high incidence of HPD. And the Fc-modified PD1 mabs without the ability to bind to FcγR may block the process of HPD.

Trends and evolution of hepatocellular carcinoma due to etiological shift from 2005 to 2020 in Germany: nationwide population-based study

Josune Cabello Calleja[1], Wenyi Gu[1], Robert Schierwagen[1], Maximilian Joseph Brol[1], Frank Erhard Uschner[1], Florian Rennebaum[1], Sara Noemi Reinartz Groba[2], Michael Praktiknjo[2], Jonel Trebicka[1,3,4]. *[1]Department of Internal Medicine B, University Hospital Muenster, Muenster, Germany; [2]Department of Internal Medicine B, University Hospital Muenster, Muenster, Germany; [3]European Foundation for Study of Chronic Liver Failure, Barcelona, Spain; [4]Department of Gastroenterology and Hepatology, Odense University Hospital, Odense, Denmark*
Email: josune.cabello@ukmuenster.de

Background and aims: Hepatocellular carcinoma (HCC) is considered the most frequent primary malignant disease of the liver and it is associated with a high mortality. The main risk of developing HCC consists in the presence of liver cirrhosis. However, its association with other potential drivers, such as comorbidities, still remains unclear. Therefore, we aimed to analyze changing trends of HCC, especially focusing on underlying etiologies and related comorbidities.

Method: This German nationwide study analyzed 393, 230 admissions with HCC from 2005 until 2020 based on the diagnosis-related-groups (DRG) system via ICD-10-GM-2023 and OPS-2023 codes. We analyzed the data focusing on the investigation of most probable etiologies related to the development of HCC as well as the all-cause in-hospital mortality rate of these patients. All trend and changes over the years were compared using linear regression or Mann-Whitney U-test.

Results: The number of recorded admissions of patients with HCC increased significantly during the last 16 years (increase of 21.78%; p < 0.001).

The most common underlying etiology was alcohol-related liver disease (ALD) (55.48%), which raised over the time (22.78% of increase; p = 0.002), but with a significant decrease of in-hospital mortality rate (p = 0.010).

The following most frequent overall etiologies were hepatitis C virus (HCV) (19.79%) and hepatitis B virus (HBV) (9.67%), both showing a decreasing trend in admissions (HCV: −66.99%, p = 0.001; HBV: −36.53%, p < 0.001), but with a similar in-hospital mortality rate.

In addition, we observed that patients with metabolic dysfunction-associated steatohepatitis/metabolic dysfunction-associated steatotic liver disease (MASH/MASLD) showed a 3.7-fold increase, the strongest among etiologies.

As indicators of metabolic syndrome, comorbidities in patients with HCC (type 2 diabetes mellitus, arterial hypertension (AHT), dyslipidemia and obesity) were significantly more frequent during the observational period (88.89% of increase; p < 0.001). In particular, AHT and dyslipidemia seemed to be related to higher risk of HCC development independent of the presence of liver cirrhosis.

Conclusion: This nationwide study shows the increasing prevalence of ALD and MASLD in patients with HCC. Especially metabolic risk factors may be drivers of HCC, even in absence of cirrhosis and should be taken into account in future investigations.

Metformin as a protective factor against hepatocellular carcinoma in chronic hepatitis C patients achieving sustained virologic response: a long-term follow-up study

Henar Calvo[1,2,3], Lorena Jara[4], Irene Villarino[1], Marta Quiñones[4], Ruben Alvarado[4], Eva Martinez[2], Vanessa Díaz[5], Maria Luisa Gutiérrez[4], Joaquin Miquel[1,3], Eduardo Sanz de Villalobos[1,3], Miguel Torralba[2,3,6], Sonia Albertos Rubio[7], Conrado Fernández-Rodríguez[4,8], Juan Ramón Larrubia[1,2,3]. *[1]Gastroenterology Section.University Hospital of Guadalajara, Guadalajara, Spain; [2]Department of Medicine and Medical Specialties, University of Alcalá, Alcalá de Henares, Madrid, Spain; [3]Group of Translational Research in Cellular Immunology (GITIC), IDISCAM, Guadalajara, Spain; [4]Service of Gastroenterology.Alcorcón Foundation University Hospital, Alcorcón, Madrid, Spain; [5]Primary Care Health Centre Josep Bertran I Miret, Sant Pere de Ribes, Barcelona, Spain; [6]Section of Internal Medicine, University Hospital of Guadalajara, Guadalajara, Spain; [7]Serivice of Gastroenterology. Hospital Sant Camil-Sitges, Sitges, Spain; [8]Department of Public Health and Medical Specialties. Rey Juan Carlos University, Alcorcón, Madrid, Spain*
Email: hcalvo@sescam.jccm.es

Background and aims: Metformin activates AMPK and the immune system while inhibiting mTORC1 pathway all of which may protect against the development of hepatocellular carcinoma (HCC). The incidence of HCC is reduced in chronic hepatitis C (CHC) after SVR, but the risk factors in advanced fibrosis remain uncertain. The aim of the study was to assess the incidence of HCC according to the grade of fibrosis and the risk factors associated with HCC after SVR, with focus on the potential protective role of metformin.

Method: We conducted an HCC-free survival study assessing incidence rates and proportional risks based on FIB-4 value at the onset of direct anti-viral agents (DAAs) treatment during post-SVR follow-up. Hazard ratio (HR) for model variables were computed, excluding cases emerging within 6 months of treatment initiation. HCC diagnosis relied on radiological and/or histological evidence. The model, developed using the stepwise backward selection with the Wald statistic, was evaluated by calculating the area under the ROC curve for survival.

Results: Between August 2012 and December 2022, the prospective data of 1518 patients with SVR after treatment of CHC with DAA (49% women) from three hospitals were retrospectively analysed. Median follow-up of 75 months (IQR 52–90). 53 HCCs were detected. The incidence rates per 100 patient-years according to FIB-4 were: <1.45, 0.03 [95%CI: 0.002–0.15]; 1.45–3.25, 0.35 [95%CI: 0.19–0.59]; >3.25, 1.7 [95%CI: 1.2–2.3], ($p < 0.001$). The multivariate Cox regression model to predict the HR of HCC ($p < 0.001$) included the following variables: FIB-4 at baseline; HR: 1.020 [95%CI: 1.004–1.037; $p = 0.013$], presence of clinically significant portal hypertension (CSPH); HR: 17.544 [95%CI: 9.183–33.516; $p < 0.001$], age in decades; HR: 1.431 [95%CI: 1.104–1.854, $p = 0.007$], smoking; HR: 4.746 [95%CI: 2.284–9.865, $p < 0.001$]; Metformin treatment; HR: 0.35 [95%CI 0.141–0.916; $p = 0.032$], female sex; HR 0.43 [95%CI: 0.232–0, 865, $p = 0.017$]; The Cox regression predictive model for HCC yielded an AUC of 0.804 [95%CI: 0.73–0.88, $p < 0.001$]. In F4 with CSPH, HCC incidence rate per 100 patient-years was higher [2.9; 95%CI: 2.1–4] than in F4 without CSPH [0.7; 95%CI: 0.3–1.5], ($p < 0.001$). In F4 with CSPH on metformin, the HCC incidence rate per 100 patient-years was lower [1.3; 95%CI: 0.4–3.3] than without metformin [3.4; 95%CI: 2.3–4.6], ($p = 0.06$).
Conclusion: The incidence rate of HCC in chronic hepatitis C after SVR is very low in patients with FIB4<3.25, which would suggest limiting HCC screening to cases with FIB4>3.25. Within this group, the highest risk is associated with CSPH, followed by tobacco use and age, while metformin treatment and female sex are protective factors.

Machine learning for risk stratification of hepatocellular carcinoma

Jan Clusmann[1,2], Paul-Henry Koop[1], Felix van Haag[1], Yazhou Chen[1], Benjamin P.M. Laevens[1], Christian Trautwein[1], Kai Markus Schneider[1], Jakob Nikolas Kather[2,3,4,5], Carolin V. Schneider[3,6]. *[1]Medical Clinic III, Gastroenterology, Metabolic Diseases and Intensive Care, University Hospital RWTH Aachen, Aachen, Germany; [2]Institute for Clinical Artificial Intelligence, EKFZ for Digital Health, TU Dresden, Dresden, Germany; [3]Department of Medicine III, University Hospital RWTH Aachen, Aachen, Germany, Aachen, Germany; [4]Division of Pathology and Data Analytics, Leeds Institute of Medical Research at St James's, University of Leeds, Leeds, United Kingdom; [5]Medical Oncology, National Center for Tumor Diseases (NCT), University Hospital Heidelberg, Heidelberg, Germany; [6]University of Pennsylvania, Philadelphia, United States*
Email: janclusmann@ukaachen.de

Background and aims: Hepatocellular carcinoma (HCC) is a highly fatal malignancy. Historically linked to cirrhosis, HCC is increasingly caused by the obesity-related Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD), expanding the population at risk of HCC along the worldwide epidemic of obesity. While risk constellations for HCC are well characterized and encompass steatotic liver disease (SLD), viral hepatitis, serum indicators, lifestyle and hereditary risk, current screening predominantly targets patients with liver cirrhosis. Stratifying SLD patients in terms of risk of HCC poses a major clinical challenge. This could be addressed through standardized risk stratification methods, augmented by machine learning and big data.
Method: We assessed data from the UK Biobank, a population-based database with electronic health records (EHR), death registers, lifestyle, physical and biological measures as well as genomics (n∼500k each) and metabolomics data (n = 250k). We trained five-fold cross-validated random forest machine learning (ML) classifiers on multimodal data of all included patients to predict HCC occurrence (n = 470). To simulate clinically relevant scenarios, we employed a layered approach in our data analysis, starting with basic physical measurements. We then incrementally integrated more comprehensive data, first adding commonly available blood counts and serum analyses, and subsequently incorporating advanced analyses such as metabolomics and genomic sequencing, analyzing gain in predictive accuracy for each step. Models were then validated on previously unseen data from UKB centers from Scotland and Wales.
Results: Random-forest classifiers developed using five-fold cross-validation on 18 UKB centers within England achieved high predictive accuracies in the validation dataset. Specifically, models utilizing only EHR and lifestyle data achieved mean AUROC scores exceeding 0.84, which further increased to AUROCs of 0.88 upon integration of serum information. Interestingly, the inclusion of metabolomic or genomic data did not significantly enhance performance. In comparison, the aMAP-score, a widely recognized and utilized score for HCC risk stratification, attained AUROC scores of only 0.74 in our dataset. Secondary analysis revealed feature importance (FI) distributions with high relevance of blood and metabolomic parameters. This was followed by FI of lifestyle and EHR parameters, while genomic factors were assigned relatively lower FI in our models.
Conclusion: Our results underscore the predictive capability of explainable machine learning models in the context of risk stratification approaches developed from real-world data. This establishes machine learning as a potential new benchmark in the realm of HCC risk assessment.

Email: tobiaspaul.seraphin@med.uni-duesseldorf.de

Background and aims: The evaluation of malignancy of focal liver lesions remains an important yet challenging task in routine patient care. Contrast-enhanced ultrasound (CEUS) is a reliable tool but depends on the examiner's expertise. The rise of artificial intelligence has given way to algorithms potentially able to assist clinicians in diagnosing such lesions. In this study, we trained a weakly supervised attention-based multiple instance learning (aMIL) algorithm to classify focal liver lesions as malignant or benign and evaluated its performance.
Method: For this retrospective study we used a cohort of patients from a tertiary care hospital in Germany undergoing routine CEUS for focal liver lesions. Frames were cut from videos recorded during examination and subsequently features extracted using a pretrained convolutional neural network. We randomly removed a class-balanced test set of 20% and used the remaining cohort to train the algorithm. We performed a hyperparameter grid-search, applying a five-fold cross-validation each time.
Of the multiple trained weakly supervised aMIL networks, we evaluated the five best performing models on our held-out test set and chose the final model based on the highest area under the receiver operating curve (AUROC) value. For this model, additional test statistics were calculated and explorative explainability methods deployed.
Results: We included 370 patients with and without cirrhosis, 201 with a benign and 169 with a malignant liver lesion. Our final model was able to diagnose malignant lesions with an AUROC of 0.94 in the cross-validation experiment and of 0.88 in the held-out test set. Accuracy, Sensitivity, and Specificity for the malignant class were 79%, 88%, and 72%, respectively. Our exploratory analysis of the model's decision-making through visual explainability methods

revealed that the model seems to focus on information also highly relevant to expert clinicians in this task.
Conclusion: Weakly supervised deep learning algorithms have shown great potential for the diagnosis of focal liver lesions. Our algorithm can distinguish malignant from benign lesions with a high degree of accuracy. Complex pre-processing (e.g. delineation of regions-of-interest) is not required for this. In the future, such algorithms could support physicians performing CEUS in decision making.

SAT-470

The risk of hepatic decompensation in patients after the treatment for steatotic liver disease-related hepatocellular carcinoma

Tatsuya Minami[1], Tomoharu Yamada[1], Mitsuhiro Fujishiro[1], Ryosuke Tateishi[1]. [1]*Department of Gastroenterology, Graduate School of Medicine, the University of Tokyo, Tokyo, Japan*
Email: minami.tatsu@gmail.com

Background and aims: The effectiveness of surveillance for hepatocellular carcinoma (HCC), especially from a cost-effectiveness perspective, is influenced by the establishment of an effective high-risk group, the proportion of patients diagnosed at an early stage, and the survival prognosis of those found. Assuming that hepatitis will be controlled in many patients with HCC with hepatitis background due to recent advance in anti-viral therapy, it is now expected that the prognosis after treatment will be different for patients with hepatitis background and others, especially those with steatotic liver disease (SLD). This study aims to compare virally controlled and SLD-related HCC in terms of prognosis, recurrence, and risk of decompensation.
Method: Among 1826 patients who underwent curative radio-frequency ablation (RFA) for primary HCC from 1999 to 2020 at our institution, we focused on 255 SLD-related HCC cases and 125 viral controlled HCC (80 hepatitis C with sustained virological response [SVR], 45 hepatitis B on nucleotide analog [NA]) with a maximum tumor diameter of 3 cm or less and three or fewer lesions. Propensity score matching was performed based on age, gender, liver function, and tumor burden in each group, and recurrence rates, decompensation rates, and survival rates were assessed using the Kaplan-Meier method and compared using the log-rank test.
Results: After propensity score matching, 102 cases each of SLD-related HCC and viral controlled HCC were extracted. The 3-year, 5-year, and 10-year recurrence rates were comparable between SLD-related HCC (55.9%, 60.6%, 82.3%) and viral controlled HCC (45.4%, 57.6%, 77.7%) with no significant difference (log-rank test $p = 0.2$). However, decompensation rates were significantly higher in SLD-related HCC (11.7%, 18.9%, 38.8%) compared to viral controlled HCC (4.2%, 5.4%, 7.0%) ($p < 0.001$), leading to better survival prognosis in viral controlled HCC (92.8%, 87.2%, 63.7%) compared to SLD-related HCC (83.3%, 73.2%, 40.4%) ($p < 0.001$).
Conclusion: SLD-related HCC, compared to viral controlled HCC, exhibits similar recurrence rates but higher decompensation rates, suggesting a potential cause for diminished life expectancy. Even with early detection, the high decompensation risk associated with SLD-related HCC underscores the importance of considering this data when planning surveillance strategies for SLD-related HCC.

SAT-472

External validation of hepatocellular carcinoma risk calculators following hepatitis C treatment in a large US cohort

Ellen Green[1], Thad Benefield[1], Rachel Swier[1], Lindsay Lane[1], Louise Henderson[1], Andrew Moon[1]. [1]*University of North Carolina, Chapel Hill, United States*
Email: andrew.moon@unchealth.unc.edu

Background and aims: Many patients with hepatitis C virus (HCV) treated with direct acting antivirals (DAAs) remain at risk of developing hepatocellular carcinoma (HCC). Validated risk stratification models, which utilize commonly available laboratory data, could guide individualized HCC screening recommendations for patients with cured HCV. Towards this goal, we validated published HCC risk models in a large cohort of patients with chronic HCV who have been treated with DAAs.
Method: Patients with chronic HCV treated with DAAs within a single health system from 1/1/2014 to 12/31/2021 were followed until death, HCC, liver transplant, last follow-up, or 12/31/2022. We excluded those with diagnosis of HCC prior to DAA-treatment. Clinical data was acquired at the time of DAA treatment to validate three published, non-genetic HCC prediction models (age-male sex-ALBI-platelet count score (aMAP), US Veteran Health Affairs (VHA), Toronto HCC risk Index (THRI)). The primary outcome analyzed was the development of HCC, accounting for death and liver transplant as competing risks. Statistical analysis examined the models' discrimination using Uno's Concordance index and calibration using 5-year predicted versus observed HCC incidences. Missing data was imputed using the Markov Chain Monte Carlo (MCMC) method and HCC risk tertiles were computed from the median of the 30 scores.
Results: Our final cohort included 2598 patients with chronic HCV treated with DAAs including 47.5% (n = 1233) with pre-treatment cirrhosis. The median follow-up interval was 1.4 years (S.D. 1.5 years). After DAA therapy, 0.6% (n = 16) developed HCC, 0.7% (n = 17) received liver transplant, and 5.9% (n = 153) died. Discrimination for aMAP, THRI, and VHA was 0.757, 0.663, and 0.596 respectively, using the multiply imputed datasets. For the aMAP model, the observed 5-year incidences of HCC by tertile were 0.0% (95% CI: [0.0%, 1.0%]), 0.3% (95% CI: [0.0%, 2.3%]), and 3.0% (95% CI: [1.7%, 5.2%]) for low, medium, and high risk, respectively, compared to the predicted values of 0.8%, 4.2%, and 19.9%. The observed incidences for the THRI model were 0.0% (95% CI: [0.0%, 1.0%]), 1.8% (95% CI: [0.9%, 3.5%]), 2.9% (95% CI: [1.2%, 7.1%]) compared to predicted values of 1.5%, 4.9%, and 15.0%. VHA calibration was omitted as only 3-year HCC incidence was reported.
Conclusion: In this cohort of patients with chronic HCV treated with DAAs, the aMAP model had the best discrimination. Observed HCC incidence was much lower for all 3 models, across all tertiles. Validated risk stratification models, which utilize commonly available serum data, are integral to the advancement of HCC health equity through access to earlier, individualized prediction for patients at risk of HCC. However, continued external validation of existing models across diverse patient datasets is needed.

SAT-473

Changes in the landscape of hepatocellular carcinoma-experience of a single tertiary center

Zehnder Jan[1], Jonas Schropp[1], Birgit Schwacha-Eipper[2], Annalisa Berzigotti[1,2], Jean-François Dufour[1], Pompilia Radu[2]. [1]*Department for BioMedical Research, Visceral Surgery and Medicine, University of Bern, Bern, Switzerland;* [2]*Department of Visceral Surgery and Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland*
Email: pia_radu@yahoo.com

Background and aims: In the last decade, the availability of highly effective oral antiviral drugs for chronic hepatitis C and novel immunotherapy agents have modified the landscape of hepatocellular carcinoma (HCC), but detailed data on changes in aetiology and survival are lacking. The aim of the present study was to evaluate how these patterns of HCC changed in the last decade at our academic center.
Method: Data of 505 HCC patients newly diagnosed with HCC included in a prospective HCC cohort of Inselpital, University Hospital of Bern, Switzerland in 2010–2021 was retrospectively reviewed. The analysed timeframe was split in 4 periods (2010–2012, 2013–2015, 2016–2019, 2019–2021 to better reflect the changes and their impact. Chi-squared test/Fisher's exact test for categorical variables. A p value of less than 0.05 was considered statistically significant.
Results: The age of diagnosis has increased over the time from 63 years to 67 years ($p < 0.001$). During the analyzed period of time

(2010–2021), the viral aetiology (i.e. chronic hepatitis B and chronic hepatitis C) decreased (50% to 23%, $p < 0.001$), while non-viral aetiologies, such as alcohol-related liver disease (ALD) and metabolic dysfunction-associated steatotic liver disease (MASLD)/Metabolic dysfunction-associated steatohepatitis (MASH) increased (48 to 62%, $p < 0.001$ and 25% to 37%, $p = 0.3$, respectively). BMI remained stable over time in newly diagnosed HCC patients, whereas the comorbidities, such as arterial hypertension, hyperlipidemia and diabetes mellitus Type 2 had a significant increase (45% to 60%, $p = 0.027$; 13% vs 40%, $p < 0.001$; 32% vs 44%, $p = 0.006$, respectively). Concerning HCC detection, the proportion of patients diagnosed as BCLC stage 0 increased gradually from 0.9% to 13%, while those diagnosed as BCLC stage C decreased from 23% to 15% ($p = 0.06$). Consequently, the therapy with curative intention increased over the time (39% to 61%, $p < 0.001$).

Conclusion: Our study highlights the important changes in the landscape of HCC that occurred in the last decade. Patients with HCC are currently diagnosed at higher age, have more comorbidities and the landscape of aetiologies changed over time. Alcohol was a major modifiable risk factor for HCC in our population, underlining that prevention in the next years should be a focus to obtain a reduction of new HCC cases. On the other hand, screening programs are likely to result in an increase in proportion of patients diagnosed at earlier stages, which may make them more susceptible to curative treatments.

Lesions hyper- to isointense to the surrounding liver in the hepatobiliary phase of gadoxetic acid enhanced MRI

Alicia Furumaya[1,2], Francois Willemssen[3,4], Razvan Miclea[5,6], Martijn Haring[7,8], Robbert de Haas[7,8], Shirin Feshtali[9,10], Inge Vanhooymissen[1,2], Daniel Bos[3,4], Robert A. de Man[3,4], Jan Ijzermans[3,4], Joris Erdmann[1,2], Joanne Verheij[1,2], Michail Doukas[3,4], Otto van Delden[1,2], Maarten Thomeer[3,4]. *[1]Amsterdam UMC, Amsterdam, Netherlands; [2]Cancer Center Amsterdam, Amsterdam, Netherlands; [3]Erasmus MC, Rotterdam, Netherlands; [4]Erasmus University Rotterdam, Rotterdam, Netherlands; [5]Maastricht University Medical Center+, Maastricht, Netherlands; [6]Maastricht University, Maastricht, Netherlands; [7]University Medical Center Groningen, Groningen, Netherlands; [8]University of Groningen, Groningen, Netherlands; [9]Leiden UMC, Leiden, Netherlands; [10]Leiden University, Leiden, Netherlands*
Email: a.furumaya@amsterdamumc.nl

Background and aims: Hyper- or isointensity in the hepatobiliary phase (HBP) of gadoxetic acid enhanced MRI has high specificity for focal nodular hyperplasia (FNH). However, hepatocellular adenoma and carcinoma (HCA/HCC) may also be hyper- or isointense in the HBP. The aim of the current study was to identify imaging characteristics to differentiate FNH and HCA/HCC hyper- or isointense on gadoxetic acid enhanced MRI.

Method: A multicenter retrospective cohort study was conducted including patients with pathology-proven FNH or HCA/HCC, hyper- or isointense in the HBP of gadoxetic acid enhanced MRI between 2010 and 2020. Imaging characteristics were compared between lesions with a pathological diagnosis of FNH and HCA/HCC. Diagnostic performance, univariable analyses, multivariable logistic regression analysis and classification and regression tree analyses were conducted. Sensitivity analyses evaluated imaging characteristics of B-catenin activated HCA.

Results: In total, 124 patients (mean age 40 years, standard deviation 10 years, 108 female) with 128 hyper- or isointense lesions were included. Pathology diagnoses were FNH in 64 lesions (50%) and HCA/HCC in 64 lesions (50%). Imaging characteristics observed only in HCA/HCC and never in FNH were: sinusoidal dilatation on T2-w, raster and atoll fingerprint pattern in the HBP, venous washout, T1-w in-phase hyperintensity or hemosiderin, and nodule-in-nodule partification in the HBP and T2-w. In our selected cohort, 14/48 (29%) of HCA were B-catenin activated, most (13/14) showed extensive hyper- or isointensity.

Conclusion: Aforementioned characteristics should be considered typical for HCA/HCC. If encountered in lesions extensively hyper- to isointense in the HBP, further investigation is warranted.

SAT-476

Development of a preference elicitation tool for treatment choice in unresectable, early/intermediate stage HCC

Andrew Moon[1], Daniel Richardson[1], Donna Evon[1], Hanna Sanoff[1], Jessica Carda-Auten[1], Myra Waheed[1], Gabrielle Ritaccio[1], Jamie Conklin[1], Ethan Basch[1], David Mauro[1], Ted Yanagihara[1], David Gerber[2], Neil Shah[1], Oren Fix[1], Tammy Triglianos[1], Jonathan Sorah[1], Jingquan Jia[1], Ashwin Somasundaram[1], A. Sidney Barritt, IV[1]. *[1]University of North Carolina, Chapel Hill, United States; [2]University of Cincinnati, Cincinnati, United States*
Email: andrew.moon@unchealth.unc.edu

Background and aims: The treatment landscape for early/intermediate stage hepatocellular carcinoma (HCC) is rapidly evolving. Discrete choice experiments (DCE) are preference-elicitation tools that can assess patients' willingness to accept therapeutic risks and inconvenience associated with treatments. We performed a mixed-methods study to identify common and important treatment attributes for inclusion in a DCE for treatment choice in unresectable, early/intermediate stage HCC.

Method: Potential attributes (i.e., treatment characteristics) and attribute levels (i.e., categories of each characteristic) for inclusion in the DCE were identified through (1) patient interviews, (2) clinician interviews, and (3) a scoping review. Interviews of patients and clinicians recruited from a large health system were recorded, transcribed, imported into Dedoose V1.2 and analysed by trained qualitative researchers using code-based thematic analysis. A scoping review was performed of studies that (1) assessed the role of preference elicitation tools for HCC treatment options and (2) included a study population of patients, caregivers and/or clinicians. We searched PubMed, EMBASE, Scopus and Cochrane Library databases for articles published before August 18, 2022 and extracted potential treatment attributes from each included study. Based on these qualitative interviews and scoping reviews, study investigators chose potential attributes and levels that were non-overlapping and relevant to treatment decisions in unresectable, early/intermediate stage HCC.

Results: Qualitative interviews involved 30 patients with HCC (13% BCLC-0, 40% BCLC-A, 33% BCLC-B, 10% BCLC-C, 10% BCLC-D) and 10 clinicians (physicians and nurse practitioners) who cared patients with HCC with representation from medical oncology, hepatology, interventional radiology, radiation oncology and transplant surgery. Based on the qualitative interviews and scoping review, we identified five attributes and levels for inclusion in a DCE: 1) overall survival beyond 3 years (0, 3, 6 months), 2) post-treatment physical function (unchanged, some assistance with daily function, bedbound), 3) short-term treatment-related side effects, such as abdominal pain, nausea and fatigue (mild, moderate requiring medications, severe requiring hospitalization), 4) likelihood of developing worsening liver function over 1 year (10%, 30%, 50%), and 5) duration of treatment (one-time outpatient treatment, few outpatient treatments over 1–2 weeks, ongoing treatments every 3–4 weeks).

Conclusion: This mixed-methods research revealed non-overlapping attributes relevant to treatment decisions in unresectable early/intermediate stage HCC for inclusion in a DCE. Use of this DCE will be used to help better understand tradeoffs between treatment options for HCC and inform patient-centered treatment development.

Email: bernardo.stefanini@gmail.com

Background and aims: Atezolizumab/bevacizumab (A+B) is the recommended first-line treatment for HCC, irrespective of the etiology of the underlying liver disease. Preclinical models showed that only intrahepatic HCC arising in mice with MASLD was less responsive to A + B, while subcutaneous tumor had a decent response, likely related to a higher proportion of exhausted T-cells being recruited in the intrahepatic lesions. Since HCC can progress with different patterns, we aimed to verify whether MASLD etiology had an impact on the pattern of progression to A + B.

Method: Multicenter study including consecutive patients with non-resectable HCC patients from the ARTE database. Patterns of progression were defined as previously proposed by Reig et al: intrahepatic/extrahepatic growth of pre-existing lesions (IHG and EHG, respectively) new intrahepatic/extrahepatic lesions (NIHL, NEHL), new vascular invasion (NVI). A Kaplan-Meier survival analysis was performed to verify whether patients with MASLD were at increased risk of specific patterns of progression.

Results: A total of 202 patients were included. Single-etiology MASLD was the cause of HCC in 46 patients (22.8%). MASLD patients were similar to controls in terms of macrovascular invasion, AFP >400, Child-Pugh Class, ALBI grade, and ECOG. Median OS of MASLD-HCC patients was similar to non-MASLD group (20.6 months vs 14.4, p = 0.084), whereas PFS was longer for non-metabolic HCC (11.6 vs 4.5 months, p = 0.006).

HCC patients with MASLD had a significantly increased risk of progressing both for IHG (HR 2.20 CI 95% 1.32–3.69, p = 0.003). Conversely, the risk of developing progression due to NVI, EHG or NEHL was similar across the etiology groups.

Conclusion: Patients with MASLD-HCC were more likely to develop an intrahepatic progression than non-MASLD patients, confirming preclinical data and suggesting biologic differences between tumors arising from different etiologies with potential implications in terms of clinical management.

External beam radiotherapy promotes contralateral liver regeneration in primary liver cancer

Ying Zhao[1], Bin Shu[2], Guangxin Li[2], Hongxuan Li[2], Liuqing Yang[2], Lizhi Xu[2], Xiaomao Yu[2], Qiang Li[2], Gong Li[2], Shizhong Yang[2], Jiahong Dong[2]. *[1]Beijing Tsinghua Changgung Hospital, School of Clinical Medicine, Tsinghua University, Beijing, China; [2]Beijing Tsinghua Changgung Hospital, Beijing, China*
Email: zy132829@126.com

Background and aims: Inadequate future liver remnant (FLR) is a contraindication of hepatectomy for primary liver cancer (PLC). Yttrium-90 transarterial radioembolization has been shown to promote FLR hypertrophy, but it is unknown whether external beam radiotherapy has a similar effect. This study aimed to explore whether radiotherapy could promote non-irradiated contralateral liver regeneration and identify the influencing factors of liver regeneration after radiotherapy.

Method: Between June 2018 and December 2022, patients with PLC who had accomplished radiotherapy were eligible for the study. The included patients had an eligibility scan (CT or MRI of the abdomen) <1 month before radiotherapy and <6 months after the end of radiotherapy. FLR was calculated before and again after radiotherapy in patients by the IQQA® –3D Liver System software from enhanced CT images. Independent predictors of contralateral liver regeneration (p value <0.05) were identified by the Logistic proportional hazards regression model.

Results: 179 patients (predominantly Barcelona Clinic Liver Cancer stage C) were enrolled in the final analysis, and 151 patients (84.4%) experienced significant contralateral FLR hypertrophy. Median FLR hypertrophy after radiotherapy was 11.4% (IQR: 3.2%–23.5%). In addition, 61 patients (34.1%) in the high FLR group had an FLR hypertrophy exceeding 20%. By analyzing patient-related factors, tumor-related factors, and treatment-related factors, we found that increasing FLR was more likely to be achieved when the interval to response assessment ≤3 Months. Compared with the patients who received a low dosage of radiotherapy, those receiving a medium to high dosage of radiotherapy (>48 Gy) had more significant FLR hypertrophy. Multivariate logistic regression analysis showed that radiotherapy dosage (OR = 0.089, 95%CI: 0.038~0.211, p < 0.01) and the interval to response assessment (OR = 2.422, 95%CI: 1.127~5.205, p = 0.023) were significantly different between the high FLR group and the low FLR group, which were independent risk factors for contralateral liver regeneration after radiotherapy. Moreover, 22 patients (31.0%) after radiotherapy underwent surgical resection among 71 patients (China liver cancer staging system CNLC stage I-IIIa) with inadequate FLR, median FLR hypertrophy was 17.7% (IQR:2.1%-43.4%).

Conclusion: This study demonstrates a substantial increase in FLR after radiotherapy and identifies independent predictors. Some PLC patients with inadequate FLR can achieve hepatectomy after radiotherapy. Therefore, external beam radiotherapy deserves further exploration as a non-invasive means of promoting non-irradiated contralateral liver regeneration.

SAT-479-YI

Lower frequency of PNPLA3 in african populations and divergent associations with hepatocellular carcinoma

Email: chotiprasidhi.perapa@mayo.edu

Background and aims: Hepatocellular carcinoma (HCC) ranks as the third leading cause of cancer-related deaths globally. A single nucleotide polymorphism (SNP) in patatin-like phospholipase domain-containing protein 3 (*PNPLA3*), rs738409, has been associated with HCC development in European and East Asian populations. However, the relevance of this SNP remains unexplored in African populations. Africa contains the most genetically and phenotypically diverse population and has the highest burden of HCC worldwide. Our study aimed to assess, for the first time, the association of *PNPLA3* with HCC in West Africa in two geographically and ethnically diverse populations, comparing it to European-descent Americans.
Method: We enrolled 363 patients diagnosed with HCC through pathology and/or radiology reports from a predominantly European descent population in the United States (n = 241), and from Ghana (n = 79), and Nigeria (n = 43). Controls comprised 2, 817 cancer-free patients from the same sites: United States (n = 2409), Ghana (n = 323), and Nigeria (n = 85). We performed whole-exome sequencing (Exome+, Helix, Inc.) and extracted data on *PNPLA3*-rs738409 for analyses. Prevalence of *PNPLA3*-rs738409 was compared using Chi-square test, odds ratios (OR), and 95% confidence intervals (CI).
Results: In the United States population, there was a significant association between *PNPLA3*-rs738409 (G) and HCC risk, with OR for CG/GG *vs*. CC of 2.68 (CI: 2.03–3.56, p < 0.0001), and with risk allele frequency of 0.46. However, we did not find a significant association between *PNPLA3*-rs738409 and HCC risk in combined West African samples (OR = 1.11, CI: 0.69–1.83, p = 0.33), with overall risk allele frequency of 0.12. When the West African samples were examined separately, we found a striking difference in the pattern of association. The Nigerian population demonstrated a strong trend toward an association between *PNPLA3*-rs738409 and HCC risk (OR = 1.87, CI: 0.77–4.35, p = 0.073), with risk allele frequency of 0.17, while the Ghanaian sample did not show this trend (OR = 0.82, CI: 0.44–1.52, p = 0.27), with a much lower risk allele frequency of 0.09.
Conclusion: Our study indicates a much lower *PNPLA3* minor allele frequency in West Africans from Ghana and Nigeria as compared to European Americans. Furthermore, there were different trends in the association between *PNPLA3* and HCC within Africans, with only the Nigerian population showing the trend toward elevated risk. These findings highlight the genomic heterogeneity of the African continent, emphasizing the importance of population diversity in future studies and the need for global multi-ethnic genetic association studies to reduce disparities in the clinical application of genetic test results in HCC.

SAT-480-YI
Comparative performance of GAAD and ASAP scores in predicting early-stage hepatocellular carcinoma

Chongkonrat Maneenil[1], Piraya Tantisaranon[1], Pimsiri Sripongpun[1], Naichaya Chamroonkul[1], Maseetoh Samaeng[1], Roongrueng Jarumanokul[1], Lalita Fonghoi[1], Amornkan Numit[1], Teerha Piratvisuth[1], Apichat Kaewdech[1,1]. [1]*Prince of Songkla University, Hatyai, Thailand*
Email: apichatka@hotmail.com

Background and Aims: The GAAD score, which includes age, gender, and two tumor markers (alpha-fetoprotein [AFP] and PIVKA-II), has been recently proposed for predicting hepatocellular carcinoma (HCC). It shows comparable performance to the established GALAD score, despite omitting AFP-L3. However, no studies have compared the GAAD score with the ASAP score, which employs similar parameters but utilizes different assays and formulas. Our aim was to assess the performance differences between these two scores.
Methods: We prospectively collected blood samples from treatment-naïve HCC patients and non-HCC chronic liver disease (CLD) patients at a gastroenterology outpatient clinic from April 20, 2023, to December 31, 2023. ASAP and GAAD scores were calculated using AFP and PIVKA-II assays from Abbott and Roche, respectively, with cutoffs set at 0.5256 for ASAP and 2.57 for GAAD. Diagnoses of HCC were confirmed following EASL or AASLD guidelines.
Results: Our cohort of 651 patients had a median age of 63 (interquartile range [IQR] 56–70) years; 58.8% were male, and 69.7% presented with cirrhosis. A total of 174 patients (26.7%) had HCC, with 47.7% in early stages (BCLC stage 0 = 23, A = 60). The leading cause of HCC was hepatitis B virus (HBV) infection (41.4%), followed by metabolic associated steatohepatitis liver disease (MASLD) (20.7%) and hepatitis C virus (HCV) infection (18.4%). The area under the receiver operating characteristic curves (AUROCs) for predicting all stages of HCC were 0.9262 for ASAP and 0.9312 for GAAD (p = 0.5261). For early stages, the AUROCs were 0.8985 for ASAP and 0.8718 for GAAD (p = 0.011), respectively. ASAP's sensitivity for detecting all-stage HCC was 88.7% with a specificity of 81.7%, while GAAD's sensitivity was 82.5% with a specificity of 89.6%. For early-stage HCC detection, ASAP's sensitivity reached 98.9% with a specificity of 21.7%. Additionally, GAAD's sensitivity for early-stage detection was 96.7% with a specificity of 32.5%.
Conclusion: The GAAD and ASAP scores both demonstrated excellent and comparable abilities in detecting all-stage HCC. However, the ASAP score exhibited superior performance in identifying early-stage HCC.

SAT-481-YI
Improved handling of BCLC 2022 update in the management of hepatocellular carcinoma in clinical practice

Eleonora Alimenti[1], Massimo Iavarone[1], Lorenzo Canova[1], Mariangela Bruccoleri[1], Barbara Antonelli[2], Anna Maria Ierardi[3], Angelo Sangiovanni[1], Pietro Lampertico[1,4]. [1]*Division of Gastroenterology and Hepatology, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy;* [2]*General and Liver Transplant Surgery Unit, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy;* [3]*Radiology Department, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy;* [4]*CRC "A. M. and A. Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy*
Email: eleonoralimenti@gmail.com

Background and aims: In 2022 the BCLC staging and treatment algorithm for hepatocellular carcinoma (HCC) management has been updated, granting for higher flexibility and customized management with a multidisciplinary decision process in the choice of the

therapeutic strategy for HCC patients as compared to the 2018 version. To evaluate the ability to adhere to BCLC 2022 in daily clinical practice as compared to the BCLC 2018 and the impact on patients' overall survival (OS).

Method: We retrospectively evaluated data of 806 prospectively enrolled (year 2006 to 2022) patients with de novo HCC in different stages according to BCLC: 571 0-A, 133 B, 85 C and 17. First line treatment allocations were discussed by a multidisciplinary team (MTD), following updated recommendations and guidelines. All patients were followed until death or end of follow-up.

Results: Overall, the adherence to BCLC increased from 50% for the BCLC 2018 to 68% for the BCLC 2022 ($p < 0.001$) considering all stages of HCC: 48% vs 71% stage 0/A ($p < 0.001$), 50% vs 61% stage B ($p = 0.06$), 59% vs 59% stage C ($p = NS$), 74% vs 74% for stage D ($p = NS$). Among BCLC 0/A patients, 131 (32%) were treated with TACE, which is the second choice of treatment according to BCLC 2022, while among BCLC B patients, 5 (6%) underwent LT and 10 (12%) were treated with systemic therapy, which are now considered treatment options for this stage in selected patients. The expected survival rate following the BCLC 2018 recommendations remains unchanged even by adhering to the BCLC 2022 update [74.5% vs 75.2% at year 2 ($p = NS$) and 41.4% vs 44.6% at year 5 ($p = NS$), respectively]. Finally, the rate of "upward stage migration" was similar by BCLC 2022 or BCLC 2018 (12% vs 14%, $p = ns$), while the rate of "downward stage migration" was lower with the new one (19% vs 36%, $p < 0.001$). Overall, the 2-year survival rate of patients treated outside the BCLC 2022 recommendations did not significantly differ from those treated according to the updated algorithm (76% vs 74.5%, $p = NS$). In BCLC B and BCLC C, an upward stage migration was associated to higher rates of 2-year survival (93.5% vs 60.6%, $p = 0.002$ for BCLC B and 36.9% vs 27.4%, $p = 0.01$ for BCLC C), while there was no difference for stage 0/A between those treated outside and those treated according to the BCLC 2022.

Conclusion: The BCLC 2022 updated version of HCC staging and treatment system allowed a greater adherence to the algorithm in clinical practice, mainly in the early stages, without adversely affecting the survival of patients. In the intermediate and advanced stages, the access to more radical treatment could offer a survival benefit.

SAT-482

A modified Charlson comorbidity index to improve management of patients with hepatocellular carcinoma: a step towards precision medicine

Eleonora Alimenti[1], Massimo Iavarone[1], Lorenzo Canova[1], Elia Fracas[1], Barbara Antonelli[2], Anna Maria Ierardi[3], Silvia Crespi[3], Arianna Zefelippo[2], Angelo Sangiovanni[1], Pietro Lampertico[1,4].
[1]Division of Gastroenterology and Hepatology, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]General and Liver Transplant Surgery Unit, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [3]Radiology Department, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [4]CRC "A. M. and A. Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy
Email: eleonoralimenti@gmail.com

Background and aims: Patients with hepatocellular carcinoma (HCC) frequently have comorbidities that limit access to treatments and might increase mortality. The Charlson comorbidity index (CCI) assigns a numeric score to 17 diseases according to their effect on mortality. In patients with cirrhosis and HCC, these variables might be excluded from the CCI (modified CCI, mCCI). Aim of the study was to evaluate the performance of CCI and mCCI for HCC patients' characterization.

Method: We used data from our retrospective monocentric study of patients with first HCC diagnosis. We evaluated the performance of CCI and mCCI in dissecting our population and predicting overall survival (OS). As secondary end point, the impact of mCCI on adherence to Barcelona Clinic Liver Cancer (BCLC) staging and treatment allocation was evaluated.

Results: The study included 385 patients (289 males, 68 years median age, 78% Child Pugh (CPT) A, 66% viral etiology) with HCC (271 BCLC 0/A, 64 B, 40 C and 10 D). According to CCI, 94% of our patients were "high-risk" (CCI≥5), 5.7% "intermediate-risk" (CCI 3–4) and 0.3% "low-risk" (CCI 0–2). These cutoffs were applied to mCCI: 21% "high-risk," 48% "intermediate-risk," and 31% "low-risk." Patients' mCCI correlated with CCI (Kendall's $\tau = 0.47$; p value <0.0001). Overall, patients belonging to a "high" or "intermediate-risk" mCCI classes had a shorter OS as compared to "low-risk" patients (median OS 37 vs 49 vs 67 months, p value = 0.007). This was confirmed in BCLC 0/A (p value = 0.002). Moreover, "high-risk" mCCI class, worse CPT class, presence of varices, BCLC stage and AFP >200 ng/ml were independently associated to mortality [HR1.36 (95% CI 1.09–1.70, p value = 0.006; HR1.62 (95%CI 1.14–2.30), p value = 0.007; HR1.58 (95%CI 1.11–2.24), p value = 0.01; HR1.96 (95%CI 1.66–2.31) p value <0.001; HR1.80 (1.17–2.79) p value = 0.008]. mCCI was also an independent predictor of mortality in BCLC 0/A, with higher tumor burden and worse CPT. No differences were observed in adherence to BCLC2022 algorithm and access to treatment among the mCCI risk classes.

Conclusion: mCCI better stratified patients with HCC as compared to CCI and independently predicted mortality. Implementation of a multiparametric therapeutic approach to treatment allocation including evaluation of comorbidities and frailty is warranted.

SAT-483-YI

The impact of competing risk bias in prognostic models for hepatocellular carcinoma in patients with cirrhosis

Laura Burke[1,2], Jessica Shearer[1], Vincent Haghnejad[2,3,4], Rebecca L. Jones[1], James Ferguson[5], Richard Parker[1], Ian Rowe[1,2].
[1]Leeds Liver Unit, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; [2]Leeds Institute for Medical Research, University of Leeds, Leeds, United Kingdom; [3]Department of Hepatology and Gastroenterology, University Hospital of Nancy, Nancy, France; [4]Faculty of Medicine of Nancy, University of Lorraine, Nancy, France; [5]Queen Elizabeth Hospital, University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom
Email: laura.burke1@nhs.net

Background and aims: Hepatocellular carcinoma (HCC) risk prediction models may provide a more personalised approach to HCC surveillance in patients with cirrhosis. Existing models do not account for competing risk events and may overestimate the probability of HCC. We aimed to demonstrate the impact of considering competing risk when estimating the cumulative incidence of HCC in a contemporary cohort of patients with cirrhosis from the United Kingdom (UK).

Method: Data were collected from consecutive patients undergoing transient elastography (TE) from 2 UK teaching hospitals between 2008 and 2019. Patients with a liver stiffness measurement (LSM) >10 kPa were included. Electronic health records were analysed to identify clinical events including decompensation, HCC and non-HCC related death. Two HCC prognostic models were developed: (1) a Cox regression model (Cox) ignoring competing risk events and (2) a Fine-Gray regression model (FGR) accounting for non-HCC mortality and decompensation as a competing risk. The same predictors (age, sex, albumin and platelets) were used in both models and were chosen based on well-established outcome associations. The 3-year probability of HCC was calculated for each patient using both models and the predicted risks compared.

Results: A total of 3028 patients (56% metabolic associated steatotic liver disease, 16% viral hepatitis, 15% alcohol related liver disease, 14% other) were included. The total follow-up was 9403 patient years with median per patient follow-up of 3.1 years. 75 patients developed HCC and 411 competing risk events (decompensation and non- HCC deaths) were observed. The mean predicted 3-year probability of HCC

for the Cox and FGR model was 1.89% and 1.27% respectively. The majority of patients (58.8%) had a difference in predicted 3-year HCC probability of >0.3% with a mean absolute difference of 0.99%. 13.5% of patients had a large discrepancy (>2%) between model predictions. A Bland-Altman plot indicates substantial disagreement between the model predictions with the disagreement increasing as HCC risk increases. 1517 patients had FIB-4 scores >1.3 and LSM >15 kPa or platelets $<150 \times 10^9$/L and would typically be considered for HCC surveillance. Applying a 1.5% annual risk threshold for HCC surveillance, the Cox model identified 260 (17.1%) patients meeting the threshold for surveillance. In contrast, the FGR model identified only 99 (6.5%) patients who met the threshold risk level, a reduction in patients requiring surveillance of 62%.

Conclusion: HCC prognostic models that ignore competing risk events overestimate the probability of developing HCC and therefore reduce their clinical utility. Decompensation has been overlooked as a 'competing risk', but its impact on HCC treatment and liver related mortality before HCC develops is substantial and should be accounted for in model development and validation.

SAT-484

Conventional and machine-learning based risk score on survival for patients with hepatocellular carcinoma

Chun-Ting Ho[1], Chien-Wei Su[2,3,4], Elise Chia-Hui Tan[5], Yi-Hsiang Huang[3,6], Ming-Chih Hou[3,6], Jaw-Ching Wu[7]. *[1]Taipei Veterans General Hospital, Taipei, Taiwan; [2]Department of General Medicine, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan; [3]Division of Gastroenterology and Hepatology, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan; [4]School of Medicine, College of Medicine, National Yang Ming Chiao Tung University, Taipei, Taiwan; [5]Department of Health Service Administration, College of Public Health, China Medical University, Taichung, Taiwan; [6]School of Medicine, College of Medicine, National Yang Ming Chiao Tung University, Taipei, Taiwan; [7]Institute of Clinical Medicine, School of Medicine, National Yang Ming Chiao Tung University, Taipei, Taiwan*
Email: cwsu2@vghtpe.gov.tw

Background and aims: To evaluate the prognostic predictability of non-invasive biomarkers and develop a machine-learning (ML)-based risk score using conventional methods and machine-learning (ML) to categorize HCC patients into distinct prognostic groups.

Method: A total of 4038 HCC patients from BCLC stage 0 to D diagnosed at Taipei Veterans General Hospital from 2012 to 2023 were retrospectively enrolled in the study. The patients were divided into training cohort (n = 2827) and validating cohort (n = 1211) randomly. The primary end point was overall survival (OS). Non-invasive biomarkers, obtained through blood sample and image at diagnosis, were analyzed by both conventional method (Cox proportional hazards model) and ML-based method (LASSO Cox regression) to determine their prognostic predictability. In the training cohort, factors showing significance in both conventional method and ML-based method were enrolled in the ML-based risk score. The risk score was computed by utilizing coefficients from the Multivariate Cox proportional hazard model and were standardized to a score ranging from 0 to 100. Patients were than categorized into three risk groups (high, medium, and low risk) based on the 33rd and 66th percentiles. The risk score's efficacy was subsequently validated in the validation cohort.

Results: After a median follow-up of 42.0 months (interquartile range IQR 33.6–50.4 months), 1931 patients died, and the 5-year OS rate was 26.0%. Both conventional and ML-based method identified the same 11 factors as significant predictors (Age, curative treatment, extrahepatic metastasis, maximum tumor size, serum albumin, serum creatinine, serum bilirubin, serum aspartate aminotransferase (AST), Lymphocyte-to-monocyte ratio (LMR), albumin bilirubin (ALBI) grade and alpha fetoprotein (AFP) level). The risk score developed accordingly demonstrated excellent predictive ability for patients' overall survival (AUC = 0.800) and showed outstanding predictability for survival within the first five years post-diagnosis (AUC: 0.873 to 0.890). Furthermore, the ML-based risk score can efficiently stratify patients into three different risk groups with significant difference on overall survival ($p < 0.001$).

Conclusion: The ML-based risk score, derived from non-invasive biomarkers through conventional and ML-based methods, can effectively stratify HCC patients into different prognostic groups and aid clinicians in personalized disease management.

SAT-485

Utility of the GAAD algorithm in the screening of hepatocellular carcinoma in a prospective cohort of at-risk patients: preliminary results

Emily Larrea[1], Gemma Serrano[1], Gloria Ruiz-Fernández[1], Eva Marín[1], Joaquín Poza[1], Marta Abadía[1], Clara Amiama[1], Irene González-Díaz[1], Carmen Amor[1], Paula Torrijos[1], Rafael Gayoso[1], José Carlos Erdozaín[1], María Sánchez-Azofra[1], Marta Cuadros[1], Patricia Mayor[1], Yolanda Zarauza[1], Rubén Fernández-Martos[1], Alberto Cerpa[1], Pilar Castillo[1], Miriam Romero[1], Araceli García-Sánchez[1], Francisco Javier Garcia-Samaniego[1], Susana Cano[1], Verónica Ucle[1], Sonia Álvarez[1], Mariana Serrés[1], María Sanz de Pedro[1], Antonio Buño[1], Antonio Olveira[1]. *[1]La Paz University Hospital, Madrid, Spain*
Email: aolveiram@gmail.com

Background and aims: The current European Association for the Study of the Liver (EASL) Clinical Guideline recommends hepatocellular carcinoma (HCC) screening through semiannual ultrasound in at-risk patients and considers adding biomarkers determination such as alpha-fetoprotein (AFP) suboptimal. There is a need to improve the performance and efficiency of screening programs. The GAAD algorithm (Gender, Age, AFP, and Des-gamma-carboxyprothrombin [DCP]) shows excellent results in HCC diagnosis, with a performance >90%. There are no studies on its utility in screening.

Method: Prospective longitudinal study still in the recruitment phase. Patients were under HCC screening program according to the 2018 EASL risk recommendations. Semiannual ultrasound (Canon Aplio i800) and simultaneous determination (Cobas E 601) of AFP, and DCP (also known as PIVKA-II [prothrombin induced by vitamin K absence-II]) were performed with subsequent calculation of Elecsys GAAD (Roche Dialog. Normal value ≤2.57; range 0–10). Ultrasound (US) findings and exploration quality were categorized according to Liver Imaging Reporting and Data System (LI-RADS) 2018. In short, patient's follow-up was conducted semiannually if US-1 (negative: no suspicious lesions) and GAAD ≤2.57; quarterly if US-2 (subthreshold: suspicious nodule <1 cm) or GAAD >2.57; and they were studied by computed tomography scan and/or magnetic resonance imaging if US-3 (positive: suspicious nodule >1 cm). The diagnosis of HCC was made according to the 2018 EASL Guideline and the disease classified as per Barcelona Clinic Liver Cancer (BCLC). Patients on warfarin or other causes of vitamin K deficiency and those in Child Pugh stage C (except if transplant candidate) were excluded.

Results: Between February and October 2023, 378 patients were included: 63 years old, 70% male, 81.5% cirrhosis, 19.5% non-cirrhotic with chronic hepatitis B ± chronic hepatitis D according to PAGE B screening criteria. The liver disease follow-up time was 8 years (interquartile range 3.9–12), 67.6% with inactive liver disease, platelets 161.000/ml, ALT 28 IU/L. 23.1% of the patients presented US-2 or US-3 categories, and 29.6% had moderate or severe limitations for ultrasound exploration. The GAAD index was >2.57 in 18.7%. 3 patients with HCC have been diagnosed (1 BCLC 0, 2 BCLC A). In these 3 patients, the GAAD index was elevated (5.94, 2.9, 4.75), while AFP values (upper normal limit <8 ng/ml) were 10.27, 2.75, and 2.22, respectively.

Conclusion: Our preliminary results suggest a high sensitivity of the GAAD algorithm in the screening of hepatocellular carcinoma in an at-risk population.

SAT-486

High SAFE scores stratify high risks of hepatocellular carcinoma in patients with chronic liver diseases

Tung-Hung Su[1], Sheng-Shun Yang[2], Wei-Yu Kao[3], Shang-Chin Huang[1], Fen-Fang Chen[1], Francis Poon[2], Lung-Wen Tsai[3], Che Lin[4], Weichung Wang[4], W. Ray Kim[5], Jia-Horng Kao[1]. *[1]National Taiwan University Hospital, Taipei, Taiwan; [2]Taichung Veterans General Hospital, Taichung, Taiwan; [3]Taipei Medical University Hospital, Taipei, Taiwan; [4]National Taiwan University, Taipei, Taiwan; [5]Stanford University School of Medicine, Stanford, United States*
Email: kaojh@ntu.edu.tw

Background and aims: Hepatocellular carcinoma (HCC) surveillance is recommended for high-risk individuals. Indicators of HCC risk to guide surveillance are lacking, especially for chronic liver diseases (CLD) from non-viral etiologies, including non-alcoholic fatty liver disease (NAFLD) and alcohol-related liver disease. The Steatosis-Associated Fibrosis Estimator (SAFE) score was developed to correlate with liver fibrosis in patients with NAFLD. This study explores the role of the SAFE score as a predictor for HCC in CLD.
Method: In this retrospective cohort study, electronic medical records from a tertiary medical center in Taiwan were used to extract data from patients with various CLDs. The SAFE score, consisting of age, BMI, diabetes, and laboratory data, was calculated using the published formula. Statistical analysis assessed the score's performance in predicting HCC risk in the data set and independent external validation sets.
Results: The primary analysis included 12, 963 CLD patients with a median follow-up of 4 years, during which 258 developed HCC. The SAFE score correlated with 1, 3, and 5-year HCC risk regardless of liver disease etiologies. High (≥100) and intermediate (0–100) SAFE scores increased HCC risk by 11 and 2 folds, respectively, compared to low (<0) SAFE scores. When lower risk tiers were combined, a high SAFE score (≥100) was associated with a 7-fold increased risk of HCC (adjusted hazard ratio [aHR]: 7.28, 95% confidence interval (CI): 5.19–10.21) compared to SAFE <100. Data in the external validation sets of 8, 103 CLD patients recapitulated the difference (aHR: 7.33, 95%CI: 4.70–11.43).
Conclusion: The SAFE score is a significant predictor of HCC risk in patients with diverse chronic liver diseases and may play a role in selecting candidates for surveillance and early detection of HCC.

SAT-487-YI

Time-trends in cholangiocarcinoma mortality-a danish nationwide cohort study

Morten Daniel Jensen[1,2], Joe West[2,3,4], Frank Viborg Mortensen[2,5], Peter Jepsen[1,2,6]. *[1]Department of Hepatology and Gastroenterology, Aarhus University Hospital, Aarhus, Denmark; [2]Department of Clinical Medicine, Aarhus University, Aarhus, Denmark; [3]Lifespan and Population Health, School of Medicine, University of Nottingham, NG5 1Pb, Nottingham, United Kingdom; [4]NIHR Nottingham Biomedical Research Centre (BRC), Nottingham University Hospitals NHS Trust and the University of Nottingham, Nottingham, United Kingdom; [5]Department of Surgical Gastroenterology, Aarhus University Hospital, Aarhus, Denmark; [6]Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark*
Email: moje@clin.au.dk

Background and aims: Cholangiocarcinomas (CCA) have a poor prognosis and the incidence of CCA is rising in Denmark. We set out to examine time trends in mortality of CCA in a nationwide Danish cohort.
Method: We included all 3, 484 Danish patients with a diagnosis of CCA (ICD-10 codes C22.1, C24.0, C24.8, C24.9) in 1999–2019 recorded in both the Danish Cancer Registry and the National Patient Registry. We computed 1-year mortality and used Cox regression to estimate adjusted mortality hazard ratios (HR) by sex, age, year of diagnosis and type of CCA.
Results: Of the 3, 484 CCA patients, 47% were men. The median age of patients diagnosed in 1999 was 73 vs. 71 in 2019. The 1-year mortality decreased between 1999 and 2019 from 76.6% (95% CI 68.9–83.6) in 1999 to 69.5% (63.6–75.2) in 2019, while 1-year mortality for the entire period was 71.7% (70.2–73.2). The 1-year mortality was: for 18–59-year-olds 56.2% (52.4–60.0), for 60–79-year-olds 70.3% (68.4–72.3), for patients over 80 years 88.6% (86.2–90.8), for intrahepatic CCA (iCCA) 71.0% (68.5–73.5), for extrahepatic CCA (eCCA) 66.5% (63.9–69.0), for unspecified CCA 80.5% (77.8–83.0), for females 72.9% (70.8–74.9), and for males 70.4% (68.2–72.6). For year of diagnosis, adjusted mortality HRs decreased with more recent diagnosis year in all age and sex groups and for both iCCA and eCCA. Adjusted HRs of 5-year increase in diagnosis year were: overall 0.90 (0.87–0.92), for 18–59-year-olds 0.87 (0.81–0.93), for 60–79-year-olds 0.90 (0.87–0.94), for patients over 80 years 0.91 (0.85–0.97), for patients with iCCA 0.86 (0.82–0.91), for patients with eCCA 0.89 (0.85–0.93), for females 0.91 (0.87–0.95), and for males 0.89 (0.85–0.93); while for unspecified CCA it was 0.98 (0.92–1.05).
Conclusion: The 1-year mortality of Danish patients diagnosed with CCA in 2019 was 69.5%, but it has decreased since 1999, overall and within subgroups defined by sex, age, or type of CCA.

SAT-490

Competitive risk analysis of spleen stiffness measurement with a spleen-dedicated module (SSM@100 Hz) for predicting de-novo HCC occurrence in cACLD patients: a prospective 5-year follow-up study

Federico Ravaioli[1], Luigi Colecchia[1], Elton Dajti[1], Amanda Vestito[1], Arianna Gobbato[1], Francesca Lami[2], Matteo Renzulli[1], Matteo Serenari[1], Lorenza Di Marco[2], Francesco Tovoli[1], Silvia Ferri[1], Alessandra Pivetti[2], Dante Romagnoli[2], Francesco Azzaroli[1], Davide Festi[1], Antonio Colecchia[2], Giovanni Marasco[1]. *[1]Department of Medical and Surgical Sciences (DIMEC), University of Bologna, Bologna, Italy; [2]Gastroenterology Unit, Department of Specialistic Medicines, University of Modena and Reggio Emilia, University Hospital of Modena and Reggio Emilia, Modena, Italy*
Email: f.ravaioli@unibo.it

Background and aims: Hepatocellular carcinoma (HCC) impact significantly the survival of patients with liver disease, and it has been shown that portal hypertension (PH) is a major contributor to its development. Notably, clinically significant portal hypertension (CSPH), as identified by HVPG, can predict the occurrence of HCC. To explore the potential of spleen stiffness measurement (SSM) as a predictor of HCC occurrence, particularly with the use of a new spleen-dedicated module (SSM@100 hz), we conducted a prospective study. Our investigation was aimed to determine whether SSM@100 hz could identify HCC occurrence in individuals with compensated advanced chronic liver disease (cACLD).
Method: We conducted a prospective study on patients who underwent paired laboratory exams, hepatic venous pressure gradient measurement (HVPG), liver stiffness measurement (LSM), and SSM@100 hz. Patients were followed as per the current international guidelines for HCC screening, and we assessed the occurrence of HCC or other complications related to liver disease. We used competing-risks regression analysis to account for liver transplantation or death as competitive events.
Results: We enrolled 69 patients with a median follow-up of 68 months until HCC or a competitive event occurrence. Competitive univariate statistical analysis showed how HCC occurrence was predicted by a higher body mass index (BMI), SSM median value (SSM@100 hz), HVPG, metabolic etiology, and combined Baveno VII single cut-off rule-in criteria (by SSM@100 hz). Further multivariate analysis was conducted, and two models were developed: one based on SSM@100 Hz and the other based on HVPG. The first one demonstrated that age (hazard ratio (HR): 0.947, 95% confidence interval (CI): (0.906–0.991), metabolic etiology (HR: 20.911 (5.349–77.54)) and higher liver stiffness values (HR: 1.04 (1.013–1.066)) were

independent factors for the development of HCC while the second one showed similar results for male sex (HR: 10.296 (1.824–58.1), etiology (HR: 18.35 (4.592–72.97) and HVPG (HR: 1.171 (1.021–1.344)). Competitive risk regression analysis demonstrated that both models can effectively predict the risk of HCC occurrence over time ($p < 0.001$ for both models).
Conclusion: SSM@100 hz, mirroring portal hypertension, can predict the de novo HCC occurrence in patients with cACLD with a median follow-up time of 5 years.

SAT-491
Assessing the relationship between human plasma metabolites and hepatocellular carcinoma: a two-sample Mendelian randomization analysis
Xi Wei[1], Ningning Zhang[1], Xuanchen Liu[1]. [1]*Tianjin Medical University Cancer Institute and Hospital, Tianjin, China*
Email: weixi@tmu.edu.cn

Background and aims: Plasma metabolites are small molecules that represent intermediate or final products in metabolic reactions. Their levels are influenced by a variety of factors, including genetics, gut microbiota, and diseases. Plasma metabolites can also affect disease risk. However, the relationship between plasma metabolites and hepatocellular carcinoma (HCC) is unclear. We utilized the Mendelian Randomization (MR) approach to assess the potential causal relationship between plasma metabolites and the risk of hepatocellular carcinoma.
Method: Genetic instrumental variables for serum metabolites were determined through genome-wide association studies (GWAS) of 1, 091 metabolites and 309 metabolite ratios in 8, 299 individuals from the Canadian Longitudinal Study on Aging (CLSA) cohort. Summary statistics for HCC (hepatocellular carcinoma) were drawn from a GWAS including 1, 866 cases and 195, 745 controls. We adopted the Inverse Variance Weighted (IVW) method as our primary analysis. We further employed MR Egger, Weighted Mode, and Weighted Median methods.
Results: We identifed suggestive associations between 24 plasma metabolites and the risk of HCC (odds ratio (OR): 1.18; $p = 0.015$ for 1-oleoyl-2-arachidonoyl-GPE (18:1/20:4); OR: 1.96; $p = 0.001$ for 1-palmitoleoyl-GPC (16:1); OR: 1.19; $p = 0.001$ for 1-palmitoyl-2-arachidonoyl-GPE (16:0/20:4); OR: 0.74; $p = 0.0046$ for 1-palmitoyl-2-linoleoyl-gpc (16:0/18:2); OR: 1.21; $p = 0.0038$ for 1-stearoyl-2-arachidonoyl-GPE (18:0/20:4); OR: 1.46;$p = 0.035$ for 1-stearoyl-GPE (18:0); OR:1.51; $p = 0.010$ for 1-stearoyl-GPG (18:0); OR: 1.29; $p = 0.035$ for 5alpha-pregnan-3beta, 20alpha-diol monosulfate (2); OR: 1.41; $p = 0.047$ for 1- (1-enyl-palmitoyl)-2-oleoyl-gpc (p-16:0/18:1); OR: 1.18; $p = 0.028$ for 1- (1-enyl-palmitoyl)-2-palmitoyl-GPC (P-16:0/16:0); OR: 0.76; $p = 0.034$ for 1- (1-enyl-stearoyl)-2-linoleoyl-GPE (p-18:0/18:2); OR: 1.45;$p = 0.048$ for Androstenediol (3alpha, 17alpha) monosulfate (3); OR: 1.33;$p = 0.041$ for Aspartate to mannose ratio; OR: 0.65; $p = 0.0010$ for Campestero; OR: 1.54; $p = 0.015$ for Carboxyethyl-gaba; OR: 1.16; $p = 0.02$ for Glycocholenate sulfate; OR: 1.22;$p = 0.018$ for N-acetyl-isoputreanine; OR: 1.15;$p = 0.039$ for Octadecadienedioate (C18:2-DC); OR:1.18; $p = 0.038$ for Octadecenedioate (C18:1-DC); OR: 2.41; $p = 0.011$ for Palmitoylcarnitine levels (Metabolon platform); OR: 1.25; $p = 0.041$ for Pregnenediol disulfate (C21H34O8S2); OR: 1.23; $p = 0.028$ for Sphingomyelin (d18:0/20:0, d16:0/22:0); OR: 1.52; $p = 0.039$ for Sphingomyelin (d18:1/22:1, d18:2/22:0, d16:1/24:1); OR: 1.63; $p = 0.012$ for Stearoylcarnitine; OR: 1.27; $p = 0.026$ for X-18922.
Conclusion: Our systematic analyses provide evidence to support a potential causal relationship between several plasma metabolites, and the risk of HCC. More studies are required to show how the plasma metabolites affects the development of HCC.

Email: j.abdelmalak30@gmail.com

Background and aims: Management of very-early and early-stage hepatocellular carcinoma (HCC) is complex with multiple treatment strategies available. There is a paucity of literature regarding variation in patterns of care and outcomes between transplant and non-transplant centres. We performed this real-world multi-centre cohort study in two large liver transplant centres and eight non-transplant tertiary HCC referral centres across Australia to assess for variation in patterns of care and key survival outcomes.
Method: Patients with Barcelona Clinic Liver Cancer (BCLC) 0/A HCC first diagnosed between 01/01/2016 and 31/12/2020 who were managed at a participating site were included in the study. Patients were excluded if they had a history of prior HCC or if they received upfront liver transplantation.
Results: A total of 887 patients were included in the study, with 433 patients managed at liver transplant centres and 454 patients managed at a non-transplant centre. After adjusting for key covariates (age, sex, diabetes, smoking, hepatitis B status, alcohol, Charlson Comorbidity Index, cirrhosis status, portal hypertension status, Child Pugh score, tumour burden category), patients managed at liver transplant centres were significantly more likely to receive trans-arterial chemoembolization (TACE) as initial treatment compared to non-liver transplant centres ($p = 0.010$) and were significantly more likely to receive liver transplantation during follow-up treatment ($p < 0.001$). After adjusting for the same key covariates using Cox-proportional hazards survival analysis, management at transplant centre was associated with improved overall survival (adjusted OR 0.704, 95%CI 0.508–0.975, $p = 0.035$) and liver-related survival (adjusted OR 0.672, 95%CI 0.461–0.978, $p = 0.038$) but similar transplant-free survival (adjusted OR 1.046, 95%CI 0.786–1.393, $p = 0.758$). Subgroup analyses of those who underwent resection and ablation alone demonstrated no significant difference in overall survival (adjusted OR 1.335, 95%CI 0.350–5.089, $p = 0.672$; and adjusted OR 0.596, 95%CI 0.235–1.509, $p = 0.275$ respectively.
Conclusion: Our study highlights systematic differences in HCC care between large volume transplant centres and other sites, with an associated improvement in overall survival, the key end point in early-stage HCC. Further work is needed to better define the reasons for differences in treatment allocation and to aim to standardise treatment decisions to maximise patient outcomes across Australia.

SAT-493-YI

ASAP score may predict HCC recurrence after complete radiological response to locoregional treatments

Lorenzo Canova[1], Massimo Iavarone[1], Eleonora Alimenti[1], Riccardo Perbellini[1], Sara Uceda Renteria[2], Roberta D'Ambrosio[1], Elisabetta Degasperi[1], Floriana Facchetti[1], Anna Maria Ierardi[3], Angelo Sangiovanni[1], Ferruccio Ceriotti[2], Pietro Lampertico[1,4]. *[1]Division of Gastroenterology and Hepatology, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]Clinical Laboratory, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [3]Radiology Department, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [4]CRC "A. M. and A. Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy*
Email: pietro.lampertico@unimi.it

Background and aims: Alpha fetoprotein (AFP) and prothrombin induced by vitamin K absence/antagonist II (PIVKA-II) are biomarkers for hepatocellular carcinoma (HCC), which have been extensively in the diagnosis of HCC, while their use in the prognosis prediction remains poorly assessed. Recently, a new algorithm (ASAP)-including age, gender, AFP and PIVKA-II-has been validated as an alternative to GALAD for prediction of HCC development with a cut-off of 0.52. The identification of predictors of HCC recurrence after curative treatment has always been relevant to patients' management, and now may have further utility with the arrival of adjuvant therapies.
The aim of our study was to evaluate the predictive role of AFP and PIVKA-II alone or combined in the ASAP score for HCC recurrence in patients who achieved a complete response (CR) after locoregional treatment.
Method: In this single-center, observational ongoing study, we have enrolled 156 consecutive patients with first diagnosis of HCC treated by ablation (MWTA) or chemoembolization (TACE). CR was evaluated by CT-scan 1 month after treatment, afterwards patients were evaluated every three months by CT-scan, clinical and biochemical features until recurrence, death or last follow-up. PIVKA-II and AFP levels were measured at the day of treatment by Fujirebio assays, Japan.
Results: 81 (52%) patients with HCC who achieved CR after the first treatment were included: median age 66 (40–87); 83% men, 57% HCV-positive, 91% Child-Pugh A, 85% BCLC 0/A, 53% MWTA. The day of treatment, the median AFP was 6.3 ng/ml (1.3–3, 537), median PIVKA-II was 112 (16–5, 090) mAU/ml, median ASAP score was 0.405 (–3.44–6.64; 47% with ASAP value >0.52). During follow-up, HCC recurred in 47 (58%) patients [median time to recurrence was 298 (41–1256) days after achieving CR]. PIVKA-II [HR 2.53 (95%CI 1.47–4.35), p = 0.001] and age [HR 1.03 (95%CI 1.00–1.07), p = 0.013] were the only independent predictors of overall HCC recurrence by a multivariable model for single variables only, while the ASAP score [HR 1.31 (95%CI 1.12–1.52), p < 0.001] was the only independent predictor of recurrence in a multivariable model including only scores and algorithms. PIVKA-II [HR 2.14 (95%CI 1.09–4.18), p = 0.026] was the only independent predictor of early recurrence in the first multivariable model, while platelet to lymphocyte ratio [PLR; HR 1.02 (95%CI 1.00–1.04)] and ASAP score [HR 1.30 (95%CI 1.03–1.64)] were independent predictors of early recurrence according to the second model. Adopting the ASAP cut-off of 0.52, the algorithm independently predicted HCC recurrence [HR 3.54 (95%CI 1.86–9.75), p < 0.001], but did not predict HCC early recurrence [HR 1.95 (95%CI 0.87–4.34), p = 0.103].
Conclusion: The ASAP algorithm may accurately predict HCC recurrence and early recurrence after complete radiological response, deserving further studies to refine the model.

SAT-494

Study on the impact of specific HCC histotypes on patients prognosis

Monica Bernasconi[1], Reha Akpinar[1,2], Camilla De Carlo[1], Barbara Durante[1], Angela Palmisano[1], Guido Costa[1], Guido Torzilli[1], Fabio Procopio[1], Luca Di Tommaso[1]. *[1]IRCCS Humanitas Research Hospital, Rozzano (Milano), Italy; [2]Department of Biomedical Sciences, Humanitas University, Pieve Emanuele, Italy*
Email: monica.bernasconi@humanitas.it

Background and aims: The 2021 WHO classification of tumors, 5th edition, describes the existence of eight hepatocellular carcinoma (HCC) subtypes [steatohepatitic (SH), clear cell (CC), macrotrabecular massive (MTM), scirrhous, chromophobe, fibrolamellar, neutrophil-rich and lymphocyte-rich (LR)] and suggests that some of these are associated with a better (CC- and LR) or worse (MTM and neutrophil-rich) prognosis. However, large series confirming these clinical features are lacking. The aim of our study is to verify, in a single institution experience, if different HCC histotypes correlate with specific clinico-pathological characteristics, i.e., with different prognoses.
Method: All the histopathological reports of HCC resected at Humanitas from 2005 to 2022 were reviewed. When the report referred to the presence of specific morphological aspects, all the slides of the case were reviewed and cases classified according to the histotypes proposed by WHO. For each case we evaluated for the presence and percentage of features suggestive of special histotypes. When these features exceeded 50% of the lesion, the case was considered as a special histotype. If the percentage did not exceed 50% of the lesion, the case was considered to have special aspects. For each case, morphological (necrosis, satellites, plurifocality, angioinvasion) and clinical data (DFS and OS) were obtained.
Results: The series included 567 HCCs; among them 152 were characterized by specific morphological aspects according to the histopathological report and were reviewed under the microscope. Special features were confirmed in 117 cases (117/567, 20%). In 35 of these cases, the steato-hepatitic areas were predominant (SH-HCC, 6%). Clear cell aspects represented the main component in 13 cases (CC-HCC, 2%). Macrotrabecular areas accounted for >50% of the lesion in 8 cases (MTM-HCC, 1.4%). Finally, we observed two cases with a dominant scirrhous component (<1%), one fibrolamellar HCC (<1%) and one lymphocyte-rich HCC (<1%). No cases with chromophobe or granulocyte-rich aspects were present. The co-existence of a specific histotype with other special features was observed in 16% of the series. At clinical level, MTM were most frequently associated with parameters presenting with greater aggressiveness (angioinvasion 81%, necrosis 36%, plurifocality 27%), as opposed to SH histotype lesions (angioinvasion 29%, necrosis 20%, purifocality 20%).
Conclusion: Our review, based on a large mono-institutional series, confirms that about 20% of HCC cases might present special features; that SH-, CC- and MTM- are the most frequent HCC histotypes; that MTM- HCC is associated with unfavorable morpho-pathological parameters. However, our analysis shows that no histotype correlates with a specific clinical behavior.

Email: pierce.chow@duke-nus.edu.sg

Background and aims: Hepatocellular carcinoma (HCC) is the 6th most commonly diagnosed cancer and the 3rd leading cause of cancer death worldwide. There is limited real-world data on clinical management practices in HCC, which is essential to guide future public health strategies. Our study aims to evaluate survival outcomes of HCC patients based on clinical and socio-economic factors, stratified by BCLC staging at diagnosis.
Method: The INSIGHT study (NCT03233360) was an investigator-initiated, multi-site longitudinal cohort study that collected information on patient demographics, clinical and socio-economic factors, HCC-directed therapy and outcomes from HCC patients of 9 Asia-Pacific countries [1]. Kaplan-Meier analyses of overall survival (OS) were run, stratified by BCLC staging at diagnosis, with differences between treatment groups assessed by log-rank test. Univariate and multiple Cox proportional hazards regression models with stratification were used to calculate un-adjusted and covariate-adjusted hazard ratios (HRs) and 95% CIs for treatment types and OS. Statistical significance was taken at $p < 0.05$. Data imputations were made for missing data for visits before the start of treatment. Analyses were performed using R (v 4.1.3).
Results: 2, 505 patients were analysed after excluding patients with missing death, last contact, last visit dates or wrong dates. Significant biological covariates included BMI, etiology, ALBI score, AFP level and presence of distant metastasis ($p < 0.05$). Education (university or higher) significantly influences OS in early HCC (HR = 0.36, 95% CI 0.14–0.94; BCLC 0 + A; HR = 0.35, 95% CI 0.13–0.94; BCLC B) after adjustment. Interesting, OS differed based on type of first-line treatment received, number of lines of treatment received and distance to hospital ($p < 0.05$) upon stratification. Patients that received liver resection as first line consistently demonstrated good OS across all stages compared to other treatment options like loco-regional and systemic therapies amongst others. Compared to BCLC B and C patients who received a single line of treatment, those who received 2 lines or more had better OS (HR = 0.44, 95% CI 0.26–0.75; BCLC B; HR = 0.45, 95% CI 0.33–0.61; BCLC C) after adjustment. To note, those who lived nearer to hospitals (<½ day) fared better than those who lived ½-1 day away ($p < 0.001$; BCLC 0 + A, $p = 0.01$; BCLC B, $p = 0.03$; BCLC C).
Conclusion: Survival outcomes of HCC depends highly on biological and socio-economic factors. Notably, our findings underscore the need to consider socio-economic factors like distance to hospital and number of lines of treatment in the development of multi-pronged, targeted public health efforts to improve outcomes in HCC.

Impacts of COVID on HCC care cascade recommendation concordance: maintained surveillance rates and improved linkage to care

Joan Ericka Flores[1,2], Alexander Thompson[1,2], Stuart Roberts[3], Marie Sinclair[2,4], Amanda Nicoll[5], Stephen Bloom[5], Ammar Majeed[3], William Kemp[3], Zina Valaydon[2,6], Gauri Mishra[7], Jessica Howell[1,2]. *[1]St Vincent's Hospital Melbourne, Fitzroy, Australia; [2]University of Melbourne, Parkville, Australia; [3]Alfred Health, Melbourne, Australia; [4]Austin Health, Heidelberg, Australia; [5]Eastern Health, Box Hill, Australia; [6]Western Health, Footscray, Australia; [7]Monash Health, Clayton, Australia*
Email: ericka@flores.com.au

Background and aims: Optimal Cancer Pathway Recommendations of Hepatocellular Carcinoma (HCC OCP) from the Cancer Council of Australia recommend time intervals for each step in the HCC care cascade. 'Lockdown restrictions' in Victoria affected access to pathology, radiological and outpatient services; leading to a transition to virtual telehealth clinics and MDTs, and community HCC surveillance scans. This study aimed to describe concordance to HCC OCP recommendations and the impact of COVID19 lockdown restrictions.
Method: Incident HCC cases referred to six tertiary hospitals were prospectively identified from 1 January 2018–31 December 2021. 'Pre-lockdown' cases were diagnosed prior to 10 March 2020, and 'during-lockdown' after. Demographic and clinical data were obtained from the hospital electronic medical record and HCC MDT databases. Proportions of concordance were determined against HCC OCP recommendations: 14 days (d) 'time to MDT' review from referral; 28d for 'staging/investigation time' from referral to diagnostic and management consensus; 28d 'time to treatment' receipt from management consensus.
Results: 1015 incident HCC cases were identified: 81% male (n = 820), median age 66 years (IQR 59–74 years). Cirrhosis was present in 83% (n = 842), of whom 29% had diagnosis made at the time of HCC diagnosis. BCLC 0-A stage HCC occurred in 47% (n = 482). 42% (n = 424) were diagnosed through surveillance. Where referral information was available (n = 928), 70% (n = 646) were concordant with time to MDT; 63% (n = 596) were concordant with staging/investigation time. Of 957 cases where data were available, 30% (n = 287) were concordant with time to treatment, median 19d.
During lockdown, 469 cases (46%) were identified. No difference in the proportion undergoing surveillance pre-lockdown (43%, n = 225) vs during lockdown (43%, n = 199; $p = 0.984$); however, proportions concordant with time to MDT significantly increased from 64% (n = 323) to 76% (n = 323) ($p < 0.0001$), and staging/investigation time concordance increased from 58% (n = 298) to 69% (n = 298) ($p < 0.0001$). There was a significant decrease in the proportion concordant with time to treatment (33%, n = 171 vs 27%, n = 116 $p = 0.033$). Numerically, there was a decrease in the proportion concordant in non-surgical treatments from 42% (n = 129) to 37% (n = 83) ($p = 0.117$).
Conclusion: These data highlight effective implementation of telehealth clinics and virtual meetings, leading to an improvement in linking new HCC cases to specialist MDM for follow-up during lockdown. However, timely treatment receipt was significantly impacted by lockdowns, seen particularly in non-surgically treated cases. HCC surveillance uptake remained suboptimal but was maintained during lockdowns through increased use of community radiology services, highlighting the need for increased resource allocation to enable timely receipt of HCC surveillance and management.

SAT-497

A risk prediction model for hepatocellular carcinoma in general population without traditional risk factors for liver disease

Byeong Geun Song[1], Aryoung Kim[1], Dong Hyun Sinn[1]. *[1]Samsung Medical Center, Seoul, Korea, Rep. of South*
Email: sinndhn@hanmail.net

Background and aims: The available hepatocellular carcinoma (HCC) prediction model for general population without risk factors for chronic liver disease is limited. In this study, we aimed to develop HCC prediction model for individuals without traditional risk factors for HCC.

Method: The total of 138, 452 adult participants without chronic viral hepatitis or significant alcohol intake who underwent regular health checkup at a tertiary hospital in South Korea were followed up for the development of HCC. Risk factors for HCC development were analyzed using Cox regression analysis and prediction model was developed using these risk factors.
Results: We developed the HCC prediction model among general population without risk factors for chronic liver disease. The predictors were age, sex, platelet count, aspartate aminotransferase, alkaline phosphatase, total cholesterol, and prothrombin time. The Harrell's C-index and Heagerty's integrated area under the receiver operating characteristics (AUROC) curve of the model were 0.88 (95% confidence interval [CI] 0.84–0.92) and 0.89 (95% CI 0.87–0.91), respectively. The AUROC were 0.89 (95% CI 0.89–0.90) at 5 years and 0.88 (95% CI 0.88–0.89) at 10 years, and the model was well calibrated. In the interval validation, predictive performance was comparable with C-index of 0.88 and 5 years and 10 years AUROC of 0.91.
Conclusion: The new model using clinical parameters is a useful tool for clinicians to stratify HCC risk in general population without risk factors for chronic liver disease.

SAT-498

Patterns and predictors of acute care utilization after liver-directed therapy for hepatocellular carcinoma

Andrew Moon[1], Chidi Iloabachie[1], Sydney Power[1], Gabriel Lupu[1], Joyce Badal[1], Yue Jiang[2], David Seligson[1], Hanna Sanoff[1], David Mauro[1], David Gerber[3], Ted Yanagihara[1], A. Sidney Barritt Iv[1].
[1]University of North Carolina, Chapel Hill, United States; [2]Duke University, Durham, United States; [3]University of Cincinnati, Cincinnati, United States
Email: andrew.moon@unchealth.unc.edu

Background and aims: Liver-directed treatments for HCC can cause post-treatment symptoms and decompensation events, resulting in ER visits and hospitalizations. To help prevent these occurrences, it is important to better understand the frequency and predictors of acute care utilization.
Method: We performed a single center retrospective analysis of adult patients with HCC treated with thermal ablation, transarterial therapies (TACE/TAE and Y90) or external beam radiotherapy (EBRT) from 4/2014 to 12/2020. We excluded treatments of metastatic HCC (e.g. external beam radiation to extrahepatic metastases) but did include patients with vascular spread. The primary outcome was any post-treatment acute care utilization defined as an emergency room (ER) visit or inpatient admission (not including post-treatment observation stays) that occurred within 90 days after treatment. We compared baseline characteristics among those with and without health care utilization and created multivariable logistic regression models to identify characteristics associated with post-treatment health care utilization.
Results: This study included 191 unique patients with HCC (10% BCLC-0, 34% BCLC-A, 11% BCLC-B, 34% BCLC-C, 11% BCLC-D) who had 320 separate procedures (40% TAE/TACE, 17% laparoscopic MWA, 17% percutaneous MWA, 11% Y90, 8% EBRT and 8% combination/other). Most patients had CP-A cirrhosis (65%), HCV etiology (39%), and ECOG performance status 0 (56%). ER visits within 90 days occurred for 56 procedures (16%) and unplanned inpatient hospitalizations within 90 days occurred for 34 procedures (11%). Patients who had acute care utilization were older (median 65.5 vs 61.5 years, OR 0.96, 95% CI 0.93–0.99) and more likely to have ER visits (55% vs 24%, OR 4.21, 95% CI 2.38–7.53) and hospitalizations (41% vs 20%, OR 2.68, 95% CI 1.49–4.81) within the prior 12 months. Compared to those with CP-A cirrhosis, post-treatment acute care utilization was more common amongst patients with Child Pugh (CP) B8 (OR 1.53, 95% CI 1.02–5.92), B9 (OR 3.79, 95% CI 1.47–9.46) or C (OR 4.33, 95% CI 1.78–10.30) cirrhosis. Compared to those treated with laparoscopic MWA, patients receiving percutaneous MWA had a significantly lower likelihood of having post-treatment acute care utilization within 90 days (OR 0.24, 95% CI 0.07–0.68). There were no statistically significant associations with other sociodemographic or clinical factors and no significant associations in multivariable models.
Conclusion: Acute care utilization with 90 days occurred for up to 15% liver-directed therapies, on par with historical cohorts of patients with metastatic non-liver cancer on chemotherapy. CP score and pre-treatment health care utilization are strong predictors of subsequent ER visits and hospitalizations. This study identifies subgroups who may benefit from enhanced nurse navigation or symptom/decompensation monitoring.

SAT-499

The inflammatory state of tumor peripheral liver tissue affects hepatocellular carcinoma progression and prognosis

Zheyu Zhou[1], Jinsong Liu[2,3], Shuya Cao[4], Xiaoliang Xu[5], Chaobo Chen[6], Beicheng Sun[1,5].
[1]Nanjing Drum Tower Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Nanjing, China; [2]Xinhua Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China; [3]Shanghai Colorectal Cancer Research Center, Shanghai, China; [4]The First Affiliated Hospital of Nanjing Medical University, Nanjing, China; [5]The First Affiliated Hospital of Anhui Medical University, Hefei, China; [6]Xishan People's Hospital of Wuxi City, Wuxi, China
Email: zhouzheyu_pumc@sina.com

Background and aims: Inflammation has been proven vital in the initiation and progression of hepatocellular carcinoma (HCC), and inflammatory tumor microenvironment was the focus of previous studies. Whether the inflammatory state of HCC peripheral liver tissue also affects tumor progression has not yet been investigated. This study aimed to explore clinical features and underlying gene expression patterns of HCC patients with different G grades (Scheuer's classification).
Method: The medical data of HCC patients at Nanjing Drum Tower Hospital from January 2020 to August 2023 was retrospectively reviewed. Patients were divided into two groups: G 0–1 and G ≥2. Six HCC tissues (three in each group) were collected, and RNA-seq was conducted. Gene Set Enrichment Analysis (GSEA) was conducted to detect differential activation of Hallmarks pathways. Kyoto Encyclopedia of Genes and Genomes (KEGG) and Gene Ontology (GO) analyses were conducted on differentially expressed genes between these two groups to elucidate enriched pathways and biological processes. Integrated machine learning algorithms and multivariate Cox regression analysis were used for prognostic gene screening and model establishment.
Results: 370 HCC patients were included in this study, with 163 patients in the G 0–1 group and 207 patients in the G ≥2 group. More significant liver fibrosis, as well as severe coagulation and hepatic function impairment, were related to the G ≥2 group, characterized by elevated S ≥2 ratio, prothrombin time, international normalized ratio, alanine aminotransferase, and aspartate aminotransferase and lower platelet and albumin. Inflammatory genes (TNFSF9, IL18, and HIF1A), hepatic fibrosis-related genes (COL3A1, COL5A1, and MMP2), and Hallmarks pathways INFLAMMATORY_RESPONSE and TNFA_SIGNALING_VIA_NFKB were significantly upregulated in the G ≥2 group. Conversely, coagulation factors (F2, F7, and F9), complement molecules (C1R, C3, and C5), fibrinolysis-related molecules (SERPINA1, SERPINC1, and SERPIND1), hepatic metabolism-related genes (GOT2, GPT2, and CYP7A1), and Hallmarks pathways COAGULATION and BILE_ACID_METABOLISM were markedly upregulated in the G 0–1 group. KEGG pathways significantly enriched in complement and coagulation cascades, biosynthesis of amino acids, and cholesterol metabolism. Consistently, GO had significant enrichment in blood coagulation, cellular amino acid catabolic processes, and transaminase activity. The established model based on seven inflammatory-related genes performed well in prognostic prediction and risk stratification across multiple datasets.

Conclusion: HCC patients with G ≥2 had an inflammatory and fibrotic phenotype with a worse prognosis, while patients with G 0–1 retained better coagulation and liver metabolic functions.

SAT-500-YI

Ethnic and racial disparities in the initial presentation of hepatocellular carcinoma: real-world data from a single non-academic hepatology clinic with a large diverse population in Los Angeles County

Isabella Martinez[1], Michel Mendler[1], Edward Mena[2]. [1]*California Liver Research Institute, Pasadena, United States;* [2]*California Liver Research Institute, Pasadena Liver Center, Pasadena, United States*
Email: isabella.martinez@caliverresearch.org

Background and aims: The increasing incidence of Hepatocellular Carcinoma (HCC) in the U.S. is attributed in part to increasing rates of obesity, diabetes (T2DM), metabolic dysfunction-associated steatotic liver disease (MASLD), and metabolic dysfunction-associated steatohepatitis (MASH). We aim to discern social and clinical characteristics associated with HCC diagnosis in an ethnically diverse population seen at a private Hepatology-focused practice in Los Angeles County, California, USA.
Method: Retrospective study of patients at their initial evaluation for HCC at our hepatology clinic from July 2018 through July 2023. HCC was diagnosed by standard MRI/CT criteria. Underlying causes of liver disease, presence of cirrhosis, pertinent clinical characteristics and socioeconomic factors were stratified according to ethnicity and race and compared by univariate analyses.
Results: 187 patients met inclusion criteria. 45.0% ethnically identified as Hispanic/Latino (HL) and 51.3% non-Hispanic/Latino (NHL). Of HLs, 82.1% racially identified as Non-White and 16.7% as White. Race distribution was 3.2% Black, 28.3% Asian, 20.9% White, 43.3% Other. The median age was 71 (27–88), and 72% were male. No significant differences were observed in gender, median household income by zip code census or satisfying Milan transplant criteria. HLs were found to have a higher prevalence of T2DM (55.3% vs 40.1%, p = 0.05) and BMIs [median 28.4 (18.3–46) vs 25.0 (14.3–50), p = 0.031] than NHLs. Overall, 88.8% had cirrhosis. When compared to NHLs, HLs had higher prevalence of cirrhosis due to MASLD (53.6% vs 19.8%, p < 0.001) and alcohol abuse (17.9% vs 9.4%, p < 0.001). Among those with HBV, majority were Asian (93.6%, p > 0.001) while for HCV the majority were White (32.1%, p < 0.001). Asians had cirrhosis mostly due to HBV and MASLD (56% and 20.8%, p < 0.001). Among those without cirrhosis, 61.1% had HBV, and 11.1% had MASLD (p < 0.001). Asians (70.7%) and non-white HLs (17.7%) comprised the majority of non-cirrhotic HCC cases (p = 0.04). Of those outside of UCSF transplant criteria, majority were non-white HLs (42.3% p = 0.043). White-HLs had higher systemic treatment rates than White-NHLs (46.2% vs. 16.0%, p = 0.007), with Asians having the lowest rates (5.7%, p = 0.007). Additionally, HLs had lower surgical resection rates than NHLs, (3.6% vs 13.5%, p = 0.044), while Asians exhibited the highest rates (68.8%, p = 0.008).
Conclusion: This real-world data from a diverse population in Los Angeles seen for HCC suggests that HLs exhibit a higher incidence of cirrhosis attributed to MASLD and alcohol-associated liver disease, increased rates of HCC without cirrhosis, higher BMIs and prevalence of diabetes. HLs appear to present with more advanced disease leading to lower rates of surgical resections and a greater need for systemic therapy. Asians had the highest prevalence of HBV-related HCC as well as non-cirrhotic HCC.

SAT-501-YI

The CRAFITY score to predict hepatocellular carcinoma disease control rate at month 12 in patients undergoing transarterial chemoembolization

Rhea Veelken[1], Anne Olbrich[1], Sabine Lieb[1], Aaron Schindler[1], Adam Herber[1], Sebastian Ebel[2], Timm Denecke[2], Thomas Berg[1], Florian van Bömmel[1]. [1]*University Hospital of Leipzig, Division of Hepatology, Department of Medicine II, Leipzig, Germany;* [2]*University Hospital of Leipzig, Department of Diagnostic and Interventional Radiology, Leipzig, Germany*
Email: florian.vanboemmel@medizin.uni-leipzig.de

Background and aims: The CRAFITY score, utilising alpha-fetoprotein (AFP ≥100 ng/ml) and C-reactive protein (CRP ≥1 mg/dL), classifies patients with hepatocellular carcinomas (HCC) for potential enhanced overall survival (OS) and treatment response to subsequent immunotherapy. This study aimed to assess the predictive utility of the CRAFITY score evaluating disease control rate (DCR) and overall survival within 12 months in patients undergoing transarterial chemoembolization (TACE). Predicting HCC disease control rate after TACE is especially vital in the context of bridging therapy for patients awaiting liver transplantation.
Method: We conducted a retrospective analysis of 1117 HCC patients diagnosed at our center between 2010 and 2020, of which 546 underwent TACE as their initial treatment. Inclusion criteria comprised documented follow-up records >3 months, three-monthly CT or MRI imaging, and availability of baseline CRP and AFP data. The study assessed the association of baseline variables using Cox regression and Kaplan-Meier estimation. The study involved 113 patients, median age 63 [range, 31–85] years, including 15 females (13%). BCLC stages were A (n = 64), B (n = 36), C (n = 11), and D (n = 2). Imaging revealed compensated cirrhosis in 101 patients (89%). Twelve months post-TACE, DCR was observed in 27 patients (23.9%), with 14 exhibiting complete response, 9 stable disease, and 4 partial response. Disease progression occurred in 35 (30.9%) patients, with 3 presenting new extrahepatic spread and 32 (28.3%) developing new intrahepatic HCC nodes. Within 12 months, 20 patients (17.7%) underwent liver transplantation.
Results: The assessment of 12-month survival demonstrated the reliability of the CRAFITY score as a predictor of DCR (p = 0.004). A CRAFITY score of 2 indicated a threefold higher risk of mortality (HR = 3.4 [95% CI 1.48–7.58]; p = 0.004) compared to a score of 0 within 12 months. Additionally, elevated CRAFITY scores, distributed as 0 (59.6%), 1 (33.8%), 2 (6.4%), were significantly associated with the occurrence of new intrahepatic tumor nodes, defining disease progression within 12 months after the first TACE (p = 0.0114). Patients with a CRAFITY Score of 2 had a 3.8 times higher risk to develop a new tumor node after 12 months than patients with a CRAFITY Score of 0 (HR = 3.8 [95% CI 1.09–13.24]; p = 0, 036). AFP at the time of TACE also showed a significant association with treatment response (AUC = 0.679; 95% CI 0.542–0.815; p = 0.017), while CRP did not (AUC = 0.568; 95% CI 0.416–0.729; p = 0.366).
Conclusion: In addition to its potential for predicting survival, the CRAFITY score could function as a predictive tool for tumor control in HCC patients post-TACE. Further studies are needed to validate these findings, with a particular emphasis on demonstrating its capacity to aid in risk stratification for HCC patients on the liver transplantation waitlist.

SAT-502-YI

Active HCV or HBV infection does not impact on clinical outcomes in patients with hepatocellular carcinoma

Arianna Bertazzoni[1], Francesco Berardi[1], Mariangela Fortunato[1], Matteo Soleri[1], Nicola Pugliese[1,2], Francesca Colapietro[1,2], Chiara Masetti[2], Roberto Ceriani[2], Vittorio Pedicini[3], Lorenza Rimassa[1,4], Ana Lleo[1,2], Alessio Aghemo[1,2], Stella De Nicola[2]. [1]*Department of Biomedical Sciences, Humanitas University, Pieve Emanuele (Milan), Italy;* [2]*Division of Internal Medicine and Hepatology, Department of Gastroenterology, Humanitas Research Hospital IRCCS, Rozzano (Milan), Italy;* [3]*Department of Interventional Radiology, Humanitas Research Hospital IRCCS, Rozzano (Milan), Italy;* [4]*Medical Oncology and Hematology Unit, Humanitas Cancer Center, Humanitas Research Hospital IRCCS, Rozzano (Milan), Italy*
Email: arianna.bertazzoni@humanitas.it

Background and aims: Hepatocellular carcinoma (HCC) is the main complication of cirrhosis. Chronic infections with hepatitis B virus (HBV) or hepatitis C virus (HCV) are among the main etiologies for advanced liver disease worldwide. Effective antiviral treatments have changed the course of viral-related liver disease, but access to treatment is not universal and many patients with HCC still present active viral infection. Impact of viral infection on the prognosis of patients with HCC is largely unknown. We analyzed the impact of viral infection on patient outcome after the first diagnosis of HCC in compensated advanced liver disease (cACLD).
Method: We retrospectively analyzed all patients discussed at multidisciplinary meetings, between 2018 and 2022, at our tertiary Hospital. We included all patients with HCC and cACLD without history of previous or active decompensation. The primary outcome was liver decompensation at one year. Secondary outcomes included one-year HCC recurrence, survival and liver transplantation (LT).
Results: 240 cACLD patients were included, of which 75% males. Median age was 71 years (I.Q.63–77). Prevalent etiology was viral cirrhosis (113 cases, 47.09%), specifically 92 patients with HCV (81.42%) and 21 patients with HBV (18.58%). Of viral cirrhoses 52 cases (46%, 52/113) had an active infection, 46 of whom (88%) had HCV infection. The Barcelona Clinic Liver Cancer (BCLC) stages were divided as follows: BCLC-0 (12/52, 23% in active vs 12/61, 19.67% in non-active cases respectively), BCLC-A (24/52, 46.15% vs 32/61, 52.46% respectively), BCLC-B (15/52, 28.85% vs 17/61, 27.87% respectively), BCLC-C (1/52, 1.92% vs 0/61, 0% respectively), BCLC-D (no patients in either case). Active and non-active cases did not differ in number and size of nodules (Milano Criteria in: 30/52, 57.69% in active disease vs 40/61, 65.57% in non-active group respectively, p = 0.252) or presence of varices (6/52, 11.54% in active vs 11/61, 10.03% in non-active infection, p = 0.524). All active HBV patients started antiviral therapy after HCC diagnosis, while 28/46 (60%) of HCV patients received DAAs. One-year incidence of ascites (2 vs 2 patients, p = 0.838), hepatic encephalopathy (1 vs 0 patients, p = 0.290) or variceal bleeding (1 vs 0 patients, p = 0.505) was similar among active and inactive hepatitis. One-year HCC recurrence (37/52, 71.15% in active vs 32/61, 52.46% in non-active infection, p = 0.122), LT (1 vs 3 patients, p = 0.391) and one-year liver-related mortality were similar in active vs inactive viral hepatitis.
Conclusion: Active viral infection in Italian patients with HCC and compensated liver disease is common but has limited clinical impact as it does not modify survival, recurrence or liver decompensation. Antiviral treatment is safe and needs to be considered in this setting.

SAT-503

Role of CD27 on IgD+ CD24+ B cell in mediating the effect of Lactobacillaceae on bile duct carcinoma

Xuanchen Liu[1], Ningning Zhang[1], Wei Lu[2], Yiyan Zhang[2], Kaipeng Liu[1], Huiru Liu[1]. [1]*Tianjin Medical University Cancer Institute and Hospital, Tianjin, China;* [2]*Tianjin Medical University Cancer Institute and Hospital, Tianjin, China*
Email: 15931873318@163.com

Background and aims: We investigated the causal relationships between the gut microbiota, bile duct carcinoma, and potential immunophenotype mediators using Mendelian randomization.
Method: The data on gut microbiota, immunophenotype, and bile duct carcinoma all come from the GWAS Catalog website (http://www.ebi.ac.uk/gwas/). The data of gut microbiota were under the study accession numbers GCST90027446-GCST90027857. Immunophenotype from GCST0001391-GCST0002121, and bile duct carcinoma from GCST90018803. We performed bidirectional MR analyses to explore the causal relationships between the GM and bile duct carcinoma, and two mediation analyses, two-step MR to discover potential mediating immunophenotype.
Results: There is a causal relationship between 12 gut microbial taxa and bile duct carcinoma, with Lactobacillaceae showing the most significant association (ivw:p = 0.015, OR:1.224 (1.040–1.441)), and there is no evidence of reverse causation. Performing a bulk MR analysis with Lactobacillaceae and 731 immunophenotypes revealed causal relationships with 17 immunophenotypes. Subsequently, conducting a bulk MR analysis with these 17 immunophenotypes and bile duct carcinoma showed a causal relationship only between the CD27 on IgD+ CD24+ B cell and bile duct carcinoma (ivw:p = 0.024, OR:0.905 (0.829–0.987)).
Conclusion: Through Mendelian randomization, it was revealed that Lactobacillaceae acts on bile duct carcinoma through CD27 on IgD+ CD24+ B cells as intermediate factors.

SAT-513

Hepatocellular carcinoma surveillance in an european tertiary hospital. Where are we failing?

Francisco Capinha[1], Inês Rodrigues[1], Miguel Moura[1], Sofia Carvalhana[1], Luís Correia[2], Helena Cortez-Pinto[2]. [1]*Serviço de Gastrenterologia e Hepatologia, Hospital de Santa Maria, Centro Hospitalar Universitário Lisboa Norte, Lisboa, Portugal;* [2]*Serviço de Gastrenterologia e Hepatologia, Hospital de Santa Maria, Centro Hospitalar Universitário Lisboa Norte, Clínica Universitária de Gastrenterologia, Faculdade de Medicina de Lisboa, Universidade de Lisboa, Lisboa, Portugal*
Email: francisco.capinha96@gmail.com

Background and aims: Surveillance of hepatocellular carcinoma (HCC) is efficient in detecting small tumors, with a positive impact on survival. In clinical practice there are several issues on the application of HCC screening: patients with unknown liver disease, poor patient adherence or problems in the health care system, leading to an underperformance. We aim to evaluate the performance of the HCC surveillance and the reasons of missed/delayed diagnosis in patients with HCC in our center.
Method: Retrospective study which included patients with HCC diagnosis discussed by the multidisciplinary team of liver tumors from 2020 to 2023 in a tertiary hospital. HCC surveillance was defined according to the EASL recommendations (2018). Considering the target population for screening, subgroups were created and compared: (a) diagnosed through screening; (b) missed screening due to poor patient adherence and/or system failure; (c) unknown advanced liver disease (UALD), that would have indication for surveillance if already diagnosed. For patients diagnosed through screening, we considered an error margin of 2 months (8 months) as "complete surveillance" and between 8 and 12 months as "incomplete surveillance." Statistical analysis has performed using SPSS® v23. A p value <0.05 was considered as statistically significant.
Results: We included 174 patients, with a median age 67 years and 90% males. From these, 158 patients had liver disease, among them 136 with cirrhosis (70% CP A; 20% CP B; 10% CP C). The most common etiologic factor for liver disease was alcohol (56%). The proportion of patients diagnosed in surveillance was 26% (n = 46). Relatively to the stage at diagnosis, 4% BCLC-0, 37% BCLC-A, 10% BCLC-B, 33% BCLC-C and 15% BCLC-D. Considering the target population (80%, n = 140): 33% (n = 46) subgroup (a); 24% (n = 34) subgroup (b); and 43% (n = 60) subgroup (c). The defined subgroups were comparable on sex and age. In subgroup (a) 59% (n = 27) have complete surveillance and 41% (n = 19) have incomplete surveillance, without any significant difference in terms of outcome. Patients in subgroup (a) had HCC diagnosed at lower stages (BCLC-0 and BCLC-A) compared to subgroups (b) and (c) together (p = 0.012), as well as comparing with subgroup (c) (p = 0.011). The subgroup (c), comparing to subgroup (a), had higher proportion CP B and C (p = 0.008), vascular invasion (p = 0.01), extrahepatic involvement (p = 0.052) and hepatic dysfunction according to ALBI score (p < 0.001) at time of diagnosis.
Conclusion: In our cohort, a minority of HCC cases (26%) were diagnosed through screening. From the patients with indication for screening, only one third achieved diagnostic yield. This study emphasizes not only the need to improve surveillance and early diagnosis of HCC, but also the importance of primary care in early

diagnosis of liver disease, since 35% of HCC patients were unaware of the diagnosis of advanced liver disease.

SAT-514

Application of machine learning model-3P to predict portal hypertension in patients with hepatocellular carcinoma

Arianna Bertazzoni[1], Francesco Berardi[1], Mariangela Fortunato[1], Matteo Soleri[1], Roberto Ceriani[2], Francesca Colapietro[1,2], Nicola Pugliese[1,2], Chiara Masetti[2], Guido Torzilli[1,3], Vittorio Pedicini[4], Dario Poretti[4], Lorenza Rimassa[1,5], Tiziana Comito[6], Ana Lleo[1,2], Alessio Aghemo[1,2], Stella De Nicola[2], Emanuela Morenghi[1,7].
[1]Department of Biomedical Sciences, Humanitas University, Pieve Emanuele (Milan), Italy; [2]Division of Internal Medicine and Hepatology, Department of Gastroenterology, Humanitas Research Hospital IRCCS, Rozzano (Milan), Italy; [3]Division of Hepatobiliary Surgery, Department of General Surgery, Humanitas Research Hospital IRCCS, Rozzano (Milan), Italy; [4]Department of Interventional Radiology, Humanitas Research Hospital IRCCS, Rozzano (Milan), Italy; [5]Medical Oncology and Hematology Unit, Humanitas Cancer Center, Humanitas Research Hospital IRCCS, Rozzano (Milan), Italy; [6]Department of Radiosurgery and Radiotherapy, Humanitas Cancer Center, Humanitas Research Hospital IRCCS, Rozzano (Milan), Italy; [7]Biostatistics Unit, Humanitas Research Hospital IRCCS, Rozzano (Milan), Italy
Email: arianna.bertazzoni@humanitas.it

Background and aims: The occurrence of decompensation due to portal hypertension (PH) in patients with hepatocellular carcinoma (HCC) could preclude access to treatment. To date, non-invasive methods to predict PH failed their application in HCC patients. Reiniš, J (JHep, 2023) proposed a new non-invasive method developed through machine learning models, called the 3P model, using as reference the invasive measurement of hepatic venous pressure gradient (HVPG). The model considered three laboratory parameters (platelet count, bilirubin, international normalized ratio) and held promising results in predicting the presence of PH in cACLD (compensated advanced chronic liver disease). The aim of our study is to verify reliability of 3P model in a cohort of patients with HCC.
Method: We retrospectively included all consecutive patients discussed in multidisciplinary HCC team (MHT) consultation from 2018 to 2022 with a diagnosis of HCC developed con cACLD. 3P score was calculated using the formula suggested by Reiniš, J., et al. (0.332 for prediction of HVPG >16 mmHg) and was compared to baseline endoscopy. For comparison logistic regression and ROC analysis were performed.
Results: Data from 240 cACLD patients with HCC were collected. 146 patients performed endoscopy at baseline and were included in statistical analysis. Main etiology of cirrhosis was viral infection (64/146, 44%) followed by metabolic disease (44/146, 30%). The HCC stage was classified using the Barcelona clinic liver cancer (BCLC) system: BCLC-0 22 patients (15.7%), BCLC-A 76 (52.5%), BCLC-B 46 (31.51%), BCLC-C 2 (1.37%). A total of 42 patients (28.77%) had varices at endoscopy. Applying the 3P score with a 0.332 cut-off in our cohort, we obtained a sensitivity of 40% and a specificity of 89% (AUC 0.65). Based on our data, another cut-off (0.15) was calculated for prediction of presence of varices at endoscopy, reaching a sensitivity of 80% and specificity of 44%, with a negative predictive value of 83.7%.
Conclusion: 3P model could be a rapid, non-invasive, economic model to predict the absence of severe PH at diagnosis of HCC in cACLD. More data are necessary to validate our proposed cut-off in HCC setting in order to bypass endoscopy and try to limit delays in starting treatment.

SAT-515

Cholangiocarcinoma across England: evidence of regional, socioeconomic, and temporal variations in incidence, survival, routes to diagnosis and treatment

Sophie Jose[1,2], Amy Zalin[1,3], Daniela Tataru[3], Craig Knott[1,4], Lizz Paley[5], Helen Morement[6], Roger Cherry[1], Kwok Wong[3], Mireille Toledano[7], Shahid Khan[8]. *[1]Health Data Insight CIC, Cambridge, United Kingdom; [2]National Disease Registration Service, NHS England, Leeds, United Kingdom; [3]National Disease Registration Service, NHS England, Leeds, United Kingdom; [4]National Disease Registration Service, NHS England, Leeds, United Kingdom; [5]National Disease Registration Service, NHS England, Leeds, United Kingdom; [6]AMMF-The Cholangiocarcinoma Charity, Essex, United Kingdom; [7]Imperial College London, MRC Centre for Environment and Health, School of Public Health, London, United Kingdom; [8]Imperial College London, London, United Kingdom*
Email: shahid.khan@imperial.ac.uk

Background and aims: Cholangiocarcinoma (CCA) is increasing in the UK and globally. Whether there are regional, socioeconomic and temporal variations in incidence, mortality, routes to diagnosis (RtD) and treatment within England is unknown. There are no published studies from any country exploring these issues. This work aimed to investigate these issues across England.
Method: Patients diagnosed in England with a CCA between 2001–2018 were extracted from the National Cancer Registration Dataset (NCRD) linked to other data sources: the Hospital Episode Statistics (HES) dataset, the Systemic Anti-Cancer Therapy (SACT) dataset. RtD data were extracted for 2006–2017, and treatment data for 2014–2017, representing the time periods for which respective data were available. Age-standardised incidence (ASRs) and mortality (ASMRs) rates were estimated overall and stratified by gender, area deprivation quintile based on the income domain of the Index of Multiple Deprivation closest to diagnosis, tumour subtype (intra/extrahepatic) and England's 21 regional Cancer Alliances. Net and overall survival estimates were also calculated. Linear probability models were used to quantify geographic variation in RtD and treatment, adjusting for potential confounders. Geographic variation was analysed by Cancer Alliance based on postcode of residence at diagnosis.
Results: ASRs, ASMRs and net survival varied by geography. ASRs and ASMRs were consistently higher in the more socioeconomically deprived groups. The least deprived CCA patients had best overall survival ($p < 0.001$). 3-year net survival rose from 9.2% in 2001–2003 to 12.6% by 2016–2018. The most common RtD was Emergency Presentation (EP), with 49.6% of patients diagnosed thus. The proportion diagnosed via Two Week Wait Urgent GP Referral (TWW) doubled from 9.9% to 19.8%. Statistically significant variation was observed in the proportions of patients diagnosed via a TWW or EP across England's Cancer Alliances. There was also significant variation between Cancer Alliances in the proportions of patients that received potentially curative surgery, systemic therapy without potentially curative surgery, or stent insertion without potentially curative surgery.
Conclusion: Geographic variations in RtD and access to resection and stenting is a novel finding and suggests opportunities for sharing of good practice across NHS organisations to continue to improve on current trends. Local review of treatment pathways and more comprehensive guidelines for the management of CCA could help to reduce potential variation in treatments received across Cancer Alliances. Whilst there were some improvements in overall survival over time, three-year survival rates remained extremely low, highlighting huge unmet need in this population.

SAT-516

In the era of effective antiviral therapy, cured hepatitis C remains a main cause of HCC

Elena Vargas-Accarino[1], Monica Higuera[1], Maria Buti[1,2,3,4], Beatriz Minguez[1,2,3,4]. [1]*Liver Diseases Research Group, Vall d'Hebron Institut de Recerca (VHIR), Vall d'Hebron Barcelona Hospital Campus, Barcelona, Spain;* [2]*Department of Medicine, Campus de la UAB, Universitat Autònoma de Barcelona (UAB), Barcelona, Spain;* [3]*Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Instituto de Salud Carlos III, Madrid, Spain;* [4]*Liver Unit, Hospital Universitario Vall d'Hebron, Vall d'Hebron Barcelona Hospital Campus, Barcelona, Spain*
Email: beatriz.minguez@vallhebron.cat

Background and aims: In the last decade, hepatitis B virus infection vaccination, total accessibility to hepatitis B and C antivirals and the global steatotic liver disease epidemic, may impact the underlying liver cancer etiologies. The aim of this study was to analyze the etiological agents of liver disease in patients diagnosed with de novo hepatocellular carcinoma (HCC) in our cohort.
Method: Retrospective study including all new hepatocellular carcinoma diagnosed between January 2019 and December 2022 in an academic center. The demographics, clinical characteristics and risk factors of hepatocellular carcinoma as well as the BCLC stage at diagnosis have been reviewed.
Results: 352 consecutive patients diagnosed with de novo HCC were included. The most frequent underlying etiology was alcoholic-related liver disease in 117 (33.3%) patients, followed by cured hepatitis C in 109 (30.9%), MASLD was detected in 43 (12.2%), active HCV infection in 28 (7.9%) and chronic hepatitis B infection in 21 (6%). The majority were male, mean age of 71 years and 82.7% had liver cirrhosis. BCLC 0 was observed in 28 (8%) of patients at the time of diagnosis, BCLC A in 144 (40.9%) patients, BCLC C in 86 (24.4%), and BCLC B in 58 (16.5%), and BCLC stage D was observed in 36 (10.2%) patients. Significant differences were found between the etiological factor of HCC and patient's sex, median age, BCLC stage at the time of diagnosis and percentage of patients with cirrhosis. Patients with cured HCV were significantly more women than patients with ALD ($p = 0.001$); patients with HBV infection were significantly younger than those with HCV infection ($p = 0.005$) or MASLD ($p = 0.001$); patients with active HCV were significantly more diagnosed at BCLC stage C and less at BCLC stage B than those patients with ALD ($p < 0.05$); and patients with ALD were significantly more cirrhotic than patients with MASLD or HBV infection ($p < 0.05$).
Conclusion: Alcohol liver related disease is the main cause of HCC, followed by solved hepatitis C. The total accessibility to DAA treatment and the high cure rate have not only not eliminated the risk of HCC, but it persists as one of the two predominant causes. The progressive increase in steatosis liver disease is not yet a major cause of HCC development.

SAT-518

Evaluation of the prognostic importance of Gustave Roussy immune score in hepatocellular carcinoma patients

Hatice Gülgün Fırat[1], İlknur Deliktaş Onur[1], Elif Sertesen Çamöz[1], Fatih Yıldız[1]. [1]*Dr. Abdurrahman Yurtaslan Oncology Education and Research Hospital, Ankara, Turkey*
Email: drhgtekin@gmail.com

Background and aims: Hepatocellular carcinoma (HCC) is a primary liver tumour that usually develops in the background of chronic liver disease.
Gustave Roussy Immune Score (GRIm score) is a score developed for appropriate patient selection in phase-1 trials using immunosuppressive inhibitors.The HCC-GRIm score was developed by adding the aspartate aminotransferase/alanine aminotransferase ratio and total bilirubin level in hepatocellular cancer patients, in addition to the serum albumin level, serum lactate dehydrogenase level and serum neurophil/lymphocyte level measured in the GRIm score. In our study, we aimed to evaluate the prognostic efficacy of GRIm score and HCC-GRIm score in hepatocellular carcinoma patients and to show whether these scores are related to the etiology of HCC.
Method: The study included one hundred thirty two patients aged eighteen years and older with HCC diagnosed between January 2015 and 2023. Age, gender, Ecog performance scores, date of diagnosis, HCC etiology, Barcelona stage at the time of diagnosis, whether local ablative procedure was performed, whether systemic treatment was received, Chıld Pugg score at the time of diagnosis, Meld score at the time of diagnosis, GRIm score and HCC-GRIm score at the time of diagnosis, final status and dates were recorded. Survival data was last updated in December 2023.
Results: GRIm score was low in seventy-five patients and high in fifty seven patients. Similarly, HCC-GRIm score was low in seventy-six patients and high in fifty six patients. Patients were grouped as low and high according to GRIm score and HCC-GRIm score. As the ECOG performance scores of the patients increased, GRIm score and HCC-GRIm score increased. A significant correlation was found between ECOG performance scores and GRIm scores and HCC-GRIm scores. A significant correlation was also found between BCLC stage and GRIm score and HCC-GRIm score. In the univariate analysis, Ecog, Chıld score, GRIm, HCC-GRIm score were prognostic for survival. In multivariate analysis, only GRIm and Chıld were prognostic.
Conclusion: In our study, GRIm score and HCC-GRIm score were found to be prognostic in univariate analysis, whereas only GRIm score was found to be prognostic in multivariate analysis. As these results, we argue that GRIm score alone is prognostic in HCC as in other tumours and there is no need to add additional parameters. In our study, we evaluated the prognostic efficacy of the GRIm score, which was used in Phase-1 studies to identify immune hot tumours suitable for immunotherapy, and its relationship with etiology. In conclusion, we believe that tumour microenvironment studies should be performed to help clinicians in the selection of patients suitable for immunotherapy in HCC. As we solve the microenvironment of the tumour, we can find an answer to the question of which treatment is effective in which patient.

SAT-519

The impact of tumor budding on tumor biology in patients with hepatocellular carcinoma

Osman Fırat Duran[1], Hale Gokcan[2], Saba Kiremitçi[3], Nermin Aras[3], Sevınc Tugce Karayel[2], Volkan Yılmaz[2], Aslı Çiftçi[4], Emin Bodakçi[5], Mesut Gumussoy[5], Zeynep Melekoğlu Ellik[6], Abdullah Mübin Özercan[7], Serkan Duman[8], Berna Savaş[3], Ramazan Idilman[2]. Email: o.firatduran@gmail.com

Background and aims: Tumor budding (TB) has recently been evaluated as a histomorphologic indicator of aggressive tumor behavior and is emerging as a valuable prognostic feature in various gastrointestinal carcinomas. However, data regarding tumor budding in hepatocellular carcinoma (HCC) are limited. The aims of the present study were to investigate TB and its effect on tumor biology of HCC.
Method: We conducted a retrospective analysis of 17 years of data from 151 resected or explanted liver tissue samples from HCC patients. TB was counted at 20x magnification, and the "hot-spot" region at the invasive edge of the tumor was selected at 10x magnification. TB has been evaluated according to the International

Tumor Budding Consensus Conference (ITBCC) method and classified into Grade 1 (0–4 buds), Grade 2 (5–9 buds), and Grade 3 (≥10 buds).
Results: Among the 151 patients, 107 (70.9%) were male, with a mean age of 69.4 ± 9.5 years. Cirrhosis was present in most patients (58.3%), and hepatitis B virus infection was the main etiology (55.6%). The median AFP level was 8.5 (0.8–123892). In histopathological examination, 23.1% of tumors were well differentiated, 76.9% of tumors were moderately to poorly differentiated. TB was observed in 70% of the patients with HCC. According to TB classification, 43.9% were classified into Grade 1 (0–4 buds), 16.2% Grade 2 (5–9 buds) and 39.9% Grade 3 (≥10 buds). No significant difference was found between TB groups and survival (p = 0.129). Microvascular invasion was seen in 40.9%, 37.5% 35.6% of patients with 1–4 TB, 5–9 TB, and greater than 10 TB (p = 0.09). There was only 16.3% microvascular invasion in the group without tumor budding.
Of note, six out of seven poorly differentiated HCC patients exhibited grade 3 tumor budding. The percentage of well-differentiated tumors was higher in patients without TB (33.3%) and 1–4 tumor buds (31.8%) compared to those with 5–9 tumor buds (16.7%) and >10 tumor buds (16.9%) (p = 0.07).
Conclusion: This preliminary study indicates that tumor budding seems to be correlated with tumor biology.

SAT-521
Impact of centre type on treatment and survival outcomes in hepatocellular carcinoma (HCC)

John Creamer[1], Katy Lillie[1], Molly Bradbury[1], Emma Owen[2], Gio McGinty[3], Gautham Appanna[1], James Orr[1]. [1]*University Hospitals Bristol and Weston NHS Foundation Trust, Bristol, United Kingdom;* [2]*Somerset NHS Foundation Trust, Taunton, United Kingdom;* [3]*North Bristol NHS Foundation Trust, Bristol, United Kingdom*
Email: john.creamer@nhs.net

Background and aims: Centre size and annual hepatocellular carcinoma (HCC) caseload impacted treatment and survival in a French review of HCC patients[1]. To our knowledge this has not been investigated in the UK. We aimed to investigate if type of hospital (level 2 liver centre vs district general hospital (DGH)) affected HCC outcomes in the Severn HPB MDT in terms of i) time to MDT discussion and commencing treatment, ii) referral for curative treatment and iii) 12-month survival.
Method: ICD-10 codes (C22.0, C22.9) were used to identify HCC patients discussed at MDT between 1.1.2020–31.12.2022. Data was collected by five reviewers. Differences between groups were assessed using the Chi-squared test for categorical variables and the Mann-Whitney U test for non-parametric data. All analysis was performed on R (ver 4).
Results: 107 patients were included in analysis; 36 presenting at a DGH (3 hospitals) and 71 at a level 2 liver centre (2 hospitals). Median time to MDT discussion from first imaging suggestive of HCC was 25 days and median time from first imaging to treatment was 112 days. Overall 12-month survival was 68% (73/107). Patients diagnosed at a DGH had a trend towards longer time to first MDT discussion (median 28.5 days (IQR 13–57) vs. 21 days (IQR 10.5–37), p = 0.068) and longer time from initial imaging to starting treatment (median 137 days (IQR 81.5–203.5) vs. 102 days (IQR 67.3–153.8), p = 0.117). A higher proportion of DGH patients also required further tests following first MDT discussion before a treatment decision could be made (33% vs 18%, p = 0.0135). There was no significant difference between DGH and level 2 centres for proportion of patients referred for curative treatment (51% vs 48% respectively, p = 0.94) or 1 year survival (72% vs 66%, p = 0.68).
Conclusion: Although there was a trend towards longer time to MDT discussion and commencing treatment for patients diagnosed at a DGH vs a level 2 liver centre, centre type did not appear to significantly influence treatment or survival outcomes. A small sample size, well-established regional MDT and relatively small distance between hospitals may have contributed to these findings. Further research may help determine the true influence of centre type on HCC outcomes, addressing known inequalities in HCC outcomes across the UK[2].

Comparison of magnetic resonance imaging (MRI) characteristics of hepatocellular carcinoma (HCC) based underlying liver disease

Hyungjin Rhee[1], Jae Hyon Park[2], Myeong-Jin Kim[1], Mi Suk Park[1], Jin-Young Choi[1], Yong Eun Chung[1], Young Nyun Park[1]. [1]*Yonsei University College of Medicine, Seoul, Korea, Rep. of South;* [2]*Armed Forces Daejeon Hospital, Daejeon, Korea, Rep. of South*
Email: hjinrhee@yuhs.ac

Background and aims: Although hepatocellular carcinoma (HCC) can occur in the background of various liver diseases, however, the difference of MRI findings according to the underlying liver disease is not well known.
Method: This retrospective study included HCC patients who underwent resection between January 2014 and December 2019. MRI findings and clinic-pathologic findings of HCCs were compared based on the underlying liver disease including hepatitis-B viral (HBV) infection, cirrhosis, and steatohepatitis. Comparison was also performed for HCCs from patients at high risk for HCC according to LI-RADS version 2018.
Results: Out of 465 HCCs in 465 patients, 212 (44%) had cirrhosis, 360 (75%) had hepatitis-B infection, 23 (5%) had hepatitis-C infection and 35 (7%) had steatohepatitis. 399 (83%) patients were at high risk for HCC, wherein 360 (75%) had hepatitis B-infection. Out of 82 (17%) patients not at high risk for HCC, 12 (15%), and 17 (21%) had hepatitis C-infection and steatohepatitis, respectively. The rate of exhibiting major features was not significantly different according to the hepatitis-B infection, cirrhosis, and HCC high-risk. HBV-related HCC and HCC in patients at high risk were commonly associated with smaller size (p < 0.001). The non-HBV related HCC and HCC in patients not at high risk were commonly associated with Nodule-in-nodule, mosaic architecture, blood products-in-mass, fat-in-mass, hepatobiliary phase (HBP) hyperintensity, and fatty liver (Ps < 0.05). Steatohepatitis was associated with fatty liver, fat sparing in mass, and fat-in-mass (Ps < 0.05).
Conclusion: Underlying liver disease is not associated with major features of HCC. In patients not at high risk for HCC, ancillary findings such as nodule-in-nodule, mosaic architecture, HBP hyperintensity, fat-in-mass were more common and these findings may be helpful in image-diagnosis of HCC in patients not at high risk for HCC.

SAT-523
Intrahepatic cholangiocarcinoma: characteristics and outcomes of patients with or without underlying liver disease

Giulia Tesini[1,2], Valentina Zanuso[1,2], Angelo Pirozzi[1,2], Elena Valenzi[1,2], Rita Balsano[1,2], Tiziana Pressiani[1], Silvia Bozzarelli[1], Lorenza Rimassa[1,2]. [1]*IRCCS Humanitas Research Hospital, Humanitas Cancer Center, Rozzano, Milan, Italy;* [2]*Humanitas University, Department of Biomedical Sciences, Pieve Emanuele, Milan, Italy*
Email: giulia.tesini@humanitas.it

Background and aims: Cirrhosis, chronic hepatitis B and C, and metabolic dysfunction-associated steatotic liver disease (MASLD) are risk factors for intrahepatic cholangiocarcinoma (iCCA). We aimed to describe disease characteristics and outcomes of patients (pts) with iCCA with or without underlying liver disease (ULD).

Method: We included consecutive pts from a prospectively maintained dataset diagnosed with iCCA between 2011 and 2023 treated at a single tertiary center. Descriptive statistics were used for pts demographics, tumor and treatment characteristics. Median overall survival (mOS) was calculated from diagnosis with the Kaplan-Meier method. A log-rank test at a two-sided significance level of 0.05 was used to determine the association between ULD and survival.
Results: 248 pts were included, 85 (34%) with ULD; in particular, 17 had liver cirrhosis (LC) and 68 chronic liver disease (CLD). The most common etiology of ULD was MASLD (35 pts, 44%), followed by hepatitis B (17 pts, 22%) and C (12 pts, 15%). 55 pts (65%) with ULD were male vs 76 without (47%, p = 0.01). Median age at diagnosis was 65 years (IQR 59–71) and 64 (IQR 56–70, p = 0.113) among pts with and without ULD, respectively. 213 pts had molecular testing, 73 (34%) with ULD. Tests were performed either through single-gene analysis (74, 35%) or Next-Generation Sequencing (139, 65%). 42 pts (58%) with ULD had molecular alterations vs 95 pts without (68%, p = 0.180). Considering druggable alterations, IDH1 mutation was detected in 10 pts (14%) with ULD vs 23 without (16%, p = 0.747), FGFR2 rearrangement in 6 (8%) vs 18 (13%, p = 0.431), while FGFR2 mutation in 4 (5%) vs 6 (4%, p = 0.739). 48 pts (56%) with ULD had surgery at diagnosis (vs 70, 43%; p = 0.065), while more pts without had stage IV disease at diagnosis [104 pts (64%) vs 39 (46%), p = 0.01]. 70 pts (82%) with and 135 (83%, p = 0.97) without ULD had metastatic disease at some point in their clinical history, but only 47 (67%) and 120 (90%) started first-line systemic therapy (1LT), respectively (p < 0.001). Among them, 5 pts (11%) with ULD and 16 pts (13%) without interrupted 1LT due to clinical deterioration (p = 0.887). After progression to 1LT, 21 pts (45%) with and 65 (54%) without ULD began second-line therapy (p = 0.352). mOS was 25 months (mos) (95% CI, 16–36) vs 24 mos (95% CI, 20–29; p = 0.85) among pts with and without ULD, respectively. In the subgroup analysis, pts with LC had a mOS of 18 mos (95% CI 8-NR; HR 1.53; 95% CI, 0.79–2.96, p = 0.211), while pts with CLD had a mOS of 26 mos (95% CI, 17–41; HR 1.04; 95% CI, 0.72–1.52, p = 0.819).
Conclusion: Pts with iCCA and ULD were primarily male and had stage IV disease at diagnosis less frequently. However, they were less likely to receive 1LT when metastatic disease was found. Although no statistically significant survival differences were observed, there was a trend toward poorer OS among pts with LC. By contrast, pts with CLD had comparable outcomes to those without ULD.

SAT-524

Risk of hepatocellular carcinoma and death among cirrhotics who carry genetic variants of epidermal growth factor, Adiponutrin and 17β-Hydroxysteroid Dehydrogenase-13: a long-term cohort study

Carla De Benedittis[1], Francesca Caldarone[2], Maia Lepore[2], Angelo Strada[2], Michela Burlone[1], Cristina Rigamonti[1,2], Carlo Smirne[1,2], Matteo Nazzareno Barbaglia[3], Rosalba Minisini[2], Mario Pirisi[1,2]. *[1]Division of Internal Medicine, AOU Maggiore della Carità, Novara, Italy; [2]Department of Translational Medicine, Università del Piemonte Orientale, Novara, Italy; [3]Department of Translational Medicine, Università del Piemonte Orientale, 28100, Italy*
Email: carla.debenedittis89@gmail.com

Background and aims: Single nucleotide polymorphisms (SNPs) of genes coding for epidermal growth factor (EGF; rs4444903), adiponutrin (PNPLA3; rs738409), and 17β-hydroxysteroid dehydrogenase-13 (HSD17B13; s72613567) are among the genetic factors thought to be involved in hepatocarcinogenesis. Whether carriage of these SNPs still modulates the risk of developing hepatocellular carcinoma (HCC) and/or survival of patients after they had progressed to cirrhosis is unknown.
Method: A retrospective cohort of 303 adults (183 males, median age 62 years) with any stage of all-cause liver cirrhosis was studied at a single center. All were initially free of HCC and underwent HCC surveillance. Follow-up data were censored at the last follow-up visit. Each patient was genotyped for rs738409, rs72613567, and rs4444903. The results of genotyping were included as predictor variables in two multivariate models.
Results: Etiologies, not mutually exclusive, were as follows: HCV, 150 (50%); HBV, 25 (8%); alcoholic liver disease, 118 (39%); metabolic dysfunction associated steatotic liver disease, 24 (8%); other, 21 (7%). The distribution for Child-Pugh Class at baseline was as follows: Class A, 228/303 (75%), Class B 64/303 (21%), Class C 11/303 (4%). The median observation time from the diagnosis of cirrhosis was 9.9 years (min 1 year, max 26 years, 2793 person-years). At the end of follow-up, 83/303 patients (27%) had developed HCC (incidence rate 0.032 per year), 160/303 (53%) patients had died and 11/303 (4%) had been transplanted. In a Cox proportional hazards model, with age at diagnosis, history of alcohol use, body mass index, diabetes, Child-Pugh class at baseline, HBV positivity, HCV positivity, as well as rs738409, rs72613567 and rs4444903 genotypes as predictor variables, the factors independently associated with development of HCC were: age (HR 1.04, 95% CI = 1.01–1.06, p < 0.001), alcohol (HR 1.74, 95% CI = 1.06–2.84, p = 0.026) and HCV (HR 1.95, 95%CI = 1.09–3.05, p = 0.023). No statistically significant association was found between the development of HCC and the presence of the allelic variants described above. Instead, in a model having the same predictor variables as above, the factors independently associated with death or transplant were age (HR = 1.07, 95%CI = 1.05–1.09, p < 0.001), alcohol (HR = 1.63, 95% CI = 1.15–2.31, p = 0.006), Child-Pugh class (HR = 1.95, 95%CI = 1.45–2.60, p < 0.001), HBV (HR = 0.48, 95%CI 0.24–0.95, p = 0.038) and rs72613567 (HR = 0.76, 95%CI = 0.58–0.98, p = 0.042).
Conclusion: Among cirrhotics initially free of HCC followed for nearly 10 years, none of the three SNPs appeared to modulate the risk of developing HCC, suggesting that their postulated hepatocarcinogenetic effect is exerted earlier in the natural history of chronic liver disease. Carriage of the rs72613567:TA allelic variant appears to exert a mild protective effect on transplant-free survival of cirrhotics.

SAT-525

Revolutionizing post-surgical outcome predictions: non-invasive tests and AI for hepatocellular carcinoma patients

Fodor," Cluj-Napoca, "Iuliu Hatieganu" University of Medicine and Pharmacy, Cluj-Napoca, Romania*
Email: iuliana.nenu@gmail.com

Background and aims: Hepatic resection is crucial for hepatocellular carcinoma (HCC) treatment, but precise patient selection based on factors like tumor size and portal hypertension is vital for accurate prognosis. This study aimed to assess serum liver tests' effectiveness in identifying clinically significant portal hypertension (CSPH) and predicting post-hepatectomy liver failure (PHLF), comparing them with liver stiffness measurement (LSM). A machine learning approach was also evaluated to develop and validate a mathematical model for PHLF.
Method: A cohort comprising 128 patients with compensated cirrhosis and hepatocellular carcinoma (HCC), who underwent hepatic resection at the Regional Institute of Gastroenterology and

Hepatology Cluj-Napoca between 2016 and 2023 was included in the study. Clinically significant portal hypertension (CSPH) was defined as either a hepatic venous pressure gradient (HVPG) of ≥10 mmHg or the presence of esophageal varices, splenomegaly, and thrombocytopenia (<100, 000/mm^3). Non-invasive serum tests were employed: APRI, FIB-4, NLR, eLIFT, and ALBI. The performance of these non-invasive tests in predicting CSPH and prognosis was evaluated using the area under the receiver operating characteristic (AUROC) curves. Logistic Regression, a machine learning algorithm, established a mathematical model for predicting decompensation.
Results: In the cohort under consideration (mean age: 65 ± 7 years; etiological distribution: 32% alcohol, 43% viral hepatitis C, 20% viral hepatitis B, and 5% other etiologies), 45% exhibited CSPH. Notably, APRI, FIB4, and eLIFT demonstrated commendable predictive capacity for CSPH (AUROC = 0.87, 95% CI: 0.79–0.95; p < 0.05; AUROC = 0.88, 95% CI: 0.81–0.96; p < 0.05; and AUROC = 0.83, 95% CI: 0.73–0.92; p < 0.05, respectively). However, it is noteworthy that liver stiffness measurement (LSM) exhibited superior performance in predicting CSPH (AUROC = 0.913, 95% CI: 0.84–0.98; p < 0.05). LSM, APRI, and FIB-4 exhibited a discernible trend in predicting PHLF. Using AI algorithms, we have determined the following equation for probability of PHLF: probability = 1/ (1+e^ (−1* (−3.4220 +1.7835*ACLF_Grade+ 0.0796 *Hospitalisation_days + −0.5725*Number_of_Organ_Failures +−0.3648 * Vent+2.6405*bili)) with an LR accuracy of 0.937.
Conclusion: While liver stiffness measurement (LSM), APRI, FIB-4, and eLIFT demonstrate the capability to identify patients with clinically significant portal hypertension (CSPH) among those with hepatocellular carcinoma (HCC) undergoing hepatic resection, it is noteworthy that they lack the predictive capacity for prognosis in this clinical context. The essence of identifying patients susceptible to postoperative decompensation may be found in the elaboration of mathematical models employing artificial intelligence algorithms.

Predicting non-responsive hepatocellular carcinoma to atezolizumab-bevacizumab therapy: a clinical and imaging-based scoring system

Jaeseung Shin[1], Jae Hyon Park[2], Hyungjin Rhee[3]. [1]*Sungkyunkwan University School of Medicine, Seoul, Korea, Rep. of South;* [2]*Armed Forces Daejeon Hospital, Daejeon, Korea, Rep. of South;* [3]*Yonsei University College of Medicine, Seoul, Korea, Rep. of South*
Email: hjinrhee@yuhs.ac

Background and aims: To develop a model score based on clinical and radiologic markers to predict first response progressive disease (PD) to atezolizumab plus bevacizumab (Atezo-Bev) therapy in advanced hepatocellular carcinoma (HCC) patients.
Method: 140 consecutive HCC patients who received Atezo-Bev therapy between January 2020 and May 2022 at two tertiary care centers were retrospectively enrolled. RECIST version 1.1 was used to assess liver dynamic computed tomography or magnetic resonance imaging, and the first response PD was defined as PD after the 1st cycle of Atezo-Bev therapy. Imaging findings were independently reviewed by two radiologists, and a consensus was reached. Logistic regression analysis was performed to develop a model score for predicting the first response PD.
Results: The first response evaluation of Atezo-Bev therapy was conducted at a median of 56 days (interquartile range, 42–64 days) after treatment initiation. 40% (56/140) of HCC patients showed progression upon the first response evaluation. The model score for predicting first response PD was defined as follows: (age ≥60 years; −1 point) + (serum AFP level ≥300 ng/ml; 3 points) + (NLR ≥2.8; 1 point) + (infiltrative appearance; 2 points). At score of 2 or higher, the model score showed sensitivity of 91.1% (95% confidence interval [CI], 83.6–98.5%) and a specificity of 53.6% (95% CI, 42.9–64.2%). At a score of 5 or higher, the model score demonstrated a sensitivity of 55.4% (95% CI, 42.3–68.4%) and a specificity of 91.7% (95% CI, 85.8–97.6%).
Conclusion: A model score combining both clinical and radiologic factors was developed to predict the non-responsiveness to Atezo-Bev therapy in advanced HCC.

SAT-528
Spleen stiffness measurement accurately predicts clinically significant portal hypertension in patients with hepatocellular carcinoma

Razvan Rababoc[1], Simu Razvan-Ioan[2], Simona Ioanitescu[3], Cristian Mugur Grasu[4], Mircea Istrate[1], Letitia Toma[5], Laura Iliescu[6]. [1]*Fundeni Clinical Institute, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania;* [2]*Fundeni Clinical Institute, "Carol Davila" University of Medicine and Pharmacy, Soseaua Fundeni, Romania;* [3]*Fundeni Clinical Institute, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania;* [4]*Fundeni clincal institute, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania;* [5]*Fundeni Clinical Institute, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania;* [6]*Fundeni Clinical Institute, University of medicine and pharmacy carol davila, Bucharest, Romania*
Email: razvan.rababoc@rez.umfcd.ro

Background and aims: Numerous studies have demonstrated the correlation between elevated spleen stiffness values (measured by transient elastography) and the presence of clinically significant portal hypertension (CSPH). Accurate and non-invasive methods for CSPH are essential for timely intervention and improved patient outcome. In hepatocellular carcinoma (HCC) patients, CSPH may translate into decreased access to therapeutic interventions, such as transarterial chemoembolization. Also, liver stiffness measurement in these patients has a low accuracy due to the non-homogenous aspect of the liver. The current study aims to evaluate the diagnostic performance of this novel module for detecting CSPH in a cohort of patients with hepatocellular carcinoma.
Method: We performed an observational clinical trial including patients with hepatocellular carcinoma and compensated liver disease. Spleen stiffness measurement (SSM) was performed during abdominal ultrasonography, using a dedicated software, with a 100 Hz probe. Portal venous pressure was assessed by hepatic venous pressure gradient (HVPG) and a value of over 10mmHg was considered CSPH.
Results: Our study included 43 patients (58% male; age 54years [42–67]). Aetiology of HCC was: 46% viral hepatitis B, 17% viral hepatitis C, 37% metabolic syndrome associated steatotic liver disease (MASLD). Mean HVPG in the study lot was 12.5 ± 6.2 mmHg, with 34 patients (79%) with criteria for CSPH. Mean SSM was 32.7 ± 11.3 Kpa. Optimal spleen stiffness cut-off to detect probable CSPH was >25 KPa (likelihood ratio: 5.3, sensitivity: 86%; specificity: 76%, positive predictive value 86.5%, negative predictive value 97.4%). The best performance of SSM was recorded in patient with viral liver disease, compared to patients with MASLD (sensitivity 92% versus 84%, specificity 81% versus 69%, positive predictive value 88.4% versus 81.5%, negative predictive value 98.5% versus 95.2%).
Conclusion: Our findings support the utility of SSM for diagnosing CSPH in patients with HCC. The addition of SSM to the Baveno VII criteria increases accuracy in detecting CSPH and can provide a useful tool in risk stratification for HCC patients.

SAT-529
Comparative performance of GAAD and ASAP scores for predicting hepatocellular carcinoma in MASLD and other etiologies

Chongkonrat Maneenil[1], Pimsiri Sripongpun[2], Naichaya Chamroonkul[2], Piraya Tantisaranon[2], Maseetoh Samaeng[2], Roongrueng Jarumanokul[2], Lalita Fonghoi[2], Amornkan Numit[2], Suraphon Assawasuwannakit[2], Teerha Piratvisuth[2], Apichat Kaewdech[2]. [1]*Prince of Songkla University, Hatyai;* [2]*Prince of Songkla University, Hatyai, Thailand*
Email: apichatka@hotmail.com

Background and Aims: The increasing incidence of hepatocellular carcinoma (HCC) associated with metabolic associated steatohepatitis liver disease (MASLD) calls for improved surveillance methods. The standard recommendation of ultrasound surveillance faces limitations in this population. Serum biomarkers, incorporating age and gender, including the GAAD and ASAP scores, have recently been proposed for HCC surveillance. However, there is limited data on their comparative performance in detecting HCC within this demographic. Our study aims to assess and compare the effectiveness of these two scores in detecting HCC among patients with MASLD and other etiologies.
Methods: We prospectively collected blood samples from treatment-naïve HCC patients and non-HCC chronic liver disease (CLD) patients at a gastroenterology outpatient clinic from April 20, 2023, to December 31, 2023. The ASAP and GAAD scores were calculated using AFP and PIVKA-II assays from Abbott and Roche, respectively, with cutoffs set at 0.5256 for ASAP and 2.57 for GAAD. Diagnoses of HCC and MASLD were confirmed following EASL or AASLD guidelines.
Results: The study comprised 651 patients, of whom 31 were diagnosed with MASLD-HCC. The area under the receiver operating characteristic curve (AUROC) for predicting HCC was 0.9352 for the ASAP score and 0.9167 for the GAAD score (p = 0.264). The AUROC for predicting HCC in patients with other etiologies was 0.923 for ASAP and 0.9315 for GAAD (p = 0.2254). Comparing the MASLD-HCC group with those having other causes of HCC, there was no statistically significant difference in the predictive ability of both the GAAD and ASAP scores (p values of 0.6527 and 0.6822, respectively). The GAAD score's sensitivity and specificity for detecting MASLD-HCC were 80.6% and 84.4%, respectively. In contrast, the ASAP score exhibited higher sensitivity at 91.4% but lower specificity at 60%. Conversely, for other causes of HCC, both scores had higher sensitivity and specificity; the GAAD score's sensitivity was 83% with a specificity of 90.1%, while the ASAP score's sensitivity was 88.1% with a specificity of 84.1%.
Conclusion: The GAAD and ASAP scores both display considerable potential for the surveillance of HCC across a range of etiologies. While the ASAP score offers higher sensitivity, its specificity is notably lower, especially in the context of MASLD-associated HCC. Conversely, the GAAD score provides a more balanced sensitivity and specificity profile, suggesting its utility as a surveillance tool in a heterogeneous patient cohort. Future research should aim to refine these biomarkers to improve the early detection of HCC, particularly within the MASLD population where traditional surveillance methods show limitations.

SAT-530

Definite characterization of well-differentiated hepatocellular lesions on biopsy: a 20-year retrospective institutional analysis in the United States of diagnostic challenging cases with long term follow-up

Swachi Jain[1,1], Ruihe Lin[2], Zahra Alipour[1], Kristen Stashek[1], Rashmi Tondon[1]. [1]*Hospital of the University of Pennsylvania, Philadelphia, United States;* [2]*Hospital of University of Pennsylvania, Philadelphia, United States*
Email: jainswachi@gmail.com

Background and aims: Definite characterization of hepatocellular lesions can be challenging, especially in core needle biopsies with atypical or overlapping morphological features. A diagnosis of well-differentiated hepatocellular lesion (WDHCL) is rendered in such cases with a broad differential diagnosis (D/d). However, a definite diagnosis can avoid the need for unnecessary biopsies and appropriate management.
Method: A 20-year retrospective review (1/1/03–6/30/23) of liver biopsies identified 42 patients with atypical/well-differentiated hepatocellular neoplasms/lesions. 19 cases in which one diagnosis was favored were excluded. 23 patients with a broad D/d were included, of which 14 had slides available for review. 3 GI/liver pathologists independently reviewed and classified lesions in 3 categories: Category 1: morphology alone; Category 2: morphology, reticulin stain and provided clinical history; Category 3: morphology, reticulin stain, additional requested clinical history and IHC. Individual results were compared, and diagnostic consensus was achieved if at least 2/3 pathologists agreed. The medical chart was reviewed for follow-up results.
Results: Of 14 cases, characterization into benign or malignant categories was possible in 3 cases (21.4%) in category 1; additional 2 cases in category 2 (5 cases, 35.7%), and a total of 10 cases (71.4%) could be characterized in category 3. Interestingly, one biopsy did not represent lesional tissue. A consensus diagnosis of WDHCL was rendered in 8 cases (57.1%, category 1), of which a definite diagnosis could be given in 6 cases (Category 3), with a diagnostic yield of 75% using additional history, reticulin and IHC. The final diagnosis was correlated with the patient's long-term follow-up data (3 months to 15 years; Table 1). Two patients with a D/d of hepatic adenoma vs. WD-HCC on final diagnosis were found to have WD-HCC on subsequent resections. Two patients with scant atypical tissue could not be further characterized. IHC was useful in 7 of 11 cases. Beta-catenin, glutamine synthetase and reticulin were the most helpful stains, especially in distinguishing lesional tissue from background liver and FNH.
Conclusion: Overall, a definite characterization of WDHCL was provided in 57.1% of patients (8/14), with likely clinical management implications. Inadequate sample size was a major limiting factor in definite characterization (14.3% in our study). Judicious use of IHC should be considered in diagnostic challenging cases and may prevent the need for a subsequent biopsy.

Background and aims: The combination of atezolizumab and bevacizumab (atezo+bev) is the current standard of care for advanced hepatocellular carcinoma (aHCC), providing median overall survival (OS) of 19.2 months. Here, we aimed to leverage the single cell resolution offered by single-cell RNA sequencing (scRNAseq) technologies to uncover the underlying cellular processes driving clinical benefit versus resistance to atezo+bev.
Method: We used scRNAseq data from 31 aHCC tumour biopsies (91.169 single cells) to derive gene signatures recapitulating 21 distinct cell phenotypes. To explore their potential as predictive biomarkers of response to atezo+bev, single-cell derived gene signatures were applied to RNA sequencing datasets comprising n = 422 aHCC patients treated with atezo+bev versus atezolizumab (n = 47) or sorafenib (n = 58) as comparators. Signatures associated with response or resistance to atezo+bev were identified by class prediction and gene set enrichment analysis. Putative biomarkers were then correlated with clinical outcome.
Results: We unveiled two distinct patterns of response to atezo+bev. First, an immune-mediated response characterized by the combined presence of two CD8+ T effector cell subtypes and pro-inflammatory CXCL10+ macrophages, representing an immune-rich microenvironment. Second, a non-immune, angiogenesis-related response distinguishable by a reduced expression of the vascular endothelial growth factor (VEGF) co-receptor neuropilin-1 (NRP1), a biomarker that specifically predicted improved OS with atezo+bev versus sorafenib (p = 0.039). Moreover, we found tumoural enrichment of two immunosuppressive myeloid populations, namely CD14+ monocytes and TREM2+ macrophages, and Notch pathway activation to be associated with primary resistance to atezo+bev.
Based on these biological insights, we defined "Immune-competent" and "Angiogenesis-driven" molecular subgroups, each associated with a significantly longer OS with atezo+bev versus sorafenib (p of interaction = 0.027), and a "Resistant phenotype" associated with significantly worse OS versus all other subtypes.
Conclusion: Our study unveils two distinct molecular subsets of clinical benefit to atezolizumab plus bevacizumab in advanced HCC: "Immune-competent" and "Angiogenesis-driven" and identifies the main traits of primary resistance. We provide a molecular framework to stratify patients based on predicted clinical outcome and guide potential strategies to overcome resistance.

Prediction of TERT promoter mutations using MALDI imaging and artificial intelligence in small hepatocellular nodules in cirrhosis

Helene Cazier[1], Remy Dubois[2], Aurélie Beaufrère[3,4], Samira Laouirem[4], Sarah Paisley[4], Benoit Schmauch[2], Martin Tabath[4], Miguel Albuquerque[3], Valérie Paradis[3,4]. *[1]Centre de recherche sur l'inflamation INSERM 1149, Univercité Paris Cité, iMAP platform, Clichy, France; [2]Owkin France, Paris, France; [3]Hôpital Beaujon APHP Pathology Department, Clichy, France; [4]Centre de recherche sur l'inflammation, INSERM 1149, Université Paris Cité, Clichy, France*
Email: helene.cazier@inserm.fr

Background and aims: Liver carcinogenesis follows a multistep process along hepatocellular carcinoma (HCC) developed from malignant transformation of preneoplastic nodules. The differential diagnosis of small hepatocellular nodules in cirrhosis, ranging from regenerative (LRN), dysplastic nodules [low (LGDN) and high grade (HGDN)] and early HCC, remains challenging, especially on biopsy specimen. The presence of *TERT* promoter (p*TERT*) mutations, the most frequent genetic alterations in HCC, may help to identify the hepatocellular nodules already engaged in the malignant process. We aimed to (1) develop an artificial intelligence-based model to predict p*TERT* mutations, and (2) identify tissue biomarkers associated with p*TERT* mutations using MALDI (Matrix Assisted Laser Desorption Ionization) imaging, an approach providing exhaustive spatial peptidic signatures from fixed and paraffin embedded (FFPE) tissue sections.
Method: We built 7 FFPE tissue microarrays (TMAs) composed of 234 hepatocellular nodules <2 cm from cirrhotic samples, divided respectively in a training set of 164 cases [HCC (n = 53, HGDN-HCC (n = 0), HGDN (n = 31), LGDN (n = 24), LRN (n = 24) and cirrhotic nodules (n = 32)] and a validation set of 70 cases [HCC (n = 25), HGDN-HCC (n = 5), LGDN (n = 6) LRN (n = 9) and cirrhotic nodules (n = 10)]. p*TERT* mutations were identified by digital droplet PCR in 1 FFPE whole block per nodule. MALDI imaging was applied on all TMAs in order to generate mass-spectrometry library of peptides. A L1 -regularized Logistic Regression model (LASSO) was then trained to predict p*TERT* mutation status from spatially pooled tissue cores spectrum. This model was trained in a leave-one-TMA-out schedule repeated three times with varying algorithm seeds, resulting in 12 trained models in total.
Results: ddPCR revealed p*TERT* mutations in 34% of the 234 nodules including 51 and 28 cases in the training and validation sets, respectively. Our AI model showed good to very good performance in predicting p*TERT* mutations (Area under the curve for all 3 test TMAs [AUC] with 95% confidence interval: 0.73 [0.52–0.95]; 0.80 [0.60–1.0]; 0.82 [0.61–1.0]). The model performed particularly well for predicting p*TERT* mutations in HCC nodules ([AUC]: 0.91 [0.71–1.0]). Finally, we identified 15 peptidic peaks correlated with p*TERT* mutations.
Conclusion: We developed and validated an AI-based model for predicting p*TERT* mutations in small hepatocellular nodules arising in cirrhosis using MALDI imaging data. These analyses led to the identification of a peptidic signature predictive of p*TERT* mutations. The further identification of these peaks will allow the development of a panel of markers that could be performed by immunohistochemistry to identify the malignant hepatocellular nodules on biopsy samples.

FRI-455

Liver cancer in ovo models for preclinical testing

Paul Garcia[1,2,3], Yan Wang[3], Jean Viallet[3], Nour-El-Houda Mehdi[1,2], Emilie Montaut[1,2,4], Thomas Decaens[1,2,5], Anouk Emadali[1,2,4], Zuzana Macek Jilkova[1,2,5]. *[1]Université Grenoble Alpes (UGA), Grenoble, France; [2]Institute for Advanced Biosciences, Research Center UGA/Inserm U 1209/CNRS 5309, La Tronche, France; [3]RandD Department, Inovotion, La Tronche, France; [4]Pôle Recherche, CHU Grenoble Alpes, La Tronche, France; [5]Service d'Hépato-gastroentérologie, Pôle Digidune, CHU Grenoble Alpes, La Tronche, France*
Email: zuzana.mjilkova@gmail.com

Background and aims: Today, more than 70% of patients with advanced liver cancer don't respond to first-line treatments. New combination therapeutic strategies are therefore currently under exploration, drastically increasing the need of models for preclinical testing of immunotherapies. Besides the obvious ethical concerns, classical animal models of HCC lack the capacity to reproduce the tumor-immune system interface that is required to test the new immunotherapy approaches. The *in ovo* (in the egg) model is based on the use of the chorioallantoic membrane (CAM) of the chicken embryo, thus bridging the gap between in vitro studies and complex animal models, as an advanced model without the need for ethical approval. The *in ovo* immune status gradually develops over time and can be described as biologically similar to humans. The gradual immune development during embryogenesis in the *in ovo* model allows the cancer cells to be grafted at embryonic development day (EDD) 9 with a low risk of xenograft rejection due to its partial immunodeficiency until it becomes fully competent by EDD18. This dichotomy makes the model interesting for immuno-oncology research, as it allows both tumor xenografting and immune infiltration.

Method: We developed several *in ovo* human liver cancer models, based on the tumor grafting of different liver cancer cell lines (HepG2, Hep3B, HuH7, PLC/PRF/5) on the chicken eggs' CAM, and characterized the collagen accumulation, angiogenesis, as well as the tumor immune microenvironment by immunohistochemistry and RNA sequencing. Treatments with atezolizumab (anti-PD-L1, TECENTRIQ®) and bevacizumab (anti-VEGF, MVASI®) were tested.

Results: Our results show the involvement of chicken immune cells in tumor growth, reproducing a classical non-inflamed "cold" as well as inflamed "hot" tumor status, depending on the *in ovo* liver cancer models. The absence of immune response on gene profile in Hep3B *in ovo* was indicative of a cold tumor profile. On the other hand, a "hot" PLC/PRF/5 *in ovo* tumor was characterized by a high presence of T-cells, and RNA-seq data revealed an increased level of immune activity.

The treatment by atezolizumab and bevacizumab was highly efficient in the "hot" tumor model PLC/PRF/5 *in ovo* with the reduction of tumor size by 76% ($p \leq 0.0001$) compared to control, while the efficacy was limited in "cold" tumor Hep3B *in ovo*. The contribution of anti-PD-L1 blockade to the anti-tumor effect in model PLC/PRF/5 *in ovo* was demonstrated by the efficacy of atezolizumab monotherapy.

Conclusion: This study provides complete information, with detailed characterization and rational arguments that could lead to the partial replacement of conventional laboratory animals with a more ethical model, better suited to the current needs of preclinical research of new immunotherapies for liver cancer.

FRI-456

Characterization of the intratumoral immune microenvironment of hepatocellular carcinoma before selective intrahepatic radiation therapy (SIRT) and study of its prognostic value on response to treatment

Email: mariastellafranze@gmail.com

Background and aims: Internal selective radiation therapy (SIRT) is a validated treatment of hepatocellular carcinoma (HCC). The role of local immune response in achievement of response remains elusive. This study was designed to characterize the HCC immunological status before SIRT and its impact on therapeutic response (primary end point) and survival.

Method: One-hundred patients from 8 University Hospitals (7 French, 1 Italian), affected by histologically proven HCC and treated with SIRT, were enrolled in the study. For each patient, clinical/biological/radiological data were collected at the diagnosis of HCC and during follow-up. Patients were defined as "responders" and "not responders" according to radiological tumor response evaluated 3 and 6 months after SIRT with mRECIST criteria. RNA sequencing was analyzed to study genes expression differences in the intra-tumoral microenvironment.

Results: Twenty-seven patients (81.5% male, median age 63 years, 67% with cirrhosis) were analyzable for primary end point. HCC

distribution across BCLC stage was: 4 A (15%), 10 B (37%), 13 C (48%). Nine patients were responders (1 complete/8 partial response), 17 not responders (3 stable/14 progressive disease). Median overall survival (OS) of patients was 15.9 months. According to RNA sequencing analysis, unsupervised hierarchical clustering identified two clusters (10 C1, 17 C2) of patients (of which most of responders in C2, p = ns) with different genes expressions. Clusters were different for cirrhosis (p = 0.008), albumin (p = 0.028) and AFP levels (p = 0.015), histological differentiation (p = 0.003) and subtype of HCC (p = 0.03), time of OS (C1: 10.6 months; C2: 18.0 months; p = 0.047). A supervised analysis for differentially expressed genes showed 480 genes down- and 1121 over-expressed in C1 vs C2. Gene set enrichment analysis with Molecular Signatures Database performed with a hypergeometric test showed that C1 was associated with genes involved in immune responses while C2 with genes involved in proliferation/differentiation liver cells. By Microenvironment Cell Populations counter method, we identified an abundance of immune infiltrates (monocytes, myeloid dendritic cells, cytotoxic lymphocytes, T and B cells) in C1 vs C2. Cox-univariate analysis showed only a higher risk of death for patients not responders at 3 months (p = 0.004).

Conclusion: These results suggest that presence of a pro-inflammatory intratumoral immune infiltrate appears predictive of a worse OS with a trend of bad response to SIRT in HCC patients. Our hypothesis is that SIRT, in analogy with external radiotherapy, can trigger the release of pro-inflammatory mediators and increase tumour-infiltrating immune cells. This phenomenon, often described in literature as turning immunologically 'cold' tumours to 'hot', may enhance the efficacy of combined with immunotherapy.

FRI-457

CXCL12 restricts hepatocellular carcinoma progression by shaping the tumor microenvironment in liver fibrosis

Marlene Kohlhepp[1], Julia Onstein[2], Jana Hundertmark[1], Thomas Ritz[3], Alma Diaz Ruiz de Zarate[1], Tobias Puengel[1], Adrien Guillot[1], Frank Tacke[1]. *[1]Department of Hepatology and Gastroenterology, Charité University Medicine Berlin, Berlin, Germany; [2]University Hospital Aachen, Department of Medicine III, Aachen, Germany; [3]Institute of Pathology, University Hospital Heidelberg, Heidelberg, Germany*
Email: marlene.kohlhepp@charite.de

Background and aims: The chemokine (C-X-C motif) ligand 12 (CXCL12) has been implicated in promoting both progression of fibrosis and primary liver tumour growth, by signaling through its two cognate receptors, C-X-C motif receptor 4 (CXCR4) and atypical chemokine receptor 3 (ACKR3, or CXCR7). In addition, CXCL12 regulates immune cell egress from the bone marrow and their recruitment to the tumour, which is considered to shape a pro-tumourigenic tumour microenvironment. This study aims at exploring the therapeutic potential of CXCL12 inhibition for the prevention and treatment of liver fibrosis and primary liver cancer.

Method: A CXCL12 inhibitor was used in two experimental mouse models of liver fibrosis induced either by repetitive carbon tetrachloride (CCl_4) injections or by feeding a high fat methionine-choline deficient (MCD) diet. To investigate the role of CXCL12 in primary liver cancer in mice, the CXCL12 inhibitor was applied in diethylnitrosamine (DEN)-induced liver cancer combined with either CCl_4 to create a fibrotic environment, or with a high-fat, high-sugar, and high-cholesterol Western diet (WD) to induce metabolic dysfunction-associated steatotic liver disease (MASLD). Immune cells were analyzed by flow cytometry and multiplex immunostaining. Serum chemokines were analyzed with a 12-plex LUNARIS™ biochip.

Results: CXCL12 inhibition had no impact on liver fibrosis (collagen deposition, Sirius Red, hepatic hydroxyproline content) but led to increased tumour burden in both the fibrosis- and MASLD-associated liver cancer model (tumour numbers, liver to body weight ratio). CXCL12 inhibition increased chemokine levels in blood plasma, which was accompanied by an increase of peripheral blood myeloid cells. In the liver, CXCL12 inhibition provoked changes in hepatic monocyte-derived macrophage (MoMF) populations characterised by a decrease of $CD11c^+MHC\text{-}II^+$ MoMF and a relative increase of $Ly6C^+$ MoMF. In addition, CXCL12 inhibition specifically reduced eosinophils and B cells in the liver of CCl_4-treated, but not in MASLD livers. Intriguingly, CXCL12 inhibition promoted tumour growth, despite reducing tumour infiltrating MoMF and increasing cytotoxic CD8+ T cells in tumour lesions. Moreover, inhibition of CXCL12 activated vascular remodeling in tumour microvessels, evident by an upregulation of CXCR4 on tumour endothelial cells and increased expression of both angiogenic (i.e., *Ang2*) and anti-angiogenic (*Ang1, Thbs1*) genes in tumour tissues.

Conclusion: This study demonstrates pro-tumourigenic effects of CXCL12 inhibition in liver cancer and suggests a pivotal role for CXCL12 in tumour control mechanisms. CXCL12 restricts liver cancer progression by a multi-faceted modulation of the tumour microenvironment.

FRI-458

Low-density neutrophils display transcriptome profiles similar to the polymorphonuclear myeloid-derived suppressor cells and predict survival and recurrence in hepatocellular carcinoma patients

Chien-Hao Huang[1], Cheng-Heng Wu[2], Po-Ting Lin[2], Tsung-Han Wu[2], Wei Teng[2], Yi-Chung Hsieh[2], Rachel Wen-Juei Jeng[2,3], Wei-Ting Chen[4], Kun-Ming Chan[5], Shi-Ming Lin[2], I-Shyan Sheen[4], Chun-yen Lin[6]. *[1]Division of Hepatology, Department of Gastroenterology and Hepatology, Chang-Gung Memorial Hospital, Linkou Medical Center, Taoyuan, Taiwan, College of Medicine, Chang-Gung University, Taoyuan, Taiwan, TaoYuan, Taiwan; [2]Chang-Gung Memorial Hospital, Linkou Medical Center, TaoYuan, Taiwan; [3]Chang Gung University, College of Medicine, Taoyuan, Taiwan; [4]Chang-Gung Memorial Hospital, Linkou Medical Cente, TaoYuan, Taiwan; [5]hang-Gung Memorial Hospital, Linkou Medical Center, TaoYuan, Taiwan; [6]Division of Hepatology, Department of Gastroenterology and Hepatology, Chang-Gung Memorial Hospital, Linkou Medical Center, Taoyuan, Taiwan, College of Medicine, Chang-Gung University, Taoyuan, Taiwan, TaoYuan, Taiwan*
Email: huangchianhou@gmail.com

Background and aims: Hepatocellular carcinoma (HCC) ranks as the sixth most prevalent global cancer, with a sobering third position in cancer-related mortality according to Globocan 2020 data. Current curative treatments are applicable to less than 30% of patients, highlighting the need for novel therapeutic approaches. Immune checkpoint inhibitor (ICI) immunotherapy, despite achieving response rates of 15–30%, has not reached optimal efficacy. Low-density neutrophils (LDNs), a subset implicated in cancer progression and metastasis, present an intriguing avenue for HCC research and novel treatment strategies.

Method: Peripheral blood was collected from both normal controls and HCC patients spanning TNM stages I to IV, with Child-Pugh class A to early B status. Isolation of LDNs from peripheral blood mononuclear cells and tumor tissue was performed using flow cytometric methods. Subsequent analyses involved the examination of clinical data, LDN percentages, and RNA sequencing (RNA-seq) to gain comprehensive insights.

Results: A total of 29 normal controls and 298 HCC patients were included in the study. LDN percentages were observed to be elevated in the peripheral blood mononuclear cells (PBMC) of HCC patients compared to controls, with further accumulation in tumor tissues. LDNs exhibited increased reactive oxygen species (ROS) levels and demonstrated dose-dependent suppression of $CD8^+$ and $CD4^+$ T cells ex-vivo. Clinically, the LDN percentages in PBMC correlated with advanced TNM staging and served as predictors for 1-year survival, along with neutrophil-to-lymphocyte ratio (NLR) and derived NLR. However, only LDN independently predict 1-year survival by multivariate logistic regression analysis among the three

neutrophil-related scores. Importantly, LDNs were exclusive predictors of HCC recurrence within one year post-curative treatment, in addition to TNM stage. RNA-seq revealed that LDN in patients with HCC shared gene profiles with polymorphonuclear myeloid-derived suppressor cells (PMN-MDSC) and displayed high glycolysis and oxidative phosphorylation potential.
Conclusion: This study highlights LDNs as valuable prognostic predictors for survival and HCC recurrence post-curative treatment in HCC patients. RNA-seq demonstrates their resemblance to PMN-MDSC and high glycolysis and oxidative phosphorylation potential.

FRI-459
Outcome of targeting ATR in high replication stress murine HCC

Email: jing.fang@inserm.fr

Background and aims: Hepatocellular carcinoma (HCC) belongs to the five most common malignancies in adult. Much effort is devoted to establishing efficient systemic treatments through many clinical trials. In recent years, targeting DNA Damage Response components has become attractive therapeutics target for cancer therapy. In the present study, we investigate whether targeting DNA Damage Response and more specifically ATR, could offer therapeutic opportunities for High Replication Stress HCC.
Method: Cohort of HCC patients was selected on TCGA dataset (N = 307) and LICA-FR (N = 222) and categorized into two groups related to high and low replication stress (RS) signatures. Pre-clinical HCC murine models were used (Non-germline mosaic GEMMs). Liver-specific deletion of ATR (ATR^{Dhep} or $ROSA26^{\Delta hep}$ (control)) was carried out by AAV8-CRISPR/Cas9 approach. Cell proliferation, apoptosis were investigated through cellular and molecular analyses. Immune cells were profiled with flow cytometry and immunostaining. Whole transcriptome sequencing (RNA-Seq) was conducted to investigate the impact of targeting ATR in High Replication Stress murine HCC.
Results: Kaplan-Meier analyses of TCGA and LICA-FR databases revealed that HCC patients with a high RS signature had worse overall survival and disease-specific survival compared to HCC patients with a low RS signature. In GEMMS mice models (n = 11), scRNAseq data were used to identify two HCC models: a High Replication Stress (HRS-HCC: MYC, sg-p53) and a Low Replication Stress (LRS-HCC: MYC, sg-Pten). Interestingly, silencing of ATR as no impact on tumoral incidence in LRS-HCC group. By contrast we observed, that in HRS-HCC, deletion of ATR impacts on: (1) tumor incidence 4 weeks after HDI (100%/$ROSA26^{Dhep}$; 37.5%/ATR^{Dhep}); (2) tumor size (11.71 mm/$ROSA26^{Dhep}$; 5.57 mm ATR^{Dhep}, $p = 0.0105$) as well as tumor number/mice (5.12/$ROSA26^{Dhep}$; 1.42/ATR^{Dhep}); (3) median survival (55 days in ATR^{Dhep} versus 43 days in $ROSA26^{Dhep}$). We also showed that hepatocyte proliferation was reduced in ATR^{Dhep} compared to $ROSA26^{Dhep}$ in paraneoplastic liver tissues. Furthermore, in ATR^{Dhep} tumoral tissue, apoptosis was more pronounced (cleaved-Caspase-3/cleaved-Caspase-9). To go deeper, bulk RNA-sequencing analysis was performed on tumor tissues. We observed that silencing of ATR enriched specific anti-tumor immune response pathways: "IFN- γ production," "Positive regulation of cell activation," "Response to IFN-γ," "T cell activation." These data were validated by flow cytometry with significantly more CD4+ iNKT cells; IFN- γ+iNKT cells and fewer Treg cells in liver tumor tissues in ATR^{Dhep} tumors.
Conclusion: Silencing of ATR in a high RS murine HCC model can delay tumor development via bolstered anti-tumor immune response. Further works will define whether targeting ATR could be a potentially effective strategy for human HRS-HCC treatment.

Aminoacyl-tRNA synthetases characterization and clinical potential in aggressive hepatocellular carcinoma
Natalia Hermán-Sánchez[1,2,3,4], Javier M. Zamora-Olaya[1,5,6], Manuel Rodríguez-Perálvarez[1,5,6], Raul M Luque[1,2,3,4], Juan L. López-Cánovas[1,2,3,4], Manuel D. Gahete[1,2,3,4]. *[1]Maimónides Institute of Biomedical Research of Córdoba (IMIBIC), Córdoba, Spain; [2]Department of Cell Biology, Physiology and Immunology, University of Córdoba, Córdoba, Spain; [3]Reina Sofía University Hospital (HURS), Córdoba, Spain; [4]CIBER Pathophysiology of Obesity and Nutrition (CIBERobn), Córdoba, Spain; [5]Department of Hepatology and Liver Transplantation, Reina Sofía University Hospital, Córdoba, Spain; [6]CIBER Hepatic and Digestive Diseases (CIBERehd), Córdoba, Spain*
Email: nataliahermansan@gmail.com

Background and aims: Hepatocellular carcinoma (HCC) genetic and transcriptomic signatures have been widely described. However, its proteomic characterization, which might increase the knowledge of potentially targetable alterations, is scarce. To provide novel insights in this field, we performed non-targeted quantitative proteomics of HCC samples from different aetiologies.
Method: Non-targeted quantitative proteomics were performed on cytosolic and nuclear fractions of hepatic samples (n = 42; HCC vs. non-tumour adjacent tissue). The alteration of the dysregulated proteins was confirmed in 7 *in silico* HCC cohorts. Functional parameters (proliferation, migration, colonies/tumorspheres) were evaluated on HCC-derived cell lines (Hep3B, SNU-387) after silencing/overexpressing *VARS1* alone or simultaneously with *MAGI1*. *VARS1*-overexpressing Hep3B cells were subcutaneously injected in athymic mice for an Extreme Limiting Dilution Assay (ELDA). Quantitative proteomics were performed on Hep3B and SNU-387 cell lines following *VARS1* overexpression.
Results: Non-targeted proteomics revealed the dysregulation of the cytosolic (n = 507 proteins) and nuclear (n = 925 proteins) proteomes in HCC. This proteomic profile discriminated two tumoral subgroups, one of them associated to aggressiveness and to a profound dysregulation of the aminoacyl-tRNA synthetases (ARSs), which catalyse tRNA aminoacylation. Their dysregulation was corroborated in other *in silico* HCC cohorts and associated to clinical features. Indeed, Gene Set Enrichment Analysis (GSEA) confirmed that patients with a general upregulation of the ARSs machinery have genomic (i.e. *TP53* mutations) and transcriptomic characteristics of the proliferative HCC. The valine tRNA-aminoacyl synthetase, VARS1, was selected to study the functional and molecular consequences of ARSs dysregulation. VARS1 modulation had a reduced effect on proliferation/migration although it significantly altered the dedifferentiation capacity of the cells and the expression of mesenchymal and stemness-related markers. Untargeted quantitative proteomics on Hep3B and SNU-387 cells overexpressing *VARS1* demonstrated a decreased expression of the scaffold protein *MAGI-1*, a known tumour suppressor in HCC, associated with the overexpression of *VARS1*. Thus, VARS1 might be exerting its role through the modulation of MAGI-1-mediated cell junctions.
Conclusion: Quantitative proteomics defines two HCC subgroups. The dysregulation of the ARSs machinery is a marker of the most aggressive one, with a potential usefulness as prognostic marker. One of the most dysregulated ARSs, VARS1, promotes aggressiveness, and could therefore be targetable, through the modulation of MAGI1.

FRI-463-YI

Identifying unique cell states in early liver oncogenesis with transcription coupled repair

Elizabeth Carmichael[1], Edward Jarman[1], Luke Boulter[1], Martin Taylor[1]. [1]*University of Edinburgh, Edinburgh, United Kingdom*
Email: e.carmichael-4@sms.ed.ac.uk

Background and aims: Hepatocellular carcinoma (HCC) is the most common type of primary liver cancer, yet what the early requirements are for a mutant cell to become a cancer remains poorly defined. We utilize the established diethylnitrosamine (DEN) induced mouse model to study HCC formation. Many hepatocytes acquire cancer-driving mutations as a result of DEN treatment, however only a small number of tumors will form per liver. We hypothesize that certain damaged hepatocytes enter cell states that promote them towards tumor formation preferentially over their neighbors. Here we identify the transcriptional states that are permissive to oncogenic transformation.
Method: Transcription coupled repair (TCR) can repair DEN induced DNA damage, and decrease the mutational burden. TCR will only decrease the mutational burden of genes that are transcribed after DEN exposure. As a result, sequenced tumors show low mutation rates in genes active post-DEN treatment, and the inverse for inactive genes. By studying patterns in mutation rates across DEN induced tumors, we can infer gene sets we believe to be up or down regulated after DEN treatment-specifically in damaged hepatocytes that have gone on to form tumors. We also preform single nuclei RNA sequencing (snRNA-seq) of DEN treated liver tissue collected shortly post DEN treatment. Pairing these techniques, we isolate sub populations of hepatocytes we predict to be permissive to HCC formation.
Results: Gene-sets associated with cell adhesion, cell motility, and cell migration appeared to have higher mutational burdens than expected given their levels of transcription in undamaged hepatocytes. These genes also appeared as significantly differentially expressed post DEN treatment compared to the undamaged control (adjusted p value <0, 01). Single nuclear RNA-seq and hierarchical clustering reveled unique expression profiles to the damaged hepatocytes, including differential expression of genes associated with cell motility and adhesion again.
Conclusion: Many gene sets, including those related to cell adhesion, migration, and motility, are been predicted to be down-regulated in response to DEN treatment, due to their high mutational burden in sequenced tumors. RNA sequencing methods identified these genes sets as being unique to post DEN damage hepatocytes, and the down-regulation of these genes sets in response to DEN treatment was directly observed using both single nuclei and bulk RNA sequencing. These findings validate the TCR technique as a robust proxy for identifying gene expression profiles associated with the likely cell type/profile of origin for HCC.

Caspases compromise SLU7 and UPF1 stability and nonsense-mediated RNA decay activity during hepatocarcinogenesis

Carla Rojo[1], María Gárate-Rascón[1], Miriam Recalde[1], Ane Álava[1], María Elizalde[1], María Azkona[1], Elisabet Guruceaga[1], Amaya Lopez-Pascual[1], Maria U. Latasa[1], Bruno Sangro[2,3,4], Maite G. Fernandez-Barrena[1,3,4], Matías A. Avila[1,3,4], Maria Arechederra[1,3,4], Carmen Berasain[1,3]. [1]*CIMA, CCUN, University of Navarra, Pamplona, Spain;* [2]*Clínica Universidad de Navarra, CCUN, Pamplona, Spain;* [3]*CIBERehd, Instituto de Salud Carlos III, Madrid, Spain;* [4]*Instituto de Investigación Sanitaria de Navarra (IdiSNA), Pamplona, Spain*
Email: cberasain@unav.es

Background and aims: Cellular transcriptome homeostasis depends on transcription and splicing. Moreover, the fidelity of gene expression, essential to preserve cellular identity and function is secured by different quality control mechanisms including nonsense-mediated RNA decay (NMD). Our previous findings demonstrated that the expression of the splicing factor SLU7 is reduced in hepatocellular carcinoma (HCC) and the damaged liver, contributing to hepatocellular de-differentiation and genome instability, associated to transcription and splicing changes. Here demonstrate that SLU7 plays a role in NMD which is inhibited in the damaged liver and in HCC. Importantly, we also decipher the mechanism by which SLU7 is downregulated during the progression of liver disease.
Method: We used several human extra-hepatic cancer and HCC cell lines, as well as mouse primary hepatocytes, SLU7 specific siRNAs, apoptosis activators, the antioxidant N-acetylcysteine and the pan-caspase inhibitor zVAD-fmk. Animal models: administration of Fas agonistic antibody Jo2 or acetaminophen (APAP), and Mdr2-/- mice. RNA-seq analysis at the transcript level by Kallisto and SLEUTH, qPCR, Western blot, and immunoprecipitation/mass spectrometry assays. Chemiluminescence-based NMD reporter assay to measure NMD activity. LIHC-TCGA RNA-seq data. Statistical analyses with GraphPad Prism 8.0.1.
Results: TCGA database analysis demonstrate the accumulation in HCC of NMD-target transcripts suggesting the inhibition of NMD activity. RNA-seq analysis in PLC/PRF/5 cells, as well as PCR and qPCR validation in different cancer cell lines revealed that SLU7 depletion induces a significant accumulation of NMD-targets and intron retention isoforms, in parallel to the upregulation of NMD factors, all events associated with NMD inhibition. Moreover, we demonstrate that SLU7 interacts with and stabilizes the NMD core effector UPF1, and that SLU7 is required for a correct NMD activity. Importantly, we found that in two animal models of acute liver injury (Jo2 and APAP) and during the process of hepatocarcinogenesis in Mdr2-/- mice, NMD is inhibited, resulting in the accumulation of different NMD targets, in parallel to the downregulation of UPF1 and SLU7 proteins. Remarkably, we provide in vitro and in vivo evidence showing that caspases activation would be responsible of the cleavage and degradation of SLU7 observed during the process of hepatocarcinogenesis in animal models and patients.
Conclusion: Here we identify the downregulation of UPF1 and the inhibition of NMD as a new molecular pathway contributing to the malignant reshaping of liver transcriptome. Moreover, and importantly, we uncover caspases activation as the mechanism responsible for the downregulation of SLU7 expression during liver disease progression, representing a new link between apoptosis and hepatocarcinogenesis.

The fetal insulin receptor isoform stimulates liver carcinogenesis through non-cell autonomous mechanisms

Fanny Leandre[1], Akila Hamimi[2], Cécile Godart[1], Isabelle Lagoutte[3], Anthony Caldiero[2], Sandra Pinto[2], Alexandre Alves[2], Sabine Colnot[2], Angélique Gougelet[2], Christèle Desbois-Mouthon[1]. [1]*INSERM UMRS1138, Paris, France;* [2]*Centre de Recherche des Cordeliers-INSERM UMRS 1138, Paris, France;* [3]*Institut Cochin-INSERM U1016, Paris, France*
Email: christele.desbois-mouthon@inserm.fr

Background and aims: The insulin receptor (IR) plays a crucial role in the liver by regulating metabolism and proliferation. In the adult liver, these functions are relayed by IRB upon insulin binding. IRA, the fetal isoform, has been reported to be expressed during the progression of hepatocellular carcinoma (HCC). IR isoforms result from the alternative splicing of exon 11 in *Insr* pre-mRNA. Recently, studies detected IRA in murine and human livers with hepatitis or cirrhosis which are risk factors for HCC. These data raise the question of the role of IRA in the pathogenesis of HCC. Therefore, the goal of our study is to investigate the role of IRA on liver homeostasis and carcinogenesis *in vivo*.
Method: An *in vivo* CRISPR strategy using hepatotropic AAV8 expressing saCas9 nuclease and small guide RNAs was developed to delete exon 11 (IRB specific) in *Insr* gene and substitute IRB for IRA in adult mouse hepatocytes. This strategy was conducted in wild-type

mice and in mice with beta-catenin activation in the liver due to hepato-specific APC loss (APC $^{\Delta Hep}$) or β-catenin mutation (BCAT$^{\Delta ex3}$). APC $^{\Delta Hep}$ and BCAT$^{\Delta ex3}$ mouse models develop differentiated HCC and undifferentiated hepatoblastoma-like tumors. *Insr* gene editing was evaluated by PCR. Glucose homeostasis was assessed with glucose and insulin tolerance tests. Tumor development was followed by ultrasonography.

Results: Short-term expression of IRA (2 months) in healthy hepatocytes did not induce disturbances in liver homeostasis, but its long-term expression resulted in the appearance of spontaneous tumors (2/8 mice) that were not edited at *Insr*. In APC $^{\Delta Hep}$ and BCAT $^{\Delta Ex3}$ models, hepatocyte expression of IRA induced a significant increase in tumor initiation and multiplicity. A higher proportion of differentiated tumors was observed in IRA/APC$^{\Delta Hep}$ mice compared to APC $^{\Delta Hep}$ mice (85% vs 44%, $p < 0.0001$). Again, the vast majority of the tumors were not edited at *Insr*, indicating that IRA-expressing hepatocytes were counter-selected during the carcinogenic process. At an early step of carcinogenesis (50 days), livers from Apc $^{\Delta Hep}$ mice with IRA expression showed increased proliferation of β-catenin-activated hepatocytes together with hallmarks of inflammation (TNFα) and apoptosis. *In vitro*, IRA-expressing hepatocytes displayed increased sensitivity to pro-apoptotic TNFα treatment.

Conclusion: IRA promotes hepatocarcinogenesis through non-cell autonomous mechanisms by modifying liver environment as IRA-expressing hepatocytes do not engage in transformation. Our data suggest a scenario of cell competition in which IRA hepatocytes are eliminated by apoptosis, leaving space for proliferation of preneoplastic APC$^{\Delta Hep}$/IRB cells. Therefore, IR-A could be considered as a risk factor for HCC.

FRI-466-YI

Implications and therapeutic potential of neddylation for pediatric liver cancer: hepatoblastoma

Email: mlmartinez@cicbiogune.es

Background and aims: Hepatoblastoma (HB) is a rare type of primary liver cancer that mainly affects children. Currently, the main treatment options include surgical resection accompanied by chemotherapeutics such as cisplatin or doxorubicin. However, these options are limited or ineffective due to poor prognosis, high recurrence rate and significant side effects. This is a tumor with a low rate of somatic mutations, in which the involvement of other mechanisms modulating its tumorigenic capacity stands out. In this regard, it is crucial to highlight the adaptive advantages conferred to the tumor by post-translational modifications. Neddylation has been extensively studied in this context. Based on this evidence, we have considered analyzing the impact that neddylation could have on the development of HB.

Method: A cohort of HB patients, preclinical animal model and *in vitro* model in tumor cells were used to characterize NEDDylation pathway in HB. Besides the modulation of NEDP1 levels using an *in vitro* approach was made to study cell proliferation, migration, and metabolic status. *In vivo*, the implications of NEDP1 overexpression as tumor suppressor was evaluated.

Results: Transcriptomic analysis in samples from patients with HB has demonstrated an increase in the neddylation cycle. Likewise, in preclinical models of HB, both *in vivo* and *in vitro*, we have identified an increase in NEDD8 and NAE1 (the NEDD8-activating enzyme E1), which is related to an increase in global neddylation. A significant reduction in the levels and activity of NEDP1 deneddylases has also been observed, which justifies the importance of this process in the development and progression of this pathology. In addition, a positive impact on proliferation driven by neddylation is evidenced. The use of pharmacological inhibitors of neddylation has been shown to decrease such proliferation, while the increase in global neddylation induced by NEDP1 inhibition has resulted in its increase. Moreover, modulation of neddylation through increased levels of NEDP1, *in vitro* and *in vivo* approaches, reveals induction of apoptosis, modulation of migratory and proliferative capacity and metabolic reprogramming, both in HB cell lines (HepT1 and HepG2) and in patient-derived xenografts (PDX) from distal metastasis. *In vivo*, *in Ovo* and *ex Ovo* experiments showed a reduction of tumorigenicity and metastatic phenotype; mice models of HB showed, at the histological level, a reduction of proliferation and tumorigenesis, as well as an increase of necrosis, and a reorganization of the proteome, with an increase of apoptotic processes.

Conclusion: The effect observed with NEDP 1 overexpression points to the importance of post translational modifications in pathologies such as HB and highlights the relevance of NEDDylation, not only in the molecular characterization of HB, but also in the development of new specific treatments.

FRI-467

Efficacy of WNTinib, a novel selective therapeutic for CTNNB1 mutant tumors, in preclinical models of hepatoblastoma

Ugne Balaseviciute[1,2], Jordi Abril-Fornaguera[1,2], Júlia Huguet-Pradell[1,2], Alex Rialdi[3], Elisa Fernández-Martínez[1,2], Albert Gris-Oliver[1], Agavni Mesropian[1,2], Gulay Ulukaya[3,4], Dan Hasson[3,4], Ieva Keraite[1,2], Roser Pinyol[1], Swan N. Thung[5], Ernesto Guccione[3,4,6], Josep Llovet[1,2,7]. *[1]Translational Research in Hepatic Oncology, Liver Unit, IDIBAPS, Hospital Clinic, University of Barcelona, Barcelona, Spain; [2]Liver Cancer Program, Division of Liver Diseases, Department of Medicine, Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, United States; [3]Department of Oncological Sciences, Icahn School of Medicine at Mount Sinai, New York, United States; [4]Tisch Cancer Institute Bioinformatics for Next Generation Sequencing (BiNGS) Shared Resource Facility, Icahn School of Medicine at Mount Sinai, New York, United States; [5]Department of Pathology, Icahn School of Medicine at Mount Sinai, New York, United States; [6]Center for OncoGenomics and Innovative Therapeutics (COGIT); Center for Therapeutics Discovery, Department of Oncological Sciences and Pharmacological Sciences, Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, United States; [7]Institució Catalana de Recerca i Estudis Avançats (ICREA), Barcelona, Spain*
Email: ugnebala@gmail.com

Background and aims: Hepatoblastoma (HB), the most frequent pediatric form of liver cancer, is a rare disease with an increasing annual incidence of 1.8 cases per million children and limited therapeutic options (i.e. surgery and chemotherapy). *CTNNB1* mutation is the most prevalent alteration and a potential therapeutic target in HB. Here, we aim *i)* to assess the efficacy of WNTinib -an effective compound blocking Wnt-CTNNB1 activation in

hepatocellular carcinoma (HCC)- in HB, and *ii)* to explore mechanisms of resistance to WNTinib in HB.
Method: To assess the efficacy, eight HB patient-derived cell lines were generated and used for testing serial dilutions of WNTinib and cisplatin (Selleckchem, Houston, TX) for IC50 calculations for 3 days. Cell viability was measured using resazurin, with absorbance readings at 560 and 590 nm. Additionally, six subcutaneous patient-derived xenograft (PDX) tumors (n = 5 *CTNNB1* mutant, n = 1 *CTNNB1* wild-type) were implanted in NSG mice and challenged with WNTinib. Animals were treated for 5 days per week with WNTinib (30 mg/kg) until the end of the study and tumor volume was monitored. To investigate WNTinib resistance mechanisms, we performed a kinome-wide CRISPR screen with 3, 052 unique single-guide RNAs targeting 763 human kinase genes using an HB-patient derived cell line and the IC30 dose of WNTinib over the course of 3 weeks.
Results: The calculated WNTinib IC50 values in HB cells were an order of magnitude higher than those in HCC cells (8.99uM vs 0.63uM, respectively). *In vivo*, mean overall survival in the WNTinib arm was longer in 4/5 *CTNNB1* mutant PDX models than in the *CTNNB1* WT model (36.4 vs 14 days, respectively). The CRISPR screen identified as top significantly enriched kinases RPS6KA3, PRKD3 and CAD and as the top significantly depleted DYRK1A, MAPK1, and TESK2, suggesting their potential role in WNTinib's response and resistance mechanisms, respectively. As in HCC, multiple members of the MAPK family were detected as drivers of WNTinib sensitivity. Top significantly depleted kinases such as DYRK1A, PRKCI, and CDK14 are currently being validated as candidate targets for dual treatment options with WNTinib in HB.
Conclusion: We have demonstrated that WNTinib is able to efficiently block tumor progression in HB and identified candidate kinases as potential targets to boost the efficacy of WNTinib activity in HB.

Deciphering the role of FXR in the rewiring of Treg polarization in hepatocellular carcinoma
Yasmeen Attia[1], Rasha Tawfiq[1], Aya Ali[2], Olfat Hammam[3], Mohamed Elmazar[1]. [1]*Department of Pharmacology, Faculty of Pharmacy, The British University in Egypt, Cairo, Egypt;* [2]*Health Research Center of Excellence, Drug Research and Development Group, Faculty of Pharmacy, The British University in Egypt, Cairo, Egypt;* [3]*Department of Pathology, Theodor Bilharz Research Institute, Giza, Egypt*
Email: yasmeen.attia@bue.edu.eg

Background and aims: Once dubbed the immune cell "graveyard", the liver was believed to evade immunosurveillance by promoting T cell dysfunction through T cell disposal/killing. This was later debunked when it became apparent that T cell avidity stems from changes within the tumor microenvironment where regulatory T cells (Tregs) play a pivotal role. Hepatocellular carcinoma (HCC) is often described as immunologically "cold", primarily due to Tregs hijacking the immune response and promoting a tolerogenic milieu with immunosuppressive cytokines such as transforming growth factor (TGF)-β1 and IL-10. Although the immunomodulatory roles of the farnesoid X receptor (FXR) have been extensively studied in different contexts, its impact on Treg modulation in HCC is not yet addressed. This study, therefore, bridges this gap by exploring how FXR activation, through obeticholic acid (OCA), might affect Treg polarization in an experimental HCC model.
Method: HCC was induced in Swiss albino male mice using diethylnitrosamine (DEN) and carbon tetrachloride (CCl_4). Three-week-old mice received a single i.p. injection of DEN at a dose of 1 mg/kg. After 5 weeks, mice started receiving i.p. injections of 0.2 ml/kg CCl_4 twice per week until the end of the experiment. After 20 weeks from induction, treatment with OCA was initiated at a dose of 10 mg/kg/day, p.o., for 12 weeks. Livers were then harvested for histopathological assessment and alpha-fetoprotein (AFP) immunohistochemical analysis. Other investigations included estimating hepatic levels of the downstream FXR target, cholesterol 7α-hydroxylase (CYP7A1) besides TGF-β1 and IL-10 using ELISA. Additionally, gene expression of forkhead box P3 (Foxp3), a Treg surrogate marker, was measured using qRT-PCR.
Results: OCA demonstrated mitigation in AFP immunoreactivity and HCC histopathological features observed in the DEN+CCl_4 group characterized by enlarged hyperchromatic nuclei and dysplastic alterations. Concurrently, CYP7A1 hepatic levels were decreased in the OCA-treated group, suggesting FXR activation. In the DEN+CCl_4 group, a 5-fold upregulation in hepatic Foxp3 compared to normal mice was observed, hence indicating a potential increase in Treg population. OCA, however, depicted a downregulation in Foxp3 reaching 50% compared to the DEN+CCl_4 group, implying a likely decrease in the Treg pool. In a similar vein, a surge in the levels of the immunosuppressive cytokines, TGF-β1 and IL-10, paralleled the increase in Foxp3 reaching 10 and 6 folds in the DEN+CCl_4 group compared to normal, whereas OCA treatment reduced their levels by 66% and 90% compared to DEN+CCl_4 group, respectively.
Conclusion: Our findings indicate that FXR activation can likely curb Treg polarization and subsequent immunotolerance in HCC, potentially guiding the development of FXR-targeted therapies to modulate the immune landscape in HCC.

FRI-471
CRISPR metabolic screen identifies UXS1 as a driver of hepatocellular carcinoma progression via regulating hippo signaling pathway
Haoying Ke[1], Zhijie Xu[1], Ruiyang Liu[1], Ji Xiao[1], Fuyuan Xu[1], Fei Xiao[1]. [1]*The Fifth Affiliated Hospital of Sun Yat-sen University, Zhuhai City, Guangdong Province, China*
Email: kehy@mail2.sysu.edu.cn

Background and aims: Metabolic reprogramming is a highlighted hallmark of hepatocellular carcinoma (HCC) and plays an important role in tumorigenesis, progression and drug resistance. However, the mechanisms underlying metabolic reprogramming and how altered metabolism in turn promotes HCC progression remain largely elusive. In this study, we aimed to elucidate the role of UDP-Glucuronate decarboxylase 1 (UXS1) in HCC progression.
Method: A CRISPR knockout screen was used to investigate metabolic genes that contribute to HCC cell proliferation. Colony formation, Incucyte, wound-healing, Transwell migration, and invasion assays, and an animal model were used to examine the role of UXS1 in HCC progression. Immunohistochemical staining was used to evaluate UXS1 expression in HCC tissues and adjacent normal liver tissues. Further, RNA-sequencing (RNA-seq) assays were performed to screen significantly altered metabolic and signaling pathways in HCC cells with UXS1 knockdown.
Results: We identified UXS1, a Golgi enzyme that converts one sugar nucleotide (UDP-glucuronic acid, UDPGA) to another (UDP-xylose), as a key metabolic regulator of HCC cell proliferation using the metabolic CRISPR knockdown screen. UXS1 promotes the proliferation, migration, and invasion of HCC. Clinically, UXS1 is upregulated in HCC and is associated with adverse clinical outcomes in patients with this disease. Mechanistically, UXS1 regulated Hippo signaling pathway and metabolism-related signaling pathways. We found UXS1 knockdown upregulated the phosphorylation levels of Hippo signaling pathway related proteins including LAST1, YAP and TAZ. Conversely, overexpression of UXS1 downregulated their phosphorylation levels. It is indicated that UXS1 up-regulated in HCC promotes tumor progression by inhibiting the Hippo signaling pathway.
Conclusion: Our study suggests that UXS1 has a crucial role in HCC progression by inhibiting the Hippo signaling pathway, providing a potential and therapeutic target for HCC. However, how UXS1 regulates sugar nucleotide metabolism and glycosylation to inhibit Hippo signaling pathway still need further study. We hypothesize that UXS1 has the potential to affect Golgi apparatus function in hepatocellular carcinoma cells, which in turn affects YAP glycosylation levels.

FRI-472-YI

Mitochondrial metabolism is disrupted by ciprofloxacin preventing cholangiocarcinoma cell proliferation

Background and aims: Metabolic reprogramming is a hallmark of cholangiocarcinoma (CCA), a heterogeneous group of biliary cancers characterized by dismal prognosis The heightened proliferation of CCA cells has been linked to increased mitochondrial metabolic activity. E2F1 and E2F2, transcription factors regulating cell cycle, also modulate mitochondrial metabolism. Minichromosome maintenance (MCM) proteins, helicases involved in DNA replication and cell cycle, are recognized targets of E2Fs that have been implicated in different cancers. YAP and TAZ, transcriptional coactivators of the Hippo signalling pathway, cooperate with E2Fs to regulate the expression of MCMs. Ciprofloxacin (CPX), a commonly used antibiotic, serves as an inhibitor of MCM helicase activity. Here, we aim to study how targeting the E2F/MCM axis in CCA influences the interplay between cell cycle progression and the associated metabolic adaptation it governs.
Method: CCA was induced in wild type (WT) or *E2f1*$^{-/-}$ mice using the Sleeping Beauty technique, with the overexpression of *Akt1* and *Yap* or *Taz*. Triglyceride (TG) concentration was measured in liver samples from these models, and in cell lines *in vitro*. Cell viability, proliferation, fatty acid oxidation (FAO), and mitochondrial respiration rates were assessed in EGI1 and HUCCT1 human CCA cell lines in the presence or absence of CPX, and an inhibitor of E2F activity (HLM006474). Their impact on the growth of organoids derived from CK19-CreER; KrasG12D-/+; Pten fl/fl CCA mouse model was tested. Data from human CCA tumours from different cohorts (TCGA-CHOL and GSE26566), and levels of these proteins in the proteome of 5 CCA human cell lines and 4 primary cultures of human cholangiocytes were assessed.
Results: Expression of E2F1 and E2F2, as well as MCM2-7, was increased in the two analyzed CCA cohorts. Additionally, a positive correlation was observed between E2Fs and each MCM, which were also upregulated in the proteome of each CCA human cell line and in the CCA mouse models. Experimental overexpression of *Akt1* and *Yap*, or *Akt1* and *Taz*, in *E2f1*$^{-/-}$ mice resulted in reduced CCA development compared to WT mice. Inhibition of MCM activity with CPX, either alone or in combination with the E2F activity inhibitor HLM006474, induced a dose-dependent decrease in tumour cell and *Kras*|*Pten* CCA mouse organoid viability. CPX also decreased proliferation of human CCA cells *in vitro*. The increased upregulation in FAO previously observed in the most proliferative CCA cells was halted when CCA cells were incubated with CPX and/or HLM006474, significantly decreasing mitochondrial respiration rate and TG accumulation.
Conclusion: Inhibition of MCMs with CPX, either alone or in combination with an E2F inhibitor, reprograms mitochondrial metabolism, leading to a decrease in proliferation and viability of CCA. Combination of MCM and E2F inhibitors arises as a novel potential target in CCA.

FRI-473

The oncogenic m6A demethylase FTO promotes tumorigenesis and immune escape by upregulating GPNMB in hepatocellular carcinoma

Vanilla Xin Zhang[1,2], Ao Chen[1], Qingyang Zhang[1], Karen Man-Fong Sze[1], Lu Tian[1], Hongyang Huang[1], Eva Lee[1], Jingyi Lu[1], Xueying Lyu[1], Joyce Man Fong Lee[1], Jack Chun-Ming Wong[1], Daniel Wai-Hung Ho[1], Irene Oi-Lin Ng[1]. *[1]Department of Pathology and State Key Laboratory of Liver Research, The University of Hong Kong, Hong Kong, Hong Kong; [2]The University of Hong Kong, Pathology, Hong Kong, Hong Kong*
Email: vanilla6@hku.hk

Background and aims: Hepatocellular carcinoma (HCC) is the 3rd leading cause of cancer-related death worldwide. Immune checkpoint inhibitor (ICI) targeting PD-L1 combined with VEGF is the first-line therapy for advanced HCC. However, the efficiency of Immune checkpoint inhibitor (ICI) is not satisfactory in HCC patients. FTO (Fat mass and obesity-associated protein) is the first identified N6-methyladenosine (m6A) demethylase and has been reported to play an oncogenic or tumor-suppressive role in liver cancer. A better understanding of the functional role and mechanistic basis of FTO in HCC is needed. In this study, we aimed to functionally characterize the roles of m6A demethylase FTO in HCC.
Method: To investigate the tumorigenic functions of FTO, colony formation, proliferation, migration and invasion assays were conducted in vitro. Co-culture system of HCC cells and CD8T cells or THP-1 cells was used to examine the activation of effector memory T cells and polarization and recruitment of macrophages upon stable knockdown of FTO (FTO-KD). Multiple xenograft and spontaneous HCC forming mouse models were used to evaluate the effect of FTO on self-renewal, tumor growth, and response to ICI treatment. RNA-sequencing and m6A-sequincing were done to identify the gene targets related to m6A modification by FTO.
Results: FTO expression was up-regulated in patients' HCC tumors, and high FTO expression (2-fold cutoff) was significantly associated with poorer survival rates. Depletion of FTO resulted in reduced pro-oncogenic functions in vitro, and suppressed tumor formation, progression, metastasis in vivo. Stable FTO-KD significantly increased tumor-infiltrating immune cells and cytotoxic CD8+ T cells in mouse tumor tissues and was accompanied by a significant reduction of PD1 + T cell exhaustion. We also observed a trend of increase in anti-tumoral M1 macrophages in mouse tumors. Consistently, in vitro co-culture assays of human HCC cells with T cells isolated from PBMC of healthy human subjects showed that FTO KD increased the proportion of effector memory T cells and enhanced the proliferation of CD8+ T cells. FTO silencing increased the anti-tumoral polarization and migration of M1 macrophages. We identified GPNMB as a novel downstream target of FTO, which reduced the m6A abundance of GPNMB, hence stabilizing it from degradation by YTHDF2. GPNMB was able to inhibit CD8+ T cell activation. Furthermore, targeting FTO by its potential inhibitor CS2 promoted the therapeutic effect of anti-

PD1 in a well-established 'cold-tumor' mouse model (Trp53KO/C-MycOE), resulting in significantly smaller tumors and higher tumor-infiltrating CD8T cells in the liver tumor tissues.
Conclusion: We demonstrated that FTO exerts oncogenic function and promotes immune escape in HCC by regulating the m6A demethylation of GPNMB mRNA. Targeting FTO may provide a new therapeutic approach for treating HCC.

FRI-474-YI
Restoring retinoic acid receptor-related orphan receptor alpha reduces intrahepatic cholangiocarcinoma proliferation and modulates cancer-associated fibroblasts
Laura Sererols Viñas[1], Paula Cantallops Vilà[1], Raquel A. Martínez-García de la Torre[1], Gemma Garcia Vicién[1], Silvia Ariño[1], Carmen Cárcamo Giráldez[1], Joana Ferrer[2,3], Alejandro Forner[3,4], Loreto Boix[2,3], María Reig[2,3], Pau Sancho-Bru[1,3], Silvia Affo[1]. *[1]Institut d'investigacions biomèdiques august pi i sunyer (IDIBAPS), Barcelona, Spain; [2]Barcelona clinic liver cancer (BCLC) group, Liver Unit, Hospital Clínic Barcelona, IDIBAPS, University of Barcelona, Barcelona, Spain; [3]Centro de investigación médica en red de Enfermedades hepáticas y digestivas (CIBERehd), Instituto de salud Carlos III, Madrid, Spain; [4]Barcelona clinic liver cancer (BCLC) group, Liver Unit, Hospital Clínic Barcelona, IDIBAPS, University of Barcelona, Barcelona, Spain*
Email: saffo@recerca.clinic.cat

Background and aims: Intrahepatic Cholangiocarcinoma (iCCA) is the second primary liver tumor, with few therapeutic options, late diagnosis, chemotherapy resistance and dismal prognosis. Retinoic acid receptor-related orphan receptor alpha (RORa) is known to be a tumor suppressor in several solid tumors however, its role in iCCA remains unknown. Therefore, with our study we aim at investigating RORa in iCCA, to explore new potential therapies for this deadly tumor.
Method: Human tumoral (n = 8) and adjacent non-tumoral (n = 8) tissues were obtained after iCCA tumor resection, from the Hospital Clínic, Barcelona. HuCCT1 human iCCA cell line and human primary cancer-associated fibroblasts (CAFs) isolated from iCCA samples (n = 3), were treated *in vitro* with RORa agonist SR1078 (5uM). To induce iCCA *in vivo*, 6 weeks old C57BL/6J male mice were injected hydrodynamically through the tail vein with the pCaggs-KRAS^{G12D}, CRISPR/Cas9 sg-p19 and SB13 plasmids (KRAS/p19). 4 weeks after the tumor induction, mice were injected intraperitoneally with vehicle (n = 7) or SR1078 (10 mg/kg) (n = 9), 3 times per week, for 2 weeks. GraphPad Prism 10 was used for the statistical analysis.
Results: As assessed by qPCR, we detected a reduction in RORa expression in iCCA tumoral (n = 8) *vs* non-tumoral tissue (n = 8) ($p = 0.03$) from patients, also confirmed by immunofluorescence ($p = 0.028$). *In vitro*, restoring RORa in cell line using SR1078, reduced tumor cell proliferation and increased apoptotic gene expression. Moreover, when tested on primary human CAFs, RORa agonist reduced the myofibroblastic markers *COL1A1* ($p = 0.01$), *HAS2* ($p = 0.001$) and *ACTA2* ($p < 0.01$), without affecting the inflammatory *STAT3* ($p = 0.52$) and *IL6* ($p = 0.30$), as assessed by qPCR. When testing *in vivo* RORa agonist SR1078 in KRAS/p19 iCCA experimental model, we found a reduction in both tumor number ($p = 0.03$) and tumor size ($p < 0.001$) in the treated mice compared to the vehicle group. After confirming that *Rora* expression was increased in treated mice compared to the vehicle group by qPCR ($p = 0.01$), we found that restoring RORa *in vivo*, reduced tumor cell proliferation ($p < 0.001$) as assessed by double staining and quantification of CK19$^+$Ki67$^+$ cells. Moreover, we encountered decreased collagen deposition as assessed by PicroSirius Red ($p = 0.03$); and reduction of *Col1a1* ($p = 0.04$) and *Has2* ($p = 0.03$) gene expression in the SR1078 treated-group, compared to the vehicle-group. As promising result, we observed reduction in *Pd-l1* gene expression ($p = 0.041$) in the treated *vs* control group.
Conclusion: RORa regulates iCCA tumor cells proliferation and affects the tumor microenvironment by modulating the CAF phenotype and reducing the expression of myofibroblastic genes both *in vitro* and *in vivo*. Our data suggest that promoting RORa activity might be a novel therapeutic strategy to target both tumor cells and CAFs in combined therapies in iCCA.

FRI-475-YI
NADPH oxidase 1 inhibition as therapeutic strategy in hepatocellular carcinoma: insights from human-relevant models
Zenzi De Vos[1,2], Lander Heyerick[1,2], Luís Abreu de Carvalho[3], Hasan Eker[3], Filip Gryspeerdt[3], Frederik Berrevoet[3], Sander Lefere[2,4], Anja Geerts[2,4], Sarah Raevens[2,4], Xavier Verhelst[2,4], Hans Van Vlierberghe[2,4], Lindsey Devisscher[1,2]. *[1]Department of Basic and Applied Medical Sciences, Gut-Liver Immunopharmacology Unit, Ghent University, Ghent, Belgium; [2]Liver Research Center Ghent, Ghent University, Ghent University Hospital, Ghent, Belgium; [3]Department of General and HPB surgery and Liver transplantation, Ghent University Hospital, Ghent, Belgium; [4]Department of Internal Medicine and Paediatrics, Hepatology Research Unit, Ghent University, Ghent, Belgium*
Email: zenzi.devos@ugent.be

Background and aims: Current preclinical models for hepatocellular carcinoma (HCC) poorly predict human response to therapy as they fail to reliably reflect human pathology and the involvement of human immunity. This is in part responsible for the lack of therapy for patients suffering from advanced HCC. NADPH oxidases (NOX) are reactive oxygen species-producing enzymes of which the isoform NOX1 is present in the tumor microenvironment (TME) of HCC and has been shown to promote HCC development and metastasis. We and others have shown that NOX1 inhibition (NOX1i) alters the TME in classical experimental HCC models and might serve as a therapeutic target. Using human-relevant models, we here aim to provide more evidence for NOX1i, compared to the current standard of care, as potential treatment strategy in HCC with a higher translatability to the clinic.
Method: Hep3B cells were implanted intrahepatically in NSG mice. Ten days post tumor induction, mice were reconstituted with peripheral blood mononuclear cells of human healthy controls and were treated with 25 µM NOX1i ML171, 3 mg/kg anti-programmed death-ligand 1 (anti-PD-L1) antibody + 5 mg/kg anti-vascular endothelial growth factor A (anti-VEGF-A) antibody (standard of care), NOX1i + standard of care or vehicle or IgG control, twice per week for 3 weeks. Immune cell engraftment and phenotype in peripheral blood, liver, tumor and TME was assessed via flow cytometry. Inflammatory markers were evaluated using RT-qPCR. Complementary to the in vivo study, ex vivo human HCC patient precision cut liver slices (PCLS) of tumor tissue and surrounding non-tumor tissue were treated with 5 µM NOX1i or vehicle for 16 h and analysed for inflammatory markers.
Results: Tumor volume and weight ranged around 4.4 cm³ and 3.9 g, respectively, with no differences between treatments. Human immune cell chimerism reached around 75% in tumors, livers and TME, and around 30% in peripheral blood, with an overall lower engraftment in NOX1i treated mice. Immune cell populations mainly comprised T cells of which CD4+ T cells, and in particular the T helper 2 subtype, were present in higher numbers than CD8+ T cells in all groups. Within both the CD4+ and CD8+ T cell populations, effector memory T cells were the most prevalent, next to effector, central memory and naïve T cells. Interestingly, the TME of NOX1i treated mice showed increased CD4+ T cells and increased PD-1 expression in CD4+ and CD8+ T cells, compared to other treatments and control. Tumor tissue of NOX1i treated mice showed reduced expression of inflammatory markers (including tumor necrosis factor-alpha, interleukin (IL)-1 beta, hypoxia-inducible factor-1 alpha and interferon-gamma), which was confirmed in NOX1i-treated ex vivo PCLS of patients with advanced HCC.

Conclusion: These findings suggest that NOX1i suppresses immune cell responses in humanized models for HCC.

FRI-478

Histological and molecular characterization of GAN diet-induced obese mouse model of advanced fibrosing MASH with progression to HCC

Monika Lewinska[1], Maja Andersen[1], Susanne Pors[1], Mogens Vyberg[2], Michael Feigh[1], Henrik B. Hansen[1]. [1]*Gubra, Hørsholm, Denmark;* [2]*Aalborg University, Center for RNA Medicine, Department of Clinical Medicine, Copenhagen, Denmark*
Email: mle@gubra.dk

Background and aims: Metabolic dysfunction-associated steatohepatitis (MASH) is a leading cause of liver cirrhosis and hepatocellular carcinoma (MASH-HCC). However, the molecular alterations leading to onset of MASH-HCC are unclear. The present study aimed to evaluate disease progression in the translational GAN diet-induced obese (DIO) mouse model of advanced fibrosing MASH-HCC (GAN DIO-MASH-HCC mice).
Method: Male C57BL/6J mice were fed the GAN diet high in fat, fructose and cholesterol for 38 78 weeks (n = 15 per group). Mice fed chow for 48–68 weeks (n = 15) served as healthy controls. Terminal end points included AI-assisted histopathological scoring and histomorphometrics, flow cytometry, tumor classification by an expert clinical histopathologist and bulk RNAseq. Single sample gene set enrichment analysis (ssGSEA) and digital cytometry (xCell, EcoTyper) was performed. Transcriptional profiles of murine MASH and MASH-HCC were compared to human hepatic transcriptomes from healthy controls to MASH (n = 57, GSE126848) and MASH-HCC (n = 45, GSE193084).
Results: GAN DIO-MASH-HCC mice demonstrated NASH (NAFLD Activity Score ≥5), progressive fibrosis (all mice demonstrating F3 at ≥60 weeks) and HCC burden consistent with human MASH-HCC. Liver inflammation was characterized by expansions in inflammatory M1 macrophages, Kupffer cells, dendritic cells and CD8+ T-cells. Hepatic neoplasms were detected from 48 weeks with progressive cohort penetrance, resulting in 100% incidence at 72 weeks of GAN diet feeding. 70% of tumors presented histological features of poor prognostic HCC; 30% were classified as hyperplastic nodules. Transcriptional analysis associated murine MASH-HCC tumors with S1 Hoshida signature, activation of immune responses, KRAS, p53 and Wnt/β-catenin signalling pathways. Digital cytometry assigned 50% of murine MASH-HCC tumors carcinoma ecotypes associated with short survival (CE1, CE2), while 30% of tumors presented an ecotype associated with positive response to immune therapy (CE9).
Conclusion: The GAN-DIO-MASH-HCC model spontaneously develops HCC on the background of progressive advanced fibrosis. The HCC molecular signature recapitulates poor prognostic human MASH-HCC and immune microenvironment. The translational GAN DIO-MASH-HCC mouse model is highly applicable for profiling novel drug therapies targeting NASH-HCC, including first-line immune checkpoint inhibitor therapies.

FRI-479-YI

The role of OSM/OSMRβ axis in shaping the immune-microenvironment favouring MASLD-related HCC immune evasion

Beatrice Foglia[1], Jessica Nurcis[1], Alessia Provera[2], Chiara Rosso[3], Gian Paolo Caviglia[3], Elisabetta Bugianesi[3], Emanuele Albano[2], Salvatore Sutti[2], Maurizio Parola[1], Stefania Cannito[1]. [1]*University of Turin, Dept. Clinical and Biological Sciences, Turin, Italy;* [2]*University Amedeo Avogadro of East Piedmont, Dept. Health Sciences and Interdisciplinary Research Center for Autoimmune Diseases, Novara, Italy;* [3]*University of Turin, Dept. Medical Sciences, Turin, Italy*
Email: beatrice.foglia@unito.it

Background and aims: Oncostatin M (OSM), a cytokine from the IL-6 family, is implicated in chronic liver diseases and hepatocellular carcinoma (HCC) progression. HCC patients with a background of metabolic dysfunction-associated steatotic liver disease (MASLD) showed elevated OSM serum levels correlating with clinical parameters and disease outcome. A murine MASLD-related HCC model showed increasing OSM expression during liver carcinogenesis, correlating with F4/80 gene expression, suggesting OSM's involvement in macrophage recruitment/functions within the tumor microenvironment. This study explores OSM's potential role in modulating the tumor microenvironment, impacting crucial events in HCC progression.
Method: To test this hypothesis, we used: a) OSMRβ−/− mice (where OSMRβ expression into hepatocytes has been abrogated) and wild-type (WT) littermates that underwent the DEN/CDAA protocol of MASLD-related liver carcinogenesis to assessing how disrupting OSM/OSMRβ signaling in hepatocytes influences MASLD-related HCC development and progression of; b) cohort of MASLD patients with/without HCC.
Results: OSMRβ−/− mice exhibited a significant decrease in tumor volumes and weights compared to WT, with unchanged nodule numbers. In terms of inflammation, OSMRβ deletion did not alter the infiltration of F4/80+ cells suggesting OSM's potential role in qualitatively modifying the immune landscape. Analysis of HCC data from the TGCA database, revealed that OSM expression correlates positively with several immunosuppressive markers (CCL2, CCL22, CD25, CXCL12, FOXP3, PD-L1, PTGSE2, TGFβ). Consistently, OSM transcripts levels in WT correlates with these markers and their expression is downregulated in the OSMRβ−/− mice as a consequence of the inhibition of P-STAT3, P-AKT, SMAD4, COX-2 signaling pathways involved in recruiting pro-tumoral Tumor Associated Macrophages (TAMs), T regulatory lymphocytes (T-regs) and Myeloid-derived suppressor cells (MDSC). Multiplex Immunoassay on sera from MASLD cirrhotic and/or HCC patients revealed a significant increase of cytokines characterizing the immunosuppressive tumor microenvironment (IL1β, CCL2, IL8, CXCL13). Transcript levels of these cytokines correlated with OSM expression in MASLD patients. Accordingly, OSMRβ deletion resulted in reduced transcript levels of these genes. Of relevance, CCL15 mRNA levels (a chemokine downregulated in the OSMRβ−/− mice and involved in MDSC recruitment and activation) correlated positively with OSM mRNA levels in MASLD-related HCC patients, assuming a role of independent prognostic factor associated with worse survival.
Conclusion: The experimental data highlight a pro-carcinogenic contribution for OSM in a MASLD background, favoring immunosuppressive tumor microenvironment, suggesting a possible role for the OSM-OSMRβ axes as therapeutic target for MASLD-related HCC.

FRI-480

Multi-dimensional profiling of hepatoblastomas and patient-derived tumor organoids uncovers tumor subpopulations with divergent WNT activation profiles and drug sensitivities

Weng Chuan Peng[1]. [1]*Princess Maxima Center, Utrecht, Netherlands*
Email: wengchuan@gmail.com

Background and aims: Hepatoblastoma, the most prevalent pediatric liver cancer, almost always carries a WNT-activating *CTNNB1* mutation, yet exhibits notable molecular heterogeneity. To characterize this heterogeneity and identify novel targeted therapies, we performed comprehensive analysis of hepatoblastomas and tumor-derived organoids using various omic methods and high throughput drug screening.
Method: Single-cell RNA-seq, spatial transcriptomics, single-cell ATAC-seq, patient derived organoid, high throughput drug profiling.
Results: Based on analysis of tumor tissues, we identified two distinct tumor epithelial signatures: hepatic 'fetal-like' and WNT-high 'embryonal-like' signatures, displaying divergent WNT signalling patterns. The liver-specific WNT targets were enriched in the fetal-like group, while the embryonal-like group was enriched in canonical WNT target genes. Gene regulatory network analysis revealed

enrichment of regulons related to hepatic function such as bile acid, lipid and xenobiotic metabolism in the fetal-like subgroup but not in the embryonal-like subgroup. In addition, the dichotomous expression pattern of the transcription factors HNF4A and LEF1 allowed for a clear distinction between the fetal- and embryonal-like tumors. Next, we performed high-throughput drug screening using patient-derived tumor organoids and identified sensitivity to multiple inhibitor classes, most notably HDAC inhibitors. Intriguingly, embryonal-like tumor organoids, but not fetal-like tumor organoids, were sensitive to FGFR inhibitor treatments, suggesting a dependency on FGFR signalling. In summary, our data uncover the molecular and drug sensitivity landscapes of hepatoblastoma and pave the way for the development of targeted therapies.
Conclusion: We uncover the molecular and drug sensitivity landscapes of hepatoblastoma, which could pave the way for the development of targeted therapies.

Email: tpollicino@unime.it

Background and aims: Chronic hepatitis B virus (HBV) infection is associated with an increased risk of developing intrahepatic cholangiocarcinoma (ICC). However, there is no direct evidence of a causal relationship between HBV infection and ICC development. In this study, we sought to investigate the characteristics and mechanisms of HBV integration in HBV-infected iCCs.
Method: We conducted a high-throughput HBV integration sequencing (HBIS) analysis on tumour specimens from 13 HBV positive patients with ICC (3 HBsAg-positive and 10 with occult HBV infection, OBI) and 8 paired non-tumour liver tissues to study HBV integration sites.
Results: A total of 2, 753 HBV integration sites were detected in the 13 patients studied, 2, 649 in tumours and 104 in non-tumour tissues, with no significant differences between HBsAg- and OBI-positive patients. All patients studied showed HBV integrations, with an average of 221 and 17 integration sites per tumour and non-tumour tissue sample, respectively. HBV integration sites were annotated to analyse their distribution in distinct genomic elements. Integrations were more frequent in intergenic region ($p < 0.001$) in tumours than non-tumour samples, whereas in non-tumours integration sites were more frequent in lncRNA ($p = 0.002$), in SINE ($p < 0.001$), and in the D-Loop region of mitochondrial DNA ($p < 0.001$). Analysis of breakpoints within the HBV genome showed a significant concentration of breakpoints in the HBx gene in tumor samples ($p < 0.0001$). Additionally, there was a notable enrichment of breakpoints in the preS/S gene region in non-tumor tissues ($p < 0.0001$). To elucidate the mechanisms of HBV integration, the presence of microhomology (MH) sequences between cell DNA and HBV DNA integrants at the level of integration sites was investigated. We found that almost all HBV integration sites detected showed the presence of MH sequences (range 3 bp–21 bp).
Conclusion: HBV integration occurs at high frequency in both tumour and adjacent non-tumour tissues of patients with ICC and HBV infection (both in cases with overt and occult HBV infection), with substantially higher insertion rates in tumours. Furthermore, our data strongly suggest the involvement of an MH-mediated mechanism in HBV integration, which could be triggered by genomic instability/fragility in the proximity of integration sites.

FRI-484
A metastasis-resident B cell subset serves as tumoricidal effectors with checkpoint- expressing in colorectal cancer liver metastasis
Yujie Bao[1], Jiayin Tang[2], Yupan Bai[1], Jugang Wu[1], Hongsheng Fang[2], Ming Zhong[2], Jie Xu[1]. *[1]Shanghai Jiao Tong University School of Medicine, Shanghai Ninth People's Hospital, Shanghai, China; [2]Shanghai Jiao Tong University School of Medicine, Renji Hospital, Shanghai, China*
Email: yujie.bao@shsmu.edu.cn

Background and aims: Liver metastasis is the leading cause of mortality in colorectal cancer (CRC), the limited therapeutic efficacy targeting metastatic lesion remains a concern. B cells emerge as a major immune cells within tumor microenvironment (TME), playing multifaceted roles in tumorigenesis. Our study has revealed critical insights into the anti-tumor function of B cells within the liver metastatic TME in CRC.
Method: Three pairs of operational samples were respectively collected from patients with colorectal cancer liver metastasis (CRLM). Each pair concluded the liver metastatic tumor tissue and matched normal liver tissue from one patient. Single-cell RNA sequencing (scRNA-seq) was adopted to map out the transcriptomic atlas of the liver metastasis TME. The main cell types were defined via SingleR and we further integrated all B cells into re-clustering process and nine distinct subclusters were identified based on their Differentially Expressed Genes. Cell-cell communications, Psudotime trajectory and GSEA analysis were performed to study the B cell immune effect on tumor cells. Validation was conducted via immunofluorenscent staining, flow cytometry assays and *ex vivo* functional experiments on another sample cohort. To avoid the sample bias, public database was analyzed to testify our results.
Results: A new B cell subset named as META-CBLs was identified in the liver metastatic TME through scRNA-Seq combined with *ex vivo* verification and database analysis. These cytotoxic META-CBLs could eliminate tumors through inducing apoptosis via granzyme-perforin pathway. META-CBLs might be activated by tumor associated antigens presented through MHC-I signaling. Nevertheless, CD96 marked META-CBLs could be driven into an immunosuppressive senescent state and restrained the production of GZMB. In addition, $PARD3^+$ metastatic tumor cell subset might escape from immunosurveillance of META-CBLs by displaying a poorly immnuogenic phenotype and educating META-CBLs by stimulating CD96 checkpoint signaling. Taken together, reinvigorating and harnessing these META-CBLs may hold promise in metastasis tumor immunotherapy.
Conclusion: In summary, our work has improved the common understanding of B cells function in the liver metastatic TME. As $CD8^+$T cells and NK cells are the classic icons of tumor killing effector cells, we highlighted the META-CBLs serve as tumoricidal effector cells in the metastatic TME. However, META-CBLs could be driven into immunosuppressive senescent state when expressing CD96. Within the liver metastasis TME, we also discovered a group of $PARD3^+$ metastatic tumor cells, which might acquire the capability of immunoescaping from META-CBLs through CD96 checkpoint signaling. Therefore, blocking CD96 might be a promising intervention to reinvigorate META-CBLs against metastatic tumor outgrowth in CRLM.

Email: jihan.sun@uca.fr

Background and aims: Metabolic dysfunction associated steatotic liver disease (MASLD) can eventually progress to hepatocellular carcinoma (HCC). Thirty to 40% of MASLD-HCC occur in the absence of fibrosis, posing a challenge for early detection. Previously, we reported 2 phenotypes of MASLD-HCC based on the severity of fibrosis (F0F1 vs. F3F4) (Buchard et al., 2021). The objective of this study is to explore lipid metabolism pathways through "omics" and identify biomarkers of MASLD-HCC based on the severity of fibrosis.
Method: Our cohort included 56 pairs of tumor and non-tumor (NTT) human liver tissues (F0F1 = 28, F3F4 = 28), and 5 healthy liver tissues (HLT) used as control (CRB Foie). A non-targeted metabolomic analysis by liquid chromatography-mass spectrometry (LC-MS) was performed. In addition, a qRT-PCR analysis focused on a panel of 16 genes involved in the main lipid metabolism pathways was conducted (SPTLC1, SPTLC2, SGMS1, SGMS2, SMPD1, SMPD3, CHKA, PCYT1A, CHPT1, PEMT, MBOAT7, DGAT1, DGAT2, ACAT2, AADACL1 and ACOX1). For each group, TT was compared to NTT and to HLT. The study was approved by the Ethic Committee Sud-Est VI Clermont-Ferrand (Agreement number AU887, 04/03/2011).
Results: First, using LC-MS, we identified 130 metabolites and 30 of them exhibited significant difference between TT and NTT. In the MASLD-HCC-F0F1, the levels of ceramide Cer (d18:1/22:0), sphingomyelin SM (41:1) and phosphatidylethanolamine PE (O-16:1_20:4) were decreased. While the levels of SM (35:1), SM (40:2), SM (42:3), phosphatidylcholines PC (16:0_14:0), PC (16:0/16:0), PC (18:0_18:1), PC (40:8) and PE (18:0_18:1) were increased. In contrast, most of metabolites content in MASLD-HCC-F3F4 were reduced compared to NTT, indicating an amplified anabolism. However, the levels of PC (18:0_18:1), PC (18:0_20:3) and phosphatidylinositol PI (16:0_18:1) were increased. Notably, PI (16:0_18:1) is considered as an onco-metabolite (Yang et al., 2018).
Second, transcriptomic data revealed that in MASLD-HCC-F0F1, among the 16 genes studied, the expression of 6 genes coding for CHKA, DGAT1, MBOAT7, SPTLC2, SMPD1 and SGMS1 were up-regulated. However, MASLD-HCC-F3F4 shown no variation in the expression of these genes. Altogether, this data supports the existence of 2 MASLD-HCC phenotypes according to fibrosis severity. Furthermore, the increased expression of CHKA in MASLD-HCC-F0F1 is in line with our previous metabolomic data, reporting a significant accumulation of phosphocholine derivatives in MASLD-HCC-F0F1. This observation suggests that choline may serve as an imaging marker to detect HCC-F0F1.
Conclusion: "Omics" analyses allow: 1) discrimination of MASLD-HCC based on fibrosis severity; 2) propose CHKA as a marker for MASLD-HCC-F0F1, which could lead to a clinical application: labeled choline may be favored as a more effective tracer for PET scanning in HCC patients with minimal fibrosis.

FRI-486
Impact of proliferative and metabolic reprogramming by the lysine-specific demethylase 1 in hepatocellular carcinoma

Jie Wang[1], Lingyu Wang[1], Hardik Makwana[1], Marcel Schmiel[1], Yefeng Shen[1], Anton Ströbel[1], Hannah Eischeid-Scholz[1], Yue Zhao[2], Evangelos Kondylis[3], Mafalda Escobar[4], Michal Schweiger[5], Reinhard Büttner[1], Margarete Odenthal[6]. Email: m.odenthal@uni-koeln.de

Background and aims: Epigenetic alterations are important features in the process of carcinogenesis. The lysine-specific demethylase 1 (LSD1) mediates chromatin remodeling by demethylation of histone 3 lysine 4 and 9 (H3K4/K9), resulting in gene activation and suppression, respectively. Overexpression of LSD1 in various cancers contributes to cancer progression and malignancy, but its role in hepatocellular carcinoma (HCC) has not yet been addressed. In the present study, we investigated the cell cycle progression as well as metabolic gene expression and function upon LSD1 inhibition in HCC.
Method: LSD1 was inhibited in different hepatoma cell lines utilizing RNA interferences or the application of specific LSD1 inhibitors. Global transcriptomics was carried out by RNA ultra-deep sequencing. Divergent expression in response to LSD1 inhibition was validated by quantitative PCR. LSD1 influence on promoter interaction and H3K4 methylation was performed by chromatin immunoprecipitation (ChIP) followed by whole genome sequencing (ChIPseq). In addition, a DEN/high-fat diet mouse HCC model was established to investigate the effect of LSD1 in hepatocarcinogenesis based on metabolic liver disease. Characteristics of expression profiles and tumor growth were determined by histology, immunohistology, immunoblot as well as by expression profiling and pathway analysis using RNA sequencing and quantitative PCR.
Results: Pharmacological or siRNA-mediated LSD1 inhibition in hepatoma cells leads to altered H3K4/K9 methylation and cell cycle arrest. Notably, gene expression profiling followed by pathway analysis revealed a prominent dysregulation of genes involved in the cell cycle control and metabolism after LSD1 inhibition in various hepatoma cell types. Subsequent comprehensive ChIPseq analysis provided evidence of alterations in the histone methylation signature and LSD1 binding at the promoter sites of genes, involved in proliferation. Especially, these identified genes are markedly down-regulated after LSD1 inhibition such as the proliferative gene PLK1, indicating that it is a direct target of LSD1 regulation. Furthermore, LSD1 inhibition resulted in a significant reduction in tumor growth and the number of proliferative Ki67-positive cells.
Conclusion: The presented studies show that LSD1 is a crucial mediator in cell cycle control affecting HCC progression not only through cell cycle arrest but also through metabolic dysregulation.

Immunosuppressive CD73 is upregulated on tumour endothelium and may limit effective immune infiltrate in hepatocellular carcinoma

Rosemary Faulkes[1,2], Daniel Patten[1], Alex Wilkinson[3], Joanne O'Rourke[1], Ayla O'Keeffe[1], James Kennedy[1], Owen Cain[2], Yuk Ting Ma[2], Tahir Shah[2], Chris J. Weston[1], Shishir Shetty[1,2]. Email: rosemary.faulkes@uhb.nhs.uk

Background and aims: Combining vascular and checkpoint inhibitor targets has shown positive results for hepatocellular carcinoma (HCC). We conducted deep RNA sequencing of human liver sinusoidal endothelial cells (LSEC), demonstrating significant differential regulation of immune pathways on tumour LSEC, including upregulation of CD73. The immunosuppressive effect of CD73-generated adenosine is a current target in cancer trials using a monoclonal antibody (Oleclumab). As LSEC are immune gatekeepers, CD73 may contribute to the immune resistant tumour niche. We sought to explore the

expression and regulation of CD73 in HCC as a potential future therapeutic target.
Method: Primary human LSEC were isolated and cultured from liver tissue. Regulation of CD73 on primary LSEC exposed to a range of tumour associated factors was explored at gene and protein level using PCR and Western blot respectively. LSEC were incubated with Oleclumab antibody and the interaction was studied using immunocytochemistry. Multiplex imaging with the Lunaphore COMET™, delineated the relationship between CD73 and immune subsets in HCC tissue. Soluble CD73 (sCD73) was measured in 50 treatment naïve HCC patients using ELISA. Multiple logistic regression compared clinical factors between high and low sCD73 expressing groups.
Results: We found CD73 is highly expressed on peri-tumour vasculature at the border of the immune infiltrate in HCC. In vitro, LSEC significantly upregulate CD73 in response to high shear stress and interferon gamma (p = <0.05). LSEC treatment with Oleclumab confirmed that Oleclumab was rapidly internalised by LSEC within 30 minutes. Additionally, two year transplant-free survival for patients with high sCD73 was significantly lower than patients with low sCD73 (43% vs 79% respectively, p = 0.035), independent of age, tumour size or number, aetiology of liver disease and AFP.
Conclusion: CD73 is expressed on peri-tumour vasculature at the border of the immune infiltrate. Primary cultured LSEC maintain their expression of CD73 and we confirmed the rapid uptake of the anti-CD73 agent Oleclumab. Our results suggest that CD73 represents a potential barrier to an effective anti-tumour immune response, and peripheral blood measurement provides potential opportunities for personalised medicine in HCC.

FRI-490-YI
Intratumoural microbiome alterations predict postoperative recurrence and mortality in hepatocellular carcinoma after hepatic resection
Saisai Zhang[1], Fung Yu Huang[1], Meng Zhao[1], Tan-To Cheung[2], Tiffany Wong[2], Danny Ka-Ho Wong[1], Lung-Yi Mak[1], Man-Fung Yuen[1], Wai-Kay Seto[1]. *[1]Department of Medicine, School of Clinical Medicine, The University of Hong Kong, Hong Kong, China; [2]Department of Surgery, School of Clinical Medicine, The University of Hong Kong, Hong Kong, China*
Email: saisaicc@hku.hk

Background and aims: The cancer microbiota, characterized by the colonization of bacteria within tumor tissues, exerts a significant influence on inflammation modulation, tumorigenesis regulation, and the overall cancer microenvironment. While the presence of intratumoral bacteria in hepatocellular carcinoma (HCC) has been documented, their specific functions and associations with HCC outcomes require further elucidation and clarification.
Method: Both tumourous and peri-tumourous tissues were collected from HCC patients who underwent liver resection. DNA was extracted from both tumourous and their corresponding non-tumourous tissues for shotgun metagenomic sequencing. Microbiome analysis was performed on bacterial composition at different taxonomic levels and microbial functions. Early recurrence and survival were monitored after liver resection.
Results: Of the included 12 HCC patients with 2-year outcome data, 11 (91.67%) were male, and the median age was 67.50 (IQR 61.25–77.5) years. The median size of HCC lesions was 7.50 (5.35–12.75) cm for the biggest lesion in each patient. Four (33.33%) patients developed early (≤2 years) recurrence; the cumulative 2-year survival rate was 25%. Immunohistochemistry staining showed lipopolysaccharide (LPS)-positive gram-negative bacteria were predominantly identified in both HCC tumourous and peri-tumourous tissues, whereas lipoteichoic acid (LTA)-positive gram-positive bacteria were notably absent. A significant increase in the median abundance of bacterial DNA per 1μg DNA was observed in both peri-tumorous and tumorous tissues when compared to negative environmental controls (11.96 [10.25–15.54] ng vs, 0.04 [0.03–0.49] ng, p = 0.002; and 8.22 [4.55–11.11] ng vs. 0.04 [0.03–0.49] ng, p = 0.015, respectively), with the dominant phylum being *Proteobacteria*. In HCC tumours, *Peribacillus psychrosaccharolyticus* was significantly enriched in patients with early recurrence when compared to those without recurrence (0.87% [0.20%-1.83%] vs. 0.00% [0.00%-0.00%], p = 0.0182); The abundance of *Peribacillus psychrosaccharolyticus* was positively correlated with the presence of satellite tumour nodules in histological specimens (r = 0.64, p < 0.05). In addition, *Melaminivora sp. SC2–9* was detected solely in HCC patients with mortality within 2 years, while completely undetectable in patients with a 2-year survival (0.73% [0.21%-0.92%] vs. 0.00% [0.00%-0.00%], p = 0.0045). Microbial functional analysis revealed an enrichment of fatty acid metabolism pathway in patients without early recurrence (linear discriminant analysis score 4.02, p = 0.0296).
Conclusion: Distinctive profiles of intratumoural microbiota exist in HCC patients and were associated with early recurrence and survival. Our findings encourage more in-depth studies to be conducted to examine the role of tumour microbiome for cancer prognostication.

FRI-491-YI
Targeting inflammasome activation by sorafenib/regorafenib as strategy to enhance efficacy in hepatocellular carcinoma therapy
Anna Tutusaus[1,2], Marco Sanduzzi Zamparelli[2], Loreto Boix[2], Patricia Rider[1,2,3], Silvia Subias[1], Montserrat Marí[1], María Reig[2], Albert Morales[1,2]. *[1]Institute of Biomedical Research of Barcelona (IIBB-CSIC), IDIBAPS, Barcelona, Spain; [2]Barcelona Clinic Liver Cancer (BCLC) Group, Liver Unit, Hospital Clínic of Barcelona, University of Barcelona, CIBEREHD, IDIBAPS, Barcelona, Spain; [3]Departament de Biomedicina, Facultat de Medicina, Universitat de Barcelona, Barcelona, Spain*
Email: albert.morales@iibb.csic.es

Background and aims: Tyrosine kinase inhibitors (TKIs), such as sorafenib and regorafenib, emerged as standard systemic treatments for advanced hepatocellular carcinoma (HCC) over the last decade before the eruption of immune-based therapies. Although previous research linked sorafenib to inflammasome activation, the beneficial role of inflammasome intervention for sorafenib/regorafenib therapy in liver cancer patients remains mainly unexplored.
Method: Microarray transcriptomic analysis of inflammasome-related genes in a murine HCC model using BCLC9-derived tumors treated with sorafenib and regorafenib. Human databases correlation of transcriptional increases in inflammasome genes with prognosis in HCC patients. Tumor and surrounding tissue from patients diagnosed with HCC (20), untreated (10) or sorafenib/regorafenib treated (10) was analyzed. Experimental tumor growth in BCLC-9 xenografts and immunocompetent Hepa1–6 tumors were evaluated combining sorafenib with inflammasome inhibition (MCC950). ELISA detection of IL1beta released by THP-1 macrophages after sorafenib/MCC950 treatment. Recording of Hep3B tumoroids treated with sorafenib/IL-1beta was taken for 7 days.
Results: Our data confirmed substantial inflammasome activation following treatment with both TKIs, showing a consistent pattern of increased gene expression. Public database analysis associated transcriptional upregulation of inflammasome genes with a poorer prognosis in male liver cancer patients. Our biopsy results from male patients treated with sorafenib/regorafenib demonstrated sustained transcriptional inflammasome activation in both HCC and surrounding tissue. Further supporting the involvement of inflammasome activation in sorafenib action, inhibition of the inflammasome (MCC950) enhanced sorafenib's anticancer activity in experimental HCC models, but not in in vitro treatment of HCC cells. Supporting a pivotal role played by the liver microenvironment, activated THP-1 human macrophages released IL-1beta after sorafenib administration by a inflammasome-dependent mechanism, while 3D Hep3B spheres exhibited increased tumor growth after IL-1beta addition.
Conclusion: This study unveils the inflammasome pathway as a promising and actionable therapeutic target to increase the efficacy of sorafenib/regorafenib therapy for HCC. The identified

inflammasome signature in HCC and surrounding tissue associates with TKI administration, suggesting that targeting inflammasome activation, particularly in male patients, may overcome sorafenib/regorafenib resistance and enhance the overall efficacy of TKI treatments in HCC.

FRI-492-YI

Tumor cell lines and patient derived xenograft models of intrahepatic cholangiocarcinoma maintain histology, transcription profiles and driver mutations of primary tumor but lose human stroma

Denise Schlösser[1], Georgina Schumann[1], Simon Peter[1], Hanna Redeker[1], Tanja Reineke-Plaaß[1], Florian Vondran[1,2], Nora Nevermann[1], Stephan Bartels[1], Ulrich Lehmann-Mühlenhoff[1], Geffers Robert[3], Doan Duy Hai Tran[1], Anna Saborowski[1], Arndt Vogel[1,4]. *[1]Hannover Medical School, Hannover, Germany; [2]Uniklinik RWTH Aachen, Aachen, Germany; [3]Helmholtz Centre for Infection Research, Braunschweig, Germany; [4]Toronto General Hospital, Toronto, Canada*
Email: schloesser.denise@mh-hannover.de

Background and aims: Intrahepatic cholangiocarcinoma (iCCA) is the second common type of primary liver cancer. 5-year-survival remains below 10%, mainly caused by the aggressive biology, late diagnosis and lack of curative therapies. In order to develop more effective therapies, there is an urgent need for a better molecular understanding of CCA as well as for appropriate preclinical models for drug testing. Primary tumor cells enable *in vitro* studies and patient derived xenografts (PDX) serve as valuable tool to mimic original tissue architecture *in vivo*.
Method: Primary material derived from resected tumors was subcutaneously implantated into immunodeficient mice, and monitored for tumor growth. Successfully engrafted tumors were passaged up to four generations; tumor tissue was subjected to histologic evaluation and molecular characterization by DNA and RNA sequencing. In addition, primary and PDX tumors were enzymatically digested in order to generate two-dimensional (2D) cell lines. Stable growing cell lines were subsequently injected into immunodeficient mice; 2D derived tumors were histologically stained. Efficiency of targeted therapy was assessed *in vitro*.
Results: PDX models were successfully established in approximately 50% of cases; tumor penetrance and latency increased upon re-transplantation whereas growth kinetics were similar across all generations. Histology of PDX tumors resembled primary iCCA and key characteristics were maintained during four PDX generations, but stroma content was reduced. Additional histologic and transcriptomic analysis revealed that human extracellular matrix components were replaced by murine orthologues. Transcriptome from PDX tumors resembled primary CCA but did not completely overlap. Success rate of 2D tumor cell line generation was approximately 20% and matching PDX models were available. Tumors derived from cell lines displayed comparable histology to their original tumor. Cell lines derived from primary tumor or PDX from the same patient expressed similar features. PDX as well as cell line derived-tumors from $ERBB2_{amp}$ primary tumor overexpressed HER2.
Conclusion: We successfully established and repeatedly passaged seven iCCA PDXs; tumors initially growing as PDX can be passaged for at least four generations with nearly complete penetrance and comparable growth kinetics. PDX tumors retained key morphological and molecular features, but human stroma was lost in PDX tumors. Additionally, we were able to generate iCCA cell lines from three patients. Tumor cell lines derived tumors mimic characteristics from primary iCCA. Driver mutations such as HER2 were stably overexpressed in PDX and cell lines. We expect that thoroughly characterized PDX and tumor cell lines will serve as valuable tool for drug testing and help to understand primary and secondary resistance mechanisms to targeted therapies in iCCA.

FRI-493

CLEC14A regulates neutrophil recruitment across liver endothelial cells and correlates with a neutrophil signature in hepatocellular carcinoma

Joanne O'Rourke[1], Daniel Patten[2], Dean Kavanagh[2], Catherine E. Willoughby[3], Tahir Shah[4], Yuk Ting Ma[5], Owen Cain[6], Derek A. Mann[7], Roy Bicknell[2], Shishir Shetty[8]. *[1]Centre for Liver and Gastrointestinal Research, University of Birmingham, Birmingham, United Kingdom; [2]University of Birmingham, Birmingham, United Kingdom; [3]Translational Research in Hepatic Oncology, Liver Unit, University of Barcelona, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Hospital Clínic, Barcelona, Spain; [4]University Hospitals Birmingham NHS Trust, Birmingham, United Kingdom; [5]Insititute of Immunology and Immunotherapy, University of Birmingham, University Hospitals Birmingham NHS Trust, Birmingham, United Kingdom; [6]University Hospitals Birmingham NHS trust, Birmingham, United Kingdom; [7]Newcastle University-Newcastle Fibrosis Research Group, Biosciences Institute, Faculty of Medical Sciences, Newscastle, United Kingdom; [8]Centre for Liver and Gastrointestinal Research, University of Birmingham, National Institute for Health Research, Birmingham Biomedical Research Centre at University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom*
Email: joanne.orourke@nhs.net

Background and aims: Immune checkpoint inhibition is now standard of care for patients with advanced hepatocellular cancer (HCC) and yet many patients remain resistant to this therapy. The presence of innate immune populations in the tumour microenvironment (TME) have been implicated in regulating the efficacy of these agents. CLEC14A has previously been shown to be upregulated on tumour endothelial cells and we found endothelial upregulation of CLEC14A in a subset of HCC tumours as well as acute liver injuries (alcoholic hepatitis and seronegative hepatitis). This led us to explore the role of CLEC14A in neutrophil recruitment, critical populations in both acute liver injury and cancer.
Method: Immunohistochemical analysis was undertaken of CLEC14A in human liver tissue across a range of liver diseases and HCC. CLEC14A regulation and function was then explored in primary human liver endothelial cells including responses to shear stress and flow based adhesion assays. Acute liver injury models were undertaken in CLEC14A knockout mice followed by intravital microscopy of the liver. Finally, CLEC14A expression was studied in both publically available HCC data sets and through spatial transcriptomics of HCC tissue.
Results: We found that CLEC14A mediates neutrophil recruitment across liver endothelium in both in vitro and in vivo models. Specifically, CLEC14A inhibition significantly reduced neutrophil adhesion to liver endothelium in flow based assays and reduced neutrophil sinusoidal recruitment during ischaemia reperfusion injury. This process appeared to be independent of its interaction with its known ligand Multimerin-2. Additionally, we demonstrated a positive correlation of CLEC14A expression in human HCC with a neutrophil transcriptional signature.
Conclusion: This study unveils a new link between a tumour angiogenic receptor and neutrophil infiltration to the liver and highlights the potential of combining current immunotherapy in HCC with agents targeting the CLEC14A pathway.

FRI-494-YI

Cabozantinib induces mtDNA-dependent cytotoxicity through cGas-STING signaling in experimental hepatocellular carcinoma

Patricia Rider[1,2,3], Anna Tutusaus[1,3], Carlos Cuño-Gómiz[1,2], Flavia Savino[1,2], Loreto Boix[3], Montserrat Marí[1], María Reig[3], Albert Morales[1,3]. *[1]Institute of Biomedical Research of Barcelona (IIBB-CSIC), IDIBAPS, Barcelona, Spain; [2]Departament de Biomedicina,*

Facultat de Medicina, Universitat de Barcelona, Barcelona, Spain; [3]*Barcelona Clinic Liver Cancer (BCLC) Group, Liver Unit, Hospital Clínic of Barcelona, University of Barcelona, CIBEREHD, IDIBAPS, Barcelona, Spain*
Email: albert.morales@iibb.csic.es

Background and aims: The tyrosine kinase inhibitor (TKI) cabozantinib is used in clinical practice against hepatocellular carcinoma (HCC). Previous studies demonstrated that TKI inhibitors such as sorafenib and regorafenib induce mitochondrial damage during cancer treatment. However, mitochondrial effects of cabozantinib have not been sufficiently explored in HCC. Cytosolic mitochondrial DNA (mtDNA) from damaged mitochondria emerges as a key driver of innate immunity. mtDNA sensing, contributed by the cyclic GMP-AMP synthase (cGas)-stimulator of interferon genes (STING) pathway is involved in immunomodulation and antitumor response. Here, we describe cabozantinib cytotoxicity as mitochondrial dependent and emphasize its association with the cGas-STING pathway.
Method: Fluorometric assessment of mitochondrial function was conducted by dihydroethidium (DHE) and JC1 staining. Cellular fractionation was performed by digitonin lysis buffer and confirmed by western blot analysis. Immunofluorescence staining and real-time qPCR were performed to detect cytosolic leakage of mtDNA in Hep3B cells. The nucleoside analog 2′, 3′ dideoxycytidine (ddc) was used for mtDNA depletion. cGas-STING axis activation and interferon stimulated genes (ISGs) downstream signaling was assessed by western blotting and real-time qPCR in hepatoma cells after cabozantinib stimulation.
Results: Cabozantinib caused mitochondrial damage in Hep3B cells increasing ROS production (DHE) and reducing mitochondrial membrane potential (JC1 shifting). We also detected mtDNA leakage into the cytosol in a dose-dependent and time-dependent manner, accompanied by an upregulation of interferon-stimulated genes (ISGs), suggesting that cabozantinib stimulates DNA sensing pathways via the cGas-STING axis. This pathway activation was verified by cabozantinib-mediated TBK-1 and IRF3 phosphorylation. Moreover, short cabozantinib stimulation also induced p65 and IRF3 nuclear translocation. To further verify whether cGas-STING activation and ISGs upregulation is mtDNA dependent, cells lacking mtDNA were generated. After 48 h ddc incubation, mtDNA content was reduced by 80% while ddC-mediated mtDNA depleted cells reduced TBK-1 phosphorylation following cabozantinib stimulation. In parallel, mtDNA depletion blocked mRNA expression of ISGs after cabozantinib treatment. Importantly, while blockage of this pathway (H-151) partially diminished cabozantinib cytotoxicity, vadimezan induction of cGas-STING potentiated the anti-tumor effect in vitro and in a Hepa1–6 3D spheroid model.
Conclusion: Cabozantinib-induced mtDNA leakage to the cytosol induces ISGs signaling by activating the cGas-STING pathway in hepatoma cells. Our results reveal mitochondrial damage and the mtDNA-cGas-STING axis as compelling targets in antitumor efficacy with a potential role in immunological responses.

Regulation of KIF23 by miR-107 controls replicative tumor cell fitness in mouse and human hepatocellular carcinoma

Mirco Castoldi[1], Sanchari Roy[2], Carolin Lohr[1], Rossella Pellegrino[3], Mihael Vucur[1], Michael Singer[1], Veronika Buettner[1], Matthias Dille[1], Lara Heij[4], Lars Zender[5], Ulf Neumann[4], Mathias Heikenwälder[6], Thomas Longerich[3], Christoph Roderburg[1], Tom Luedde[1]. [1]*Medical Faculty, Heinrich Heine University Düsseldorf, Dusseldorf, Germany;* [2]*Medical Faculty and University Hospital Düsseldorf, Dusseldorf, Germany;* [3]*University Hospital Heidelberg, Heidelberg, Germany;* [4]*University Hospital RWTH Aachen, Aachen, Germany;* [5]*University Hospital Tubingen, Tubingen, Germany;* [6]*Deutsches Krebsforschungszentrum, Heidelberg, Germany*
Email: mirco.castoldi@med.uni-duesseldorf.de

Background and aims: In hepatocellular carcinoma (HCC), there is a lack of successful translation of experimental targets identified in mouse models to human patients. This study utilized a comprehensive transcriptomic approach in mice to identify novel potential targets for therapeutic intervention in humans.
Method: Genome-wide miRNA and mRNA expression data were analyzed in three distinct mouse models of liver cancer. The effects of target genes on hepatoma cell fitness were evaluated through proliferation, survival, and motility assays. The impact of mouse targets on human HCC prognosis was assessed using TCGA and GEO databases, in combination with TMAs. Finally, the functional effects of the identified targets on tumorigenesis were tested in HDTVi-based preclinical HCC models in vivo.
Results: We discovered that miR-107, along with other tumor suppressor miRNAs, potentially inhibited the translation of a nexus of genes controlling the assembly and function of the mitotic spindle. Among these potential targets, we identified that Kif23, a protein that controls key stages of cytokinesis, was directly regulated by miR-107 and that the activity of the miR-107/KIF23 signaling module was functionally conserved between mice and humans. In humans, KIF23 expression was found to be a prognostic marker in liver cancer, with high expression associated with poor prognosis. HDTVi of vectors carrying either pre-miR-107 or anti-Kif23 shRNA inhibited the development of highly aggressive cMyc-NRas-induced liver cancers in mice.
Conclusion: Disruption of the miR-107/Kif23 axis inhibited hepatoma cell proliferation in vitro and prevented oncogene-induced liver cancer development in vivo, offering a novel potential avenue for the treatment of HCC in humans.

FRI-498-YI
Role of ganglioside GD2 in the stem-like compartment of intrahepatic cholangiocarcinoma

Antonella Mannini[1], Mirella Pastore[1], Margherita Correnti[2], Elisabetta Rovida[3], Cedric Coulouarn[4], Jesper Andersen[5], Claudia Campani[1], Fabio Marra[1], Chiara Raggi[1]. [1]*University of Florence, Florence, Italy;* [2]*University of Milan, Milan, Italy;* [3]*University of Florence, Florence;* [4]*University of Rennes, Rennes, France;* [5]*University of Copenhagen, Copenhagen, Denmark*
Email: chiara.raggi@unifi.it

Background and aims: Among the ganglioside family (sialic acid-containing glycosphingolipids), GD2 has been recently investigated as a potential cancer stem cell (CSC) biomarker in several tumor types. However, the possible role of GD2 and its biosynthetic enzyme, GD3 synthase (GD3S), in intrahepatic the cholangiocarcinoma (iCCA) stem subset is currently unknown.
Method: Stem-like subset of iCCA cell lines (HUCCT1, CCLP1) was enriched by sphere culture (SPH) and compared to monolayer parental cells (MON). iCCA ganglioside (GS) profiles were evaluated by chromatographic analytical procedures, after feeding with radioactive sphingosine. Plasma membrane GD2 expression was evaluated by FACS, while GS biosynthesis enzymes were analyzed by RT-qPCR during spherogenesis. The modulation of stem features by GS was investigated *in vitro* and *in vivo* by using iCCA GD3S-transfected cells, and corroborated by global transcriptomic analysis.
Results: In both iCCA lines, SPH showed severe changes in GS composition, including an increased content of GM3 and GD1a, reduction of GM2, and, among complex GS, increase or appearance of GD2. These findings were corroborated by high levels of GM3 synthase as well as GD3- and GM2/GD2 synthase expression. Cancer-stem features related to GD2 availability depend on the GD3S, the synthase that provides the precursor (GD3) to produce GD2. Significant correlations between GD3S expression and lymph node invasion were found in a published iCCA cohort by exploring the possible relevance of GD3S involvement in the clinical setting. After GD3-stable transfection, iCCA cells overexpressing GD3S showed *in vitro* enhanced sphere-forming ability, invasive properties as well as higher drug resistance compared to the transfected control. *In vivo* experiment, CCLP1 cells overexpressing GD3S developed a tumor

mass volume 2–3 fold greater compared to the control. By global transcriptomic analysis, ontology investigations identified 74 processes shared by the iCCA-SPH and GD3S-transfected cells, with enrichment for development and morphogenesis processes, signaling, in particular MAPK pathway and locomotion.
Conclusion: We demonstrate that the iCCA stem-like properties are related to the GS synthetic pathways and patterns. GD3 synthase and GD2 ganglioside could represent potential markers for iCCA stem phenotype.

FRI-499-YI
Counterfactual explanations for histopathology slides of hepatocellular carcinoma and cholangiocarcinoma enhance the understanding of artificial intelligence models
Laura Žigutytė[1], Katherine Hewitt[1], Jakob Nikolas Kather[1,2,3]. [1]*Else Kroener Fresenius Center for Digital Health, Technical University Dresden, Dresden, Germany;* [2]*Department of Internal Medicine I, University Hospital Carl Gustav Carus, Dresden, Germany;* [3]*National Center for Tumor Diseases (NCT), University Hospital Heidelberg, Heidelberg, Germany*
Email: laura.zigutyte@tu-dresden.de

Background and aims: Deep learning (DL), a type of artificial intelligence (AI), is increasingly used in biomedical sciences, e.g., for predicting cancer subtypes, or a range of biomarkers from whole slide images. Challenges arise after the training of complex DL models, as it is essential to analyze the underlying reasons for the predictions to avoid biases or confounding factors. Traditional explainability methods, such as saliency maps and feature visualization, are difficult to interpret and may lead to confirmation bias. Therefore, in this work, we explore another type of explainability method-counterfactual explanations that we create using a generative AI model for liver hepatocellular carcinoma (HCC) and cholangiocarcinoma (CCA). These explanations show how an image would look to be classified as a different cancer type, aiding in understanding the reasoning and enhancing trust in the DL model.
Method: We use tiles derived from tumor areas in digitized whole slide images, which are part of The Cancer Genome Atlas Program (TCGA), to train a generative diffusion model. These tiles originate from scanned tissue samples of patients diagnosed with HCC or CCA. Simultaneously with a generative diffusion model, we train a semantic encoder to extract semantic information from each tile. Then, a classifier (HCC vs CCA) is trained, enabling us to determine the direction for the manipulation. By conditioning the generative diffusion model on manipulated semantic information according to the determined direction, we can alter any tile from the dataset to appear like the opposite class. We perform quantitative evaluation of the trained diffusion model, and qualitative analysis of generated counterfactual explanations.
Results: Preliminary results indicate that the trained diffusion model is capable to effectively reconstruct histopathology tiles while maintaining a high level of structural similarity. This model serves as a foundation for generating counterfactual explanations to elucidate the predictions made by the classifier when distinguishing between HCC and CCA. As we gradually modify an image to resemble the opposite class (for example, transforming an HCC image to look like CCA, and vice versa), we are able to observe and pinpoint the specific morphological alterations that transpire during this transformation. By adjusting the degree of manipulation, we create a series of images that depict a gradual transition of the image towards the opposite class, all while retaining a great portion of the original image's distinctive features.
Conclusion: Our work shows the potential of generative AI to aid the analysis of the reasoning behind uninterpretable DL models. The generation of counterfactual explanations offers a promising direction for gaining insights into predictions of other biomedical targets and potentially facilitating a deeper understanding of tissue morphology.

FRI-500-YI
ERAL1 down-regulates NADH: ubiquinone oxidoreductase core subunit V1 through N6-methyladenosine reader Insulin like growth factor 2 mRNA binding protein 2 to inhibit mitochondrial adenosine triphosphate synthesis and metastasis in hepatoma cells
Li Zhou[1], Siqi Liao[1], Siyuan Chen[1], Song He[1], Zhihang Zhou[1].
[1]*Chongqing medical university, Chongqing, China*
Email: zhouzhihang@cqmu.edu.cn

Background and aims: One of the most prevalent malignant tumors is hepatocellular carcinomas (HCC), but its 5-year survival rate is less than 20%. Exploring the genes associated with HCC metastasis and determining the underlying process is a critical and challenging subject. Recent research has demonstrated that alterations in mitochondrial metabolism are directly associated with the development and metastasis of HCC. The primary metabolic activity of mitochondria is oxidative phosphorylation (OXPHOS), and due to mitochondrial dysfunction, this metabolic mode will be reprogrammed in HCC.
Method: We constructed mouse HCC metastasis models using CRISPR/Cas9 genome-wide knockout library to compare HCC primary and metastatic sites. Clinical samples were used to analyze the expression of ERAL1 in HCC and its relationship with prognosis. Then, we constructed cell lines with stable knockdown or overexpression of ERAL1 by lentivirus transfection to verify its effects on tumor development in vivo and in vitro. Metabolomics and transcriptomics were used to search for metabolic pathways and gene information closely related to ERAL1. Lactic acid assay and mitochondrial membrane potential were used to verify cellular glycolysis and oxidative phosphorylation levels. ChIP and MS were used to search for proteins that interact with ERAL1. MeRIP-qPCR, RIP-qPCR and actinomycin D experiments were used to verify whether the mRNA of NDUFV1 binds to IGF2BP2 and affects its stability.
Results: Firstly, we found that the guide RNA of ERAL1 was significantly enriched in the metastasis, suggesting that it was a tumor metastasis suppressor gene. Clinicopathological analysis showed that ERAL1 was low-expressed in HCC and positively correlated with prognosis of patients. Then, we confirmed that ERAL1 could inhibit HCC invasion and metastasis. Mechanically, following ERAL1 knockdown, various metabolites were enriched in the OXPHOS metabolic pathway. ERAL1 inhibited ATP production and metastasis of HCC cells by regulating NDUFV1. Notably, the Warburg effect did not appear in HCC cells after ERAL1 knockdown, and glucose metabolism was still mainly conducted by OXPHOS rather than glycolysis. ERAL1 could bind to and down-regulates the m6A reader protein IGF2BP2, which recognizes NDUFV1 mRNA through the m6A site and enhances its stability. Subsequently, a series of experiments proved that IGF2BP2 regulates NDUFV1 mRNA stability in HCC through m6A modification and facilitates tumor invasion and metastasis.
Conclusion: ERAL1 binds to and down-regulates IGF2BP2, inhibits the m6A modification of NDUFV1 mRNA by IGF2BP2, reduces the stability of NDUFV1 mRNA, and thus inhibits the generation of ATP in mitochondria. This study revealed a new mechanism of regulation of mitochondrial metabolism and metastasis of HCC cells, which is expected to provide a new sight for the treatment of HCC.

Email: angela_rojas16@hotmail.com

Background and aims: Hepatocellular carcinoma is a primary liver cancer that develops in an environment of chronic inflammation and liver damage where platelets have been proposed as key mediators of carcinogenesis. Platelet activation induces the release of extracellular vesicles (PEVs) which represent around 70–90% of circulating microparticles in the blood. The study aims to determine the use of PEVs as a potential circulating biomarker of HCC.
Method: Eighty-seven patients living with cirrhosis (82% males and average age: 64.5+9.4 years) were followed for 5 years: 35/87 (40%) did not develop HCC during the follow-up and 52/87 (60%) developed HCC. Plasma-heparin samples collected at the entry of the study was used to characterize PEVs by size, (0.2–1 µm Megamix Plus SC protocol, BD) and the expression of CD42b (glycoprotein Ib) and phosphatidylserine (the binding partner of annexin V) cell surface. Levels of PEVs Annexin V CD42b+ were quantified in plasma-heparin samples by flow cytometry.
Results: Alpha-fetoprotein and AST serum level were increased significantly in HCC in comparison with non-HCC cirrhotic patients (AFP: F4: 2.70 ± 0.25 vs HCC: 376.06 ± 147.30 ng/ml; p = <0.001 and AST: 35.21 ± 4.99 vs HCC: 49.41 ± 5.31 U/l; p = 0.024). In patients with HCC development a significant increase of total EVs (Annexin V+) was found (7816 ± 1310 vs 3147 ± 559 U/µl; p < 0.001) and PEVs-CD42b were also increased significantly in HCC (PEVs-CD42b: 1762 ± 266 vs 486 ± 111 U/µl; p < 0.001), despite no significant differences in serum total platelets (126.1 ± 43.6 vs 155.4 ± 100.8 × 10^9/l; p = 0.578). Diagnostic accuracy of PEVs-CD42b was addressed by AUROC: 0.80 (0.70–0.89; p < 0.001) with sensitivity 78.8%, specificity 71.4%; PPV 81% and NPV 71.4% for HCC diagnosis (Cut off: 467.47 U/µl). In multivariate analysis age (OR: 1.16 (1.04–1.297; p = 0.007), sex (OR: 19.25 (1.23–299.25; p = 0.035) AFP serum levels (OR: 1.95 (1.27–2.99; p = 0.002) and PEVs-CD42b (OR: 1.001 (1, 000–1, 002; p = 0.009) were independently associated with HCC diagnosis.
Conclusion: Circulating PEVs levels are raised in patients with HCC despite no changes in platelet levels. In clinical settings, PEVs showed a potential as non-invasive biomarker for HCC diagnosis. Further studies are needed to elucidate the role of platelets in cancer.

FRI-502

KDM2A chromatin regulator constrains senescence program and immunoresponse in liver cancer

Email: vinicio.carloni@unifi.it

Background and aims: Maintenance of genomic stability is essential for normal development and to prevent cancer. Genetic information is packaged into chromatin and accumulating evidence suggest that modulation of components of chromatin structure such as histones assumes a relevant significance in genomic integrity. However, how the chromatin remodelers intervene in maintaining genomic integrity and how they affect genetic information remain poorly understood. KDM2A is a chromatin remodeler and it has been implicated in the regulation of CpG islands and genes transcription. KDM2A specifically removes methyl moieties from lysine 36 of histone H3 (H3K36).
Method: Human HCC cell lines (HepG2, Huh7), mouse HCC cell line (Hepa1-6) and hTert immortalized human hepatocytes (Hus) were employed. To assess the functional role of KDM2A, gain on-and loss-of-function, chromatin immunoprecipitation, RNA-seq, immuno-fluorescence/live imaging were performed. Mitochondria function, NADPH, lactate and H_2O_2 were evaluated. Hepa 1–6 cells depleted of KDM2A by using CRISPR/Cas9 were further analyzed in in vitro and in vivo experiments.
Results: To identify chromatin regulators of genomic stability, knocked down of checkpoint kinase 2 (CHK2) a central effector of DNA repair was performed, hence RNA-seq was performed. RNA-seq analysis revealed that between upregulated genes were several immune response genes. Importantly, Huh7 cells that did not reveal any modifications of immune response genes expressed high levels of KDM2A. To explore the biological function of KDM2A we depleted KDM2A with RNA interfering in Huh7, HepG2 and Hepa1–6 and all cell lines tested showed increased expression of DNA damage marker phospho-histone H2AX. To explain the source of DNA damage we hypothesized an imbalance of redox homeostasis. Indeed, KDM2A depleted cells exhibited a defective antioxidative function represented by reduced NADPH and altered one carbon folate pathway. Furthermore RNA-seq and WB analysis on KDM2A depleted cells showed expression changes of CDKN2A, CDKN1A and LMNB1, markers of senescence. Significantly, we found that depletion of KDM2A coincided with increased H3K36me2 in CpG islands and led to re-expression of adaptive immunity proteins PD-L1 and MHC-I in human cancer cells and H2-D1, H2-T23, Mr1 in Hepa 1–6 cells, activation of AIM2/IFI16-STING signaling, and cell growth inhibition in vitro and in vivo. Consistent with these data, TGCA data analysis showed KDM2A overexpression in liver cancer and inverse correlation between KDM2A expression and $CD8^+$ T cell infiltration.
Conclusion: These findings suggest a role for KDM2A as an epigenetic controller of cellular senescence program and its over-expression in liver cancer constrains the program and immune response. Along these lines targeting KDM2A by e.g. siRNA-GalNAc conjugated could represent a novel strategy in liver cancer treatment.

Email: mario.mondelli@unipv.it

Background and aims: Intrahepatic cholangiocarcinoma (iCCA) is the second most common primary hepatic malignancy. Metabolic reprogramming is a hallmark of cancer pathobiology to sustain tumour growth and anabolic pathways. Lipids are crucial for cell survival as components of biological membranes, energy suppliers and bioactive mediators. However, information on the iCCA lipidome profile is still lacking. Fatty acid (FA) synthesis is downregulated in iCCA while active uptake by specific transporters is enhanced, even though conflicting data exist on the mechanism of FA accumulation.

Proliferation of CCA cell lines rely on lipid uptake to fuel FA catabolism and to promote FA storage in lipid droplets (LD) as neutral lipids. Several studies suggested that LDs are associated with cancer cell proliferation, resistance to death, aggressiveness, and support cancer stem cell functionality. In this study we investigated the iCCA lipidome in paired iCCA and non-tumour (NT) liver tissue and serum from iCCA patients, focusing on fatty acid metabolism.
Method: Lipid profile characterization of serum, surgically resected iCCA specimens and NT tissue was analyzed by liquid chromatography-tandem mass spectrometry analysis. In iCCA specimens and NT tissue, gene and protein expression were analysed by qPCR and Western Blot analysis. Immunohistochemistry was performed on iCCA and NT tissues. Healthy subjects' (HC) sera served as control.
Results: The untargeted lipidome profile showed a clear-cut separation between iCCA and NT tissues as well as between iCCA and HC sera. Indeed, FA accumulated both in iCCA tissue and patients' sera. Expression of Acetyl-CoA Carboxylase Alpha *ACACA*, the rate-limiting enzyme of *de novo* lipogenesis, was higher in iCCA tissue than in NT tissue. FABP5 membrane-associated transporter expression was unchanged; conversely, *FABP4* and *CD36* gene expression was down-regulated in iCCA tissue. Expression of Acyl-CoA Dehydrogenase Medium chain *ACADM*, which catalyses the initial step of FA β oxidation, was lower in iCCA tissue compared with NT tissue. LD were found in the cytoplasm of hepatocytes and macrophages of non-neoplastic parenchyma. Conversely, only small amounts of LD were found in neoplastic cells, while clusters of small droplets were found in the extracellular matrix and in intratumoral fibrous tissue. Several species of phospholipids and sphingolipids, the main components of plasma membranes, were upregulated in iCCA compared with NT tissues.
Conclusion: These findings suggest that FA accumulation could promote iCCA aggressiveness by supporting membrane biogenesis and generation of bioactive lipids. Differences in lipidome serum profile between iCCA patients and HC suggest a mean to identify individuals with iCCA by liquid biopsy.

FRI-515
TOX3 inhibits the progression of HCC through Jag1/Notch2 pathway
Shaoping She[1], Dongbo Chen[1], Hongsong Chen[1]. [1]*Peking University People's Hospital, Peking University Hepatology Institute, Beijing Key Laboratory of Hepatitis C and Immunotherapy for Liver Diseases, Beijing, China*
Email: sheshaoping@126.com

Background and aims: Hepatocellular carcinoma (HCC) is the most common primary malignancy of the liver and represents a major global health-care challenge. Thymocyte selection-associated high mobility group box factors (TOXs) are members of an evolutionarily conserved DNA-binding protein family, and are expressed in several immune-relevant cell subsets. The transcription factor TOX3 can play different roles in different cancer types as a proto-oncogene or tumor suppressor gene, and can be used to predict the prognosis of certain tumor patients. However, the role and mechanism of TOX3 in HCC have not yet been elucidated.
Method: The expression of TOX3 was detected in different HCC patients cohorts and its correlation with patients' prognosis was analyzed. *In vivo*: In TOX3 knockout ($Tox3^{-/-}$) and wild-type (WT) mice, subcutaneous tumorigenesis models and liver orthotopic tumorigenesis models were established using two mouse HCC cell lines (Hepa1–6, H22); In nude mice, subcutaneous tumorigenesis models were established using two human HCC cell lines (Hep3B, SK-Hep1). The direct effects of TOX3 on HCC cells were studied *in vitro*. In addition, we performed RNA sequencing of HCC cells with TOX3 overexpression or knock out.
Results: Through the detection of clinical HCC patient samples, we found that TOX3 is upregulated in human HCC tissues, and its expression level is positively correlated with the prognosis of HCC patients. By immunohistochemistry and immunofluorescence staining, we found that TOX3 expression in human HCC tissues was positively correlated with the infiltration level of $CD8^+$ tumor-infiltrating lymphocytes (TILs) and negatively correlated with PD-L1 expression. In addition, we found that TOX3 expression in HCC tissues was positively correlated with the infiltration level of M1 macrophages and NK cells based on the TCGA database. *In vivo*, we found that overexpression of TOX3 inhibits the formation of subcutaneous tumors in nude mice. *In vitro*, we observed that overexpression of TOX3 inhibits the proliferation and migration of HCC cells, while knockout of TOX3 promotes the proliferation and migration of HCC cells. Furthermore, analysis of RNA sequencing results showed that TOX3 may inhibit the proliferation and migration of HCC cells through activating the Jag1/Notch2 signaling pathway.
Conclusion: Taken together, TOX3 inhibits the proliferation and migration of HCC cells by activating the Jag1/Notch2 signaling pathway, thereby limiting the progression of HCC and improving the prognosis of patients. The results are expected to clarify the role and mechanism of TOX3 in the liver tumor microenvironment for the first time, and explore the potential value of TOX3 as a prognostic indicator for HCC patients.

Email: luca.grisetti@fegato.it

Background and aims: Aurora Kinase A (AURKA) is a pivotal mitotic kinase implicated in tumorigenic processes and overexpressed in most cancer types. Recent evidence suggests a new regulatory role for AURKA in modulating Programmed Death-Ligand 1 (PD-L1) expression in breast cancer. Despite its critical role, limited information exists on AURKA's involvement in hepatocellular carcinoma (HCC), and the regulatory interplay with PD-L1 remains unexplored. This study aims to explore AURKA and PD-L1 expression in HCC and precancerous conditions and the impact of AURKA inhibition and knockdown on the regulation of PD-L1 *in vitro*.
Method: AURKA and PD-L1 (CD274) mRNA and protein expression were assessed using qRT-PCR and Western blot, respectively. Human samples included healthy (n = 14), metabolic dysfunction-associated steatotic liver disease (MASLD) (n = 17), tumor, and paired adjacent non-tumoral (NT) tissues from HCC patients (n = 56). Mouse samples were collected from transgenic (TG) mice with chronic hepatitis B, progressing to HCC by 12 months, and wildtype (WT) mice sacrificed at 3, 6, 9, 12, and 15 months (n = 11 per condition). AURKA was inhibited by alisertib or AK-01 for 72 h, and knockdown was achieved through siRNA for 72 h or 144 h in HCC-derived JHH6 and Huh7 cell lines. The effects were evaluated in terms of cell viability, cell cycle arrest (flow cytometry), and PD-L1 protein expression (Western blot).
Results: *AURKA* and *PD-L1* gradually increased from healthy to MASLD ($p < 0.05$) and from MASLD to HCC-adjacent NT tissues ($p \leq 0.05$). *AURKA* overexpression was observed in 75% of HCC tissues

compared to NT tissues ($p < 0.001$), aligning with the results from the TG mouse model, where the gene was increased in early tumor stages compared to pre-tumoral stages ($p < 0.001$), NT ($p < 0.05$), and WT tissues ($p < 0.001$). *Cd274* exhibited a marked increase during neoplastic progression in mice ($p = 0.01$). *AURKA* positively correlated with *PD-L1* in HCC, NT, and MASLD tissues (all $p < 0.001$). Despite the decrease of AURKA protein expression in HCC tissues ($p < 0.001$), the percentage of phosphorylated AURKA (Thr288) was increased in HCC, suggesting augmented kinase activity. AURKA inhibition or knockdown increased aneuploidy (+19–48%, all $p < 0.01$) and reduced viability ($p < 0.001$) in both cell lines. AK-01 treatment decreased PD-L1 glycosylated mature forms ($p < 0.01$), while 144-hour knockdown reduced unglycosylated PD-L1 ($p < 0.05$) in both cell lines.
Conclusion: *AURKA* and *PD-L1* expression positively correlate in liver disease, both increasing with the progression of the disease. AURKA exhibits higher kinase activity in tumors than in NT tissues. *In vitro,* AURKA inhibition or silencing decreases PD-L1 expression through two mechanisms, implying multiple roles of AURKA in the regulation of PD-L1. This suggests a potential use of AURKA-targeted therapy in combination with immune checkpoint inhibitors in cancer therapy.

FRI-517
Single-cell sequencing reveals differential efficacy of targeted therapy combined with immunotherapy in patients with hepatocellular carcinoma
Boxiang Zhang[1], Xin Song[1], XiyAo Chen[1], Xingrong Zheng[1], Tao Pan[1], Chan Xie[1], Liang Peng[1]. [1]*Department of Infectious Diseases, The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*
Email: happyxiechan@hotmail.com

Background and aims: In the treatment of hepatocellular carcinoma, targeted therapy combined with immunotherapy is increasingly favored by clinics. However, there are still some patients who do not benefit from it, and the reasons for this are still not clear. In our study, we would like to analyze the tumor microenvironment of patients with different efficacy differences and reveal the reasons for the efficacy differences, so as to improve the efficacy of targeted therapy combined with immunotherapy in patients with hepatocellular carcinoma.
Method: We collected cancer and paracancer tissue samples from three patients with hepatocellular carcinoma who received targeted therapy combined with immunotherapy. Based on the Recist assessment criteria at 6 months after treatment, patients with good efficacy were categorized into the PR group, and those with non-significant efficacy were categorized into the PD group. Cellular heterogeneity and immune cell characteristics of hepatocellular carcinomas with different treatment responses were determined by single-cell nuclear sequencing.
Results: First, we found that the number of tumor cell subpopulations was significantly increased in the PD group. This suggests that the tumor cells of PD patients are significantly heterogeneous. Further functional analysis of up-regulated genes in different subpopulations revealed that tumor cells in the PD group mainly exhibited enhanced fatty acid metabolism, enhanced proliferation ability, and weakened adhesion ability. Next, we found that the tumor microenvironment in the PD group exhibited significant immunosuppression. This was manifested by a significant decrease in the number of T cells and macrophages and a significant increase in the proportion of suppressive immune cells. In the PD group, the proportion of Treg cells was significantly increased. In addition, we performed a pseudotemporal analysis of T cells, which showed that Treg cells were in the middle to late stage of differentiation. This suggests that the tumor-suppressive immune microenvironment is one of the important reasons for the difference in efficacy. At the same time, this immunosuppressive microenvironment promoted the conversion of T cells from tumor-promoting immune CD8+ T cells to immunosuppressive Treg cells.
As far as macrophages are concerned, the function of TAM cells in the PD group tended to functionally suppress T cells.
Conclusion: This study provides a comprehensive understanding of the tumor cellular and immune microenvironment in hepatocellular carcinoma and reveals the complex mechanisms underlying tumor response and resistance to anti-targeted therapy combined with immunotherapy. These insights provide potential avenues for improving the efficacy of immunotherapy in cancer patients.

Promoter DNA demethylation restores CYGB expression and attenuates hepatocellular carcinoma progression
Hoang Hai[1], Le Thi Thanh Thuy[1,2], Nguyen Thi Ha[1], Pham Minh Duc[1], Shoji Kubo[3], Akihiro Tamori[1], Atsushi Hagihara[1], Etsushi Kawamura[1], Sawako Uchida-Kobayashi[1], Masaru Enomoto[1], Norifumi Kawada[1]. [1]*Department of Hepatology, Osaka Metropolitan University Graduate School of Medicine, Osaka, Japan;* [2]*Department of Global Education and Medical Sciences, Osaka Metropolitan University Graduate School of Medicine, Osaka, Japan;* [3]*Department of Hepato-Biliary-Pancreatic Surgery, Osaka Metropolitan University Graduate School of Medicine, Osaka, Japan*
Email: kawadanori@omu.ac.jp

Background and aims: Cytoglobin (*CYGB*) acts as a tumor suppressor gene and DNA methylation in the *CYGB* promoter region has been reported in various types of cancers. This study aims to investigate whether *CYGB* promoter demethylation restoring *CYGB* expression and attenuating hepatocellular carcinoma (HCC).
Method: Forty-two pairs of tumor and adjacent non-tumor tissues from liver cancer patients with chronic hepatitis C virus infection were evaluated for *CYGB* promoter methylation using Ion GeneStudio S5. Restoration of CYGB expression was implemented in four HCC cell lines treated with 5-aza-2′- deoxycytidine (DAC). DAC-treated and untreated Huh7 cells were subcutaneously injected into the right and left flanks in 9 nude mice, respectively.
Results: Methylation frequency in tumors is significantly higher than that in non-tumor tissues at all of 33 CpG sites ($p = 1.02E-8$) in promoter region. Reversely, CYGB mRNA expression in tumor is significantly lower than that in non-tumor tissues (−60%, $p < 0.05$). Almost no methylation was found in human HSCs that correspond to positive CYGB expression. In contrast, high methylation frequency and no CYGB expression at RNA and protein levels were found in HCC cells (HepG2, Huh7, SNU-387, HLE) and myofibroblast LX-2 cells. Interestingly, DAC treatment time- and dose-dependently restored CYGB expression at both mRNA and protein levels in SNU-387, HLE and Huh7, and at mRNA level in HepG2 cells while no change in those of LX-2. Notably, after inducing CYGB expression in SNU-387, discontinuation of DAC treatment resulted in regressing of CYGB expression at both mRNA and protein levels. The mean tumor volume in left flanks injected with Huh7 was $3570 \pm 61\ mm^3$, significantly higher than that of $61 \pm 94\ mm^3$ in right flanks injected with DAC-treated Huh7.
Conclusion: Down-regulation of CYGB through promoter methylation is associated with HCC progression. Demethylation of *CYGB* gene promoter may lead to cancer regression.

FRI-519-YI
NKT cells play a protective role against MASH-derived HCC, particularly in female Balb/c mice
Carlos Cuño-Gómiz[1,2], Anna Tutusaus[1,3], Nalika Conesa[1], Patricia Rider[1,2,3], Flavia Savino[1], Albert Morales[1,3], Montserrat Marí[1]. [1]*Institute of Biomedical Research of Barcelona (IIBB-CSIC), IDIBAPS, Barcelona, Spain;* [2]*Departament de Biomedicina, Facultat de Medicina, Universitat de Barcelona, Barcelona, Spain;* [3]*Barcelona Clinic Liver Cancer (BCLC) Group, Liver Unit, Hospital Clínic of Barcelona, Barcelona, Spain*
Email: monmari@clinic.cat

Background and aims: Metabolic dysfunction-associated steatohepatitis (MASH) is emerging as the new major cause of hepatocellular carcinoma (HCC). Both MASH and HCC are sex-biased diseases, affecting men 3 times more than women due to biological and environmental factors. Intrinsic protection against HCC in females has classically been attributed to estrogen-driven IL-6 inhibition. Previous studies in our lab have demonstrated that natural killer T (NKT) cells, a non-conventional T-cell type mostly found in the liver, play a differential role in males and females in a murine MASH model. NKTs were found to be a protective factor against MASH development in male mice, but not in females. Here, our goal was to determine the role of NKTs in MASH-derived HCC development and to assess the potential differences between sexes.
Method: Male and female, Balb/c (wild-type or WT) or Cd1d−/− (Cd1d-KO, NKT-deficient) mice were injected intraperitoneally with diethylnitrosamine (DEN) at 14 days of age and were fed with a high-fat choline-deficient (HFCD) diet for 20 weeks. Blood samples were taken every 4–5 weeks to quantify alpha-fetoprotein (AFP) and ALT activities. Livers were harvested to determine the presence of tumors, and tissue sections were obtained for hematoxylin-eosin (HandE) staining or immunohistochemistry (IHC). RNA was purified from liver lysates to quantify gene expression by reverse transcription qPCR.
Results: Most mice from all groups (9/10 WT males, 7/8 Cd1d-KO males, 7/9 C1d1d-KO females) developed HCC, except for WT females (0/14). Male Cd1d-KO mice displayed a more aggravated HCC phenotype compared to WT males. An increase in serum AFP concentration was detected at an earlier timepoint in Cd1d-KO males compared to the other groups. AFP was also increased in Cd1d-KO females and WT males at the end of the experiment, but remained unchanged in WT females. The mRNA expression of different tumor associated genes (Afp, Gpc3, Ki67), and ALT activity were significantly increased in Cd1d-KO male mice compared to WT male mice.
Conclusion: From this work the following conclusions were obtained: a) NKT cells in Balb/c mice play a protective role against the development of HCC in a MASH context; b) Female mice are naturally protected against DEN+HFCD-induced HCC, but this protection is eliminated in NKT-deficient individuals.

FRI-521

Mannose receptor (CD206) as a therapeutical target in the liver metastatic microenvironment of colorectal cancer

Ines Alonso[1], Alba Herrero[1], Francesca Mastrotto[2], Luisa Martinez-Pomares[3], Giuseppe Mantovani[4], Beatriz Arteta[1], Aitor Benedicto[1]. *[1]Cancer and Translational Medicine. School of Medicine and Nursing, University of Basque Country, Leioa, Spain; [2]Department of Pharmaceutical and Pharmacological Sciences, University of Padova, Padova, Italy; [3]School of Life Sciences, University of Nottingham, Nottingham, United Kingdom; [4]School of Pharmacy, University of Nottingham, Nottingham, United Kingdom*
Email: aitor.benedicto@ehu.eus

Background and aims: Colorectal cancer (CRC) is one of the most prevalent cancers worldwide. Liver metastases of CRC is a very complex scenario that decreases substantially the prognosis of this disease, been the major cause of CRC related deaths. Previous works from this group have shown that in the liver metastatic microenvironment mannose receptor (ManR) expression and activity is modulated by mediating in the regional immune response. While the role of this receptor is well known in antigen presentation and innate immunity, its role as a potential therapeutical target is unknown. Thus, we aim to elucidate the effect of Mannose Receptor blockage in the tumour microenvironment and its role as a prometastatic factor.
Method: *In vitro*, primary liver sinusoidal endothelial cells previously treated with either ManR antibodies or specific sulphated glycopolymers was culture in the presence of either C26 murine colon carcinoma cells or the secretome of basal and sICAM-1 activated C26 cells. Then, endocytosis and processing of ovalbumin was assessed. Secretome, cell protein and RNA was collected and analyse. Additionally, the motility of LSECs was analyse under such conditions. *In vivo*, experimental metastasis assay was carried out to stablish the effect of ManR blockage in the volume of hepatic tissue occupied by the tumour. Also, the recruitment of macrophages, hepatic stellate cells and collagen deposition was analysed.
Results: *In vitro,* the blockage of ManR in LSEC before interaction with C26 cells or the secretome abrogates the stimulation inf ManR activity, along with the capacity of motility in treated LSECs. The analysis of the secretome, protein expression and RNA showed decrease of proinflammatory, pro angiogenic and profibrotic markers involved in metastatic development, such us IL-1beta, IL-6 and VEGF, while others were slightly, although not significantly, reduced. *In vivo,* a significant reduction in metastatic development was observed under ManR inhibition along with a reduction in myofibroblasts and macrophages recruitment, along with a reduced desmoplastic response.
Conclusion: ManR modulate the prometastatic microenvironment development of colorectal carcinoma. The reduction in prometastatic markers after ManR inhibition in vivo and in vitro points out ManR as a potential therapeutical target in the treatment of hepatic colorectal metastasis.

FRI-522

Loss of Toll-like receptor 9 protects from hepatocellular carcinoma in murine models of chronic liver disease

Hannes Hatten[1], Leticia Colyn[1], Ines Volkert[1], Twan Lammers[2], Kai Markus Schneider[1], Christian Trautwein[1]. *[1]University Hospital RWTH Aachen, Department of Internal Medicine III, Aachen, Germany; [2]University Hospital RWTH Aachen, Institute for Experimental Molecular Imaging (ExMI), Aachen, Germany*
Email: hhatten@ukaachen.de

Background and aims: Toll-like receptor 9 (Tlr9) is a pathogen recognition receptor, sensing unmethylated DNA derivatives from pathogens and damaged host cells. Hence, it is an important modulator of innate immunity. It has been shown that Tlr9 not only detects CpG motifs but also DNA-containing nucleotide derivatives of other origins, being able to recognize endogenous DNA derived from apoptotic neighboring cells. Given the increase in cell death during chronic liver disease, this further emphasizes the importance of Tlr9 in inflammation-associated cell damage and the progression of inflammatory liver diseases. We aimed to investigate the role of Tlr9 in fibrogenesis and hepatocellular carcinoma (HCC) progression in chronic liver diseases.
Method: We treated mice with constitutive deletion of *Tlr9* (*Tlr9*$^{-/-}$) with DEN/CCl_4 for 24 weeks. As a second model, we used hepatocyte-specific Nemo knockout (*Nemo*$^{\Delta hepa}$) mice to induce liver damage and disease progression. We generated double knockout (*Nemo*$^{\Delta hepa}$*Tlr9*$^{-/-}$) animals and sacrificed them without performing any treatment at the age of 52 weeks.
Results: *Tlr9* deletion resulted in reduced fibrosis as well as HCC burden. We observed down-regulation of hepatic stellate cell activation and consequently decreased collagen production in both models. *Tlr9* deletion was associated with decreased hepatocyte apoptosis and proliferation, modulating the initiation and progression of hepatocarcinogenesis. This observation was accompanied by a decrease in interferon-β (*Ifnb1*) and an increase in expression of chemokines with anti-tumoral ability. We show that *Tlr9* is primarily expressed in Kupffer cells, suggesting a key role of Tlr9 in intercellular communication during liver damage.
Conclusion: Our data define Tlr9 as an important pathway involved in fibrogenesis, but also in the initiation and progression of hepatocellular carcinoma during chronic liver diseases. Here, the downregulation of *Ifnb1* seems interesting as it is already known to cause apoptosis leading to compensatory proliferation and disease progression, although potential pleiotropic effects of Tlr9 cannot be excluded.

Enhancing the response of cholangiocarcinoma to chemotherapy by inhibiting MRP3-mediated drug export

Maitane Asensio[1,2], Oscar Briz[1,2], Elisa Herraez[1,2], Ricardo A. Espinosa-Escudero[1], Laura Perez-Silva[1], Marta Romero[1,2], Alvaro Temprano[1], Nazaret Hortelano-Hernandez[1], Kevin Delgado-Calvo[1], Rebeca P. Marijuan[1], Ana Peleteiro Vigil[1], Oliver Poetz[3,4], Thomas Efferth[5], Elisa Lozano[1,2], Onat Kadioglu[6], Jose J. G. Marin[1,2], Rocio Macias[1,2]. *[1]University of Salamanca, IBSAL, Salamanca, Spain; [2]National Institute for the Study of Liver and Gastrointestinal Diseases (CIBERehd), Carlos III National Health Institute, Madrid, Spain; [3]Signatope GmbH, Reutlingen, Germany; [4]Natural and Medical Sciences Institute at the University of Tubingen (NMI), Reutlingen, Germany; [5]Institute of Pharmaceutical and Biomedical Sciences, Johannes Gutenberg University, Mainz, Germany; [6]Institute of Pharmaceutical and Biomedical Sciences, Johannes Gutenberg University, Mainz, Spain*
Email: rociorm@usal.es

Background and aims: The activity of ATP-binding cassette (ABC) pumps hinders the response of many cancers to pharmacological treatment. The relevance of MRP3 (gene ABCC3) cholangiocarcinoma (CCA) chemoresistance has been elucidated. Moreover, the effect of inhibiting MRP3 has been evaluated.
Method: MRP3 expression in CCA was investigated in silico using data from the TCGA database (CHOL-TCGA) and determined by RT-QPCR in intrahepatic (iCCA) and extrahepatic (eCCA) CCA and paired adjacent liver tissue (Salamanca cohort). Protein expression and subcellular location were assayed by WB, immunoaffinity LC-MS/MS, and IHC. Several monoclonal cell sublines with overexpression or silencing of MRP3 were developed by transduction with lentiviral vectors. Cell viability was determined by the MTT test. The predicted interaction between MRP3 and ~40.000 natural and semisynthetic compounds (ZINC database) was calculated using a docking approach. Potential inhibitors (EM) were selected based on their interaction score, commercial availability, and price. Tyrosine kinase inhibitors (TKI) were also screened as potential MRP inhibitors. The ability to inhibit MRP3 was validated by flow cytometry and cell viability assays. SynergyFinder online tool was used to calculate the degree of synergistic-additive-antagonistic effects of drug combinations.
Results: MRP3 was the most abundantly expressed ABCC pump both in iCCA and eCCA. CCA-derived cells (EGI-1 and TFK-1) showed high mRNA ABCC3 and MRP3 levels at the plasma membrane. Overexpression of ABCC3 in HEK293T cells resulted in a significantly lower cytostatic effect of etoposide (a known MRP3 substrate), platinum-based drugs, SN-38, 5-FU, mitoxantrone, and cabozantinib as compared with Control (Mock) cells. Besides, silencing ABCC3 in EGI-1 cells using shRNAs enhanced the sensitivity to etoposide, cisplatin, SN-38, and mitoxantrone, suggesting a reduction in MRP3-mediated efflux of these drugs. The in silico screening of natural compounds identified 8 potential MRP3 substrates with high ligand binding energy. Flow cytometry-based transport assays of these potential chemosensitizers and 20 TKIs revealed that EM-114, EM-188, and sorafenib reduced the ability of MRP3 to transport carboxyfluorescein (CF), a well-known MRP substrate. However, only sorafenib and MK571 (a pan-MRP inhibitor) could sensitize CCA cell lines to agents presumably transported by MRP3, such as etoposide, SN38, and cisplatin. Thus, the combination of sorafenib with etoposide or cisplatin synergistically reduced the viability of CCA cells.
Conclusion: MRP3, which is highly expressed in CCA, may determine the response of this cancer to several antitumor drugs, such as cisplatin and SN-38. Moreover, pharmacological inhibition of this transporter with sorafenib can be a sound synergistic strategy to enhance the response of CCA to chemotherapy.

FRI-524

Novel genetic loci for hepatocellular carcinoma identified through genome-wide association study meta-analysis from 909, 722 individuals

Ifechukwuamaka Chinaka[1], Jake Mann[2]. *[1]University of Dublin, Dublin, Ireland; [2]University of Birmingham, Birmingham, United Kingdom*
Email: jpmann.gsy@gmail.com

Background and aims: Hepatocellular carcinoma (HCC) has high mortality, limited treatment options, and is increasing globally. It is a complication common to all end-stage liver disease. To date, genome-wide association studies (GWAS) for HCC have been aetiology-specific. Here, we conducted trans-ethnic GWAS meta-analysis for all-causes in order to identify genetic drivers independent of aetiology.
Method: Four GWAS were included: FinnGen project (287, 590 total, 982 cases), BioBank Japan (197, 611 total, 1, 866 cases), a European alcohol-associated HCC GWAS conducted by Trepo et al (4, 040 total, 1, 649 cases) and the Pan-ancestry UK Biobank (420, 531 total, 154 cases). Meta-analysis was performed using MR-MEGA (Meta-Regression of Multi-AncEstry Genetic Association).
Results: The complete cohort included 4, 651 HCC cases and 905, 121 controls, with 4, 287, 267 variants used in meta-analysis. We established rs72613567:T > TA in *HSD17B13* as a protective genome-wide significant locus for all-cause HCC (p = 4.6e-8) and replicated well-recognised risk loci in *PNPLA3* (rs738409:C > G, p = 2.3e-21) and *TM6SF2* (rs58542926:C > T, p = 2.0e-12). In addition, we found five novel loci at suggestive significance, including the tumour suppressor gene *FLI1* (rs1238566:A > G; p = 9.3e-6) and *NOTCH4* (rs499691:C > T; p = 9.3e-7), which has aberrant expression in HCC. Variants in *MDGA2* (rs2297926:G > A; p = 1.2e-7) were also associated with increased risk of HCC; these are also associated with body mass index (p = 5.6e-24) and all-cause cirrhosis (p = 1.1e-4). Meta-analysis also identified signals in CCDC63 (rs4766521:T > C, p = 1.3e-6), which is associated with alcohol intake, and *IFNL3* (rs12971396:C > G, p = 3.7e-6), which influenced hepatitis C viral response.
Conclusion: In the largest genetic study of liver cancer to date, we identified six novel loci that provide insights into aetiology of all-cause HCC.

FRI-525

Phosphoinositide 3-kinase delta promotes plasticity and development of the microenvironment in cholangiocarcinoma

Background and aims: The cholangiocarcinoma (CCA) is a highly aggressive liver cancer increasing worldwide. Surgery is the main therapeutic option but few patients are eligible at the time of diagnosis. Unsolved questions on the onset and progression of CCA remain. The high plasticity of liver epithelial cells largely contributes to generate stem cells, promoting resistance to treatment in CCA. We previously reported that PI3Kdelta regulates polarity via extracellular matrix (ECM) assembly and our recent data revealed its critical role in epithelial to mesenchymal transition (EMT)-dependent plasticity. Thus, inducing the reprogramming of liver carcinoma cells into polarized stem-like cells via the transforming growth factor-βeta (TGF-βeta) signalling. This study aims to elucidate the involvement of PI3Kdelta in CCA progression and malignancy.
Method: We used different human CCA cell lines including EGI-1 cells, established from the advanced stage of primary bile duct carcinoma (DSMZ, Germany) cultured in 3D. Xenograft tumors were established with PI3K delta -overexpressing EGI-1cells (EGI-1-PI3Kdelta) injected in immunodeficient mice. Moreover, PI3Kdelta was overexpressed in the mouse liver by Adeno-Associated Virus (AAV) gene transfer plasmids. Protein expression was assessed using immunoblot and immunostaining techniques, and gene expression using RT-qPCR. Besides, ELISA assays were conducted on mouse sera to quantify cytokine secretion. The CCA tumors from patients were obtained from the "Centre de Ressources Biologiques Paris-Sud Villejuif, France.".
Results: We showed by immunostaining that PI3Kdelta expression in patient CCA tumors is related to pluripotent stem cell and EMT markers. To evaluate the role of PI3Kdelta in CCA, we analyzed organoids derived from PI3Kdelta-overexpressing CCA cells. The cells exhibited strong expression of mesenchymal markers, stem cell markers and TGFβ/Src signaling molecules. The expression of ECM proteins like fibronectin, type IV collagen, and laminin increased, indicating ECM remodeling. The xenografts derived from EGI-1-PI3Kdelta cells showed higher growth rates and volumes compared to controls. Notably, histological staining revealed fibrosis and increased CD31 expression in these xenografts. Analysis of the serum from mice revealed the secretion of pro-angiogenic cytokines. Interestingly, the sinusoids in the AAV-PI3Kdelta liver were wider than in the AAV-control mice liver. The CD31 expression increased by the over-expression of PI3Kdelta, indicating its critical role in angiogenesis. Finally, our recent studies indicated the involvement of PI3Kdelta in lymphangiogenesis and immunity.
Conclusion: This work highlights the crucial role of PI3Kdelta in the development of a dense stroma and tumour progression in CCA by promoting angiogenesis and ECM remodelling through EMT-dependent plasticity signalling.

FRI-526
Role of the splicing factor PCBP2 in cholangiocarcinoma malignancy and chemoresistance

Candela Cives-Losada[1,2], Maria Reviejo[1,2], Maitane Asensio[1,2], Elisa Lozano[1,2], Sara Ortiz-Rivero[1,2], Maria J. Monte[1,2], Maria A. Serrano[1,2], Oscar Briz[1,2], Rocio Macias[1,2], Jose J. G. Marin[1,3].

Email: candelacives@usal.es

Background and aims: Poly (rC)-binding protein 2 (PCBP2), a splicing factor member of the hnRNP family of regulatory proteins, was reported to be altered in different types of cancer, affecting tumorigenesis and chemoresistance. However, its relevance in cholangiocarcinoma (CCA) is yet unknown. Thus, this study aimed to elucidate the role of PCBP2 in developing CCA malignant characteristics and drug resistance.
Method: PCBP2 expression was investigated in CCA (n = 36) and adjacent non-tumor (n = 9) tissues in silico using data from The Cancer Genome Atlas (TCGA) and determined by Taqman Low-Density Array (TLDA) and immunohistochemistry in samples from intrahepatic CCA (iCCA; n = 13), extrahepatic CCA (eCCA; n = 10) and adjacent non-tumor tissue (n = 9), obtained at the Salamanca University Hospital. Besides CCA cells (EGI-1), primary human cholangiocytes and hepatocellular carcinoma-derived cells (Huh7) were analyzed as in vitro models. Lentiviral vectors carrying shRNA against PCBP2, and empty vectors (Mock) were generated to transduce liver cancer cells. PCBP2 silencing was confirmed by RT-qPCR and western blot. Transcriptomic analysis of these cells was carried out by RNA-Seq. Migration and proliferation studies were performed by holographic microscopy. Cell cycle characterization was performed by flow cytometry. Induction of apoptosis was assessed by determining the expression of apoptosis-related genes using RT-qPCR. MTT assay was performed to determine the effect on cell viability of anti-tumor drugs (cisplatin, oxaliplatin, gemcitabine, 5-FU, sorafenib, and regorafenib).
Results: In silico analysis showed that PCBP2 is abundantly expressed in CCA, which was confirmed experimentally in tumor samples at mRNA and protein levels. Both iCCA and eCCA presented significantly higher levels of PCBP2 than non-tumor cholangiocytes. Moreover, immunohistochemistry revealed intense nuclear expression of PCBP2 in cancer cells. Compared with Mock cells, silencing of PCBP2 in liver cancer cell lines did not induce changes in the response to the studied anti-tumor drugs. In contrast, a significant decrease in cell proliferation and viability, a lower migration capacity, and enhanced expression of the pro-apoptotic factor BAX, consistent with apoptosis activation, were found. RNA-Seq analyses revealed that PCBP2 silencing affected the expression of several genes known to be associated with the oncogenic process, i.e., downregulation of MEX3A, NRIP1, and NRP2 and alteration of the alternative splicing pattern of MAP4K4.
Conclusion: PCBP2 may act as a relevant factor in regulating cell migration and proliferation in CCA and, therefore, a potential target to be considered in developing novel strategies to treat this cancer.

FRI-527
ACSL4 affects the invasion and metastasis of hepatocellular carcinoma by regulating the activation of arachidonic acid

Yusufukadier Maimaitinijiati[1], Shizhong Yang[1], Yunfang Wang[2], Guifang Du[2], Xiong Chen[3], Jiahong Dong[1]. *[1]Tsinghua University, Beijing, China; [2]Tsinghua university, Beijing, China; [3]peoplès hospital of Xinjiang Uyghur Autonomous Region, Beijing, China*
Email: 1554504825@qq.com

Background and aims: Hepatocellular carcinoma (HCC) has an insidious onset, easy recurrence and metastasis, and often has a poor prognosis. Tumor invasive front (TIF) is the most active site for tumor cells to invade outwards, and it is also the source of tumor micro-metastasis. Therefore, a comprehensive understanding of the invasive front of HCC and the mining of its key biomarkers may not only deepen the understanding of the mechanisms of HCC invasion and metastasis, but also pave the way for the development of new

therapeutic strategies for HCC. This study was to explore the key biomarkers are closely associated with invasion and metastasis of HCC and its clinical value.
Method: Firstly, we based on the spatial transcriptomic sequencing data of HCC clinical specimens, the biological characteristics of HCC invasive front were deeply analyzed, and an innovative algorithm was used to mine the key biomarker of TIF, which is closely related to HCC invasion and metastasis. Then, the clinical value of biomarker demonstrated through multi-center cohort that recruited 243 HCC patients from 3 clinical centers in China. Finally, the functional mechanism was revealed through in vivo、in vitro and multi-omics joint analysis.
Results: ACSL4 has significant tissue specificity and spatial specificity in HCC, and was strongly positive in the whole process of HCC invasion and metastasis, such as circulating tumor cells, microvascular invasion, intrahepatic metastases and distant metastases lesions. Multicenter study shows that the overall survival rate ($p < 0.05$) and recurrence-free survival rate ($p < 0.05$) of the high ACSL4 expression patients were lower than the low ACSL4 expression patients. Correspondingly, the MVI occurrence rate of patients with high ACSL4 expression was higher than that of patients with low ACSL4 expression ($p < 0.05$). The results of in vivo and in vitro experiments indicate that the ACSL4 gene is closely related to the invasive and metastatic abilities of HCC cells. Transcriptomics and metabolomics joint analysis observed that after knocking down ACSL4, key enzymes (CPT1A, CPT2, ACOX1) and metabolic products (arachidonic acid, Acetyl-CoA) involved in fatty acid beta-oxidation process underwent significant changes ($p < 0.01$).
Conclusion: ACSL4 affects the invasion and metastasis of hepatocellular carcinoma by regulating the activation of arachidonic acid.

FRI-530
Gut microbiome signature is distinct in cirrhosis with HCC compared to cirrhosis without HCC and controls in a southeast asian cohort and is linked with gut permeability and metabolite biomarkers

Thananya Jinato[1], Patrick Gillevet[2], Masoumeh Sikaroodi[2], Pisit Tangkijvanich[3], Jasmohan Bajaj[4], Natthaya Chuaypen[1]. [1]*Center of Excellence in Hepatitis and Liver Cancer, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand;* [2]*Microbiome Analysis Center, George Mason University, Manassas, United States;* [3]*Center of Excellence in Hepatitis and Liver Cancer, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, Bangkok, Thailand;* [4]*Virginia Commonwealth University, Richmond VA Medical Center, Richmond, United States*
Email: natthaya.ch56@gmail.com

Background and aims: The gut microbiota and bacterial by-products may contribute to the pathogenesis of liver diseases including cirrhosis and hepatocellular carcinoma (HCC). However, most studies are from Western or East Asian countries but not South-East Asia. In this study, we aimed to characterize gut dysbiosis, gut permeability, and butyrate biomarkers in patients with/without HCC from Thailand.
Method: This cross-sectional study included 30 healthy controls, 33 patients with cirrhosis without HCC (16 viral and 17 non-viral), and 44 with HCC (29 viral and 15 non-viral). Fecal samples were sequenced with 16S rRNA and analyzed for alpha/beta diversity and individual taxa comparisons between 3 groups. Circulating biomarkers of gut permeability including intestinal fatty acid-binding protein (I-FABP) and lipopolysaccharide-binding protein (LBP) were measured. The butyrate-associated gene (BCoAT) expression was assessed in fecal samples.
Results: Diversity: alpha-diversity (Chao1 index) was significantly higher in healthy controls (139.0 ± 33.9, $p < 0.001$) and cirrhosis without HCC (138.0 ± 46.4, $p = 0.008$) compared to HCC groups (109.0 ± 37.9). Beta-diversity demonstrated distinctions between healthy controls and HCC groups ($p = 0.006$), but not between pts with cirrhosis with/without HCC. Taxa differences: Multiple pairwise comparisons using ANCOM-BC2 (FDR<0.05) among the top 50 relative abundance at genus level identified significantly increased *Ligilactobacillus, Catenibacterium*, and *Alloprevotella* in both cirrhosis (HCC/not) compared to healthy controls. The *[Ruminococcus] gnavus (R. gnavus) group*, related to inflammation and metabolic diseases, was significantly increased, while butyrate-producing bacteria including *Coprococcus* and *Subdoligranulum*, were significantly decreased in HCC. However, only *Subdoligranulum* showed a significant decline in HCC compared with no-HCC cirrhosis. For permeability and inflammation, Within the entire cohort, a positive correlation between BCoAT levels and the abundance of *Subdoligranulum* ($r = 0.227$, $p = 0.023$) was observed, while its levels were negatively correlated with the *R. gnavus group* ($r = -0.387$, $p < 0.001$). Additionally, I-FABP and LBP levels exhibited positive correlations with the *R. gnavus group* ($r = 0.401$, $p = 0.001$) and *Alloprevotella* ($r = 0.293$, $p = 0.012$), but were negatively correlated with *Subdoligranulum* ($r = -0.390$, $p = 0.002$).
Conclusion: In a prospective Thai cohort, distinctive gut microbial alterations in cirrhosis, especially related to HCC were found. Increased gut permeability was linked to enriched pathogenic bacteria and lower beneficial bacteria. These data highlight the role of gut dysbiosis and altered bacterial by-products in progressive liver diseases.

FRI-531
Metabolic dysfunction associated steatohepatitis derived HCC model mouse for immune-oncology

Taishi Hashiguchi[1]. [1]*SMC Laboratories, Inc., Ota-city, Japan*
Email: hashiguchi@smclab.co.jp

Background and aims: Metabolic dysfunction-associated steatohepatitis (MASH) is a is linked to type II-diabetes and marked by steatosis, steatohepatitis, fibrosis and eventually HCC. The number of patients with MASH-derived HCC is increasing worldwide. Currently, the first line of cancer treatment drugs are immune checkpoint inhibitors (ICIs). Although ICIs have been approved by the FDA for various cancers, it has been reported that the response rate for HCC is low, and the development of new therapeutic drugs including ICIs for HCC is expected. Therefore, a mouse model for evaluating MASH-derived liver cancer is needed for drug discovery against HCC. In this study, in order to examine whether the STAM mouse, a MASH-HCC model mouse, can be used for the evaluation of ICIs, we conducted an analysis of immunohistochemistry and RNA-seq related to the immuno-oncology (IO) of HCC derived from STAM mice.
Method: MASH was induced in male mice by a single subcutaneous injection of 200 µg streptozotocin solution 2 days after birth and feeding with high fat diet after 4 weeks of age. The mice were sacrificed and livers collected at 6, 8, 10, 12, 16, 20 and 24 weeks of age. For RNA-seq analysis, total RNA from the left lateral lobe was isolated using RNeasy mini kit. Liver specimens were stored at –80°C embedded in Optimal Cutting Temperature compound for immunohistochemistry (IHC). IHC for PD-1, PD-L1, CTLA-4, CD8, FOXP3, a-SMA and FAP was performed.
Results: Expression analysis of IO-related genes was performed. Increased expression was observed in CCl5, CD4, CD8a, CD274, CXCR4, CXCR10 and PDCD1. Additionally, mutations were observed in some genes. As a result of IHC, PD-1, PD-L1, CTLA-4, CD8, a-SMA and FAP -positive signals were detected in the peri-tumor region. Furthermore, CD8-positive signals were also detected in the intra-tumor region.
Conclusion: STAM mouse model, is the model that allows the evaluation of drugs that genetic mutations, immune cells, and tumor microenvironment in addition to molecular targeted drugs.

FRI-532

Metformin boosts the sensitivity of hepatocellular carcinoma to sorafenib via reshaping the tumor microenvironment metabolism

Juan Gao[1,2]. [1]*Karolinska Institutet, Laboratory Medicine/BCM, Stockholm, Sweden;* [2]*The Third Affiliated Hospital of Sun Yat-sen University, Department of Infectious Diseases, Guangzhou, China*
Email: gaoj59@mail2.sysu.edu.cn

Background and aims: Metabolic syndrome (MS), such as obesity and type 2 diabetes mellitus (T2DM), is considered an independent risk factor for hepatocellular carcinoma (HCC). Hepatic free fatty acids (FFAs) accumulation, shown as Metabolic-associated fatty liver disease (MAFLD), supports tumor progress by leading the tumor metabolic reprogram. Our previous studies suggested anti-metabolism disorder therapies, such as cold exposure, suppress tumor growth by altering global metabolism (Seki et al., 2022, Nature 608). Sorafenib is the first-line anti-HCC treatment. However, Sorafenib resistance was reported in the MS-HCC combined patients. Metformin, a well-known insulin-sensitizing drug in anti-T2DM treatment and modulator of systematic metabolism. We are interested in how the systematic metabolism reshapes the HCC microenvironment. We also gain insight into the potential mechanisms of combining metabolic stimulators and existing drug therapies.
Method: To establish MS in animal models, adult male C57BL/6N mice were fed with high-fat diet (HFD, 60% fat calories) for more than 3 months to reach obesity. Hepa1–6 cells were implanted in the mice's liver as the orthotopic HCC models. Approximately 1 week after, mice were randomly grouped and orally treated with 10 mg/kg sorafenib (S group), or 10 mg/kg sorafenib with 150 mg/kg metformin (S+M group), or equivalent diluted polyethylene glycol (PEG) (vehicle group) for the next 4 weeks. The Glucose tolerance test (GTT) and insulin tolerance test (ITT) were performed to evaluate the host metabolic condition during the treatment. Terminally, mice were sacrificed, blood, liver with tumor were collected for histological and biochemistry analysis. All data were presented as the mean ± SEM and analyzed with unpaired Student's t-test or one-way ANOVA analysis.
Results: After 4 weeks of treatment, the body weight and BMI of HCC-HFD mice showed no significant difference between the 3 groups ($p > 0.05$). Surprisingly, compared to the other 2 groups, the liver weight decreased in the S+M group ($p < 0.05$). And the visible tumor volume showed the same difference ($p < 0.05$). Both GTT, ITT (AUC), and metabolite biochemical analysis (blood glucose, triglycerides, total cholesterol) suggested host systematic glucose and lipid metabolic disorders were improved in the S+M group ($p < 0.05$). Histological analysis of the non-tumor liver area showed that the liver steatosis (Oil Red staining) was relieved in the S+M group ($p < 0.05$). Further, histopathology showed the cell proliferation, glucose uptake, and fatty acid uptake of the tumor were decreased in the S+M group, showed by IHC staining of KI67 and CD36 and Glut1 ($p < 0.05$).
Conclusion: Metformin boosts sorafenib's anti-tumor therapeutic effects and may reshape tumor metabolic programming. The combination of Metformin and Sorafenib may contribute to better outcomes in HCC patients with metabolic syndrome.

FRI-533

Anti-MFAP-5 siRNA loaded polycarbonate nanohydrogels for anti-stromal therapy in hepatocellular carcinoma

Paul Schneider[1], Alexander Fuchs[2], Lutz Nuhn[2], Barbara Schroers[3], Mustafa Diken[3], Twan Lammers[4], Stephan Grabbe[1], Jörn M. Schattenberg[5], Leonard Kaps[6]. [1]*Department of Dermatology, University Medical Centre of the Johannes Gutenberg University, Mainz, Germany;* [2]*Institute of Functional Materials and Biofabrication, Department of Chemistry and Pharmacy, Julius-Maximilians-Universität Würzburg, Würzburg, Germany;* [3]*TRON-Translational Oncology, Mainz, Germany;* [4]*Department of Nanomedicine and Theranostics, Institute for Experimental Molecular Imaging, RWTH Aachen University Clinic, Aachen, Germany;* [5]*Department of Medicine II, Saarland University Medical Center, Saarland University, Homburg, Germany;* [6]*Department of Medicine II, Saarland University Medical Center, Saarland University, Homburg, Germany*
Email: leonardkaps@googlemail.com

Background and aims: Cancer associated fibroblasts (CAF) are promising target cells for anti-stromal therapy as they support tumor growth and metastasis in the tumor microenvironment (TME) [Kaps, Schuppan, Cells 2020]. CAF derived MFAP-5 promotes tumor angiogenesis in solid tumors [Yeung TL et al., Clinical Cancer Research 2019]. We have designed a novel generation of nanohydrogels with improved biodegradability, consisting of a polycarbonate backbone (NP) for in vivo siRNA delivery [Kaps L et al., J Control Release. 2021]. Anti-MFAP-5 siRNA loaded NP were tested in a murine model of hepatocellular carcinoma for antitumor therapy.
Method and Results: MFAP-5 was highly upregulated in 3T3 fibroblasts and hepatic stellate cells (both precursor cells for CAF in vitro) when co-cultured with the hepatocellular carcinoma (HCC) cells (Dt81Hepa1–6). Transcriptome analysis of HCC cells showed a transcript pattern also found in human HCC as tumor key genes (e.g. *AFP*, *SPATS2*) were upregulated, while genes of healthy hepatocytes (e.g. *HP*, *Apoa3/4*) were downregulated. For HCC induction, C57BL/6J mice were gavaged with escalating doses of CCl4 for liver fibrosis induction over four weeks. Fibrotic mice received an intrasplenic injection of 500.000 HCC cells to develop macroscopic tumor lesions exclusively in the liver after 28 days. *In vivo* biodistribution of Cy-5.5 siRNA loaded NP was assessed in fibrotic tumor mice. NP accumulated preferentially in the liver (80%), while free Cy-5.5 siRNA was rapidly cleared via the urinary tract. *Ex vivo* FACS analysis of liver single cell suspension revealed preferential colocalization of NP with CAF (α-SMA+) >dendritic cells (CD45+, F4/80+, CD11c+) >macrophages (CD45+, F4/80+). For *in vivo* anti-stromal therapy, fibrotic tumor mice ($n = 5$) received three injections of NP loaded with anti-MFAP-5 (corresponding to 0.5 or 1 mg/kg siRNA) in week four, while controls received equal amounts of scramble siRNA (scsiRNA) loaded NP. Liver weights of mice treated with anti-MFAP-5 siRNA were significantly ($p < 0.05$) lower compared to mice treated with encapsulated scsiRNA, indicating less hepatic tumor burden. Morphometric analysis of liver sections supported ($p < 0.05$) the antitumor effect in siRNA treated mice. In vivo knockdown of MFAP-5 was confirmed on RNA and protein level by qPCR and FACS analysis, respectively, while controls had similar MFAP-5 levels like healthy mice. The treatment was well tolerated by the mice and serum parameters for liver- and nephrotoxicity remained in the normal range. Knockdown of MFAP-5 reduced markers for tumor vascularization (e.g. CD34, CD105) in the TME as indicated by histological and qPCR analysis, suggesting an anti-angiogenic effect.
Conclusion: CAF derived MFAP-5 is a promising therapeutic target for anti-stromal therapy in HCC, which can be inhibited by RNA interference with liver targeting NP loaded with anti-MFAP-5 siRNA.

New 3D chimeric model to study hepatic stellate cell activation during primary liver cancer

Alba Herrero[1,2], Elisabeth Knetemann[2], Jens U. Marquardt[3], Inge Mannaerts[2]. [1]*Basque country university, Leioa, Spain;* [2]*Vrije universiteit Brussels, Jette, Belgium;* [3]*University medical center of the Johannes-Gutenberg university of Mainz, Mainz, Germany*
Email: alba.herrero@ehu.eus

Background and aims: Primary liver cancer (PLC) is a frequently occurring cancer worldwide. Around 80% of the PLC cases are from two main types: hepatocellular carcinoma (HCC) and intrahepatic cholangiocarcinoma (iCCA). The etiology of both types is different; however, the development is similar, based on extracellular matrix changes, such as collagen deposition. Moreover, liver non-parenchymal cells, as hepatic stellate cells (HSCs), are activated during PLC helping the development of the cancer. Due to its role during several pro-tumoral processes, these activated HSCs are grouped into cancer-

associated fibroblasts (CAFs). However, it is not known if different populations of CAFs are present in HCC or iCCA development. To do so, we have developed a 3D chimera spheroid model to mimic in vitro the HSC activation in HCC or iCCA and analyzed the potential of different CAF markers depending on the PLC.
Method: Creation of a 3D chimera spheroid model with mouse primary hepatocytes and HSCs, at a 1:2 ratio with 30 HCC or iCCA human patient-derived cells, labeled with fluorochrome mKate2. Spheroids were seeded in 96-well U-bottom plates and cultured under gentle rotation in an incubator. During the time experiment, spheroids were evaluated with live-dead cell assays, and images at day 7 were taken, to check the viability of the cells into the spheroids. Finally, on day 14 they were collected for further analysis. Moreover, we analyzed public sc-RNAseq databases from mouse and human HCC and iCCA by bioinformatics tools for searching possible specific markers for CAFs based on HCC or iCCA cancer.
Results: 3D chimera spheroids for HCC and iCCA were stable during the time experiment without high cell death and a moderate proliferation of tumor cells into the spheroids. The presence of tumor cells promotes HSC activation based on RNA levels of Acta2, Lox, Col1a1, and Fap. Moreover, the fibrillar collagen deposition was increased in spheroids with both PLC cell lines. After we validated our model, we tested supposedly specific CAFs markers for each PLC, which we found using bioinformatics analysis on public sc-RNAseq databases, on RNA analysis for further investigations.
Conclusion: The 3D chimera spheroid model is a new stable complex in vitro model with the capacity to activate HSCs in the presence of HCC or iCCA cells and a valid model for new CAF markers screening.

FRI-535
Effect of the metabotropic glutamate receptor 3 on liver cell survival: a potential biomarker in hepatocarcinoma
Bibiana Elena Juarez-Rivera[1], Andy Hernández-Abrego[1], Ericka de los Ríos-Arellano[2], Lizeth Vanessa Hernández-Quijano[1], Mauricio Díaz-Muñoz[1], Isabel Méndez[1]. *[1]Instituto de Neurobiología, UNAM, Querétaro, Mexico; [2]Instituto de Neurobiología, UNAM, Queretaro, Mexico*
Email: isabelcm@unam.mx

Background and aims: Metabotropic glutamate receptors (mGluRs) are expressed in the liver in physiological and pathological conditions. mGluRs have been characterized into eight types (mGluR1–8) and classified into three groups according to their pharmacology, sequence of amino acid homology, and signal transduction pathways. mGluR2 and mGluR3 belong to group II and are activated by glutamate and selective agonists. Our group has observed mGluR3 expression in normal hepatocytes and its elevated expression in pathological conditions such as cirrhosis and hepatocarcinoma. However, its role in hepatocarcinoma is still being studied. We aim to evaluate the expression of mGluR2 in hepatocarcinoma induced by DEN in rats and the role of mGluR3 on survival using a selective agonist that activates mGluR3 but not mGluR2.
Method: Male Wistar rats received weekly intraperitoneal injections of diethylnitrosamine (DEN- 50 mg/kg body weight) to induce the progressive pathologies fibrosis, cirrhosis, and HCC. Control rats received saline solution. Histopathological analyses confirmed the establishment of each pathology. Expression of mGluR2 and mGluR3 was analyzed in tissue samples by Western-blot and Immunohistochemistry. Both proteins were analyzed in the normal hepatocytes cell line C9 and the hepatocarcinoma cell line HepG2 by Western-blot. Effects of mGluR2 and mGluR3 activation by glutamate or LY354740, a selective group II metabotropic glutamate receptor agonist, were evaluated on live and dead cells. The NF-kappa B activation by glutamate or LY354740 was evaluated using the inhibitor BAY 11-7082. Microarray analysis was performed to further analyze markers of survival in HepG2 cells treated with N-Acetyl-Aspartyl-Glutamate (NAAG), a selective mGluR3 agonist.
Results: Overexpression of mGluR3 was confirmed according to the progression from normal condition to HCC in rats. An opposite expression profile was observed for mGluR2, since it practically disappeared in hepatocarcinoma. These observations were corroborated in HepG2 compared to C9 normal hepatocytes. The activation of mGluR2 and mGluR3 by glutamate and by the selective agonist LY354740 promoted the proliferation in HepG2 and avoided death in C9 cells. These effects were blocked by the NF-kappa B inhibitor. The effect on proliferation by mGluR3 of HepG2 but not in C9 was corroborated by using the selective agonist NAAG.
Conclusion: Our study demonstrates that group II mGluRs contribute to liver cell survival. mGluR2 seems to avoid cell death in normal hepatocytes, while mGluR3 promotes cell proliferation in hepatocarcinoma. Moreover, mGluR2 and mGluR3 have a role in the survival of hepatocytes via NF-kappa B pathway. Also, mGluR3 could be a possible biomarker and therapeutic target in hepatocarcinoma. This research was supported by DGAPA-PAPIIT, UNAM (N222821), and CONAHCyT (CF-2023-I-768).

Fecal microbiota transplant combined with atezolizumab plus bevacizumab in patients with hepatocellular carcinoma who progressed on atezolizumab plus bevacizumab-interim analysis of the FAB-HCC phase II pilot study
Katharina Pomej[1,2], Adrian Frick[1], Bernhard Scheiner[1,2], Lorenz Balcar[1,2], Larissa Pajancic[1,2], Anton Klotz[1], Katharina Regnat[1], Kerstin Zinober[1], Michael Trauner[3], Dietmar Tamandl[4], Christoph Gasche[1], Matthias Pinter[1,2]. *[1]Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Medicine III, Vienna, Austria; [2]Medical University of Vienna, Liver Cancer (HCC) Study Group Vienna, Department of Medicine III, Vienna, Austria; [3]Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Medicine III, Vienna, Austria; [4]Medical University of Vienna, Department of Biomedical Imaging and Image-guided Therapy, Vienna, Austria*
Email: katharina.pomej@meduniwien.ac.at

Background and aims: The gut microbiota is often altered in chronic liver diseases and hepatocellular carcinoma (HCC), and increasing evidence suggests that it may influence response to cancer immunotherapy. Strategies to modulate the gut microbiome (i.e., fecal microbiota transplant (FMT)) may help to improve efficacy of immune checkpoint inhibitors (ICIs) or even overcome resistance to ICIs.
Method: In this single-center phase II pilot study (ClinicalTrials.gov ID: NCT05750030), we plan to include 12 patients with advanced HCC who progressed on atezolizumab/bevacizumab. Patients will receive atezolizumab/bevacizumab every 3 weeks in combination with a single FMT via colonoscopy from donors with HCC who responded to PD- (L)1-based immunotherapy. The primary end point is safety, measured by incidence and severity of treatment-related adverse events (TRAEs). The main secondary end point is best overall response (BOR) according to RECISTv1.1 and mRECIST. Here, we report results of a preplanned interim analysis.
Results: Of 6 patients included so far, 5 were male, 5 had BCLC stage C, and 5 had Child-Pugh class A. All patients underwent successful FMT without any periinterventional complications. TRAEs related to FMT were all low-grade (grade 1–2) and included bloating (n = 2), constipation (n = 2), and diarrhea (n = 1). TRAEs related to atezolizumab included one grade 2 pruritus, and TRAEs related to bevacizumab included arterial hypertension (one grade 3 and two grade 2) and proteinuria (one grade 3 and one grade 1). All patients had at

least one follow-up imaging. Two patients had partial response, 3 patients had stable disease, and 1 patient had progressive disease as BOR according to both RECISTv1.1 and mRECIST, which corresponds to an objective response rate of 33% and a disease control rate of 83%.
Conclusion: Based on acceptable safety and promising efficacy results, the decision to continue recruitment in this trial was made. An update with longer follow-up will be presented at the meeting, including analyses of the gut microbiome if already available.

Predicting post-hepatectomy liver failure in patient with hepatocellular carcinoma: nomograms based on deep learning-analyzed gadoxetic acid-enhanced hepatobiliary phase images
Boryeong Jeong[1], Seung Soo Lee[1], Subin Heo[1], Seon-Ok Kim[2].
[1]*Department of Radiology and Research Institute of Radiology, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea, Rep. of South;* [2]*Department of Clinical Epidemiology and Biostatistics, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea, Rep. of South*
Email: seungsoolee@amc.seoul.kr

Background and aims: Post-hepatectomy liver failure (PHLF) remains a serious complication, especially for patients with hepatocellular carcinoma (HCC) due to the coexistence of liver disease. While the potential utility of functional liver volumetry using gadoxetic acid-enhanced MRI has been reported, and it has strength in adequately reflecting regional liver function when liver damage is heterogeneous, a practical model for estimating the risk of PHLF has not yet been established. Therefore, the purpose of our study was to develop nomograms predicting PHLF in patients with HCC, by incorporating clinical and surgical variables, along with functional and volumetric MRI variables derived from the deep learning analysis of the gadoxetic acid-enhanced hepatobiliary phase (HBP) images.
Method: Patients with Barcelona Clinic Liver Cancer stage 0 or A HCC who underwent hepatic resection following preoperative gadoxetic acid-enhanced MRI between January 2017 and December 2020 at Asan Medical Center and between January 2016 and December 2020 at Ajou University Hospital were retrospectively evaluated. The functional and volumetric MRI variables were automatically derived from deep learning-generated whole liver and spleen segmentation. The remnant liver volume was segmented with the expected resection plane drawn by radiologists. The primary outcome was the occurrence of PHLF, assessed and graded according to the International Study Group of Liver Surgery criteria. Two nomograms to predict PHLF grade A-C were developed using multivariable logistic regression analysis: 1) the whole liver nomogram and 2) the remnant liver nomogram.
Results: A total of 1760 patients (1395 male; mean age ± standard deviation, 60 ± 10 years) were evaluated. The predictors for PHLF in both nomograms included clinical variables such as gamma glutamyl peptidase, platelets, prothrombin time-international normalized ratio, along with liver volume and signal intensity parameters, potentially reflecting hepatic uptake function. Additionally, the extent of liver resection and the spleen volume, reflecting portal hypertension were included for whole liver and remnant liver nomograms, respectively. The whole liver and remnant liver nomograms demonstrated good discrimination performance, with an optimism-corrected AUC of 0.78 (95% confidence interval [CI], 0.74–0.82) and 0.81 (95% CI, 0.77–0.86; p = 0.001), respectively, for predicting PHLF grade A-C, and 0.81 (95% CI, 0.77–0.85) and 0.84 (95% CI, 0.80–0.88; p = 0.02), respectively, for predicting PHLF grade B-C. The nomograms outperformed most of previously reported models and liver functional indices (apparent AUC range, 0.56–0.79).
Conclusion: The nomograms based on deep learning-analyzed gadoxetic acid-enhanced HBP images accurately stratified the risk of PHLF and may be useful for selecting suitable surgical candidates.

Predicting the efficacy and prognosis of immunotherapy combination therapies for hepatocellular carcinoma based on radiomics and deep learning
Xin Song[1], Xingrong Zheng[1], Xiyao Chen[1], Boxiang Zhang[1], Chan Xie[1].
[1]*Department of Infectious Diseases, The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*
Email: happyxiechan@hotmail.com

Background and aims: With the emergence of immune checkpoint inhibitors, immunotherapy combined with other therapies is increasingly used for the treatment of advanced hepatocellular carcinoma (HCC) and how to identify potential treatment beneficiaries before treatment is particularly important. We aim to develop a predictive model based on patients' clinical characteristics and MRI images to predict efficacy and prognosis for patients receiving immunotherapy combination therapies.
Method: Clinical data and MRI images (including T1 weighted image, T2 weighted image and Liver Acquisition with Volume Acceleration) were retrospectively collected from HCC patients who took immunotherapy with targeted therapy and chemotherapy from January 2019 to June 2022 in our hospital. Patients were divided into response and non-response groups after assessing their response to treatment according to the Modified RESICT criteria. Radiomics and deep learning features were extracted from the MRI sequences, different features were used for modeling and AUC was used to assess the predictive ability of the different models.
Results: 116 patients were included in the final outcome analysis, with 50 patients in the response group and 56 patients in the non-response group. Baseline characteristics (Age, Gender, Barcelona Clinic Liver Cancer, Child-Pugh score, Extrahepatic spread, Macrovascular invasion) were not significantly different between the two groups. the integrated model using Light Gradient Boosting Machine achieved the best prediction performance with AUC of 0.856 (95%CI = 0.698–1.000).
Conclusion: We developed an efficacy prediction model for HCC patients by combining radiomics and deep learning features. which can quickly and accurately predict the efficacy of patients receiving immunotherapy combination therapies. We provided a new approach for non-invasively identifying patients potentially benefiting from therapy before treatment.

Identification of biomarkers for the treatment efficacy of atezolizumab plus bevacizumab in unresectable hepatocellular carcinoma, based on chemokine alterations during treatment
Tomoharu Yamada[1], Tatsuya Minami[2], Mitsuhiro Fujishiro[2], Ryosuke Tateishi[2]. [1]*The University of Tokyo Hospital, Tokyo, Japan;* [2]*Graduate School of Medicine, The University of Tokyo, Tokyo, Japan*
Email: tyism123@gmail.com

Background and aims: Atezolizumab plus bevacizumab (atezo + bev) is used as a first-line treatment for unresectable hepatocellular carcinoma (uHCC), however, approximately 20% of patients are non-responders, necessitating the development of biomarkers for predicting therapeutic outcomes and additional combinational agents to enhance the treatment efficacy. We aimed to identify circulating biomarkers predictive for the therapeutic outcomes and to investigate adjunctive drugs that could enhance the treatment efficacy.
Method: We enrolled 54 patients who treated with atezo + bev for uHCC as either first- or later-line systemic therapy in our institution between October 2020 and January 2022. Forty chemokines and cytokines were measured in serum before and after one course of the treatment by multiplex assay. Logistic regression analysis, using the median values of change in each protein before and after the administration, was conducted with progressive disease (PD)/non-PD as the objective variable to identify factors contributing to treatment efficacy. These factors were adjusted with clinical factors (age, gender,

hepatitis B surface antigen, hepatitis C virus antibody, treatment line, total bilirubin, albumin, aspartate aminotransferase (AST), prothrombin time, platelet count, alpha-fetoprotein, Child-Pugh score, Barcelona Clinic Liver Cancer (BCLC) staging) in a multivariate analysis using the Cox proportional hazards model for predicting progression-free survival (PFS).
Results: The median age of the patients was 76 years, with 43 males (80%). Forty-four patients (82%) were Child-Pugh A, and 10 patients (19%) were Child-Pugh B. There were 24 patients (44%) with BCLC stage B and 30 patients (56%) with BCLC stage C. Logistic regression analysis showed that ΔCXCL12 (OR 3.95, p = 0.0398), ΔCCL3 (OR 0.25, p = 0.0398), and ΔCCL26 (OR 0.25, p = 0.0398) as significant predicting factors for PD/non-PD. Multivariate analysis, including significant clinical factors predicting PFS such as treatment line (first vs. later: HR 1.74, p = 0.0325) and AST (HR 1.01/1 IU, p = 0.0884), revealed that ΔCXCL12 (HR 2.55, p = 0.0061) and ΔCCL3 (HR 0.44, p 0.0369) were independent predictors of PFS.
Conclusion: The increase in CXCL12 or decrease in CCL3 contributed to the worsening of PFS for patients treated with atezo + bev. Anti-CXCR4 antibodies that inhibit CXCL12 have already received FDA approval for other diseases, and recently, phase 1–2 trials combining anti-CXCR4 antibodies and immune checkpoint inhibitors in other cancers are in progress. From the results of our study, it is worth considering whether combining anti-CXCR4 antibodies with atezo + bev in uHCC could suppress the increase in CXCL12 and improve PFS.

TOP-506
Atezolizumab/bevacizumab as downstaging in hepatocellular carcinoma: an intention-to-transplant analysis
Marianna Maspero[1], Sherrie Bhoori[1], Veronica Fedele[1], Nicolò Simonotti[1], Valentina Bellia[1], Marco Bongini[1], Carlo Sposito[1], Vincenzo Mazzaferro[1]. [1]*Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*
Email: marianna.maspero@istitutotumori.mi.it

Background and aims: Atezolizumab-bevacizumab has recently become the standard of care for advanced hepatocellular carcinoma (HCC). Patients who achieve downstaging within transplant criteria after atezolizumab-bevacizumab may undergo liver transplantation within investigational trials.
Method: This was an intention-to-transplant analysis of patients without absolute contraindications to transplant who started atezolizumab/bevacizumab at our center. The primary aim was to determine how many were deemed transplantable into our ImmunoXXL trial (NCT05879328) and were successfully transplanted.
Results: 28 patients without absolute contraindications to transplant started atezolizumab-bevacizumab (86% male, median age 61). Chronic liver disease was due to HBV in 5, HCV in 10, alcohol in 8 and MASLD in 11. Twenty-three (81%) were Child-Pugh score A, 5 (19%) B. Twenty-three (82%) were BCLC B, while 5 (18%) were C due to segmental portal vein thrombosis. At baseline, the median size of the lesions was 60 (IQR 35–81) mm and median number 3 (1–5). Nineteen (68%) had undergone therapies before atezolizumab-bevacizumab (9 chemoembolization, 15 radioembolization, 4 surgery). After a median follow-up of 9 months, five patients died. The mRECIST response to atezolizumab-bevacizumab was complete in 7 (25%) cases, partial in 7 (25%), stable disease in 9 (32%) and progression in 5 (18%). Twenty (74%) patients stopped atezolizumab-bevacizumab after a median of 6 cycles: 8 due to transplant listing, 1 due to curative-intent surgical resection, 2 due to toxicity, 5 due to progression and 4 due to liver decompensation. Of the 8 listed patients, 7 were successfully transplanted while one is still on the waiting list.
Conclusion: Atezolizumab-bevacizumab seems to be a successful downstaging-to-transplant strategy for patients with intermediate-advanced HCC.

Email: camilla.decarlo@humanitas.it

Background and aims: VETC (*vessel that encapsulate tumor clusters*) is a peculiar vascular phenotype associated with a worse prognosis in HCC. It predicts also the response to chemoembolisation and it has been associated with a better response also to sorafenib. The aim of the study is to test the predictive significance of VETC in patients with advanced HCC undergoing systemic treatment.
Method: The predictive significance of VETC was first explored in a retrospective, mono-institutional series of 81 patients with advanced HCC (study cohort) and later validated in an external, retrospective series of 83 patients (validation cohort). The VETC phenotype was determined in the liver biopsy obtained just before systemic treatment.
Results: Both in the study and validation cohorts, VETC+ was associated with a significant better response to anti-angiogenic drugs (TKI and/or bevacizumab). In the whole series of 163 patients, those with VETC+ (43%) treated with TKI and/or bevacizumab had a significant longer OS compared to those treated with Immune

Checkpoint Inhibitors (19.2 months versus 10.2 months, HR 0.4; 95% CI 0.24-0.70; P = 0.0012). Similar findings were seen for Sorafenib versus ICI (16.3 months vs 8.7 months; HR 0.4; 95% CI 0.25-0.93; P = 0.03). The same benefit from anti-angiogenic drugs was not seen in VETC- cases.
Conclusion: VETC+ is predictive of the response to anti-angiogenic drugs in advanced HCC.

Email: f.colapietro2@gmail.com

Background and aims: The management of patients undergoing ultrasound (US)-guided percutaneous liver biopsy (PLB) is not standardized. Despite a low risk of major complications (<1%), many scientific societies still recommend repeated blood count and in-hospital stay up to 4 hours. We retrospectively assessed the rates and predictors of complications in a large cohort of patients who underwent US-PLB in three tertiary centers in Lombardia, Italy.
Method: We included all consecutive patients undergoing both parenchymal and lesion targeted PLB from January 2018 to December 2023. We collected clinical, biochemical and procedural features, including needle type, number of insertions, time of observation after the procedure and concomitant antiplatelet/anticoagulant regimens. The safety of US-guided PLB was defined by the incidence of pain and major complications including vaso-vagal reaction, bleeding, pneumothorax, shock; hospitalization; and death.
Results: 1838 patients underwent either parenchymal (1367, 74%) or lesion-targeted (471, 26%) PLB. Mean age was 55.1 years, with 46.1% females and mean BMI of 25.1 Kg/m2 (±4.8); 252 PLB (13.7%) were performed on patients who had undergone previous liver transplantation. Few patients were on anticoagulant/antiplatelet therapy (4.2%/16.2%). Mean platelet count and PT INR value were 209.7 ± 80.74 x103/mm3 and 1.04 ± 0.12, respectively; 17 patients (0.9%) received prophylactic therapy. Needle aspiration was predominant (92.0%), mainly with 18G (59.5%) or 16G (22.1%) needles. After a mean time of observation of 5.4 ± 2.0 hours, pain occurred in 7.4% of patients (134/1838). Major complications were few (26/1838, 1.4%), with transient hypotension being the most common (14/1838, 0.8%); ten bleeding events were observed (0.5%), with a median time of onset of 1 hour. Hospitalization was rare (12/1838, 0.7%), primarily for bleeding management, though most cases resolved spontaneously. No fatalities were recorded. Pain was the sole significant independent predictor of major complications (18/26, 69.2%, $p < 0.05$), particularly when referred within one hour following the procedure (15/18, 83.3%, p = 0.002). No baseline, procedural or post-procedural variables (including heart rate, mean arterial pressure and hemoglobin values) were associated with major complications.
Conclusion: Complications following PLB are few and associated with pain developing within one hour from the procedure. No other pre-procedure or post-procedure variable was useful in identifying patients with major complications. Our results suggest that in the absence of pain developing within 1 hour following PLB patient monitoring can be safely stopped.

THU-454
Induction of systemic immune activation by liver transplant and effects of previous VEGF/PD-L1 blockade in HCC patients
Sherrie Bhoori[1], Michela Dosi[2], Valentina Bellia[1], Marco Bongini[1], Maria Flores[1], Luca Lalli[2], Giovanni Di Maio[2], Jeanette Salsetta[2], Marta Zorza[2], Agata Cova[2], Martina Stroscia[2], Licia Rivoltini[2], Vincenzo Mazzaferro[3]. *[1]Hepato-Pancreatic Biliary Surgery and Liver Transplantation Unit, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy; [2]Translational Immunology Unit, Department of Experimental Oncology, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy; [3]Hepato-Pancreatic Biliary Surgery and Liver Transplantation Unit, Fondazione IRCCS Istituto Nazionale dei Tumori, Department of Oncology, University of Milan, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*
Email: sherrie.bhoori@istitutotumori.mi.it

Background and aims: HCC patients treated with immune checkpoint inhibitors (ICIs) based combinations can achieve tumor downstaging and become eligible to liver transplantion (LT) for long-term tumor control. However, while ICIs have been described to increase the risk of post-LT graft rejection, post- LT immunosuppression administered at more intensive regimens in this specific setting, may instead exert detrimental effects on ICIs-induced antitumor immunity.
We investigated changes of circulating immune cells on HCC patients undergoing LT with or without ICI pre-treatment, with the purpose of comparing immune kinetics that might jeopardize tumor immunosurveillance.
Method: 7 LT after ICIs (LT-ICI) and 6 LT-alone were enrolled in cirrhotic patients with a downstaged HCC. Lymphoid and myeloid cell subsets were immunomonitored by high resolution flow cytometry at stringent intervals before and after LT. Post-LT immunosuppressive regimen was intensified in LT-ICI patients.
Results: A significant decrease of most T, B and NK cell subsets was registered, with respect to pre-LT levels, within the first 2 weeks after LT in both groups. At 1 month levels of all circulating immune cell subsets related to anti-tumor surveillance were significantly higher in LT-alone patients as compared to LT-ICI ($p < 0.05$). This refers particularly to CD8+ expressing the early activation markers PD-1 and CD38, NK cells, terminally differentiated effectors (TEMRA), effector memory (TEM), naive CD8+ T cells as well as intermediate and non classical CD14+ monocytes expressing an activated phenotype (HLA-DRbright, PD-L1+ CX3CR1+ and CD36+). No rejection was registered in LT-ICI patients and no cancer recurrence occurred at a median follow-up of 8 months.
Conclusion: Altogether, these data indicate a potent immunostimulating effect of LT on systemic immunity which is suggestive in cancer recipients of a general reprogramming toward antitumor immunosurveillance. The evidence that this effect was instead less pronounced in patients receiving ICIs before LT may be due to the stronger immunosuppressive regimen administered in this specific clinical subset to minimize rejection risk. Longer follow-up is needed to investigate the role of pre-transplant ICIs in reducing peripheral innate immune responsiveness in liver transplant recipients.

Email: 303722@hospital.cqmu.edu.cn

Background and aims: The efficacy and safety of systemic Sintilimab and bevacizumab (sinti/bev) in the treatment of patients with unresectable hepatocellular carcinoma (HCC) have been demonstrated. However, the efficacy of this treatment in patients with HCC and portal vein tumor thrombus (PVTT) is not satisfactory. Hypofractionated Radiotherapy (HFRT), had be employed as a non-invasive local therapeutic option for HCC. Multiple studies have demonstrated that HFRT can promote tumor antigen release and enhance the efficacy of immunotherapy. Therefore, this study aimed to investigate the efficacy and safety of combining HFRT with systemic sinti/bev treatment in patients with unresectable HCC and PVTT.
Method: This is a single-center, open-label, randomized trial that recruited patients with HCC with type II/III/IV PVTT, who had not previously received systemic therapy. Patients were randomly assigned (2:1) to receive standard treatment Sintilimab (200 mg, every 3 weeks) and bevacizumab (15 mg/kg, every 3 weeks) with or without HFRT [95% planning target volume (PTV), 36Gy/3Gy]. The primary end point was overall survival (OS), and the secondary end points were progression-free survival (PFS), objective response rate (ORR), disease control rate (DCR), and safety.
Results: Ninety patients were enrolled and randomly assigned to two prospective cohorts. The median follow-up was 10.2 months. Median OS were 13.2 months [95% confidence interval (CI), 9.2-not available (NA)] and 8.9 months (95% CI, 5.4-NA), and median PFS were 5.2 months (95% CI, 3.6–8.6) and 3.6 months (95% CI, 2.5–7.0) for the HFRT and non-HFRT cohorts, respectively. The ORR and DCR were 63.5% and 92.5% in the HFRT cohort, and 32.0% and 56.0% in the non-HFRT cohort. The most common TRAEs at all levels were anorexia/nausea 57/90 (63.3%), neutropenia 39/90 (43.8%), and the most common grade 3/4 TRAE was hypertension 14/90 (15.6%). There was no treatment-related deaths.
Conclusion: First-line treatment of HFRT combining with Sintilimab-bevacizumab showed clinical benefits in patients with unresectable HCC and PVTT, with an acceptable safety profile. Thus, these combination regimens may be potential options for such patients.

THU-456

Curative therapy after atezolizumab-bevacizumab and role of liquid biopsy in patient selection

Anand Kulkarni[1], P Kumaraswamy[1], Mithun Sharma[1], Balachandran Menon[1], Anuradha Sekaran[1], Sowmya Iyengar[2], Manasa Alla[1], Shantan Venishetty[1], Nagaraja Padaki[1], Nageshwar Reddy[1]. [1]*AIG Hospitals, Hyderabad, India;* [2]*AIG Hosptials, Hyderabad, India*
Email: anandvk90@gmail.com

Background and aims: Locoregional therapy (LRT) is an excellent modality to downstage unresectable hepatocellular carcinoma (uHCC). The role of atezolizumab-bevacizumab (atezo-bev) in downstaging and the outcomes of such patients who undergo curative surgery, including liver transplantation (LT), is still unknown, which we aimed to assess.
Method: In this single-center retrospective study, we included consecutive patients who received atezo-bev with or without LRT and were subsequently considered for surgical therapy after downstaging (Milan criteria). We describe the course of such patients while assessing the utility of liquid biopsy in this context.
Results: Twelve patients (age-58.4 ± 8.2 years; women-17%; MASH-50%) willing for LT after being downstaged are described here. Fifty-eight percent were in Child-Pugh class A, and the remaining were in Child B, and 41.6%% were in BCLC B, while the remaining were in BCLC C at the time of initiation of atezo-bev. The median AFP at the initiation of atezo-bev and at the time of listing was 116.6 (4.1–23, 090) ng/ml and 15.9 (2.9–930) ng/ml, respectively. Four patients had undergone LRT prior to listing. Six patients underwent curative therapies: four underwent living donor LT (LDLT) after a median time of 79.5 (54–114) days after the last dose, one underwent deceased donor LT (DDLT) after 38 days of the last dose, and one underwent resection. Three patients (50%) experienced wound healing complications, with one undergoing re-exploration and eventually succumbing to sepsis and graft dysfunction. Except for one, all patients had complete pathologic response with no viable HCC. Of the remaining six patients, three died of infections on the waitlist, and the other three were waiting for LT. Among the patients who underwent curative therapy, there have been no HCC recurrence or rejection episodes after a median follow-up of 8 months. Five patients underwent liquid biopsy using next generation sequencing (NGS) method at the time of listing for LT. Three of the patients who underwent LT had low tumor fraction, no MSI, and <3 mut/mb of blood tumor mutational burden (TMB) and are stable. Of the other two, one had 6 muts/mb of TMB with mutations in CTNNB1 and TP53 and died on waitlist. The other one waiting LT has 3 muts/mb of TMB along with TERT promoter and TP53 mutation.
Conclusion: Curative therapies, including LT, is possible after atezo-bev therapy in well-selected patients after downstaging. Liquid biopsy may be useful in identifying ideal candidates for LT.

Email: ursula.ehmer@tum.de

Background and aims: Treatment of hepatocellular carcinoma (HCC) with immune checkpoint inhibitor (ICI) combination therapies is the standard of care in advanced stage HCC and in intermediate stage

HCC not amenable to locoregional therapy. Even with successful downstaging of intermediate stage HCC to meet transplant criteria (e.g. Milan or UCSF criteria), liver transplantation (LT) after ICI remains controversial due to the increased risk of acute and potentially fatal organ rejection. As ongoing clinical trials explore the use of ICI in BCLC B patients, the proportion of patients converted to a potentially transplantable stage is going to increase. To evaluate the outcome of LT after ICI and investigate risk factors contributing to rejection, we established a multicenter case registry.

Method: Data from seven liver transplant centers in Germany and Switzerland with one or more patients transplanted after ICI were included. RFS and overall survival (OS) were analyzed by Log-rank test. Patient and tumor characteristics, ICI regimen, duration of ICI, time between ICI and LT, and immunosuppressive therapy after LT were documented.

Results: Nine patients underwent liver transplantation after ICI for HCC (7 male/2 female). The median age at transplant was 63 years, and the majority of patients (7/9) were treated with atezolizumab and bevacizumab. Median follow-up was 531 days (range 155–1062 days). Two rejections were documented in our cohort. One major rejection occurred 21 days after LT with fatal outcome due to subsequent chronic liver failure and infectious complications. One minor rejection (Rejection Activity Index 3–4) was observed five months after LT and was well controlled by increased immunosuppression. HCC recurrence with pulmonary metastasis was histologically confirmed in one patient 229 days after LT. Within this cohort and in line with previously published data, time between ICI and LT was a strong predictor for a major rejection (ICI to LT interval 13 days in the patient with major rejection vs 54–680 days in all other patients).

Conclusion: Despite an overall rejection rate of 22% (2/9), only one major rejection occurred, and this single patient had a short ICI wash-out period of only 13 days. The results of this international registry underscore the critical significance of allowing an adequate time interval between last dose of ICI and liver transplantation (LT), consistent with previously published data. In summary, our study suggests that LT after immunotherapy is generally safe for the majority of patients. However, the optimal and sufficient period for ICI wash-out still needs to be defined.

No correlation between MASLD and poor outcome of Atezolizumab-Bevacizumab therapy in patients with advanced HCC

Francisca Copil[1], Claudia Campani[2], Marie Lequoy[3], Philippe Sultanik[4], Lorraine Blaise[4], Mathilde Wagner[3], Nathalie Ganne-Carrié[3], Violaine Ozenne[4], Jean Charles Nault[3], Dominique Thabut[4], Vlad Ratziu[3], Manon Allaire[1]. *[1]APHP, PARIS, France; [2]Centre de recherche des cordeliers, Paris, France; [3]APHP, paris, France; [4]APHP, Paris, France*
Email: allama5@hotmail.fr

Background and aims: Recent concerns have emerged, indicating that non-viral hepatocellular carcinoma (HCC), specifically NASH-HCC, may display limited responsiveness to immunotherapy. We aim to investigate the treatment outcomes of patients facing metabolic-associated steatotic liver disease (MASLD) and associated metabolic risk factors (MRF) when subjected to Atezolizumab-Bevacizumab (AtezoBev) therapy.

Method: Data from all patients treated with AtezoBev in 3 tertiary centers were collected prospectively since August 2020. MRF were defined by the presence of current/past BMI>30 kg/m^2, type 2 diabetes, arterial hypertension and dyslipidemia. Alcohol intake was less than 30 g daily for men and 20 g in women and no others cause of liver disease was present for MASLD patients. Progression was defined as a composite (progression and/or side effects/hepatic decompensation requiring discontinuation). The influence of baseline characteristics on events during follow-up was assessed by uni/multivariate analysis using a Cox model.

Results: Data from 295 patients treated with AtezoBev were analyzed (median age 66 years, 16% women, 81% cirrhotic patients). Among the cohort, 27% had 1 MRF, 23% 2 MRF, 15 3 MRF and 6% 4 MRF. Only 13% had MASLD, 18% MetALD, 17% ALD and 30% viral infection only. At inclusion, 73% of the patients were Child-Pugh A and 49% had esophageal varices. On the day of treatment, 62% of patients were BCLC-C. HCC was multi-nodular in 76% of cases, 41% had infiltrating HCC and 41% vascular invasion. Of the patients, 15% had an ALBI score of 3 and 41% had AFP ≥400 ng/ml. Characteristics of the patients were similar according to the number of MRF.

Median follow-up was 10.3 months and The PFS was 30% at 12 months (median PFS 6.5 months). In univariate analysis, age (HR = 0.99, p = 0.02), MELD score (HR = 1.08, p = 0.002), ALBI grade 3 (HR = 1.86, p < 0.001), AFP level (HR = 1.00, p = 0.02) and the presence of metastasis (HR = 1.61, p = 0.002) were associated with PFS, but not the presence of MASLD (p = 0.49). Only the ALBI grade 3 (HR = 1.60, p = 0.03), AFP level (HR = 1.00, p = 0.01), and the presence of extrahepatic metastasis (HR = 1.77, p < 0.001) were associated with PFS in multivariate analysis.

OS was 59% at 12 months (median OS 15.6 months). Death was related to HCC in 82%, liver failure in 12% and other causes in 6%. In multivariate analysis, only dyslipidemia (HR = 1.69, p = 0.001), the MELD score (HR = 1.07, p = 0.02), AFP≥400 ng/ml (HR = 1.84, p = 0.001), multinodular HCC (HR = 2.03, p = 0.002), and the presence of infiltrative HCC (HR = 1.44, p = 0.05) were associated with OS.

During the follow-up, 10% of patients presented immune-related adverse events (IRAE). Only age (HR = 1.05, p = 0.004) and female gender (HR = 2.63, p = 0.02) were independently associated with IRAE.

Conclusion: our study suggests that the presence of MASLD or the number of MRF did not lead to worse outcomes in advanced HCC patients treated with AtezoBev.

THU-459-YI

Long-term oncological results of percutaneous radiofrequency ablation for intrahepatic cholangiocarcinoma: a multicentric retrospective study

Clémentine Alitti[1], Agnès Rode[2], Hervé Trillaud[3], Philippe Merle[2], Jean-Frédéric Blanc[4], Lorraine Blaise[1], Alix Demory[1], NKontchou Gisèle[1], Véronique Grando Lemaire[1], Marianne Ziol[5], Pierre Nahon[1], Nathalie Ganne-Carrié[1], Arthur Petit[6], Olivier Seror[6], Olivier Sutter[6], Jean Charles Nault[1]. *[1]CHU Avicenne, Hepatology, Bobigny, France; [2]Croix-Rousse Hospital, Hospices Civils de Lyon, Lyon, France; [3]CHU Bordeaux, Bordeaux, France; [4]Hôpital Haut-Lévêque, Pessac, France; [5]CHU Avicenne, Anatomopathology, Bobigny, France; [6]CHU Avicenne, Interventional Radiology, Bobigny, France*
Email: alitti.clementine@gmail.com

Background and aims: Percutaneous radiofrequency (RF) is a curative treatment for hepatocellular carcinomas (HCC), but its effectiveness in intrahepatic cholangiocarcinomas (iCCA) remains insufficiently studied.

Method: We conducted a retrospective study in three tertiary liver centers including patients with histologically proven iCCA within Milan criteria treated by percutaneous RFA from December 2020 to December 2022. Primary outcome was overall survival in treatment-naive patients and secondary outcomes included ablation completeness, adverse events, local and distant recurrence. 494 patients with HCC on cirrhosis treated by RFA were included as a comparison group. Oncological events were analyzed using Kaplan-Meier, log-rank, and univariate/multivariate Cox models.

Results: The main population included 71 patients, mostly cirrhotic (80%) with solitary tumors (66%) with a median size of 24 mm. Underlying liver diseases were attributed to chronic alcohol intake (46%), metabolic syndrome (39%), chronic hepatitis C (20%), and/or chronic hepatitis B (13%). Complete ablation was achieved in 93% of

cases. Local recurrence was 45% at 5 years, and was lower in multibipolar versus monopolar RFA (22% vs. 55%, P = 0.007). In multivariate analysis, both tumor size (HR = 1.09, CI95%: 1.02–1.16, P = 0.13) and monopolar RFA (HR = 3.48, CI95%: 1.11–10.92, P = 0.03) were independently associated with a higher local tumor recurrence. In treatment-naive patients (n = 45), median overall and recurrence-free survivals were 26 and 11 months, respectively. Tumor size (HR = 1.05, 95%CI 1.009–1.094, P = 0.01) and Child-Pugh B (HR = 14.9, 95%CI 2.8–79, P = 0.001) were associated with death. The rate of distant recurrence was 59% at 5 years, and was significantly lower for single tumors of less than 2 (p = 0.002) or 3 cm (p = 0.02). The size of the main tumor was the sole factor independently associated with distant tumor recurrence (HR = 1.06, CI95%: 1.02–1.11, P = 0.0007). Next, we compared the outcomes of 40 patients with iCCA developed in cirrhotic patients naïve of previous treatment with 494 patients with HCC developed in cirrhotic patients naïve of previous treatment. Overall survival was shorter in iCCA than in HCC (26 vs 68 months, P < 0.0001), with more local recurrences (p < 0.0001). Among distant recurrences, 50% were extrahepatic metastases in iCCA compared to 12% in HCC (p < 0.001).

Conclusion: Multibipolar RFA provides better results in term of tumor recurrence than monopolar RFA and could be used to treat small iCCA (<3 cm). Adjuvant chemotherapy should be discussed due to the frequent extra-hepatic metastasis at recurrence.

THU-462

Efficacy and safety of neoadjuvant therapy in narrow-margin hepatocellular carcinoma: a propensity score matching analysis

Hongxuan Li[1], Qiuyang Ren[2], Pan Qi[2], Bin Shu[3], Xiaojuan Wang[3], Xiaoying Zhu[2], Gong Li[3], Yuewei Zhang[3], Shizhong Yang[1]. *[1]Beijing Tsinghua Changgung Hospital, School of Clinical Medicine, Tsinghua University, Bejing, China; [2]Qinghai University Affiliated Hospital, Qinghai, China; [3]Beijing Tsinghua Changgung Hospital, School of Clinical Medicine, Tsinghua University, Beijing, China*
Email: lhxa04369@btch.edu.cn

Background and aims: The clinical role of neoadjuvant therapy (NAT) for narrow-margin hepatocellular carcinoma (HCC) is unclear. The purpose of this study was to investigate the efficacy of NAT combined with surgery versus surgery alone in patients with narrow-margin HCC.

Method: This study retrospectively analyzed the clinical data of 181 patients with narrow-margin HCC who received NAT combined with surgery or surgery alone at two medical centers. NAT is defined as preoperative treatment, which includes local therapy (radiotherapy or interventional therapy) alone, or local therapy plus systemic therapy (PD-1 inhibitor + lenvatinib). Propensity score matching (PSM) was used to balance clinicopathological characteristic differences between the two groups.

Results: A total of 181 patients were included, of which 43 were assigned to the NAT combined with surgery group and 138 to the surgery alone group. Before PSM, the respective 6-, 12-, and 24-month overall survival (OS) rates were 93.0%, 89.6%, and 81.9% in the NAT combined with surgery group and 96.4%, 83.3%, and 56.9% in the surgery alone group (p = 0.062). The respective 6-, 12-, and 24-month disease-free survival (DFS) rates were 93.0%, 84.6%, and 55.7% in the NAT combined with surgery group and 88.4%, 68.2%, and 40.4% in the surgery alone group (p = 0.047). After PSM, the 6-, 12-, and 24-month OS rates were 93.9%, 89.7%, and 82.2% in the NAT combined with surgery group and 90.7%, 79.1%, and 49.7% in the surgery alone group (p = 0.033). The respective 6-, 12-, and 24-month DFS rates were 93.9%, 83.4%, and 54.9% in the NAT combined with surgery group and 81.8%, 54.5%, and 35.3% in the surgery alone group (p = 0.022). Subgroup analysis of the NAT combined with surgery group demonstrated that patients who received combined local and systemic therapy had significantly better DFS than of those who received local therapy alone (p = 0.028). According to RECIST, version 1.1, the objective response rate and disease control rate were 51.2% and 100%, respectively, among 43 evaluable patients in the NAT combined with surgery group. Regarding safety, the incidence of grades 1 – 3 adverse events (AEs) was 76.7% in patients in the NAT combined with surgery group, with no occurrence of grade 4 or 5 AEs. In addition, postoperative pathological analysis showed that patients in the NAT combined with surgery group had significantly less microvascular invasion (p = 0.0013) and microvessel density (p < 0.001) compared with those in the surgery alone group, potentially offering insights into the mechanism of NAT.

Conclusion: Patients with narrow-margin HCC who received NAT combined with surgery had a better prognosis and showed an acceptable safety profile than those who received surgery alone.

THU-463

Pre-treatment serum N-glycans predict poor immunotherapy response and survival in hepatocellular carcinoma

Nicky Somers[1], Theresa Holtmann[2], Fabian Artusa[2], Emma Butaye[1], Lorenz Grossar[1], Sarah Raevens[1], Anja Geerts[1], Sander Lefere[1], Lindsey Devisscher[3], Leander Meuris[4], Nico Callewaert[4], Hans Van Vlierberghe[1], Raphael Mohr[2], Xavier Verhelst[1]. *[1]Department of Gastroenterology and Hepatology, Liver Research Center Ghent, Ghent University Hospital, Gent, Belgium; [2]Medizinische Klinik m. S. Hepatologie und Gastroenterologie, Charité-Universitätsmedizin Berlin, Berlin, Germany; [3]Gut-Liver Immunopharmacology Unit, Dpt Basic and Applied Medical Sciences, Liver Research Center Ghent, Ghent University, Gent, Belgium; [4]VIB-UGent Center for Biotechnology, Department of Biochemistry and Microbiology, Ghent University, Gent, Belgium*
Email: nicky.somers@ugent.be

Background and aims: Patients with hepatocellular carcinoma (HCC) frequently present with advanced disease, for which immunotherapy is the most promising first-line agent-despite the fact that only a quarter of patients show a favourable response. Although serum N-glycans (glycomics) are altered in HCC, they have not been assessed as a predictive marker for treatment response. We investigated glycomics as a predictive indicator of poor response to immunotherapy and associated survival in advanced HCC.

Method: A total of 90 immunotherapy-naive HCC patients were retrospectively recruited with a pre-treatment serum sample. Whole serum N-glycomic analysis was performed using the optimised 96-well on-membrane deglycosylation technique (DSA-FACE). Uni- and multivariate Cox regression analyses were conducted to develop the prognostic GlycanScore and GlycanLabScore, with associated Kaplan Meier survival method (log-rank test). A multivariate Cox proportional hazards model was built to identify independent predictive factors.

Results: This cohort included 90 HCC patients receiving atezolizumab and bevacizumab combination therapy, of which 40 of them had no prior locoregional treatment and were thus completely treatment-naive. Pre-treatment NA3Fc and NA3Fbc glycans were significantly increased in patients who showed poor response (progressive disease) after a median treatment time of 5.9 months as compared with patients who did not. Other independent risk factors were decreased hemoglobin (Hb) and increased aspartate aminotransferase (AST) pre-treatment levels. For the complete treatment-naive patients (n = 40) with a baseline GlycanScore (compositescore of NA3Fc and NA3Fbc) above the cut-off value of 1.75, the HR for poor response was 2.16 (95% CI [1.36–3.42], p = 0.001). Combination of this GlycanScore with Hb and AST resulted in the GlycanLabScore with an HR of 2.72 (95% CI [1.677–4.401], p < 0.001) for patients at risk of poor response with low survival (p < 0.001), exceeding the cut-off value of −0.83. Similar findings could be retained when the total cohort was considered, thus including the 50 patients who did receive prior locoregional treatment before the start of immunotherapy. In these patients, the risk for having progressive disease with low survival (p = 0.0017, p = 0.028) was related to a GlycanScore with HR of 1.82 (95% CI [1.40–2.37], p < 0.001) and a GlycanLabScore with HR of 2.63 (95%

CI [1.91–3.63], p < 0.001), based on the same cut-off values. In comparison, the alphafetoprotein (AFP) level was not able to significantly differentiate between treatment response, nor was it retained as an independent predictor in the Cox proportional Hazards model.
Conclusion: Pre-treatment tri-antennary core and branch fucosylated glycans, combined or not with Hb and AST levels, might be predictive of poor immunotherapy response and low survival in advanced HCC.

Email: mathew.vithayathil@doctors.org.uk

Background and aims: Atezolizumab plus bevacizumab a first line-treatment for unresectable hepatocellular carcinoma (HCC). The aMAP score comprises of age, sex, bilirubin, albumin and platelets, and has been shown to predict HCC risk in patients with chronic liver disease. aMAP has also been identified as a prognostic tool for patients undergoing resection and ablation, but its role in patients having immunotherapy has not been studied. Our study investigated its prognostic value in a large real-world patient cohort receiving atezolizumab plus bevacizumab.
Method: Patients from twenty-six international centres receiving atezolizumab plus bevacizumab were recorded retrospectively. Overall survival (OS), progression-free survival (PFS), overall response rate (ORR) and disease control rate (DCR) defined by RECIST v1.1 were measured in patients with a low- (<50) and high- (≥50) aMAP score. Kaplan-Meier and Cox regression analysis were measured. For multivariate Cox regression, aMAP group, Barcelona Clinic Liver Cancer Stage (BCLC), Child-Pugh stage, tumour diameter, alpha-fetoprotein and extrahepatic disease were used as co-variates. Treatment-related adverse events (trAEs) were evaluated in each aMAP cohort.
Results: 933 consecutive patients receiving atezolizumab plus bevacizumab were assessed. After exclusion of patients who received previous HCC therapy, 641 patients were studied. Barcelona Clinic Liver Cancer stage and Child-Pugh stage were comparable between low aMAP (n = 67) and high aMAP (n = 574) patients. Patients with a low aMAP score had a significantly shorter median progression-free survival (3.3 months; 95% confidence interval 2.3–4.8) compared to high aMAP patients (6.4 months; 95% CI 5.3–7.6; p = 0.004). In Cox regression analysis, high aMAP was associated with a significant reduction in PFS in both univariate (hazard ratio 0.64; 95% CI 0.47–0.87; p = 0.04) and multivariate (HR 0.69; 95% CI 0.51–0.94; p = 0.02) models. There was no association between aMAP and OS in univariate or multivariate analysis. High aMAP was associated with significantly higher DCR (25.4% vs. 38.0%; p = 0.04), with no difference in ORR seen (65.7% vs. 75.8%; p = 0.07). The high aMAP group had higher rates of bevacizumab-related toxicity (41.1% vs. 28.4%; p = 0.04), with no difference in atezolizumab-related observed (51.9% vs. 40.3%; p = 0.28). There was no difference in liver-related toxicity, acute hepatic decompensation or bleeding between aMAP cohorts.
Conclusion: Higher aMAP score is associated with better response to immunotherapy in treatment-naïve HCC patients, independent of BCLC and Child-Pugh stage, with higher rates of bevacizumab-related toxicity. aMAP score has potential use as a theragnostic tool for HCC patients undergoing immunotherapy.

Impact of antibiotic exposure and co-medication on the efficacy of immunotherapy for the treatment of advanced hepatocellular carcinoma
Matthias Jeschke[1], Marie Möller[2], Florian P. Reiter[2], Sebastian Wiener[1], Hartmut Schmidt[1], Leonie Jochheim[1]. *[1]University Hospital Essen, Essen, Germany; [2]University Hospital Würzburg, Würzburg, Germany*
Email: matthias001.jeschke@gmail.com

Background and aims: The advent of immuncheckpoint inhibitors (ICI) has markedly altered the treatment landscape of advanced hepatocellular carcinoma (HCC), and studies are examining its application to the adjuvant and neoadjuvant treatment setting, further extending their utility. However, there is a growing body of evidence that the efficacy of ICI in solid tumors might be impaired by the application of antibiotics, possibly through alterations in the gut microbiome. The aim of this study was to evaluate the association between survival and antibiotic exposure, its timing or co-medication affecting the gut microbiome.
Method: We analysed data from 121 patients, who began treatment with ICI therapy for advanced HCC (BCLC stages B and C) in two tertiary care centers between February 2020 and July 2023. Primary

end points included overall survival (OS) and progression-free survival (PFS). Multivariable Cox models evaluated the association between antibiotic exposure or co-medication and OS or PFS.
Results: The mean age in our patient cohort was 68.0 years (SD 11.4 years); 28 patients (23%) were female. In total, 50 patients (41%) received antibiotic treatment during ICI therapy. Among them, early antibiotic treatment (within a time frame of 40 days prior or after initiation of ICI therapy) occurred in 37 patients (30.5%). The most common indications for antibiotic therapy were urinary tract infections (30%), cholangitis (10%) and pneumonia (10%); the most common antibiotic classes included penicillin derivatives (66%) and cephalosporines (20%). Broadspectrum antibiotic treatment was used in almost half of all cases (48%). Univariate and multivariate analysis did not reveal a significant discrepancy with regards to OS or PFS between patients receiving early antibiotic treatment and those who did not ($p = 0.24$ and $p = 0.38$, respectively). Proton pump inhibitors, Metformin, SGLT2-inhibitors, betablockers or SSRI did not affect Overall survival. The treatment with Rifaximin seemed to negatively affect overall survival ($p = 0.045$) in univariate analysis, although this might be due to a confounding effect.
Conclusion: While some studies report a negative impact of antibiotic exposure on the efficacy of ICI therapy, this could not be shown in our patient cohort. Further studies are needed to improve the management of patients under ICI treatment in clinical practice.

Background and aims: The results of the Imbrave 150 study have revolutionized the management of advanced HCC with the Atezolizumab-Bevacizumab combination (AtezoBev). In this study, patients were highly selected, with a 30% response rate and a trend to higher response in patients with a viral etiology. Our objective was to evaluate the tolerability and efficacy of AtezoBev in the French HCC population, which is distinctive for its prevalent presence of underlying advanced non-viral chronic liver disease.
Method: Data from all patients treated with AtezoBev as first-line systemic treatment in the multicentric CHIEF cohort (32 centers) were prospectively collected between July 2020 and January 2023. Overall survival (OS) and progression-free survival (PFS) were evaluated using the Kaplan-Meier method. The objective response rate was assessed by the presence of a complete or partial response. The influence of inclusion characteristics on events during follow-up was evaluated using a log-rank analysis.
Results: Prospective data from 552 patients treated with AtezoBev were analyzed (median age 68 [62–75] years, 86% men, 77% cirrhotic patients, Child-Pugh A 81%, 18% Child-Pugh B). Chronic liver disease was of viral origin in 27%, related to excessive alcohol consumption in 58%, to a metabolic cause in 35% of cases. Among these patients, 22% had large esophageal varices (EV) on endoscopy. At the initiation of AtezoBev, 44% of new cases were treatment-naive for HCC, 28% were classified as BCLC-B, and 67% as BCLC-C. HCC comprised more than 3 lesions in 31% of cases and was infiltrating in 21% of cases, with vascular invasion in 31% of patients and extrahepatic lesions in 27%. Among patients, 4% had an ALBI score of 3, and 32% had an AFP≥400 ng/ml. The median follow-up was 21.2 months, 95% CI [19.8–22.4]. At the first evaluation, 27% of patients showed an objective response (4% complete response and 23% partial response), and 22% of patients progressed. The 12-month overall survival rate was 66%. OS was significantly higher in BCLC-B patients (median OS not reached) versus BCLC-C (17.1 months, $p < 0.001$), as well as in Child-Pugh A patients (median OS not reached) versus Child-Pugh B (12 months, $p < 0.001$). OS was similar across VO stage, etiology of liver disease (viral versus metabolic), and tumor characteristics (AFP ≥400 ng/ml, presence of metastases, previous HCC treatment). In the overall cohort, PFS was 15.8% at 12 months (median PFS 4.6 months). PFS was significantly higher in BCLC-B patients (6.8 months) compared to BCLC-C (3.4 months, $p = 0.02$).
Conclusion: These initial real-world data from the prospective multicentric CHIEF cohort show survival and response data similar to those obtained in the phase 3 IMbrave 150 study. These results confirm the effectiveness of the treatment in routine practice, taking into account the clinical and epidemiological characteristics of the French HCC population.

Email: mauro@clinic.cat

Background and aims: In biliary tract cancer (BTC), the addition of immunotherapy (durvalumab or pembrolizumab) to gemcitabine and cisplatin (GemCis) has significantly improved overall survival (OS) in phase 3 clinical trials (RCTs). However, the interpretation of the results is challenging because OS and progression-free survival (PFS) Kaplan-Meier curves violate the proportional hazards (PH) assumption. Analysis using the restricted mean survival time (RMST) allows quantification of the absolute benefit in the absence of PH. This systematic review and meta-analysis aim to quantitatively assess

the benefit of immunotherapy-based regimens (IOs) for both OS and PFS at 24 months, using RMST analysis.
Method: Systematic searches were conducted using databases, clinical trial registries, and conference abstracts of studies published until November 8, 2023. Only phase 3 RCTs evaluating the use of anti-PD-1/PD-L1 combined with GemCis and reporting OS and PFS rates were included. KM curves for OS and PFS were digitized using WebPlotDigitizer v.4.6, and the data were reconstructed. A meta-analysis of extracted data for OS and PFS using RMST at 24 months was performed, employing common-effect models to estimate weighted average RMST and mean differences between treatment and control groups. Heterogeneity was assessed using the I^2 statistic.
Results: A total of 1, 754 participants from the KEYNOTE-966 and TOPAZ-1 trials were included. In the TOPAZ-1 study, RMST OS at 24 months was 13.52 (7.92) and 12.21 (7.22) months with GemCis plus durvalumab and GemCis, respectively. In the KEYNOTE-966 study, OS at 24 months was 13.60 (7.76) and 12.45 (7.73) months with GemCis plus pembrolizumab and GemCis, respectively. IOs regimens showed a mean OS difference at 24 months by RMST of 1.21 months [(95% CI: 0.49–1.93), $p < 0.001$, $I^2 = 0\%$]. RMST PFS at 24 months in TOPAZ-1 was 8.10 (6.74) and 6.56 (4.82) months with GemCis plus durvalumab and GemCis, respectively. Similarly, in the KEYNOTE-966 study, it was 8.51 (8.54) and 7.49 (7.56) months with GemCis plus pembrolizumab and GemCis, respectively. The meta-analysis of mean PFS difference by RMST was 1.31 [(95% CI: 0.66–1.96), $p < 0.001$, $I^2 = 0\%$] months in patients undergoing IOs.
Conclusion: Combining IOs with GemCis offers a significant benefit for the survival of patients with advanced BTC. With this magnitude of benefit, it is essential to weigh individual patient factors, preferences, and potential risks in therapeutic decision-making. RMST analysis provides valuable information to patients and physicians, facilitating decision-making in a value-based medical environment.

THU-470-YI

Analysis of treatment benefits and prognostic factors for post-transplant hepatocellular carcinoma recurrence in a large Euro-American-Asian cohort

Zhihao Li[1], Itsuko Chih-Yi Chen[2], Grainne O'Kane[3], Arndt Vogel[4], Luciano De Carlis[5], Leonardo Centonze[6], Quirino Lai[7], Neil Mehta[8], Chao-Long Chen[2], Gonzalo Sapisochin[1]. *[1]University Health Network, Toronto, Canada; [2]Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan; [3]Trinity St James's Cancer Institute, Princess Margaret Hospital, Dublin, Ireland; [4]University Health Network, Hannover Medical School, Toronto, Canada; [5]Niguarda-Cà Granda Hospital, University of Milano-Bicocca, Milano, Italy; [6]Niguarda Ca' Granda Hospital, University of Modena and Reggio Emilia, Milan, Italy; [7]Sapienza University of Rome, Rome, Italy; [8]UCSF, San Francisco, CA, United States*
Email: zhihao.li@uhn.ca

Background and Aims: Post-transplant recurrence of hepatocellular carcinoma (HCC) significantly impacts survival, yet its management is challenging due to limited evidence. Improvements in systemic therapies necessitate updated data on managing recurrent disease.
Method: Our retrospective study (2000–2022) across five international centers (Canada, USA, Italy, Belgium, Taiwan) analyzed treatment outcomes and prognostic factors of post-transplant HCC recurrence. We employed Kaplan-Meier analysis to compare survival post-HCC recurrence and utilized multivariable Cox regression to identify prognostic factors.
Results: In our study, 431 of 3630 (12%) transplanted HCC patients developed recurrence with median time from transplant (LT) to recurrence of 18 (IQR 9–33) months. The median age at recurrence was 57 (IQR 51–63), patients were predominantly male (85%), with hepatitis C (41%), hepatitis B (30%) and alcohol-related liver disease (17%) as common underlying liver disease. 25% received deceased-donor LT and 75% living-donor LT. Tumor differentiation varied, with 18% poor, 65% moderate, and 10% well-differentiated; 46% exhibited microvascular invasion. The median RETREAT score was 3 (IQR 2–5). Within the first year post-LT, 35% of patients developed recurrence. Recurrence patterns included 24% intrahepatic-only, 27% both intrahepatic and extrahepatic, and 49% extrahepatic-only. 34% underwent curative-intent treatments (surgery/ablation), 48% received palliative treatments, and 18% were given best-supportive care. Patients undergoing curative-intent treatments had significantly better survival at 1/3/5 years (90%/56%/43%) compared to those receiving non-curative treatments (46%/10%/7%, $p < 0.001$). Patients with recurrence diagnosed in the era 2018–2022 (24%) showed improved 1/3/5-year survival (67%/43%/37%) compared to those diagnosed earlier (59%/22%/16%, $p < 0.001$). No significant survival difference was noted between living-donor and deceased-donor transplants ($p = 0.52$). The median follow-up post-HCC recurrence was 16 (IQR 7–30) months. Multivariable analysis revealed 5 prognostic factors for post-transplant HCC survival: ineligibility for curative-intent treatment (HR 3.7, 95% CI 2.8–4.8, $p < 0.001$), recurrence within 1-year (HR 1.7, 95% CI 1.4–2.2, $p < 0.001$), poor tumor differentiation (HR 1.4, 95% CI 1.1–1.9, $p = 0.02$), higher RETREAT score at transplant (HR 1.1, 95% CI 1.0–1.1, $p = 0.02$) and recurrence diagnosis before 2018 (HR 1.5, 95% CI 1.2–1.9, $p < 0.001$).
Conclusion: Curative-intent treatments should be advocated for patients with post-transplant HCC recurrence whenever possible. Prognostic factors linked to aggressive tumor biology help to identify high-risk patients for adjuvant therapies and tailored surveillance. Survival outcomes have improved in the past five years reflecting improvements in systemic therapies.

Email: gf.manfredi01@gmail.com

Background and aims: The treatment landscape of advanced hepatocellular carcinoma (aHCC) has been revolutionised in recent years following demonstration of survival benefit from atezolizumab plus bevacizumab (A+B) in 2019. It is unknown if the efficacy observed from immunotherapy combinations in randomised controlled trials (such as IMbrave150) translates to preserved effectiveness in routine clinical practice.
Method: We conducted a systematic review and meta-analysis of MEDLINE, Embase and Cochrane libraries to compare baseline characteristics and therapy outcomes in patients treated with first-line systemic therapies for aHCC in routine clinical practice. Individual patient-level data were reconstructed from published Kaplan-Meier survival curves. Pooled estimates of overall survival (OS) and progression free survival (PFS) at 6 months and 1 year were calculated using random-effects analysis. Secondary outcomes included pooled overall response rate (ORR), disease control rate (DCR) and adverse events (AEs).
Results: The 12 studies selected for meta-analysis included 2179 patients treated with A+B. Most patients were male (80.5%) median age 66 years (IQR 61.6–73.0). In total, 83.7% were of Child-Pugh (CP) class A, 58.1% classed as albumin-bilirubin grade 1 and the most reported liver disease aetiology was viral (21.4% hepatitis B, 10.9% hepatitis C and 23.8% not further specified). Most patients belonged to Barcelona Clinic Liver Cancer stage C (61.6%). Among the 12 studies, one did not provide published Kaplan-Meier curves for OS but only for PFS, and another study did not present curves for PFS but only for OS. The pooled 6-month and 12-month OS rate were 82% (95% CI: 76–86%; $I^2 = 80\%$) and 68% (95% CI: 63–73%; $I^2 = 66\%$), respectively. No significant difference was found between the median OS of the IMbrave150 cohort (19.2 months, 95% CI 17.0–23.7) and that of real-world patients classified as CP-A (20.9 months, 95% CI 15.7–20.9; $p = 0.58$). The pooled PFS at 6 and 12 months were 57% (95% CI 53–61%; $I^2 = 49\%$) and 35% (95% CI 31–39%, $I^2 = 60\%$), respectively. Median PFS was longer in real world patients (11.8 months, 95% CI 10.45–18.08) compared to IMbrave150 (6.9 months, 95% CI 5.7–8.6, $p < 0.001$). The pooled ORR was 32% (95% CI 29–35%, $I^2 = 50\%$), whereas DCR was 78% (95% CI 73–81%, $I^2 = 63\%$). AEs were reported in 9 studies: pooled all-grade AEs were seen in 75% (7 studies), grade ≥3 AEs were 26% (8 studies), and discontinuation due to toxicity was 12% (7 studies).
Conclusion: Combination immunotherapy with A+B confirmed its efficacy and safety for aHCC in routine clinical practice, mirroring estimates published in the registration trial.

Background and aims: Patients receving atezolizumab/bevacizumab (AB) for HCC may have a primary resistance to this combination. Another relevant proportion of patients will develop a secondary resistance and, eventually, experience progression disease. Randomized clinical trials (RCTs) trying to identify second-line treatments are undergoing. If such trials are not available or patients are non-eligible, sorafenib is often prescribed, based on European approval and reimbursement policies. However, evidence supporting these policies is lacking, as no RCTs explored sorafenib in this setting. We aimed to To assess the efficacy of sorafenib in patients who permanently stopped AB.
Method: The ARTE database collects prospectively enrolled patients treated with AB in a real-life setting (March 2022-ongoing). We analysed the outcome of patients who received sorafenib as second-line treatment. Moreover, we performed a case-control matching with historical controls who had received sorafenib as a frontline treatment before AB had become available in clinical practice. Patients were matched 4:1, based on known predictor of overall survival (OS) in sorafenib-treated patients (Child-Pugh class, AFP > 400 ng/ml, macrovascular invasion, extrahepatic spread, ECOG-PS>0).
Results: Amongst the 157 patients included in the ARTE database as of November 2023, 130 (67.4%) permanently discontinued AB. Of them, 57 received a second-line treatment. Sorafenib was prescribed in 29 patients. The disease control rate (DCR) was 17.2%, with no objective responses. The median PFS and OS were 3.2 and 7.9 months. When compared with historical controls, patients who received sorafenib as a second-line therapy had worse DCR (17.1 vs 47.4%, $p < 0.01$) and PFS. A trend toward a worse OS was also noted.
Conclusion: In the post-AB setting, we found suboptimal efficacy outcome of sorafenib. The very low DCR suggest that resistance to AB might select tumour cells able to escape the therapeutic targets of sorafenib. Enrollment of these patients in RCTs is strongly recommended to identify better therapeutic strategies.

THU-473
Complications of transarterial chemoembolization for hepatocellular carcinoma- 10 years' experience of a tertiary center

Laura Iliescu[1], Simona Ioanitescu[2], Razvan Rababoc[2], Andreea Simu[2], Mihai Toma[2], Radu Dumitru[2], Cristian Mugur Grasu[2]. *[1]Fundeni Clinical Institute, Carol Davila University of Medicine and Pharmacy, Bucharest; [2]Fundeni Clinical Institute, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania*
Email: laura_ate@yahoo.com

Background and aims: Transarterial chemoembolization (TACE) is a fundamental therapeutic option in intermediate stage hepatocellular carcinoma (HCC), indicated in patients with preserved liver function, as bridge towards liver transplantation or as means of down-staging. Careful patient selection and increased experience of hospital staff can reduce the incidence the incidence of postprocedural complications and mortality (estimated at 2–7% and 1% respectively). This

study aims to determine risk factors for TACE complications in a large cohort in a tertiary care center.
Method: Between January 2013 and November 2023 1673 TACE procedures were performed in our clinic, in 1256 patients. We analyzed incidence and risk factors for developing post TACE complications, by recording demographic, biologic and imagistic data.
Results: Out of 1673 procedures, 22.8% were performed in patients with chronic hepatitis and 77.2% in patients with compensated cirrhosis. Periprocedural complications were: post-embolization syndrome (14.22%), acute liver decompensation (6.45%), infection (2.45%), acute kidney injury (1.01%). Rare complications include acute cholecystitis in 6 patients, acute pancreatitis in 2 patients, hepatic artery dissection in 2 patients, ruptured hepatoma: 4 patients. Overall, TACE related mortality was 0.3% (6 patients). Risk factors for complications included hepatitis B and delta as etiology of liver disease (OR 1.46, CI 1.13–1.89, p = 0.04), older age (OR 2.17, CI 1.45–2.64, p = 0.02) and diabetes (OR 3.17, CI 2.89–3.64, p = 0.01). Tumor size more than 5 cm and the presence of more than 3 nodules were independent risk factors for acute decompensation (OR 2.16, CI 1.98–2.57, p = 0.03, OR 1.61, CI 1.52–1.83, p = 0.03 respectively) and post-embolization syndrome (OR 1.42, CI 1.18–1.73, p = 0.02, OR 1.71, CI 1.55–1.93, p = 0.03 respectively). Diabetes and older age were independent predictors for development of kidney injury (OR 3.91, CI 3.26–4.18, p = 0.01 and OR 2.76, CI 2.48–3.12, p = 0.02). Serologic markers associated with complications were increased transaminases before TACE (OR 2.57, CI 2.11–3.03, p = 0.03), low total cholesterol (<100 mg/dL, OR 1.82, CI 1.56–2.18, p = 0.02), low hemoglobin levels (OR 2.12, CI 2.03–2.57, p = 0.01) and increased C-reactive protein (OR 1.65, CI 1.28–1.93, p = 0.04).
Conclusion: TACE complications are rare in experienced centers. Risk factors include: diabetes, older age, inflammation and impaired liver synthesis function.

Immunotherapy in cholangiocarcinoma: understanding the immune landscape reveals treatment response

Rita Balsano[1,2], Tiziana Pressiani[2], Giulia Milardi[3], Silvia Bozzarelli[2], Valentina Zanuso[1,2], Angelo Pirozzi[1,2], Giulia Tesini[1,2], Ana Lleo[1,4], Lorenza Rimassa[1,2]. *[1]Humanitas University, Pieve Emanuele, Milan, Italy; [2]IRCCS Humanitas Research Hospital, Medical oncology and hematology unit, Rozzano, Milan, Italy; [3]IRCCS Humanitas Research Hospital, Hepatobiliary immunopathology lab, Rozzano, Milan, Italy; [4]IRCCS Humanitas Research Hospital, Department of gastroenterology, Internal medicine and hepatology, Rozzano, Milan, Italy*
Email: rita.balsano@cancercenter.humanitas.it

Background and aims: Cisplatin, gemcitabine and durvalumab has emerged as first-line standard of care for patients (pts) with advanced cholangiocarcinoma (CCA). Despite this result, prognosis remains poor and identification of predictive markers could represent a crucial turning point to select patients who might benefit more from the treatment. Our aim is to dissect pts' immune cell type subgroups to identify markers of treatment response.
Method: This observational study evaluated 26 pts with advanced CCA receiving first-line cisplatin, gemcitabine and durvalumab between April 2022 and December 2023 at a single tertiary center. For 16 pts (61.5%) molecular profiling by Next-Generation Sequencing was available. Peripheral blood cell count was collected at ten different time points. The correlation between immune cell type subgroups and treatment response was analyzed performing a student's t-test. A two-sided p < 0.05 was considered statistically significant.
Results: Pts were divided into two subgroups based on radiological response within 6 months (range 1–6 months) from treatment start: those with disease control (DC+) (17, 65%) including stable disease (SD) or partial response (PR) and those with progressive disease (PD) as best response (DC–) (9, 35%). Among DC+, 7 pts (41%) had PR and 10 (59%) had SD. We assessed the absolute counts of neutrophils, lymphocytes, eosinophils and the neutrophil-to-lymphocyte ratio (NLR) at baseline and at the last available tumor assessment. We found no difference in lymphocyte count at baseline (p = 0.09) and at the time of the last tumor assessment (p = 0.07) between DC+ and DC-. Instead, we observed a significant difference in eosinophil count at baseline (0.84 vs 0.58 M/ml; p = 0.0188) and at the time of the last tumor assessment (1.18 vs 0.59 M/ml; p = 0.001) between DC– and DC+. Although there was no difference in neutrophil count at baseline (p = 0.07), a difference was detected at the time of the last tumor assessment between DC– (7.48 M/ml) and DC+ (3.48 M/ml) (p = 0.005). This result was confirmed observing the NLR ratio, which showed no difference at baseline but a difference at the time of the last available tumor assessment and it was lower in DC+ (2.30) than DC– (4.79) (p = 0.037). The molecular profiling showed some differences in the two groups. In the DC+ subgroup, BAP1 mutation was the most common alteration, detected in 3 pts (18.75%) while mutations in AKT1, ARID1A, TP53, KRAS (G12D), and CD22, MDM2 amplification, FGFR2 rearrangement, and BRCA2 truncation were observed in 1 pt each (6.25). In the DC– subgroup, mutations in IDH1 (R132C), ARID1A, NF1, CDKN2A loss and EGFR amplification were observed in 1 pt each (6.25%).
Conclusion: In our study, a lower eosinophil count and NLR ratio were significantly associated with a better disease control. While a more comprehensive analysis is warranted, we observed a higher prevalence of BAP1 mutation in the DC+ subgroup.

Email: hangh@fmmu.edu.cn

Background and aims: Current prognostic models for patients with HCC undergoing transarterial chemoembolization (TACE) are not extensively validated and widely accepted. The aim of this study was to develop and validate a continuous model incorporating tumour morphology and biology for individual survival prediction and risk stratification.
Method: 4, 377 treatment-naïve recommended TACE candidates from 37 centres in 5 countries were enrolled and divided into a training dataset, an internal validation dataset and two external validation datasets. The novel model was developed using a Cox multivariable regression analysis, and compared to our original 6-and-12 model (the largest tumour size [ts, centimeters] + tumour number [tn]) and other available models in terms of predictive accuracy.
Results: The proposed model named "6-and-12 model 2.0" was generated as "ts + tn + 1.5 × log10α-fetoprotein [AFP])," showed good discrimination (C-index 0.674) and calibration (Hosmer-Lemeshow test p = 0.147), and outperformed current existing models. An easy-to-use stratification was proposed according to the different AFP levels (≤100, 100–400, 400–2, 000, 2, 000–10, 000, 10, 000–40, 000, and >40, 000 ng/ml) along with the corresponding tumour burden cut-offs (8/14, 7/13, 6/12, 5/11, 4/10, and any tumour burden), ie. if AFP was 400–2, 000 ng/ml, the stratification should be low- (≤6)/intermediate- (6–12)/high-risk (>12) strata. Hence, it could divide the patients into three distinct risk categories whose median overall survival 45.0 (95% CI, 40.1–49.9), 30.0 (95% CI, 26.1–33.9), and 15.4 (95% CI, 13.4–17.4) months ($p < 0.001$) from low-risk to high-risk strata, respectively. These findings were confirmed in validation and subgroup analyses.
Conclusion: 6-and-12 model 2.0 significantly improved individual outcome prediction and better stratified the recommended TACE candidates, which could be used in clinical practice, as well as trial design.

THU-478

RECIST 1.1, mRECIST, and Choi criteria for evaluating treatment response and survival outcomes in hepatocellular carcinoma patients treated with Atezolizumab plus Bevacizumab

Bohyun Kim[1], Dong Hwan Kim[1], Eun Jeong Moon[2], Joon-Il Choi[3], Jong Young Choi[4]. *[1]Seoul St. Mary's Hospital, Seoul, Korea, Rep. of South; [2]Department of Medical Life Science, College of Medicine, The Catholic University of Korea, Seoul, Korea, Rep. of South; [3]Department of Radiology, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Rep. of South; [4]Seoul St. Mary's Hospital, Seoul, Korea, Rep. of South*
Email: baboojum@naver.com

Background and aims: The combination of atezolizumab and bevacizumab (atezo-bev) has substantially advanced the systematic therapeutic approach for hepatocellular carcinoma (HCC). However, conventional size-based response assessment criteria may not fully capture treatment effectiveness, particularly in the context of immunotherapy and targeted agents. We compared early responders with advanced HCC receiving atezo-bev. Complete or partial responses were evaluated with Response Evaluation Criteria in Solid Tumors (RECIST) 1.1, modified RECIST (mRECIST), and Choi criteria and correlated with progression-free survival (PFS) and overall survival (OS).
Method: This retrospective study included 65 patients with advanced HCC (56 men, 9 women; mean age, 62.5 ± 12.7 years) treated with ≥3 cycles of atezo-bev. Responses were assessed using RECIST 1.1, mRECIST, and Choi criteria by 2 independent reviewers. Kaplan-Meier curves with log-rank tests and restricted mean survival time (RMST) at 1 year were used to evaluate and compare PFS and OS among responders and non-responders. Cox proportional hazards models identified survival outcome predictors. Kappa statistics assessed inter-reader agreement.
Results: Choi criteria identified the highest proportion of early responders (43.1%-49.2%), followed by mRECIST (33.8%-35.4%) and RECIST 1.1 (24.6%-27.7%), with excellent inter-reader agreement in all criteria (κ, 0.84–0.90). A similar incidence of progressive disease (20–22 patients) was identified consistently across criteria. In responders,

all criteria showed longer PFS (log-rank $ps \leq 0.009$), but only Choi criteria demonstrated significantly longer OS (log-rank $p \leq 0.018$). Choi criteria showed cumulative 1-year OS rates of 83.9% for responders and 62.2% for non-responders. RMST analysis at 1 year revealed a significant difference in OS between RECIST 1.1 and mRECIST ($ps \leq 0.003$). Univariable Cox analysis identified Choi criteria as a significant OS predictor.
Conclusion: Choi criteria identified more early responders than RECIST 1.1 and mRECIST, and correlated with improved PFS and OS in patients with advanced HCC treated with atezo-bev. Future studies with longer follow-up periods could validate these findings and refine the response assessment.

THU-479
The features of gut microbiota and metabolites in non-viral unresectable hepatocellular carcinoma undergoing immunotherapy
Pei-Chang Lee[1], Ya-Wen Hung[2], Chi-Jung Wu[1], Chieh-Ju Lee[1], Chen-Ta Chi[1], I-Cheng Lee[3], Yu-Lun Kuo[4], Shih-Hsuan Chou[4], Jiing-Chyuan Luo[1], Ming-Chih Hou[1], Yi-Hsiang Huang[5]. *[1]Taipei Veterans General Hospital, Taipei, Taiwan; [2]Taipei Veterans General Hospital, Taoyuan branch, Taoyuan; [3]Taipei Veterans General Hospital, Taipei; [4]Biotools, Co., Ltd, New Taipei City, Taiwan; [5]Taipei Veterans General Hospital, National Yang Ming Chiao Tung University, Taipei, Taiwan*
Email: yhhuang@vghtpe.gov.tw

Background and aims: Growing evidence suggests that non-viral hepatocellular carcinoma (HCC) may derive less benefit from immunotherapy. Gut microbiota and metabolites are considered to be associated with response to immune checkpoint inhibitors (ICIs) in unresectable HCC (uHCC). In this study, we aimed to investigate the features of gut microbiota and metabolites in non-viral uHCC and the association with tumor response to ICI immunotherapy.
Method: From May 2018 to September 2022, patients who received ICI therapy for uHCC in Taipei Veterans General hospital were prospectively enrolled. Pre-treatment fecal and plasma samples from 69 viral uHCC and 25 non-viral uHCC were collected. The differences of fecal microbiota, metabolites and plasma cytokines between non-viral and viral uHCC, and the relationship with tumor response were analyzed.
Results: A significant bacterial dissimilarity was observed between non-viral and viral uHCC before immunotherapy ($p = 0.019$ by Anoism test). Shigella flexneri and Shigella dysenteriae were predominant and abundant faecal microbiota in non-viral uHCC, whereas Phocaeicola vulgatus was predominant in viral uHCC. Significant enriched fecal isocaproic acid and plasma monocyte chemoattractant protein-1 (MCP-1) were also found in non-viral uHCC. In objective responders (16.0%) and durable disease controllers (24.0%) of non-viral uHCC, fecal Shigella flexneri and Shigella dysenteriae were less abundance, circulatory MCP-1 was less elevated, but significantly enriched anti-inflammatory taurochenodeoxycholic acid, ursodeoxycholic acid and ursocholic acid were noted as compared with non-responders.
Conclusion: Non-viral uHCC are characterized with more inflamed gut microbiota, metabolite and circulatory cytokines. However, responders to ICIs were characterized by more anti-inflammatory bile acids and less pro-inflammatory metabolites in their feces.

An artificial intelligence-derived model for classification of tumor morphology based on computed tomography images in patients with hepatocellular carcinoma
I-Cheng Lee[1,2], Chia-Hsun Yen[3], Yen-Chen Lin[3], Chien-An Liu[4], Shinn-Ying Ho[3], Yi-Hsiang Huang[5]. *[1]Division of Gastroenterology and Hepatology, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan; [2]School of Medicine, College of Medicine, National Yang Ming Chiao Tung University, Taipei, Taiwan; [3]Institute of Bioinformatics and Systems Biology, National Yang Ming Chiao Tung University, Hsinchu, Taiwan; [4]Department of Radiology, Taipei Veterans General Hospital, Taipei, Taiwan; [5]Healthcare and Service Center, Taipei Veterans General Hospital, Taipei, Taiwan, Institute of Clinical Medicine, National Yang Ming Chiao Tung University, Taipei, Taiwan*
Email: iclee@vghtpe.gov.twEmail:

Background and aims: Tumor morphology pattern had significant impact on the treatment response and survival in patients with hepatocellular carcinoma (HCC). However, the classification of tumor morphology is time-consuming and labor-intensive. The aim of this study is develop an artificial intelligence (AI)-derived model for automatic classification of tumor morphology using dynamic computed tomography (CT) images from HCC patients.
Method: Dynamic CT images before transarterial chemoembolization (TACE) treatment in 515 HCC patients were used for model development (n = 307) and validation (n = 208). Another cohort of 643 patients receiving surgical resection were used to validate the prognostic value of AI-predicted morphology. Tumor morphology patterns were classified as low-risk (simple nodular type), intermediate-risk (simple nodular type with extranodular growth), and high-risk morphology (confluent multinodular or infiltrative type). A ResNet-based deep-learning model (HCC-MorphoNet model) was developed to classify the tumor morphology of HCC.
Results: The HCC-MorphoNet model achieved the overall accuracy of 86.3% and 86.1% in predicting tumor morphology in the training set and the test set, respectively. The accuracy for predicting low-, intermediate-, and high-risk morphology was 83%, 89.9% and 95.3%, respectively. The AI-classified tumor morphology could significantly discriminate the radiologic response ($p < 0.001$) and overall survival ($p < 0.001$) after TACE, and the predicted outcomes were similar to those from human-classified tumor morphology. The AI-classified tumor morphology also significantly discriminated recurrence-free survival ($p < 0.001$) and overall survival ($p < 0.001$) in HCC patients receiving surgical resection.
Conclusion: We developed an HCC-MorphoNet model based on dynamic CT images for classification of tumor morphology in patients with HCC. The AI-classified morphology significantly discriminated the outcomes of HCC after TACE and surgical resection.

THU-481-YI
Hepatic resection in patients with hepatocellular carcinoma: the message coming from real world data
Lorenzo Lani[1], Laura Bucci[1], Valentina Santi[1], Benedetta Stefanini[1], Franco Trevisani[1]. *[1]Unit of Semeiotics, Liver and Alcohol-related diseases, IRCCS Azienda Ospedaliero-Universitaria di Bologna. For ITA.LI.CA group, Bologna, Italy*
Email: lorenzo.lani@studio.unibo.it

Background and aims: Hepatic resection (HR) is a curative option for hepatocellular carcinoma (HCC). The recently updated Barcelona Clinic Liver Cancer staging system identifies as "ideal candidates" (ICs) for HR patients with single lesion and without clinically significant portal hypertension (CSPH) or hyperbilirubinemia. We aimed to compare the outcome of HR between ICs and non-ICs [bilirubin >1.1 mg/dL; presence of CSPH; multinodular tumours (mHCC)] in a large population of resected patients for HCC in real-world practice and assess whether their characteristics and outcomes changed over time.
Method: We extracted from the ITA.LI.CA. database 1085 Child-Pugh A patients and without extrahepatic tumour spread undergoing HR for HCC between 2000 and 2022. We analysed 3 periods (T1 = 2000–2008; T2 = 2009–2015; T3 = 2016–2022). CSPH was defined as presence of gastro-oesophageal varices and/or platelet count <100,000/mmc. Hyperbilirubinemia was accepted up to 2 mg/dL. Overall survival (OS) was measured from the time of HR to death, loss to or end of follow-up (31/12/22). Patients undergoing liver transplantation (LT) were censored at the time of LT. OS was calculated

using the Kaplan-Meier method and compared with the log-rank test.
Results: Prevalence of ICs tended to increase over time (32.9%, 42.3% and 42.9% in T1, T2 and T3, respectively; p = 0.083) but remained lower than that of non-ICs. Among non-ICs, the proportion of those with CSPH alone did not change over time (from 22.4% to 27.6% to 29.5%; p = 0.407) while mHCC increased (from 33.7% to 48.7% to 49.6%; p = 0.018). An opposite trend was observed for hyperbilirubinemic alone (from 23.5% to 13.8% to 11.9%; p = 0.018) and hyperbilirubinemic+CSPH patients (from 20.4% to 10.0% to 9.0%; p = 0.006). Over a median follow-up of 41.1 months (IQR = 56.0), median OS was higher in ICs compared to non-ICs (104.9 months, 95%CI 78.3–131.4 vs 75.0 months, 95%CI 64.0–86.0; p < 0.001). However, compared to ICs, median OS did not significantly differ in patients with CSPH alone (93.1 months, 95%CI 73.7–112.5, p = 0.417) or with hyperbilirubinemia alone (86.0 months, 95%CI 58.3–113.8, p = 0.257), while those with mHCC (63.0 months, 95%CI 45.2–80.8, p < 0.001) or hyperbilirubinemia+CSPH (60.0 months, 95%CI 42.6–77.4, p < 0.001) had a worse OS. The 6-month mortality rate (perioperative mortality) of hyperbilirubinemic, CSPH, and mHCC groups did not differ from that of ICs (p ≥ 0.211), while it was higher in hyperbilirubinemic+CSPH patients (p < 0.001).
Conclusion: Real-world data show that since 2000 the proportion of ICs remained steady over time and lower than that of non-ICs. HR can be offered to Child-Pugh A patients with CSPH or modest hyperbilirubinemia without compromising its outcome. The presence of two of these features, as well as mHCC, generates a poorer prognosis. In these patients, specific studies assessing if HR is superior to non-surgical therapies are needed.

THU-484
External beam radiation therapy improves the response to Atezolizumab plus Bevacizumab in patients with unresectable hepatocellular carcinoma with portal vein tumor thrombosis
Yunjeong Lee[1], Jin-Wook Kim[1]. [1]*Seoul National University Bundang Hospital, Seongnam, Korea, Rep. of South*
Email: leey217@gmail.com

Background and aims: The combination of atezolizumab plus bevacizumab regimen has been considered the first-line systemic therapy for unresectable hepatocellular carcinoma (HCC). However, the presence of portal vein tumor thrombosis (PVTT) remains a clinical challenge due to more advanced disease burden and poorer response to systemic treatment. The use of external beam radiation therapy may increase tumor control rate in HCC patients with PVTT. However, it is not clear whether the additional radiotherapy improves the tumor response to atezolizumab plus bevacizumab regimen in these patients. In this single-center retrospective cohort study, we assessed the effect of radiotherapy in HCC patients with PVTT who received atezolizumab plus bevacizumab as a first-line therapy.
Method: We reviewed 203 patients who started atezolizumab plus bevacizumab for unresectable HCC at our center between April 2003 and December 2023. The presence of portal vein thrombosis was identified on CT or MRI. The modified response evaluation criteria in solid tumors (mRECIST) was used to assess treatment responses. A multivariate Cox analysis was performed to compare the prognosis of patients who received the combination systemic therapy with or without external beam radiation therapy. A p value of <0.05 was considered significant.
Results: Of the 203 patients, the prevalence of PVTT was 38% (n = 78). Among the 78 patients, 27 received additional radiotherapy. The radiation dose used ranged from 30 to 60 Gy, with an average of 48 Gy. A multivariate Cox analysis adjusting effects of age and sex showed that the concomitant radiotherapy significantly improved the tumor response to atezolizumab plus bevacizumab therapy and prolonged progression-free survival (hazard ratio = 0.50 with 95% confidence interval = 0.25–0.99; p = 0.048).
Conclusion: The addition of external beam radiation therapy improved the tumor response to atezolizumab plus bevacizumab systemic therapy in HCC patients with PVTT. It is notable that this study reached statistical significance in a small patient cohort over a short history of application of the combination regimen. Further experiences with atezolizumab and bevacizumab, as well as the investigation of the nature of HCC with PVTT, would be warranted to validate our finding.

THU-485-YI
Hepatic and peripheral blood neutrophil: lymphocyte ratios offer paradoxical associations with clinical outcome in advanced hepatocellular carcinoma treated with immune checkpoint inhibitors plus transarterial chemoembolization
Paul Armstrong[1,2], Aoife Moriarty[1,2], Erinn McGrath[3], Jennifer Russell[1], Lindsey Clarke[3], Stephen Stewart[1,2], Austin Duffy[2], Cliona O'Farrelly[4]. Email: drpaulrichardarmstrong@gmail.com

Background and aims: The complexity of the liver immune environment, which demonstrates significant inter-individual variation, is likely to influence and reflect local tumour growth. Changes in the relative proportions of lymphoid and myeloid populations in the liver may therefore be of useful prognostic value in patients with hepatocellular carcinoma (HCC). Here we aimed to evaluate liver lymphoid and myeloid populations as prognostic biomarkers in patients with advanced HCC treated with immune checkpoint inhibitors (ICI) plus transarterial chemoembolization (TACE).
Method: Patients with HCC (Childs Pugh A/B7; Barcelona Clinic Liver Cancer Stage B/C; ECOG 0/1; sorafenib-naïve or experienced) were enrolled in a clinical trial (UCDCRC/19/01 EudraCT no. 2019-002767-98) of tremelimumab plus durvalumab and subtotal TACE performed on week 6. Full blood counts including differential sample assessments were performed at baseline and on treatment (after Cycle 3 Durvalumab). Liver biopsies were taken from the tumour, the tumour margin, portal tracts and uninvolved parenchyma. HandE stained slides were assessed for lymphocyte and granulocyte populations by two experienced independent histopathologists. Neutrophil: lymphocyte ratios (NLR) defined as the hepatic neutrophil count divided by the lymphocyte count in each x40 HPF, were calculated.
Results: Thirteen patients were enrolled in the study. Primary outcome was defined as 6 month progression free survival (PFS) and secondary outcome was overall survival (OS) measured at 1 year. Six patients (46%) exhibited PFS at 6 months, and 9 (69%) achieved one year OS. Lower 'on treatment' peripheral blood NLRs were associated with improved 1 year OS (p 0.02, Spearman rho 0.74).
Adequate tissue samples for study were obtained pretreatment from 10 patients. Patients with lower numbers of lymphocytes in their tumour tissue had better rates of 6-month PFS (p 0.025, Spearman rho 0.75). Thus, higher NLRs in tumour were associated with improved 6-month PFS (p 0.011, Spearman rho 0.85). Cases with a high intratumoural NLR (≥0.08) had a median PFS of 7.95 months (6.64–9.41) vs 3.69 (2.78–4.24) for those with low intratumoural NLR (<0.08) (p 0.048). In contrast, lower NLRs in the liver portal tracts correlated with improved one year OS (p 0.036, Spearman rho 0.734).
Conclusion: Lower NLRs in the peripheral blood and uninvolved liver predict improved survival in advanced HCC treated with ICI plus TACE. Paradoxically, higher NLRs in the tumour correlate with improved clinical response. These findings emphasize the variability of microenvironmental influences on immune populations in primary HCC tumour and surrounding liver tissue. We propose that these interindividual differences have important prognostic value and may also indicate new therapeutic targets.

THU-486-YI

A multi-center comparison of Atezolizumab plus Bevacizumab and Lenvatinib as primary systemic therapy for unresectable hepatocellar carcinoma: focus on thrombotic and hemorragic adverse events

Marco Tizzani[1], Chiara Mazzarelli[2], Michela Emma Burlone[3], Patrizia Carucci[4], Gian Paolo Caviglia[5], Chiara Lisi[1], Chiara Canalis[1], Lucia Cesarini[2], Mario Pirisi[6], Antonio Acquaviva[7], Emanuela Rolle[4], Paolo Pochettino[8], Katia Bencardino[9], Federica Villa[9], Martina Angiolillo[10], Eleonora Castellana[11], Matilde Scaldaferri[11], Francesco Cattel[11], Mario Airoldi[8], Giorgio Maria Saracco[1], Silvia Gaia[4]. *[1]Division of Gastroenterology and Hepatology-AOU Città della Salute e della Scienza, University of Turin, Turin, Italy; [2]Hepatology and gastroenterology ASST GOM Niguarda, Milan, Italy; [3]Medicina interna 1, AOU Maggiore della Carità-Novara, Novara, Italy; [4]Division of Gastroenterology and Hepatology-AOU città della salute e della scienza, Turin, Turin, Italy; [5]Department of Medical Sciences, University of Turin, Turin, Italy, Turin, Italy; [6]Università del Piemonte Orientale, dipartimento di Medicina Traslazionale, Novara, Italy; [7]Università del Piemonte Orientale and Division of Internal Medicine, Azienda Ospedaliero-Universitaria Maggiore della Carità, Novara, Italy; [8]Division of Oncology-AOU città della salute e della scienza, Turin, Turin, Italy; [9]Division of Oncology-ASST GOM Niguarda, Milan, Italy; [10]Division of Hospital Pharmacy, A.O.U. Città della Salute e della Scienza di Torino, University of Turin, Turin, Italy; [11]Division of Hospital Pharmacy, A.O.U. Città della Salute e della Scienza, Turin, Turin, Italy*
Email: silvia.gaia74@gmail.com

Background and aims: First line therapy for unresectable hepatocellular carcinoma (HCC) are Atezolizumab plus Bevacizumab (AB) and Lenvatinib (Len). The aim is to compare their efficacy and safety, mainly focusing on thrombotic and hemorrhagic adverse events.
Method: A multi-center retrospective study was conducted. All patients treated with Len or AB for HCC in 3 northern Italian centers were consecutively enrolled. Demographic, clinical and radiologic data were collected. All patients were treated following EASL guideline for the HCC systemic therapy.
Results: Overall 173 patients receiving AB (n = 65) or Len (n = 108) were enrolled. At baseline the 2 groups were similar for sex (85% male), median age (69 y), diagnosis of cirrhosis (81%) vs chronic liver disease (19%), Child-Pugh A (100%), HCC staging (75% BCLC-C, 25% BCLC-B), presence of low-risk esophageal varices (39%), median platelet count (150 x10^9/L), AFP (median 24.5 ng/ml), and anticoagulant therapy (21%). Anti-aggregant therapy was more frequent in Lev group (27.8%) compared to AB (12.3%), p = 0.022. Viral aetiology was higher in AB group (66.7%) vs Len group (48.1%), (p = 0.050). Median follow-up was longer in Lev group (11.3 months, IQR 5.7–21.4) vs AB (6.8 months, 4.1–11.1), p < 0.001. In Len group 6 patients underwent liver transplantation and 1 patient in AB group. Mean overall survival (OS) was 18.7 months (95% CI 15.9–21.5), without difference between Len and AB group (p = 0.682). OS was related to radiological response at 3 months (p < 0.001) in both groups. Baseline AFP value was associated to higher mortality only in Len group (p < 0.001). Disease control rate at 3, 6 and 12 moths were similar in Lev group *vs* AB group: 77% *vs* 66%, 64% *vs* 56% and 48% *vs* 37%, respectively (p = ns). Thrombotic events were uncommon in both groups: 5/108 (4.6%) in Len group [2 acute coronary syndrome, 1 portal vein thrombosis (PVT), 1 Pulmonary embolism, 1 transitory ischemic attack] *vs* 3/65 (4.6%) in AB group (3 PVT) (p = 0.561). No thrombotic events occurred in patients with anticoagulants. Overall, the use of anti-platelets drug did not reduce the risk of thrombotic events (HR = 1.71, p = 0.472) nor increased the risk of hemorrhagic events (HR = 1.08, p = 0.870). Mild and/or severe hemorrhagic events occurred in 15/108 (13.9%) in Lev group and in 10/65 (15, 3%) in AB group (p = 0.421): the use of anticoagulant drugs showed a trend of association with hemorrhagic events (HR 2.22, p = 0.06). Hospitalization for any reason occurred in 17/108 (15.7%) patients treated with Len and in 22/65 (33.8%) patients treated with AB (p = 0.008): two cases related to hemorrhagic and 2 to thrombotic events in Lev group, whereas 2 related to hemorrhagic events in AB group.
Conclusion: AB or Lev had comparable overall survival and disease control rate. In both group thrombotic events were uncommon: therapy with anticoagulants avoided the risk of thrombotic events but increased the hemorrhagic risks.

THU-487-YI

Upfront multi-bipolar radiofrequency ablation for hepatocarcinoma in transplant-eligible cirrhotic patients with salvage transplantation in case of recurrence

Carina Boros[1], Olivier Sutter[1], Francois Cauchy[2], Nathalie Ganne-Carrié[1], Pierre Nahon[1], NKontchou Gisèle[1], Marianne Ziol[1], Véronique Grando Lemaire[1], Alix Demory[1], Lorraine Blaise[1], Federica Dondero[3], Francois Durand[3], Olivier Soubrane[4], Mickael Lesurtel[3], Olivier Seror[1], Jean Charles Nault[1]. *[1]Avicenne Hospital, Bobigny, France; [2]Department of Hepato-biliary and Pancreatic Surgery and Liver Transplantation, Geneva, Switzerland; [3]Beaujon Hospital, Paris, France; [4]Institut Mutualiste Montsouris, Department of Surgery, Paris, France*
Email: carinna.bs@gmail.com

Background and aims: We aim to assess the long-term outcomes of percutaneous multi-bipolar radiofrequency (mbp RFA) as the first treatment for HCC (hepatocarcinoma), in transplant-eligible cirrhotic patients, followed by salvage liver transplantation for an intrahepatic at distance tumor recurrence or for liver failure.
Method: We included transplant-eligible patients with cirrhosis and a first diagnosis of HCC within Milan criteria, treated by upfront mbp RFA. Transplantability was defined by age <70 years, social support, absence of significant comorbidities, no active alcohol use and no recent extrahepatic neoplasia. Baseline variables were correlated with outcomes using Kaplan-Meier and Cox models.
Results: Among 435 patients with HCC, 172 were considered transplantable and had HCCs >2 cm (53%), unimodular tumor (87%) and AFp >100 ng/ml (13%). Median overall survival was 87 months, 75% of patients were alive at 3 years, 61% at 5 years and 43% at 10 years, respectively. Age (p = 0.003) and the MELD score >10 (p = 0.01) were statistically significant associated with the risk of death. Recurrence occurred in 118 patients, among which 81% of cases were within Milan criteria for liver transplantation. At 10 years, local recurrence was observed in 24.5% of patients, while distant recurrence rate was 69%. Furthermore, the 10 year survival rate after a local recurrence was 69%. Patients with local tumor recurrence alone (n = 23) experienced a longer post-recurrence survival rate in compared to patients with distant tumor recurrence (n = 83) or those with concomitant distant and local tumor recurrence (n = 12) (p = 0.0023). At the time of the first tumor recurrence, 75 patients (65%) were considered transplantable. In Cox multivariate analysis, the age (HR = 1.10, 95% CI = 1.04–1.17, p = 0.0008) was the only baseline variable data negatively associated with the transplantability at the time tumor recurrence. Forty-one patients underwent a liver transplantation mainly for distant intrahepatic tumor recurrence. The overall 5-year survival post-transplantation was 72%, with a tumor recurrence rate of 2.4%.
Conclusion: Upfront multi-bipolar RFA as a first treatment of early HCC on cirrhosis followed by salvage liver transplantation has a favorable long-term prognosis, allowing for the preservation of liver grafts.

THU-490

Grip strength complements performance status in assessing general condition in patients with unresectable hepatocellular carcinoma treated with atezolizumab and bevacizumab

Kei Endo[1], Takuya Watanabe[1], Hidekatsu Kuroda[1], Takayuki Matsumoto[1]. *[1]Iwate medical university school of medicine, Yahaba, Japan*
Email: keiendo@iwate-med.ac.jp

Background and aims: Accurate assessment of the general condition of patients with hepatocellular carcinoma (HCC) is essential. We evaluated the impact of grip strength (GS) and Eastern Cooperative Oncology Group performance status (ECOG-PS) on the clinical outcomes of patients with unresectable HCC (u-HCC) who were treated with atezolizumab plus bevacizumab (ATZ+BEV).
Method: This observational cohort study analyzed 89 patients with u-HCC who were treated with ATZ+BEV between October 2020 and October 2023. Low GS was defined as GS <28 kg and GS <18 kg in men and women, respectively. A Cox proportional hazards model and a Kaplan-Meier curve were used to identify the prognostic factors associated with survival outcomes.
Results: There were 33 patients who had low GS, and 16 who had ECOG-PS≥1. The frequency of low GS was 27.4% (20/73) in patients with ECOG-PS0, 76.9% (10/13) in patients with ECOG-PS1 and 100% (3/3) in patients with ECOG-PS2. The frequency of patients with low GS increased as the ECOG-PS score increased ($p < 0.01$). The overall survival (OS) of the normal GS group was significantly higher than that of the low GS group ($p < 0.01$). There was no significant difference in PFS between the normal GS group and the low GS group ($p = 0.28$). The OS and PFS of the ECOG-PS0 group were significantly higher than those of the ECOG-PS≥1 group ($p < 0.01$ and <0.01, respectively). Among the patients in the ECOG-PS0 groups, the OS in the normal GS group was significantly higher than that in the low GS group ($p < 0.01$). A multivariate analysis revealed that the mALBI 2b (hazard ratio [HR] 2.34; 95% CI, 1.19–4.59), AFP ≥100 ng/ml (HR 2.39; 95% CI, 1.25–4.55) and low GS (HR 3.11; 95% CI, 1.57–6.16) were independently associated with poor OS.
Conclusion: The present study demonstrated that GS is a sensitive marker for detecting a subclinical loss of general condition and a candidate predictor of the outcome of u-HCC patients treated with ATZ+BEV.

THU-491

Prognostic value of the timing of immune checkpoint inhibitors infusion in patients with advanced hepatocellular carcinoma

Alina Pascale[1], Marc Antoine Allard[2], Amal Benamar[1], Francis Levy[2], René Adam[2], Olivier Rosmorduc[3]. *[1]CHU Paul Brousse, APHP, Villejuif, France; [2]CHU Paul Brousse, APHP, Paris Saclay University, Villejuif, France; [3]CHU Paul Brousse, APHP, Paris Sorbonne University, Villejuif, France*
Email: olivier.rosmorduc@aphp.fr

Background and aims: Experimental and clinical data in melanoma and lung cancer suggest that the response to immune checkpoint inhibitors (ICI) may be influenced by circadian rhythms. However, similar findings are lacking in hepatocellular carcinoma (HCC). The aim of this study was to assess the impact of infusion timing of atezolizumab, an ICI, associated or not with bevacizumab, as first line systemic treatment in advanced HCC.
Method: We retrospectively analyzed all consecutive patients, who received, as first line systemic treatment, at least two cycles of atezolizumab ± bevacizumab for advanced HCC in Paul Brousse Hospital, Villejuif, France, between January 2020 and October 2022. We split them in two groups: 1) patients receiving the first two cycles after 1 pm (afternoon group); 2) patients receiving at least one of the two first cycles before 1 pm (morning or mixed group). Cox regression models were used to assess the prognostic value of ICI infusion timing for the overall survival (OS).
Results: A total of 131 patients were analyzed. 119 patients (90.8%) were male, with a median age of 70 years [35; 88]; 40 patients (31%) had performance status (PS) ≥1. 103 patients (79%) had cirrhosis; 61 patients (46.6%) had portal hypertension. 49 patients (37.4%) had metastatic HCC and 52 patients (40.6%) had portal vein thrombosis at diagnosis. The mean initial level of alpha-fetoprotein was 5, 212.8 ng/ml (SD: 18, 681.8). 36 patients (27.5%) received only atezolizumab. 41 patients were included in the first group and were compared to 90 patients included in the second group. There were no significant clinical differences between the two groups. The median OS was significantly lower in the afternoon group compared to the morning or mixed group (11.5 months vs 18.7 months, $p = 0.015$). In univariate analysis, PS ≥1 ($p = 0.025$), initial level of alpha-fetoprotein ($p = 0.030$), monotherapy by atezolizumab ($p = 0.004$) and the first two cycles of ICI infusion after 1 pm ($p = 0.018$) were significantly correlated with OS. The first two cycles of ICI infusion after 1 pm remains an independent factor significantly associated with OS in the multivariate Cox model, with HR 2.29, 95% CI: 1.27–4.14, $p = 0.005$.
Conclusion: Our results suggest that the afternoon infusion of the first two cycles of ICI is associated with lower outcomes in patients with advanced HCC, independently of other prognostic factors. There may be confounding factors due to the variability of administration of further perfusions. Larger data are needed to confirm such findings.

THU-492

Prognostic significance of liver decompensation, liver function and portal hypertension in cirrhotic patients with advanced hepatocellular carcinoma treated with Atezolizumab plus Bevacizumab

Maria Pallozzi[1], Leonardo Stella[1], Lucia Cerrito[1], Francesco Santopaolo[1], Maurizio Pompili[1], Antonio Gasbarrini[1], Fabio Marra[2], Claudia Campani[3], Elisa Pellegrini[3], Francesco Tovoli[4], Fabio Piscaglia[4], Clemence Hollande[5], Sabrina Sidali[5], Mohamed Bouattour[5], Francesca Romana Ponziani[1]. *[1]Fondazione Policlinico Universitario Agostino Gemelli, IRCCS, Università Cattolica del Sacro Cuore, Roma, Italy; [2]AUC Ospedale Universitario Careggi, Università degli studi di Firenze, FIrenze, Italy; [3]AUC Ospedale Universitario Careggi, Università degli studi di Firenze, Firenze, Italy; [4]Policlinico Universitario Sant'Orsola-Malpighi, IRCCS, Alma Mater Studiorum-Università di Bologna, Bologna, Italy; [5]Beaujon University Hospital -Assistance Hopitaux Publique de Paris, Clichy, France*
Email: mariapallozzi@yahoo.it

Background and aims: Atezolizumab/Bevacizumab changed the landscape of advanced hepatocellular carcinoma (HCC) treatment but its efficacy and safety in presence of reduced liver function or portal hypertension is still debated. Moreover, it is unknown if liver decompensation may impact on efficacy and safety outcomes. We aimed to evaluate the efficacy and safety of Atezolizumab/Bevacizumab in a real life cohort of patients with unresectable HCC and to evaluate the impact of liver decompensation on survival outcomes and its prognostic significance.
Method: A multicentric cohort of 247 patients with unresectable HCC eligible for Atezolizumab/Bevacizumab treatment was retrospectively enrolled between 2018–2023 and matched in a 1:2 ratio with a cohort of 494 patients treated with tyrosine kinase inhibitors (TKIs). Safety and efficacy outcomes of patients in the Atezolizumab/Bevacizumab cohort were evaluated according to liver function, presence of portal hypertension and development of liver decompensation. We defined time-to-decompensation as the interval from the first treatment administration to the occurrence of any event related to the decline in liver function or the aggravation of portal hypertension. Its impact on the overall survival (OS) was assessed.
Results: Patients in the Atezolizumab/Bevacizumab group showed better median OS (18.3VS 10.20 months, $p < 0.0001$), time to progression (TTP; 13.6 VS 10.6 months, $p = 0.006$) and progression free survival (PFS;10.5 VS 6.10 months, $p < 0.0001$) compared with TKIs. Although survival was better in Child Pugh A patients than in Child Pugh B patients (20.2 vs 9.83 months, $p = 0.0008$), no clear difference in TTP ($p = 0.31$) and overall treatment safety was observed. Portal hypertension did not impact on OS and TTP. 63 patients reported liver decompensation (ascites:84.12%, hepatic encephalopathy:38.09% and variceal bleeding:19.04%). Decompensated patients showed a reduced survival (10.50 vs 20.20 months; $p = 0.06$). 26 patients (41.26%) were able to resume Atezolizumab/Bevacizumab after decompensation achieving an OS comparable to that of never decompensated subjects (20.87 vs 20.20

months; p = 0.77), and significantly better than patients who had to stop permanently (8.07 months; p = 0.02). Treatment interruption following liver decompensation was an independent predictor of survival (HR 3.04, 95%CI 1.97–4.68; p < 0.0001), as were Child Pugh B (HR 1.87, 95%CI 1.08–3.25; p = 0.03) and portal hypertension (HR 1.86, 95%CI 1.01–3.39; p = 0.04) for decompensation.
Conclusion: This real-life multicentric study shows that Atezolizumab/Bevacizumab is equally effective on HCC progression in both Child Pugh A and B patients, who present a higher risk of decompensation.
Because resuming treatment is associated with a survival advantage, integrated hepato-oncology.
management is critical to maximize Atezolizumab plus Bevacizumab efficacy.

THU-493

Systemic therapy of hepatocellular carcinoma on non-cirrhotic liver: a prospective spanish multicentre study

Email: m.romero.gutierrez@gmail.com

Background and aims: Systemic therapy (ST) can be initial (I) or sequential (S) treatment of hepatocellular carcinoma (HCC). However, data are still scarce in patients without liver cirrhosis. We aim to characterize non-cirrhotic patients treated with ST, both in the initial treatment and after progression or recurrence, describing survival benefit and safety profile.
Method: A prospective Spanish multicentre study included 141 non-cirrhotic patients with HCC diagnosed by histology from May 2018 to September 2023. Liver cirrhosis was excluded by histology (89.6%), elastography (4.7%) or Mittal 2 criteria (5.7%). Forty-seven patients (33.3%) treated with ST were evaluated.
Results: (n = 47). The median age was 69 years and 85.1% were male. Other cancers 25.5%. DM 38.3%. Non-alcohol 40.4%, non-smoker 21.3%. Seventy-six percent had underlying liver disease, mainly caused by viral infection ± alcoholic liver disease (ALD) 25.6% (HCV 21.3%, HBV 4.3%), MASLD ± ALD 25.5%. Liver fibrosis stage: 0–1 in 42.6%, 2–3 in 38.3%, unknown 19.1%. HCC diagnosis was incidental (53.2%), by symptoms (34%) or at follow-up ultrasonography (12.8%). ST was administered at diagnosis in 21 cases (44.7%), and sequentially due to progression or recurrence in 26 (55.3%): 16 after surgery (ST in 11 and TACE-ST in 5), 10 after TACE/TARE. The reason for ST initiation were: 25.5% presentation as BCLC C, 19.1% presentation as BCLC B not candidate for other therapy, 53.2% progression or recurrence, 2.1% others. At the time of ST initiation, 31.9% had macrovascular invasion and 31.9% had extrahepatic spread. ECOG 0 55.3%. BCLC stage: A 2.1%, B 38.3%, C 59.6%. AFp >200 ng/ml: 25.5%. Drugs at 1st line (1L): sorafenib (SOR) 59.6% (I 17/S 11), lenvatinib (LEN) 14.9% (I 4/S 3), atezolizumab + bevacizumab (AB) 19.1% (I 0/S 9), others 6.4%. Patients received 2 ST lines in 29%, and 3 lines in 8.5%. Adverse events (AE) of any grade: SOR 21/27 (77.8%), LEN 8/10 (80%), AB 5/8 (62.5%). Median treatment time was 15.5 months: 9.5 months (RIQ 3–22) in initial group and 21.1 months (RIQ 12–32) in sequential. Discontinuation 1L was due to symptomatic progression 34%, radiological progression 14.9% or severe AE 12.8%. Median follow-up was 29.1 months. Median overall survival (OS) from ST initiation was 16.3 months (95%CI: 11–22): OS in ST prescribed at diagnosis was 10 months (95% CI 6–14) compared OS sequential ST was 21.4 months (95%CI 12–31) (p = 0.022). OS 1L drug: tyrosine kinase inhibitor (SOR/LEN) 13.4 months (95%CI 8–19); AB 26.3 months (95%CI 13–39) (p = 0.22). Seventy percent of patients died (87.9% due to HCC).
Conclusion: In our series, patients with HCC on non-cirrhotic liver required more frequently ST due to tumour progression/recurrence after previous treatments than initial therapy for advanced disease. Survival was similar and safety profile was slightly better than clinical trials data, being severe AE uncommon reason for discontinuation.

THU-494

Selective internal radiation therapy for unresectable hepatocellular carcinoma in a tertiary center in France, update and final analysis

Hélène Regnault[1], Julia Chalaye[2], Athena Galletto[2], Clara Perrin[3], Giuliana Amaddeo[2], Marie Lequoy[4], Hicham Kobeiter[2], Sébastien Mulé[2], Edouard Reizine[2], Emmanuel Itti[2], Christophe Duvoux[2], Alexis Laurent[5], Daniele Sommacale[2], Vincent Leroy[2], Alain Luciani[2], Haytham Derbel[2], Julien Calderaro[2], Vania Tacher[2], Brustia Raffaele[2]. *[1]Henri Mondor Hospital, Creteil, France; [2]Henri Mondor University Hospital, Créteil, France; [3]Antoine Béclère, Clamart, France; [4]Saint Antoine, Paris, France; [5]Henri Mondor University Hospital, Créteil*
Email: helene.regnault@aphp.fr

Background and aims: Selective Internal Radiation Therapy (SIRT) is not yet recommended as first line treatment of unresectable hepatocellular carcinoma (HCC) except in solitary HCC <8 cm. The aim of this study was to report the results of an acquired experience in the real life in a tertiary center.
Method: We conducted a retrospective, observational study using data collected from all consecutive patients undergoing SIRT between October 2013 and June 2020. Downstaging was considered achieved when a curative treatment could be proposed after evaluation 6 months following SIRT.
Results: 127 patients (Male = 90%, 64 ± 11) were included. 112 patients (n = 88%) had cirrhosis. HCC was mostly advanced according BCLC in 64 patients (50%), with a median diameter of 61 mm, infiltrative pattern in 51 patients (40%) and portal vein invasion in 62 (49%). 50 patients (39%) achieved downstaging 6 months following SIRT, 29 of them (23%) had access to a curative treatment in a median time of 4.3 months: 17 (13%) were transplanted, 11 (85%) had liver resection and one patient had a radiofrequency ablation. Median overall survival (OS) of patients with or without downstaging was 51 months versus 10 months respectively (p < 0, 001). In patients who achieved downstating, PFS was higher in patients who underwent surgery (40 vs 13 months). Four variables were independently associated to downstaging: age (p = 0.02), baseline AFP (p = 0.034), CHC distribution (p = 0.012) and ALBI grade (p = 0.014).
Conclusion: These results suggest that, in real life, SIRT in HCC patients could be an effective treatment leading to downstaging of about 35% of patients with unresectable HCC, and allowed curative treatment in more than half of them.

THU-495

Baseline neutrophil-to-lymphocyte ratio, liver disease etiology and morphomolecular histological classification could predict clinical outcome in Atezolizumab-Bevacizumab treated cirrhotic patients with advanced hepatocellular carcinoma

Spyridon Pantzios[1], Iakovos Vlachos[2], Antonia Syricha[1], Orestis Sidiropoulos[1], Emmanouil Nychas[1], Ioanna Maria Grypari[2], Despoina Myoteri[2], Dina Tiniakos[2], Ioannis Elefsiniotis[1]. [1]*Academic Department of Internal Medicine-Hepatogastroenterology Unit, General Oncology Hospital of Kifissia, National and Kapodistrian University of Athens, Greece, Athens, Greece;* [2]*Dept of Pathology, Aretaieion Hospital, Medical School, National and Kapodistrian University of Athens, Greece, Athens, Greece*
Email: spiros_pant@hotmail.com

Background and aims: Non-viral etiology of chronic liver disease has not been related with survival benefit in advanced HCC treated with Atezo-Bev. Moreover, a high neutrophil to lymphocyte ratio (NLR) has been related with worse clinical outcomes whereas data regarding the histological evaluation of these patients are limited. The aim of our study was to evaluate the survival of White European cirrhotic patients with advanced HCC treated with Atezo-Bev according to viral/non-viral etiology as well as baseline NLR and histological HCC status.

Method: Forty-four cirrhotic patients with advanced HCC were included (35 males, mean age = 66.6, median MELD-Na = 8, 39 CPT-A, 18 with MVI, 17 with EHD, 22 with viral etiology). Twenty-three HCCs were classified by morphomolecular analysis as proliferative (PR) and 21 as non-proliferative (N-PR), according to the classification by Nault JC et al, J Hepatol 2018. Baseline NLR was evaluated in all patients and a ratio above 4 was considered as high. Four groups were constructed [A: PR/NLR-H (n = 6), B: PR/NLR-L (n = 17), C: N-PR/NLR-H (n = 6), D: N-PR/NLR-L (n = 15)]. Patients with complete or partial response according to mRECIST were categorized as having objective response (OR).

Results: PR HCC was observed in 13/23 (56.5%) patients of viral and 10/23 (43.5%) of non-viral etiology, whereas N-PR HCC was observed in 9/21 (42.8%) patients of viral and 12/21 (57.2%) of non-viral etiology. Totally, OR was observed in 9/44 (20.45%) patients (1/5/1/2 from group A/B/C/D respectively) and was significantly related with overall survival (OS, p = 0.009).

Baseline characteristics of NLR-L patients (n = 32) were comparable to those of NLR-H (n = 12) but median OS was significantly better in NLR-L (12 m vs 6 m, p = 0.05). Among 22 patients with non-viral etiology, those with PR (n = 10) presented worse survival compared to N-PR (n = 12) HCC (6 m vs 12 m, p = 0.03) in univariate and a significant trend for worse OS (p = 0.07) in multivariate analysis considering age, presence of varices, MELD-Na and MVI. Moreover, patients of non-viral etiology and NLR-L presented the best median OS (26 m) in univariate (p = 0.005) as well as in multivariate analysis (p = 0.01). The 4 groups were comparable for all baseline parameters evaluated. Median OS was 10 m for group A, 12 m for B, 5.5 m for C and 12 m for D. A trend for worse OS was observed in patients with NRL-H and N-PR HCC (p = 0.07) compared to the other groups.

Conclusion: PR and N-PR morphomolecular subgroup HCCs were equally observed among White European cirrhotic patients with advanced HCC of viral or non-viral etiology. Non-viral etiology per se should not be considered as a negative predictor of clinical outcome in patients treated with Atezo-Bev, as the subgroup of them who present low baseline NLR seem to benefit the most from treatment whereas patients with N-PR HCCs and high baseline NRL seem to exhibit a significant trend for worse clinical outcome.

THU-498

Safety and Efficacy of Atezolizumab-Bevacizumab in Non-Viral and Viral Etiologies of Hepatocellular Carcinoma: A Multicenter Retrospective Comparative Study

Anand Kulkarni[1], Karan Kumar[2], Mithun Sharma[1], Sameer Shaik[1], Sowmya Iyengar[1], Shantan Venishetty[1], Manasa Alla[1], Vivek Saraswat[2], Nagaraja Padaki[1], Nageshwar Reddy[1]. [1]*AIG Hospitals, Hyderabad, India;* [2]*Mahatma Gandhi Medical College, Jaipur, India*
Email: anandvk90@gmail.com

Background and aims: Atezolizumab-bevacizumab is the first-line approved drug for unresectable hepatocellular carcinoma (uHCC). There have been conflicting reports suggesting better efficacy of atezo-bev in patients with viral etiology than non-viral etiology due to altered microenvironment in non-viral etiology HCC. We aimed to assess the efficacy and safety of atezo-bev in non-viral and viral etiologies of HCC.

Method: In this multicenter retrospective study, patients who received atezo-bev between November 2020 and December 2023 were included. The primary objective was to compare the overall survival (OS), and the secondary was to compare the progression-free survival (PFS), radiological response rate based on mRECIST criteria, and adverse events among non-viral and viral HCC patients. Propensity-matched analysis (PSM) using multivariate logistic regression analysis was performed using SPSS ver.29.

Results: Eighty-one non-viral etiology (age-61 yrs; females-11.1%; MASH-82.7%) were compared with 52 viral etiology HCC patients (age-57 yrs; females-9.6%; HBV-75%). The proportion of patients with diabetes mellitus (52% vs. 15.4%) and hypertension (40.7% vs. 25%) were higher in the non-viral group. However, the proportion of non-cirrhotics (16% vs. 27%;P = 0.12) and the distribution of CTP class (A/B: 45.5%/54.5% vs. 39.5%/60.5%) was similar in both groups. Most patients were in BCLC C in both groups (86.7% vs. 79%). Twelve percent in non-viral group and 21.2% in viral group had received some form of prior locoregional therapy (LRT) (p = 0.13). On Kaplan Meier analysis, survival was 64.2% (95%CI, 52.7–74.5) in the non-viral group compared to 57.7% (95%CI, 43.2–71.3) in the viral group (p = 0.36). The median overall survival was 12.5 months (95%CI, 9.4–15.6) in non-viral group compared to 9 months (95%CI, 6.8–11.2) in viral group. The median PFS was 9 months (95%CI, 3.9–14.1) in non-viral group compared to 7 (5.2–8.8) months in viral group (p = 0.79). The cumulative overall response rate (32.1% vs. 32.7%; P = 0.94) and disease control rate (49.4% vs. 42.3%;P = 0.42) were similar among both groups. The incidence of adverse events was similar in both groups (64.1% vs. 53.8%; P = 0.24). After PSM, adjusted for age, diabetes, hypertension, non-cirrhosis, prior LRT, absence of portal vein thrombosis, and extrahepatic spread, 52 patients with viral etiology were matched with 39 patients with non-viral etiology HCC. There were no differences in OS, PFS, radiological response rate or adverse event rate even after PSM analysis.

Conclusion: Atezolizumab-bevacizumab is safe and effective in hepatocellular carcinoma, regardless of the etiology.

THU-499

Clinical efficacy of HAIC (FOLFOX) combined with tyrosine kinase inhibitors plus PD-1 inhibitors vs. HAIC combined with bevacizumab plus PD-1 inhibitors in the treatment of advanced hepatocellular carcinoma

Wenwen Zhu[1], Ningning Zhang[1], Wei Lu[1], Yiyan Zhang[1], Kaipeng Liu[1], Huiru Liu[1]. [1]*Tianjin Medical University Cancer Institute and Hospital, Department of Hepatobiliary Oncology, Liver Cancer Center, National Clinical Research Center for Cancer, Key Laboratory of Cancer Prevention and Therapy, Tianjin's Clinical Research Center for Cancer, Tianjin Medical University, Tianjin, China*
Email: zhuwenwenjc@163.com

Background and aims: Unresectable hepatocellular carcinoma (uHCC) still accounts for the majority of newly diagnosed HCC which with poor prognosis.Molecular targeted therapy combined

with immunotherapy significantly and hepatic arterial infusion chemotherapy (HAIC) can improve the prognosis of patients with advanced HCC. This study aimed to evaluate the clinical efficacy of HAIC combined with tyrosine kinase inhibitors (TKIs) and programmed cell death protein-1 (PD-1) inhibitors vs. HAIC combined with bevacizumab and PD-1 inhibitors in the treatment of unresectable hepatocellular carcinoma (HCC).

Method: We retrospectively reviewed data of 133 patients with uHCC treated with HAIC with TKIs and PD-1 inhibitors or HAIC with bevacizumab and PD-1 inhibitors in Tianjin Medical University Cancer Institute and Hospital from 2018 to 2021.The overall survival (OS) and progression-free survival were compared. For sensitivity analysis, inverse probability weighting (IPW) was used to balance the influence of the tested confounding factors between groups to verify the robustness of conversion surgery for survival benefits.

Results: A total of 133 patients were enrolled in this study, including 77 cases in the HAIC+TKIs+PD-1 group and 56 cases in the HAIC +bevacizumab+PD-1 group. The mOS of HAIC+TKIs+PD-1 group and HAIC+bevacizumab+PD-1 group were 24.00 months and NA, respectively ($p = 0.225$). The mPFS of the two groups were 11 and 15 months, respectively ($p = 0.756$). Surgical conversion rate of HAIC+TKIs+PD-1 group and HAIC+bevacizumab+PD-1 group were 37.5% (21/56) and 23.4% (18/77), respectively ($p < 0.05$). IPW-adjusted Kaplan-Meier curves showed that successful conversion surgery was an independent prognostic factor for both PFS and OS.

Conclusion: Compared with HAIC in combination with TKIs and PD-1 inhibitors, HAIC (FOLFOX) in combination with bevacizumab and PD-1 inhibitors can improve tumor response and be more likely to prolong OS, PFS in uHCC patients.

ISPA. FINBA., Oviedo, Spain; [13]Barcelona University, Barcelona, Spain*
Email: mreig1@clinic.cat

Background and aims: The combination of Atezolizumab +Bevacizumab (AB) and Tremelimumab+Durvalumab (TD) are first-line systemic treatments for hepatocellular carcinoma (HCC). Additionally, Durvalumab (D) and Lenvatinib demonstrated to be non-inferior to sorafenib. The aim of this study is to describe the profile of immune-related adverse events (irAE) that condition temporally treatment interruption (interruption) and/or discontinuation, as well as outcome after AB, TD or D.

Method: Patients (p) treated with first-line immunotherapy from two medical centres in Spain were assessed retrospectively. Demographic characteristics, the number and type of irAEs leading to treatment interruption or discontinuation, dates of irAEs' appearance, and reasons for interruption/discontinuation of AB, TD, or D, as well as the types of second-line treatments received, were all recorded. The irAE was defined as all those AE ≥grade II in which the relationship with AB, TD or D cannot be excluded.

Results: Of the 109 p included in the study, 83 p were treated with AB, 23 p with TD and 3 p with D. Among them, 52.3% were BCLC-C, 84.4% were Child-Pugh A and the remaining patients did not have cirrhosis. The median follow-up was 8.5 months [range 4.6–16.6], during this period 55 (50%) patients interrupted treatment due to irAE and 32 (29.4%) died, 2p (1.83%) for grade 5 irAE. The median time until the first irAE that led treatment interruption was 64 days [21–192] and 12.8% of patients developed it after the first dose of immunotherapy. The most frequent AEs were proteinuria (7p), diarrhea/colitis (5p), arterial hypertension (4p), myocarditis (4p) and encephalitis (4p). Of the total number of patients, 53.2% discontinued treatment: 22p due to due to symptomatic progression, 16p radiological progression, 15p AEs (not all irAEs), 1p by patient's decision and 4p for other reasons (3 for a second neoplasia and 1 for an unrelated death). Of those who discontinued treatments such as AB, TD, or D, 29.3% (17p) went on to receive second-line treatment, with 53% (9p) participating in second-line clinical trials.

Conclusion: Although 53.2% of patients discontinued the 1st line immunotherapy schemes, only in 13.8% of them was due to adverse events. The median time to the first adverse event that required treatment interruption was 64 days, and in 12.8% of the patients, this adverse event occurred after the first dose of immunotherapy. This data emphasizes the importance of establishing hospital networks for early detection and management of immune-related adverse events, ensuring timely access to experienced specialists.

THU-501

Safety and efficacy preliminary analysis of first-line systemic therapy with atezolizumab plus bevacizumab in Spanish patients with unresectable hepatocellular carcinoma not previously treated with systemic therapy: phase IIIb ATHECA trial

Email: mreig1@clinic.cat

Background and aims: Atezolizumab plus Bevacizumab (ATZ+BEV) was approved as first-line systemic treatment for advanced or unresectable hepatocarcinoma (HCC) after showing higher efficacy than sorafenib with manageable safety profile in the pivotal phase III trial IMbrave150. The aim of the ATHECA study was to evaluate the safety and efficacy of ATZ+BEV in Spanish pts with unresectable HCC

(uHCC) or unsuitable for locoregional treatments not previously treated with systemic therapy.
Method: Phase IIIb, one arm, multicenter, open label study of ATZ +BEV in pts with uHCC or unsuitable for locoregional treatments not previously treated with systemic therapy. This study evaluated 3-week intravenous cycles of ATZ+BEV (1200 mg+15 mg/kg). Inclusion criteria matched those of the IMbrave150 clinical trial, including prior upper endoscopy. Adverse Events (AEs) were considered for the safety analysis, while overall survival (OS), progression free survival (PFS), time to progression (TTP), duration of response (DOR), and objective response rate (ORR) were considered for the efficacy analysis. Here are presented data from a non-prespecified data cut-off in the study protocol and the study is still ongoing.
Results: 124 pts were screened in 26 Spanish centers and 100 pts were treated (85 males, median age 66 years) with ATZ + BEV. At the cut-off date the median follow-up was 18.5 months (mo), and the median treatments duration were 8.9 mo (ATZ) and 8.1 mo (BEV), 20 pts were still on treatment and 80 discontinued either BEV (80 pts) or ATZ (78 pts) mainly due to disease progression. Treatment Emergent AEs (TEAEs) grade ≥3 leading to treatment discontinuation were reported in 16% pts, (gastrointestinal haemorrhage, haemoperitoneum, intestinal perforation, intra-abdominal haemorrhage, oesophageal varices haemorrhage, increased blood bilirubin, increased hepatic enzyme, toxic nephropathy, proteinuria, dyspnoea, pleural effusion, immune-mediated hypothyroidism, hepatitis, abdominal sepsis, fall, and hepatic encephalopathy). Treatment related AE (TRAE) G3–4 occurred in 28% pts. The 7 TEAEs leading to death (1 each) were hepatitis (the only TRAE), abdominal sepsis, aspiration pneumonia, dyspnoea, pleural effusion, hemoperitoneum, jaundice and hepatic encephalopathy (these last two events occurred in the same patient). At this cut-off, 60.6% of pts remained alive, median OS (m OS) was not reached out. Median PFS was 10.9 mo (95% confidence interval (CI) 7.1–12.7), median TTP was 12.4 mo (95% CI 8.4 to 15.2), median DOR was 21.3 mo (95%CI 11.40-NA), and ORR was 26.6% (95%CI 18.7%–36.3%).
Conclusion: At this cut-off data, ATHECA preliminary safety data showed a TEAE profile similar to previous studies and consistent with the underlying disease and known safety profile of each agent, with a higher preliminary efficacy data in terms of OS, PFS, TTP, DOR, and a similar ORR compared to the IMbrave150 trial.

THU-502
Everolimus mitigates the risk of hepatocellular carcinoma recurrence after liver transplantation

Paolo De Simone[1], Arianna Precisi[2], Quirino Lai[3], Juri Ducci[2], Daniela Campani[1], Piero Marchetti[1], Stefano Gitto[4]. *[1]University of Pisa, Pisa, Italy; [2]Azienda Ospedaliero Universitaria Pisana, Pisa, Italy; [3]Azienda Ospedaliero Universitaria Pisana, PIsa, Italy; [4]University of Florence, Florence, Italy*
Email: paolo.desimone@unipi.it

Background and aims: To obtain long-term data on the use of everolimus in patients who underwent liver transplantation for hepatocellular carcinoma, we conducted a retrospective, single-center analysis of adult recipients transplanted between 2013 and 2021. Patients on everolimus-incorporating immunosuppression were matched with those on tacrolimus using an inverse probability of treatment weighting methodology.
Method: Two propensity-matched groups of patients were thus compared: 233 (45.6%) receiving everolimus versus 278 (54.4%) on tacrolimus.
Results: At a median (interquartile range) follow-up of 4.4 (3.8) years after transplantation, everolimus patients showed a reduced risk of recurrence versus tacrolimus (7.7% versus 16.9%; RR = 0.45; P = 0.002). At multivariable analysis, microvascular infiltration (HR = 1.22; P < 0.04) and a higher tumor grading (HR = 1.27; P < 0.04) were associated with higher recurrence rate while being within Milan criteria at transplant (HR = 0.56; P < 0.001), a successful pre-transplant downstaging (HR = 0.63; P = 0.01) and use of everolimus (HR = 0.46; P < 0.001) had a positive impact on the risk of post-transplant recurrence. EVR patients with earlier drug introduction (≤30 days; P < 0.001), longer treatment duration (p < 0.001), and higher drug exposure (≥5.9 ng/ml; P < 0.001) showed lower recurrence rates versus TAC.
Conclusion: Based on our experience, everolimus provides a reduction of the relative risk of hepatocellular carcinoma recurrence, especially for advanced-stage patients and those with earlier drug administration, higher drug exposure, and longer time on treatment. These data advocate for early everolimus introduction after liver transplantation to reduce the attrition rate consequent to chronic immunosuppression.

THU-503
Hepatocellular carcinoma in metabolic dysfunction-associated steatotic liver disease (MASLD): multicenter study comparing patients with or without underlying cirrhosis

Carole Vitellius[1], Elvire Desjonqueres[2], Marie Lequoy[3], Giuliana Amaddeo[4], Isabelle Fouchard[1], NKontchou Gisèle[2], Clémence M. Canivet[1], Marianne Ziol[2], Hélène Regnault[5], Adrien Lannes[1], Frédéric Oberti[1], Jerome Boursier[1], Nathalie Ganne-Carrié[2]. *[1]CHU Angers, Angers, France; [2]CHU Avicenne, Bobigny, France; [3]AP-HP, Saint-Antoine Hospital, Paris, France; [4]Henri Mondor University Hospital, Créteil, France; [5]Henri Mondor University Hospital, Créteil, France*
Email: carole.vitellius@chu-angers.fr

Background and aims: Despite its growing incidence, hepatocellular carcinoma (HCC) related to metabolic dysfunction-associated steatotic liver disease (MASLD) in non-cirrhotic liver remains poorly characterized. We compared the characteristics, management, survival, and trends of MASLD-related HCC in patients with or without underlying cirrhosis in a large multicenter cohort.
Method: 354 patients with MASLD-related HCC presented at the liver tumor meetings of four French university hospitals between 2007 and 2018 were included in the study. Data were extracted from the meetings' databases and from the French Birth and Death Registry.
Results: 124 HCC (35%) occurred in the absence of cirrhosis. HCC was diagnosed through screening in 60% of patients with cirrhosis, incidentally in 72% of patients without cirrhosis, and as expected more often by histology in non-cirrhotic patients (81% vs. 49% in cirrhotic patients, p < 0.001). Non-cirrhotic patients were older, had greater tumor burden ≥5 cm (55% vs. 28%, p < 0.001) but also better liver function than cirrhotic patients. Half the patients had a localized tumor stage (BCLC 0 or A) whether or not they had cirrhosis. In univariate analysis, non-cirrhotic patients showed better overall survival than those with cirrhosis did (p = 0.043). However, cirrhosis was not independently associated with overall survival, for which the independent predictors were age, liver function, tumor burden and BCLC classification. Non-cirrhotic patients underwent surgery more frequently than cirrhotic patients did (41% vs. 11%, p < 0.001), even in cases where the largest tumors were ≥5 cm (42% vs. 14%, p = 0.002) or there were four or more lesions (19% vs. 2%, p = 0.024). Among the cirrhotic and non-cirrhotic patients who underwent surgery, survival was not significantly different (p = 0.074). The cirrhosis/no cirrhosis ratio remained stable over the study period.
Conclusion: 35% of MASLD-related HCC occure in a non-cirrhotic liver. While they present poor prognostic factors (higher age and larger tumor), HCC related MASLD in non-cirrhotic liver benefit from more radical management thanks to preservation of liver function, thus probably accounting for the lack of significant difference in overall survival compared with patients with HCC on cirrhosis observed in multivariate analysis.

THU-514

Outcomes of ultrasound-guided artificial ascites induction to facilitate radiofrequency ablation for hepatocellular carcinoma in high-risk positions

Ahmed Hashim[1], Sofia Maria Bakken[1], Fabio Piscaglia[1], Carla Serra[1].
[1]*IRCCS Azienda Ospedaliero Universitaria di Bologna, Bologna, Italy*
Email: ahmed.hashim@nhs.net

Background and aims: The induction of artificial ascites (or hydrodissection) can potentially be effective in reducing injury to adjacent anatomical structures during radiofrequency ablation (RFA) for hepatocellular carcinoma (HCC) lesions in anatomically high-risk sites. We aimed to evaluate the outcomes of an ultrasound (US)-guided dissection technique to facilitate RFA for such lesions.
Method: Our technique involved the injection of 5% dextrose into the peritoneal space to create a non-target organ gap before undertaking RFA under ultrasound guidance. We retrospectively reviewed the records of all patients who received this technique between December 2013 and March 2021 at the Policlinico St. Orsola Malpighi, Bologna.
Results: A total of 134 procedures were undertaken for 95 patients over the study period. The mean age of the cohort was 68 (SD = 11); 72 (76%) were males. The majority of patients had viral hepatitis (B or C) = 69/95 (73%). Cirrhosis was evident in 87/95 (92%) with 83 (87%) being Barcelona Clinic Liver Cancer (BCLC) stage 0/A. The mean Model For End-Stage Liver Disease (MELD) score was 9.7 (SD = 2.9, n = 92) and the median alpha-fetoprotein was 3.9 ng/ml (IQR = 13.7, n = 78). HCC was diagnosed primarily on imaging criteria alone; only two were confirmed on liver biopsy. At the time of ablation, the majority of HCC lesions treated (n = 134) were new (92), 41 being recurrent and 1 was a completion treatment. Artificial ascites was successfully induced by injecting an average of 232mls (SD = 180) of 5% dextrose and the median duration of RFA treatment was 11 mins (IQR = 6) using a median power of 157W (IQR = 25). Of the 134 procedures, the target lesion was located in segments: 6 (adjacent to the colon, n = 30); 7and8 (adjacent to diaphragm, n = 36); 5 (adjacent to the gallbladder, n = 20); 2and3 (adjacent to the stomach, n = 37), other (n = 11). Procedure-related pain was controlled with simple analgesia in 115/134 cases. Early complications (within 48 hours) occurred in 23/134 (17%) procedures; the vast majority of which were minor with 3 cases recording a hematoma, 1 hepatic insufficiency, and 1 pneumothorax. Fourteen required prolonged hospital stay. On follow-up, progression of the HCC nodule treated was observed in 39/134 (29%) cases at a median duration of 6 (IQR = 9) months post-procedure.
Conclusion: Our work demonstrates that US-guided percutaneous RFA using artificial ascites for treating HCC in difficult anatomical locations is feasible and effective with a good safety profile.

THU-515

Impact of varices on bleeding risks and overall survival in unresectable hepatocellular carcinoma treated with atezolizumab plus bevacizumab

Jeayeon Park[1], Dong Ho Lee[2], Moon Haeng Hur[1], Yun Bin Lee[1], Eun Ju Cho[1], Jeong-Hoon Lee[1], Yoon Jun Kim[1], Jung-Hwan Yoon[1], Su Jong Yu[1]. [1]*Department of internal medicine and liver research institute, Seoul National University College of Medicine, Seoul, Korea, Rep. of South;* [2]*Department of Radiology, Seoul National University College of Medicine, Seoul, Korea, Rep. of South*
Email: ydoctor2@snu.ac.kr

Background and aims: The IMbrave150 trial has led first-line systemic therapy for unresectable hepatocellular carcinoma (HCC) to include immunotherapy, remarkably improving life expectancy. However, the use of atezolizumab plus bevacizumab is often challenged due to the increased risk of bleeding. In this study, we aimed to identify factors associated with bleeding events during the treatment with atezolizumab plus bevacizumab, as well as factors that affect overall survival (OS).
Method: We retrospectively included consecutive patients who treated with atezolizumab plus bevacizumab as first-line systemic therapy for unresectable HCC from October 2020 to December 2022 at a tertiary referral center. Primary end point was the incidence of the first bleeding event during treatment. Secondary end point included OS.
Results: A total of 124 patients were included: 82 had varices found on either esophagogastroduodenoscopy (EGD) or computed tomography (CT) (EGD only, n = 3; CT only, n = 46; and both EGD and CT, n = 33; varices group), while 42 showed no varices on both EGD and CT (no varices group). Prior to treatment with atezolizumab plus bevacizumab, no high-risk varices were noted. During the median follow-up duration of 11.1 months (interquartile range, 6.1–14.9), bleeding events occurred in 15 patients. The cumulative incidence of bleeding in the varices group was 12.5%, 21.1%, and 31.0% at 6, 12, and 18 months, respectively, significantly higher than the 0.0% incidence at the corresponding time points in the no varices group (p = 0.003). In addition, the presence of varices was identified as the only significant predictor of bleeding events on multivariate Cox model (adjusted hazard ratio [aHR], 13.56; p = 0.006). However, the median OS was similar between the two groups (11.6 months in the varices group versus 11.8 months in the no varices group), with no significant difference in OS based on the presence of varices (aHR, 0.92; p = 0.74). Baseline PIVKA level ≥1000 mAu/ml (aHR 1.98; p = 0.007) and neutrophil to lymphocyte ratio ≥3 (aHR 1.77; p = 0.01) were significant predictors of OS.
Conclusion: The presence of varices on baseline imaging study was significantly associated with an increased risk of bleeding events during treatment with atezolizumab plus bevacizumab, although the OS was similar regardless of the presence of varices.

THU-516

Beneficial effect of combined radiation therapy in atezolizumab plus bevacizumab treatment of hepatocellular carcinoma patients with main portal vein tumor thrombosis

Sangyoun Hwang[1], Hyun Young Woo[2], Jeong Heo[2], Hyung Jun Kim[1], Young Joo Park[2], Kiyoun Yi[2], Yu Rim Lee[3], Soo Young Park[4], Woo Jin Chung[5], Byoung Kuk Jang[5], Won Young Tak[4]. Email: jheo@pusan.ac.kr

Background and aims: Atezolizumab (ATE) plus bevacizumab (BEV) was established as the first-line therapy for patients with advanced hepatocellular carcinoma (HCC) through phase 3 clinical trial. However, survival is still poor in HCC patients with main portal vein tumor thrombosis.
Method: This is a multicenter retrospective study. Between January 2020 to June 2022, 215 patients treated for advanced HCC with at ATE +BEV from four tertiary hospital was analyzed. Among them, 70 patients had vp4 portal vein tumor thrombosis. Tumor response was evaluated with the Response Evaluation Criteria in Solid Tumors (version 1.1.).
Results: Among 70 patients with Vp4 portal vein tumor thrombosis, Child-Pugh class was A in 57 (81.5%) and B in 13 (18.5%). 45 (64.3%) received neoadjuvant or concomitant radiation treatment. Baseline characteristics did not differ significantly with or without radiation. In overall, objective response rate was 24.3%. disease control rate was 75.7%. The median progression free survival (PFS) was 7.75 months

(95% CI, 5.71–9.79) and median overall survival (OS) was 9.25 months (95% CI, 7.76–10.74). In multivariate analysis, bile duct invasion, preemptive or concomitant radiation therapy and Hb level was significant prognostic factor for survival and progression free survival. Median OS was 10 months (95% CI, 7.85–12.15) in patients with radiation and 7.75 months (95% CI, 3.47–12.03) in patients without radiation. Median PFS was 9.25 months (95% CI, 7.91–10.59) in patients with radiation and 5.00 months (95% CI, 2.23–7.77) in patients without radiation. A total of 58 (82.9%) patients experienced any grade of adverse events (AEs). The most common AEs was proteinuria (14.8%). The rate of grade 3 or higher AE is similar in patients with or without radiation (18.2% vs. 16.7%).
Conclusion: ATE+BEV treatment was tolerable in patients with Vp4 portal vein tumor thrombus. Furthermore, radiation therapy could improve the OS and PFS in these patients.

THU-517

Off-label use of nivolumab beyond first-line in advanced hepatocellular carcinoma: experience from two international centres

Silvia Gaia[1], Francesco Frigo[2], Najib Ben Khaled[3], Gian Paolo Caviglia[4], Emanuela Rolle[1], Ignazio Piseddu[3], Paolo Pochettino[5], Enrico de Toni[3], Matilde Scaldaferri[1], Francesco Cattel[1], Eleonora Castellana[1], Alberto De Giorgi[6], Giorgio Maria Saracco[4], Patrizia Carucci[1]. *[1]AOU Città della salute e della scienza di Torino, Turin, Italy; [2]AOU Città della salute e della scienza di Torino, Turin; [3]University Hospital, LMU Munich, Munich, Germany; [4]University of Turin, Turin, Italy; [5]AOU Città della salute e della Scienza di Torino, Turin, Italy; [6]University of Turin, Turin*
Email: silvia.gaia74@gmail.com

Background and aims: Investigational use of nivolumab as first-line therapy for the treatment of hepatocellular carcinoma (HCC) yielded promising results but failed to demonstrate a statistically significant overall survival (OS) advantage compared to sorafenib. The aims are to evaluate the efficacy and safety of nivolumab as monotherapy beyond first-line in patients with HCC ineligible for other treatments.
Method: we retrospectively analyzed data from 30 HCC patients receiving off-label nivolumab at two referral centers in Italy and Germany between May 2016 and December 2023. Enrolled patients were ineligible for local or surgical therapy, had disease progression or intolerance to prior tyrosine kinase inhibitors therapy, and were not candidates for other systemic therapies. Measured outcomes were overall survival (OS), progression-free survival (PFS), disease control rate (DCR), and biological response (BR), defined as an ≥25% decrease in alpha-fetoprotein (AFP) levels after 3 months of therapy. The safety profile of nivolumab was assessed.
Results: 30 patients were enrolled (Italy n = 24, Germany n = 6). Patient characteristics were as follows: median age 65 (range 30–82) years, Child-Pugh A 80%, BCLC C 87%, viral etiology 83%. One patient received nivolumab as I-line (ineligible for any other therapy), 19 as II-line, 8 as III-line, and 2 as IV-line of systemic treatment. Median OS was 9.1 (95%CI 6.4–14.2) months and median PFS was 3.5 (95%CI 2.8–6.4) months. DCR at 3 months was 27% (8/30) with two patients achieving complete radiologic response after 12 and 21 months of therapy. BR was obtained in 23% (7/30) of patients. Median OS in patients with radiological disease control at 3 months was 27.7 (95% CI 4.7–41.2) months compared to 7.3 (95%CI 4.0–9.1) months in patients with disease progression ($p < 0.001$). Median OS in patients with BR was 38.0 (95%CI 23.5–41.2) months compared to 7.8 (95%CI 3.6–12.1) months in patients without BR ($p < 0.001$). At baseline, better performance status, presence of metastatic lymph nodes, serum AFP ≥400 μg/L, and lower disease burden were associated with longer OS on univariate analysis (all $p < 0.05$). Ten patients (33%) experienced grade 3–4 adverse events, but only three cases (10%) were deemed treatment-related. Only one patient had to discontinue therapy due to adverse events.
Conclusion: nivolumab could represent a valuable option in patients without other therapeutic alternatives, showing an OS greater than 6 months in 73% of patients and an acceptable safety profile. Radiological response and BR at 3 months predict a significantly longer survival.

THU-518

Analysis of varix bleeding after Atezolizumab plus Bevacizumab for advanced hepatocellular carcinoma patients

Ahlim Lee[1,2], Hee Yeon Kim[3]. *[1]Division of Gastroenterology, Department of Internal Medicine, St. Vincent's Hospital, College of Medicine, The Catholic University of Korea, Suwon, Korea, Rep. of South; [2]The Catholic University Liver Research Center, College of Medicine, The Catholic University of Korea, Seoul, Korea, Rep. of South; [3]Division of Gastroenterology, Department of Internal Medicine, Bucheon St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Bucheon, Korea, Rep. of South*
Email: hee82@catholic.ac.kr

Background and aims: After the IMbrave150 trial, atezolizumab plus bevacizumab (AteBeva) became the gold standard for unresectable hepatocellular carcinoma (HCC). However, since this trial included well-selected patients without any history of acute variceal bleeding (AVB) nor high-risk esophageal varices, real-world data from advanced HCC patients with any history of AVB or large varices were unknown under this new combination of treatment. We aimed a study to provide real-life data on the therapeutic effect and the safety of AteBeva and to identify risk factors of AVB during treatment in Korea.
Method: We conducted a prospective study including all patients diagnosed with advanced HCC and received AteBeva from seven centers of Catholic Medical Center between September 2020 to December 2022. We followed up on these patients until December 2023 and analyzed therapeutic efficacy and safety, especially AteBeva-related variceal bleeding. Time-to-events were estimated by Kaplan-Meier with the log-rank test, along with Cox models.
Results: One hundred fifty-four patients treated with AteBeva were included. In baseline characteristics, the median age was 64.0 (56.0–73.0), the male sex was 85.1%, the most common etiology was hepatitis B virus infection (62.2%) and alcohol-related liver disease (26.5%). Child-Pugh class was A or B, and Barcelona Clinic Liver Cancer (BCLC) stage was B or C. The Objective response rate (ORR) of AteBeva was 38.3% and the Disease control rate (DCR) was 70.9%. Median overall survival (OS) 14.000 ± 2.788 (95% CI: 8.536–19.464), median progression-free survival 5.000 ± 0.570 (3.882–6.118), median time-to progression (TTP) was 3.000 ± 0.352 (2.310–3.690). In multivariable analysis, variables associated with OS were the Eastern Cooperative Oncology Group (ECOG) performance scale, liver cirrhosis, Child-Pugh class, largest intrahepatic tumor size, and treatment duration. The patient underwent all grades of gastrointestinal bleeding events after AteBeva was 40 (26.0%), varix bleeding was 23 (14.9%), and 18 (11.7%) received endoscopic band ligation (EBL). In multivariable analysis, variables associated with varix bleeding after AteBeva were Child-Pugh score and ulceration from prophylactic EBL before AteBeva.
Conclusion: In this study, the most common adverse event after AteBeva was all grades of gastrointestinal bleeding events. Risk factors for varix bleeding after AteBeva were Child-Pugh score at baseline and ulceration from prophylactic EBL before AteBeva. Therefore, for patients with prophylactic EBL before AteBeva, ulceration monitoring and management are needed after EBL. Further studies on large scale are needed.

Surgical outcomes of laparoscopic versus open liver resection for intrahepatic cholangiocarcinoma: Multicenter study

Jongman Kim[1], Gi Hong Choi[2], Je Ho Ryu[3], Dong-Sik Kim[4], Hae Won Lee[5], Ki-Hun Kim[6]. *[1]Samsung Medical Center, Seoul, Korea, Rep. of South; [2]Yonsei University College of Medicine, Seoul, Korea, Rep. of South; [3]Pusan National University College of Medicine, Busan, Korea, Rep. of South; [4]Korea University College of Medicine, Seoul, Korea, Rep. of South; [5]Seoul National University Bundang Hospital, Seongnam, Korea, Rep. of South; [6]Asan Medical Center, Seoul, Korea, Rep. of South*
Email: yjongman21@gmail.com

Background and aims: Laparoscopic liver resection (LLR) remains controversial in the treatment of intrahepatic cholangiocarcinoma (IHCCC). The aim of the present study is to investigate the outcomes of LLR for IHCCC compared to open liver resection (OLR).
Method: We retrospectively reviewed patients who underwent hepatectomy for IHCCC from six medical centers between January 2013 and February 2020. During the study period, 616 patients met the inclusion criteria (OLR = 514 patients and LLR = 102 patients).
Results: The median operation time and median blood loss in the LLR group were significantly shorter and less blood loss than in the OLR group. In addition, the incidence of sever postoperative complications in the LLR group was significantly less than in the OLR group. The cumulative disease-free survival and overall survival are comparable between the two groups. Multivariate analyses showed that multiple tumors, R1 resection, intrahepatic metastasis, and metastatic lymph node were predisposing factors for tumor recurrence. Increased age, long operation time, and multiple tumors were closely associated with mortality.
Conclusion: The present study suggests that LLR should be considered in selective IHCCC because of better postoperative short outcomes and comparable disease-free survival and overall survival compared with OLR group.

Email: alfredo.marchetti@unimi.it

Background and aims: Metabolic dysfunction associated steatotic liver disease (MASLD) is a global epidemic and is the most rapidly rising cause of hepatocellular carcinoma (HCC). Clonal hematopoiesis of indeterminate potential (CHIP) contributes to neoplastic and cardiometabolic disorders and is considered a harbinger of tissue inflammation. CHIP was recently associated with increased risk of liver disease. The aim of this study was to examine whether CHIP is associated with HCC development in patients with SLD.
Method: We considered individuals with MASLD-HCC (n = 208) and controls with (n = 414) and without (n = 259) advanced fibrosis who underwent whole exome sequencing. DNA was extracted from peripheral blood and sequenze by the HiSeq 4000/NextSeq2000 platforms (Illumina). Somatic mutations were identified accepting a minimum variant coverage of 20, a minimum alternative allele count of 3 and a variant allele frequency (VAF) between 0.02 and 0.46. Variants with a population mean allelic frequency higher than 1 in a 1000 were treated as polymorphisms. Variants were then curated to include only variants known to be somatic and associated to either malignancy or CHIP with the use of a semi-automatic pipeline. Age, sex, presence of type 2 diabetes (T2D), advanced liver fibrosis, AST and ALT levels at the time of study enrolment were available in all patients.
Results: CHIP was observed in 116 participants (13.1%), most frequently in DNMT3A (DNA methyltransferase 3 alpha), TET2 (Tet methylcytosine dioxygenase 2), TP53 (tumor protein 53) and ASXL1 (additional sex combs like 1) genes, and correlated with age ($p < 0.0001$) and advanced liver fibrosis ($p = 0.001$). Higher AST levels predicted non-DNMT3A-CHIP, in particular with VAF ≥10% (OR 1.14, 1.03–1.28 and OR 1.30, 1.12–1.49, respectively, $p < 0.05$). After adjustment for sex, diabetes and a polygenic risk score of inherited MASLD predisposition CHIP was associated with cirrhosis (2.00, 1.30–3.15, $p = 0.02$), and with HCC even after further adjustment for cirrhosis (OR 1.81, 1.11–2.00, 1.30–3.15, $p = 0.002$). Despite the strong collinearity among aging and development of CHIP and HCC, non-DNTM3A-CHIP and TET2 lesions remained associated with HCC after full correction for clinical/genetics covariates and age (OR 2.45, 1.35–4.53; OR 4.8, 1.60–17.0, $p = 0.02$).
Conclusion: We observed an independent association between CHIP, particularly related to non-DNTM3A and TET2 genetic lesions, and MASLD-HCC.

TOP-307

The interplay between alcohol consumption and cardiometabolic risk factors in patients with MASLD and MetALD

Yee Hui Yeo[1], Fajuan Rui[2], Yixuan Zhu[3], Xiaoming Xu[4], Xiaoyan Ma[3], Wenjing Ni[5], Xinyu Hu[6], Chao Wu[3], Junping Shi[7], Jie Li[3], Philip N. Tower Hospital Clinical College of Nanjing University of Chinese Medicine, Nanjing, China; [5]Nanjing Drum Tower Hospital Clinical College of Traditional Chinese and Western Medicine, Nanjing, China; [6]Department of Infectious Disease, Shandong Provincial Hospital, Shandong University, Jinan, China; [7]The Affiliated Hospital of Hangzhou Normal University, Hangzhou, China; [8]Centre for Liver and GI Research, Birmingham, United Kingdom
Email: p.n.newsome@bham.ac.uk

Background and aims: The synergistic impact of incremental alcohol consumption and cardiometabolic risk factors on the prognosis of patients with metabolic dysfunction-associated steatotic liver disease (MASLD) and metabolic and alcohol-associated liver disease (MetALD) remains unclear. Herein, we aimed to investigate the interplay between varying levels of alcohol consumption and the number of cardiometabolic risk factors (CMRFs) on all-cause mortality in patients with MASLD and MetALD.
Method: Adult participants who underwent ultrasound between 1988 and 1994 were identified from a population-representative cohort, NHANES III. Those with MASLD or MetALD were categorized based on their CMRF count (one, two, or three to five) and alcohol consumption: 0–10/15 g of alcohol/day 0–10/15 g of alcohol/day for females/males (F/M), 10/15–20/30 g/day, and 20/30–50/60 g g/day. Multivariate Cox proportional hazards models were conducted to investigate the association between incremental CMRFs and alcohol consumption and mortality, with adjustment for age, sex, race, and poverty income ratio.
Results: During a median follow-up period of 47, 046 person-years, 695 (36.1%) died during this period. The adjusted hazard ratios (aHR) for all-cause mortality showed a stepwise increase with higher levels of alcohol consumption and a greater number of CMRFs. However, statistical significance was only observed in the subgroup with 3–5 CMRFs and alcohol consumption levels greater than 10/15 g/day (F/M). Subgroup analysis by age was performed. For those aged <65 years, the effect of CMRFs and alcohol use was more prominent. Specifically, compared to one CMRF, the aHRs was 1.08 (95%CI: 0.68–1.73) for 2 CMRFs and 2.92 (95%CI: 1.95–4.39) for 3 to 5 CMRFs among participants with 0–10/15 g/day alcohol use. For those who drink 10/15–20/30 g/day, aHRs were 1.05 (95%CI: 0.43–2.57) for one CMRF, 2.06 (95%CI: 1.14–3.73) for two CMRFs, and 3.89 (95%CI: 2.44–6.21) for three to five CMRFs. A synergistic effect between alcohol use and CMRFs was shown, with the aHR peaking at 5.17 (95%CI: 3.20–8.37) for those drinking 20/30–50/60 g/day and with 3–5 CMRFs. Conversely, participants aged ≥65 years displayed no significance in any combination of CMRFs and alcohol use, compared to those with one CMRF and minimal alcohol intake.
Conclusion: We found a significant synergistic effect on mortality risk between CMRFs and alcohol consumption in participants with MASLD and MetALD, particularly in those younger than 65 years. This study has implications for managing modifiable risk factors among those with steatotic liver disease.

TOP-308
Steatotic liver disease subclasses have prognostic relevance for liver-related outcomes in the general population

Ville Männistö[1,2], Veikko Salomaa[3], Antti Jula[3], Annamari Lundqvist[3], Satu Männistö[3], Markus Perola[3], Fredrik Åberg[4]. *[1]Kuopio University Hospital, Kuopio, Finland; [2]University of Eastern Finland, Kuopio, Finland; [3]Finnish Institute for Health and Welfare, Helsinki, Finland; [4]Helsinki University Hospital, Helsinki, Finland*
Email: ville.mannisto@kuh.fi

Background and aims: Steatotic liver disease (SLD) is the most common chronic liver disease. The primary objective of this study was to validate the prognostic relevance of the recently proposed SLD subclasses in a Finnish population-based sample. We also evaluated the relevance of number of metabolic disturbances and the level of alcohol use for liver-related outcomes in SLD subclasses.
Method: A total of 27383 individuals (46% men, mean age 50.8 ± 14.3 years, BMI 27.0 ± 4.8 kg/m^2) with registry linkage available were included from Finnish population based FINRISK 2002, 2007, 2012 and Health 2000 studies. SLD was diagnosed as ALT >20 U/l for female and >30 U/l for male. In sensitivity analyses, fatty liver index (FLI) >60 was used. Incident severe liver-related outcomes and non-liver death were identified through linkage with national registries for hospitalization, cancer, or death.
Results: A total of 10380 (43%) individuals in the study cohort had SLD. The overall prevalences of the SLD subclasses were 34.5% for metabolic-dysfunction associated steatotic liver disease (MASLD), 4.2% for co-existent MASLD and alcohol-related liver disease (ALD), i.e. MetALD, and 1.8% for ALD, respectively. During the median follow-up of 13.3 ± 4.7 years, a total of 129 liver-related events were observed (65 in MASLD group, 34 in MetALD group and 30 in ALD group). The absolute cumulative incidences for liver-related outcomes and non-liver death were highest in the ALD group followed by MetALD and MASLD groups. Those with MetALD had 4-fold (HR 3.92, 95% CI 2.56–6.02, p < 0.001) and those with ALD 8-fold (HR 8.08, 95% CI 5.16–12.65, P < 0.001) increase in liver-related outcomes compared to those with MASLD in age- and sex-adjusted Cox regression analysis. Metabolic risk factors were present in 93% and 96% of individuals with SLD or ALD, respectively. The number of metabolic risk factors was significantly associated with liver-related outcomes in MASLD. Furthermore, alcohol use within the limits of MASLD diagnosis increased the risk of liver-related outcomes. The sensitivity analyses using FLI as a marker of SLD provided similar results as our primary analyses.
Conclusion: The prevalence of SLD is considerable high in the general population. Individuals with ALD exhibit the highest risk for both liver-related outcomes and non-liver death when compared to those with MASLD and MetALD, and the prevalence of metabolic disturbances is notably high in individuals with ALD. Alcohol use amplifies the risk of liver-related outcomes in individuals with MASLD.

TOP-309
Identifying patient characteristics associated with the risk of long-term liver and cardiovascular outcomes and high healthcare costs in metabolic dysfunction-associated steatohepatitis: a retrospective cohort analysis using an artificial intelligence model

Kamal Kant Mangla[1], Semiu Gbadamosi[2], Daniel Semeniuta[3], Benjamin Soule[2], Helene Nordahl[1], Jigar Bandaria[3], Joseph Zabinski[3], Gary Curhan[3], Costas Boussios[3]. *[1]Novo Nordisk A/S, Søborg, Denmark; [2]Novo Nordisk Inc., Plainsboro, United States; [3]OM1 Inc., Boston, United States*
Email: kknm@novonordisk.com

Background and aims: Significant heterogeneity in non-alcoholic steatohepatitis (NASH; also termed metabolic dysfunction-associated steatohepatitis [MASH]) complicates efforts to identify individuals with high unmet need and in need of better management. We used artificial intelligence (AI) phenotyping to identify factors associated with risks of long-term outcomes and high healthcare costs.
Method: Patients diagnosed with NASH between Oct 1, 2015 and Jun 17, 2022 were identified in the OM1 Real-World Data Cloud, a US electronic medical records and claims dataset. The index date was the date of first NASH diagnosis. Core eligibility criteria were a Fibrosis-4 record within 90 days of index, sufficient follow-up data, and no other liver conditions. The AI-based PhenOM™ platform (OM1 Inc., Boston, MA, USA) grouped characteristics from patients' histories (including diagnoses, procedures, and medications) into themes. Using machine learning, these groupings were iteratively refined and evaluated for strength of association with each outcome and clinical plausibility. Cirrhosis and related liver outcomes were assessed in a 'non-cirrhotic' cohort with no evidence of clinical cirrhosis pre-, at, or 6 months post-index. Liver-related outcomes other than cirrhosis were

assessed in a 'cirrhotic' cohort with clinical cirrhosis pre- or at index. Cardiovascular (CV) outcomes were assessed in a 'non-CV' cohort with no evidence of a CV-related outcome pre- or at index. Factors associated with incurring mean annual healthcare costs in the highest decile were also identified.
Results: In total, 37, 309 patients met the core eligibility criteria. In the non-cirrhotic cohort (n = 12, 555), the strongest factors associated with liver-related outcomes were chronic diseases, kidney issues, and heart issues. In the cirrhotic cohort (n = 807), key factors were medication for coronary heart disease, blood pressure, and type 2 diabetes. In the non-CV cohort (n = 12, 566), the strongest factors associated with CV-related outcomes were CV history (other than outcomes of interest), hypertension, atherosclerosis, atrial fibrillation, kidney issues, diabetes, anaemia, osteoarthrosis, and metabolic issues. In the healthcare cost analysis (n = 10, 133), key factors associated with incurring the highest healthcare costs were myocardial infarction, heart failure, kidney issues, gastrointestinal issues, abdominal imaging, and other chronic comorbidities including diabetes, hypertension, anaemia, and chronic kidney disease.
Conclusion: This study identified factors meaningfully associated with clinical and economic outcomes in NASH, demonstrating the application of AI phenotyping to multidimensional real-world data. The results potentially provide evidence to identify patients in clinical practice, via predictive modelling, who would benefit from closer monitoring and management.

Genetic determinants of disease progression in metabolic dysfunction-associated liver disease patients unresponsive to lifestyle intervention: implications for personalized medicine

Aruhan Yang[1], Xiaoxue Zhu[1], Qiang Yang[2], Xiao Teng[3], Yanhua Ding[4].
[1]Phase One Clinical Research Center, First Hospital of Jilin university, Changchun, China; [2]Hangzhou Choutu Technology Co., Ltd., Hangzhou, China; [3]HistoIndex Pte Ltd, Singapore, Singapore, Singapore; [4]Phase One Clinical Research Center, First Hospital of Jilin University, changchun, China
Email: arh22@mails.jlu.edu.cn

Background and aims: Lifestyle intervention with 5% weight loss (WL) is the primary approach for managing MASLD. Identifying genetic traits in non-responders may pave the way for personalized pharmacotherapy in this population.
Method: In this study with 724 participants, 146 had liver biopsies. All participants completed questionnaires, blood tests, and MRI-PDFF assessments. Genetic sequencing was performed on collected blood samples, and SHG/TPEF microscopy with computer-assisted analysis was used for pathological specimens. Patients with liver biopsies received lifestyle interventions, while others received health education. MASLD was diagnosed based on new criteria, and disease regression was assessed by comparing two sets of pathological (NAS reduction ≥2 points) or MRI findings (Liver Fat Content, LFC reduction ≥30%).
Results: In this 12-month study, 145 (99%) and 602 (83%) participants were diagnosed with MASLD via liver biopsy and MRI-PDFF, respectively. In individuals achieving MASLD remission (N = 213, 35.3%), significant improvements in liver damage markers (ALT, AST, GGT) and metabolic parameters (Glucose, Insulin, HOMA, LDL, TG) were observed, highlighting enhanced hepatic health and glucose-lipid metabolism. Genetic analysis in the whole cohort revealed significant effects of VPS8 (rs1011147, T >C) and DPP6 (rs144355748, G >A) mutations on disease progression (LFC changes for wild-type vs. mutant: −9.2% vs. 0.3% and −6.5% vs. 0.7%, respectively). After adjusting for lifestyle factors (smoking, alcohol, physical activity, sedentariness), mediation analysis found 25% of the gene's effect on improving MASLD was indirectly mediated through WL >5%, while the remaining 75% represents the direct influence of the gene independent of WL >5%. MASLD patients achieving over 5% WL (N = 200) showed an average 34% LFC reduction and 2 points NAS reduction, supported by digital pathology showing significant decreases in most steatosis markers (Area: −9.7; Area PT: −6.6; ABubblePT: −55.7) and some fibrosis-related markers (Str: −7.7, StrLenthPS: −7093), indicating notable improvements in fat content and select fibrosis-related measures. However, 52 individuals with WL >5% (26%) didn't achieve remission. 28 SNPs affecting MASLD regression were identified among the WL >5% group, and GRS scores calculated. Low GRS individuals displayed more improvement in fibrosis (dStrLength: −3.6 vs. 191.5; dSHG: −0.2 vs. 2.8) and steatosis (dArea: −24.5 vs. 5.6; dABubble: −168.2 vs. 58.6; dAreaCV: −14.1 vs. 14.4) compared to high GRS individuals. Functional enrichment analysis revealed a focus on the RISC complex, RNAi effector complex, and Estrogen signaling pathway for these genes.
Conclusion: Our study underscores the role of genetic traits in determining disease progression in MASLD patients resistant to 5% weight loss, pointing towards personalized medicine possibilities.

Email: maurice.michel@icloud.com

Background and aims: With the implementation of the new nomenclature on steatotic liver disease (SLD), three main subgroups consisting of metabolic dysfunction-associated liver disease (MASLD), MASLD with increased alcohol intake (MetALD), and alcohol-related liver disease (ALD) have been defined. However, the risk of SLD for all-cause mortality and adverse outcomes as well as the different risks between MASLD, MetALD, and ALD needs further clarification.
Method: Data from 13, 599 participants without cancer of the population-based Gutenberg Health Study (baseline enrollment between 2007 and 2012) were cross-sectionally and prospectively analysed. The fatty liver index (FLI) with a score of ≥60 was used to define SLD. The subgroups of SLD (MASLD, MetALD, and ALD) were defined according to the new nomenclature based on five cardiometabolic criteria and alcohol consumption. The fibrosis-4 score (FIB-4)

was calculated to determine patients at risk of fibrosis (≥1.3). All-cause mortality (10-year follow-up) and several adverse outcomes (hepatic decompensation, major adverse cardiac events (MACE), extrahepatic cancer) were analysed and compared across the subgroups of SLD. Cox regression models were used to estimate adjusted hazard ratios (aHR) and their 95% confidence intervals (CIs). Adjustments were made for age, sex, socioeconomic status, education, and smoking.

Results: The overall prevalence of SLD was 37.3% (n = 5, 074), whereas the prevalence of MASLD, MetALD, and ALD were 30.5% (n = 4, 154), 5.3% (n = 717) and 1.5% (n = 202), respectively. Almost half of the population were women (48.9%, n = 6, 644), and the mean age was 54.3 (±11.0) years. An elevated FIB-4 ≥1.3 was present in 20.2% (n = 1, 021) with SLD compared to 13.9% (n = 1, 184) without SLD ($p < 0.0001$). The cumulative incidence of all-cause mortality was higher in SLD and all its subgroups MASLD, MetALD, and ALD compared to no SLD ($p < 0.0001$). Stratification by FIB-4 ≥ 1.3 revealed a higher risk of all-cause mortality across all investigated SLD subgroups compared to FIB-4 < 1.3 ($p < 0.0001$). Each subgroup of SLD was associated with a higher risk of all-cause mortality: MASLD (aHR 1.6, 95% CI 1.4–1.9, $p < 0.0001$), MetALD (aHR 1.6, 95% CI 1.3–2.1, $p = 0.00024$) and ALD (aHR 1.6 95% CI 1.0–2.5, $p = 0.033$). The risk of adverse outcomes was increased in MASLD (hepatic decompensation: aHR 1.2, 95% CI 1.0–1.5, $p = 0.0045$; MACE: aHR 1.5, 95% CI 1.2–1.8, $p < 0.0001$; extrahepatic cancer: aHR 1.2, 95% CI 1.1–1.4, $p = 0.0086$), whereas no differences were seen for MetALD and ALD.

Conclusion: The prevalence of SLD and especially MASLD is high in the general population. Patients with SLD and any of its three main subgroups show a higher risk of all-cause mortality, whereas the risk for adverse outcomes is particularly increased in those with MASLD. These results highlight the importance of screening for SLD and related risk factors to improve outcomes.

FRI-195

Genetically determined circulating protein biomarkers and risk of advanced fibrosis

Jun Wang[1], Gabriel Cuellar-Partida[1], Robert W. Read[2], Karen A. Schlauch[2], Gai Elhanan[3], W. James Metcalf[3], Lisa Boyette[1], Timothy R. Watkins[4], Joseph J. Grzymski[3], Scott D. Patterson[1], Shahed Iqbal[1], Andrew N. Billin[1]. *[1]Gilead Sciences, Inc., Foster City, United States; [2]University of Nevada, Reno, United States; [3]University of Nevada, Renown Health, Reno, United States; [4]Gilead Sciences, Inc., Seattle, United States*
Email: jun.wang37@gilead.com

Background and aims: Numerous biomarkers from circulating proteome have been associated with MASH severity. However, it is not known whether any of these biomarkers are also potential drivers of disease. We assessed genetically determined circulating protein biomarkers in relation to risk of advanced fibrosis with the aim of identifying potential drivers for disease progression.

Method: We conducted a case-control study leveraging Renown Health's Healthy Nevada Project (whole exome sequencing and electronic medical records). Participants of European ancestry, including 9078 controls (no MASH and no type 2 diabetes [T2DM]), 1084 MASH at-risk of fibrosis (FIB-4 ≤ 1.3 and with T2DM), and 1200 advanced fibrosis due to MASH (FIB-4 ≥2.67 with or without T2DM) were included in this study. Genetically determined circulating protein levels were computed using participants' genotype data and summary statistics of *cis*-protein quantitative trait loci from other proteogenomic studies. Nine previously reported fibrosis-related proteins (ADAMTSL2, ACY1, ASL, ADH4, C7, COLEC11, NFASC, PTGR1, and YKL-40) were evaluated. Multinomial logistic regression models were used to estimate odds ratio (OR) and 95% confidence interval (CI), adjusting for age, sex, genetic ancestry, BMI, and sequencing batch.

Results: More women were included in this study (N = 7722, 68%) and the mean age was 52.6, 62.7 and 67.7 years in controls, MASH at-risk of fibrosis and advanced fibrosis. Genetically predicted circulating proteins were associated with slightly higher risk of MASH without fibrosis, but the risk of advanced fibrosis was significantly elevated for ADAMTSL2, COLEC11, NFASC and PTGR1 in patients with concurrent T2DM. For instance, compared to the lowest tertile, the highest tertile of predicted COLEC11 was linked to 84% higher risk (OR = 1.84, 95%CI = 1.07–3.17) of advanced fibrosis with concurrent T2DM, but no increased risk of advanced fibrosis was noted in those without T2DM (OR = 0.70, 95%CI = 0.46–1.07). Similar results were found for ADAMTSL2, NFASC and PTGR1. Further, associations were different between men and women for ADAMSL2 (interaction p = 0.01); for NFASC, associations were notably stronger in men than in women. For the other 5 proteins, significantly increased risk for advanced fibrosis was not observed for higher predicted protein levels. However, genetically predicted ADH4 was inversely associated with advanced fibrosis without T2DM (highest tertile OR = 0.73, 95% CI = 0.84–0.98) but not for advanced fibrosis with T2DM.

Conclusion: Combining genomics and proteomics, we identified several proteins (*e.g.,* ADAMSL2, COLEC11, and NFASC) with their genetically determined circulating levels associated with higher risk of advanced fibrosis in the context of concurrent T2DM. Our integrated analysis provides genetic evidence to support that these protein biomarkers may drive disease progression.

FRI-196

Association between liver histology and long-term clinical outcomes in patients with biopsy-proven metabolic dysfunction-associated steatotic liver disease in Sweden: a real-world cohort study (BRIDGE-MASH)

Ying Shang[1], Johan Vessby[2], Kamal Kant Mangla[3], Elisabeth de Laguiche[3], Mattias Ekstedt[4], Hannes Hagström[1,5]. *[1]Karolinska Institutet, Stockholm, Sweden; [2]Uppsala University, Uppsala, Sweden; [3]Novo Nordisk A/S, Søborg, Denmark; [4]Linköping University, Linköping, Sweden; [5]Karolinska University Hospital, Stockhom, Sweden*
Email: ying.shang@ki.se

Background and aims: The link between fibrosis stage and prognosis in metabolic dysfunction-associated steatotic liver disease (MASLD) is well established, however, limited evidence exists for other histologic features of steatohepatitis. We aimed to evaluate the association between these features and the occurrence of major adverse liver outcomes (MALO), cardiovascular (CV) outcomes and mortality in a large cohort of individuals with MASLD.

Method: This cohort study included adults diagnosed with biopsy-proven MASLD between 18 Dec 1974 and 31 Dec 2020 at three Swedish university hospitals. Histologic features were categorized by severity: lobular inflammation (low: grade 0–1; high: grade 2–3), hepatocellular ballooning (low: grade 0–1; high: grade 2), steatosis (low: grade 1–2; high: grade 3) and non-alcoholic fatty liver disease activity score (NAS; low: <4; high: ≥4). Outcomes were obtained from medical charts or linkage to national registers. Multivariable hazard ratios (HRs) were calculated using Cox regression models according to fibrosis stage and other histologic parameters, adjusting for age, sex, type 2 diabetes, body mass index, hypertension and hyperlipidemia. An additional analysis assessed event rates stratified by fibrosis stage.

Results: Of 959 eligible patients, median age at diagnosis was 52 years (interquartile range [IQR]: 39–60) and 368 (38.4%) were women. Over a median follow-up of 17 years (IQR: 7–27) there were 99 MALO events. Compared with F4 fibrosis, HRs for MALO and mortality were significantly lower in F0 (MALO: HR 0.10, 95% confidence interval [CI] 0.04–0.24; mortality: 0.44, 0.27–0.73), F1 (MALO: 0.12, 0.05–0.25; mortality: 0.48, 0.30–0.77) and F2 (MALO: 0.28, 0.14–0.56; mortality: 0.50, 0.31–0.80). In addition, compared with corresponding high-grade groups, significantly decreased HRs for MALO were observed in those with low-grade inflammation (HR 0.60, 95% CI 0.38–0.94) and ballooning (0.58, 0.36–0.93). In the stratified analysis, HRs for MALO were numerically higher in more

advanced (F2–3) than earlier (F0–1) fibrosis stages for inflammation, ballooning, steatosis and NAS; for example, HRs (95% CI) for low- versus high-grade ballooning were 0.56 (0.23–1.36) in F0–1 and 0.99 (0.52–1.87) in F2–3. Patients with lower fibrosis stages or inflammation had a reduced incidence of CV outcomes, but no significant reduction was noted after adjusting for covariates.
Conclusion: Lower fibrosis stage is associated with a reduced risk of MALO and overall mortality. The association between inflammation and ballooning and incident MALO appeared to depend on fibrosis stage, indicating that fibrosis is a mediator in the process of cirrhosis. Additional evidence is needed to assess whether reducing inflammation or ballooning would reduce the rate of fibrosis progression and consequently the incidence of MALO.

FRI-197

Implication of recent international consensus criteria for metabolic hyperferritinemia diagnosis and grade in a large cohort of patient with hepatic iron content assessed by magnetic resonance imaging

Sophie Stephant[1], Oumnia Masrour[2], Laine Fabrice[1], Jeff Morcet[1], Yves Gandon[1], Edouard Bardou-Jacquet[1]. [1]*CHU Rennes, Rennes, France;* [2]*CHU Rennes, Rennes, France*
Email: edouard.bardou-jacquet@chu-rennes.fr

Background and aims: Metabolic hyperferritinemia (MHF) is the most frequent cause of elevated ferritin. Recently consensus statement has defined diagnosis criteria and grading based on cutoff value for ferritin and hepatic iron concentration (HIC). The impact of this iron overload on metabolic liver disease remains unclear and there is limited data available on the correlation between serum ferritin and liver iron overload in this setting. The aim of our study was to describe in a large cohort of patients with MHF, the relationship between HIC and ferritin, and evaluate the relevance of the proposed cut-off value.
Method: Patients with the following criteria were included: increased ferritin with available HIC as determined by liver MRI, and fulfilling criteria for MHF: fatty liver (as determined by MRI), or type 2 diabetes or BMI>30, or two or more features of altered metabolism associated with insulin resistance (overweight, increased triglycerides, low HDL cholesterol, increased fasting glucose, arterial hypertension). Patient exceeding WHO recommended alcohol consumption were excluded. Multivariate regression analysis were used to identify determinant of HIC and ferritin. ROC curves were used to assess the cut-off suggested.
Results: A total of 534 patients (age:58.6 ± 10.6; 79.8% male, BMI 29.5 ± 4.6) were included. Diabetes, arterial hypertension, dyslipidemia, were prevalent in 49.6%, 75.8%, 75.5%, and 29.5% of patients respectively. Mean ferritin was 866 ± 655 µg/L, and HIC was 93 ± 65 µmol/g. Strong correlation between ferritin and HIC was observed (rho = 0.70, $p < 0.001$). Multivariate analysis revealed significant associations of ferritin with HIC, Aspartate amino transferase (ASAT), transferrin saturation (Tsat), triglycerides, and smoking. HIC was associated with ferritin, Tsat, BMI, smoking, ASAT, hemoglobin, age, and alcohol consumption. Grading according to ferritin was 25.3% grade 1, 42.5% grade 2, and 30.9% grade 3. According to HIC grading were 22.3%, 28.3% and 49.4% respectively. The AUC for ferritin diagnosing HIC ≥ 74 µmol/g (Grade 3 MHF) was 0.83, with a 1000 µg/L cutoff showing 51% sensitivity, 90% specificity. For HIC < 36 µmol/g (Grade 1 MHF), the ferritin AUC was 0.91, with a 550 µg/L cutoff providing 83% sensitivity and 81% specificity. Patients with Grade 3 MHF according to HIC, were characterized by older age, male predominance, lower BMI, higher Tsat, lower ASAT, lower ALT, and lower GGT. Fib4 test results were comparable between MHF grade determined by HIC or ferritin.
Conclusion: Our study confirms the strong correlation between ferritin and HIC in MHF. The proposed ferritin and HIC cutoffs effectively stratify MHF severity, patients with higher grade exhibiting distinct clinical features. However, in our population ferritin tends to underestimate HIC thus emphasizing the importance of integrating both serum ferritin and HIC for comprehensive MHF assessment.

FRI-198

The infamous ballooned hepatocye-fact or fiction: combined data from multiple therapeutic trials including more than 10, 000 patients

Julie Dubourg[1], Vlad Ratziu[2], Jörn M. Schattenberg[3], Mazen Noureddin[4], Naim Alkhouri[5], Michael Charlton[6], Stephen A. Harrison[7]. [1]*Summit Clinical Research, San Antonio, United States;* [2]*Sorbonne Université, Institute for Cardiometabolism and Nutrition, Hospital Pitié-Salpêtrière, INSERM UMRS 1138 CRC, Paris, France;* [3]*Saarland University Medical Center, Homburg, Germany;* [4]*Houston Research Institute, Houston, United States;* [5]*Arizona Liver Health, Phoenix, United States;* [6]*University of Chicago, Chicago, United States;* [7]*Radcliffe Department of Medicine, University of Oxford, Oxford, United Kingdom*
Email: jdubourg@summitclinicalresearch.com

Background and aims: Due to its high inter- and intra-reader variability, liver histology has been known as a challenge in metabolic dysfunction-associated steatohepatitis (MASH) drug development. One of the most debated histological features is the hepatocyte ballooning. The definition of ballooning is subjective and is highly variable among international recognized liver pathologists. We aimed to compare characteristics between patients with or without ballooning in the setting of similar fibrosis stages; to investigate if the absence of ballooning in a specific population could be reasonably attributed to reading variability.
Method: We combined screening data from 10 industry-funded MASH phase 2 trials. We compared characteristics between patients with or without ballooning in 2 subgroups: 1) fibrosis stage 3 with presence of inflammation and steatosis; 2) fibrosis stage 2 with presence of inflammation and steatosis.
Results: The subgroup of F3 with the presence of inflammation and steatosis, and with or without ballooning, included 1, 030 patients. Among them, 103 (10%) did not have hepatocytes ballooning at central reading. Liver enzymes were significantly higher in patients with ballooning (AST: 51 IU/L, SD: 19; ALT 61 IU/L, SD:36) compared to patients without ballooning (AST: 37 IU/L, SD: 24; ALT 48 IU/L, SD: 28) ($p < 0.0001$). Glycated hemoglobin (HbA1c), as a reflect of glycemic control, was higher in patients with ballooning (HbA1c: 6.6%, SD: 1.1) compared to patients without ballooning (HbA1c: 6.2%, SD: 1.0) ($p < 0.0001$). Platelet count was lower in patients with ballooning (227 G/L, SD: 64) versus 245 G/L (SD: 66) in patients without ballooning ($p = 0.009$). In a multivariate model, the presence of ballooning was associated with age ($p = 0.036$), AST ($p < 0.0001$), HbA1c ($p = 0.003$), and platelets ($p = 0.01$). The subgroup of F2 with presence of inflammation and steatosis, included 778 patients. Among them, 178 (23%) did not have hepatocyte ballooning at central reading. Liver enzymes were significantly higher in patients with ballooning (AST: 44 IU/L, SD: 27; ALT 61 IU/L, SD:38) compared to patients without ballooning (AST: 35 IU/L, SD: 15; ALT 51 IU/L, SD: 27) ($p < 0.0001$). Glycated hemoglobin (HbA1c), as a reflect of glycemic control, was higher in patients with ballooning (HbA1c: 6.5%, SD: 1.1) compared to patients without ballooning (HbA1c: 6.1%, SD: 1.0) ($p < 0.0001$). In a multivariate model, the presence of ballooning was associated with age ($p = 0.017$), AST ($p < 0.0001$), and HbA1c ($p = 0.001$).
Conclusion: Based on significant differences in clinical parameters between patients with and without hepatocyte ballooning within a similar subset of fibrosis, the presence of ballooning in this patient population seems to be linked to more severe hepatocyte injury/inflammation and glycemic control rather than the variability of histopathological assessment.

FRI-199

Insulin resistance as an independent predictor of metabolic dysfunction-associated steatohepatitis (MASH) severity: combined data from multiple therapeutic trials including more than 10, 000 patients

Vlad Ratziu[1], Jörn M. Schattenberg[2], Naim Alkhouri[3], Mazen Noureddin[4], Michael Charlton[5], Julie Dubourg[6], Stephen A. Harrison[7]. [1]*Sorbonne Université, Institute for Cardiometabolism and Nutrition, Hospital Pitié-Salpêtrière, INSERM UMRS 1138 CRC, Paris, France;* [2]*Saarland University Medical Center, Homburg, Germany;* [3]*Arizona Liver Health, Phoenix, United States;* [4]*Houston Research Institute, Houston, United States;* [5]*University of Chicago, Chicago, United States;* [6]*Summit Clinical Research, San Antonio, United States;* [7]*Radcliffe Department of Medicine, University of Oxford, Oxford, United Kingdom*
Email: jdubourg@summitclinicalresearch.com

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) and metabolic dysfunction-associated steatohepatitis (MASH) are closely associated with the metabolic syndrome, with insulin resistance as a key driver of the disease. Advanced fibrosis, defined as fibrosis stages F3 or F4, is the strongest predictor of major liver-related outcomes. We aimed to evaluate whether the level of fasting insulin at baseline, as a reflect of insulin resistance, is associated with the clinical and histological severity of MASH.
Method: Using combined screening data from 10 industry-funded MASH phase 2 trials, we examined patients with biopsy-proven MASLD/MASH and available fasting insulin levels. 1, 085 patients with available data were divided into 3 groups according to the fasting insulin tertiles: lower, ≤17.19 mIU/L (n = 362); middle, 17.20–28.38 mIU/L (n = 362); upper ≥28.39 mIU/L (n = 361). Univariate and multivariate logistic regressions were performed to predict histological severity.
Results: The upper tertile of fasting insulin was associated with a higher histological severity, especially regarding fibrosis and hepatocyte ballooning. While the proportion of F2 patients were unchanged among insulin tertiles, the proportion of F0-F1 was lower with increased insulin levels (42%, 31% and 19% in the lower, middle and upper tertiles, respectively ($p < 0.0001$)) and the proportion of patients with advanced fibrosis (F3-F4) was higher with increased insulin levels (34%, 45%, and 55% in the lower, middle and upper tertiles, respectively ($p < 0.0001$)). The presence of ballooning was highly associated with insulin levels. The proportion of patients with ballooning was 77%, 88%, and 96% in the lower, middle and upper tertiles, respectively ($p < 0.0001$). There was a slight association with steatosis ($p = 0.030$) and no association with inflammation. The upper tertile was also associated more severe clinical characteristics: higher liver enzymes, HbA1c, LDL and triglycerides, uric acid, CK-18, FIB-4, liver stiffness measurement (LSM) by FibroScan, and ELF. In a multivariate model, the upper insulin tertile was associated with fibrosis ($p < 0.0001$) and ballooning ($p < 0.0001$) severity, independent of HbA1c and diabetes level.
Conclusion: Fasting insulin, as a surrogate of insulin resistance, predicts severity of ballooned hepatocytes and hepatic fibrosis, independent of HbA1c level and diabetes status. Insulin resistance is strongly associated with the severity of MASH.

Email: i.ayada@erasmusmc.nl

Background and aims: Steatotic liver disease (SLD) is the fastest growing etiology for liver transplantation (LT) in the USA and it remains of concern post-LT as de novo or recurrent steatosis. We aimed to quantify this burden in the pre- and post-LT setting and to identify associated risk factors through a systematic review and meta-analysis. Moreover, we studied the impact of immunosuppressants on steatosis development in a clinical setting and in an experimental model of 3D cultured human liver organoids.
Method: Medline, Embase, Cochrane Central Register of Controlled Trials and Web of Science were searched from inception to March 2023. Data were extracted and cross-checked by two investigators. Analyses were conducted according to the PRISMA guidelines. Included studies reported on the prevalence of LT related to NAFLD/NASH (non-alcoholic steatohepatitis) or recurrent and de novo NAFLD/NASH alongside associated risk factors. Experimentally, the effects of 8 immunosuppressants on the size and number of formed lipid droplet were studied in human liver organoids. Clinically, we attempted to cross-sectionally verify the experimental results by establishing associations between steatosis development and immunosupressants use in a cohort of LT recipients (N = 312).
Results: The meta-analysis included 80 studies and the estimated prevalence of LT related to NAFLD/NASH was 11% (95% CI 9.0%–13.0%). The prevalence of de novo and recurrent NAFLD was 27% (95% CI 19.0%–34.0%) (16 studies) and 42% (95% CI 32.0%–53.0%) (22 studies), respectively. The prevalence of de novo and recurrent NASH was 7% (95% CI 4.0%–10.0%) (11 studies) and 22% (95%CI 14.0%–26.0%) (17 studies), respectively. In organoids, treatment of mTOR inhibitors reduced the size and number of formed lipid droplets. Consistently, the use of mTOR inhibitor containing regimen (N = 68, mean age [SD] 51.33 years [11.79]) was inversely associated with steatosis development in the post-LT setting OR (0.51 95%0.28–0.93 p 0.03) in comparison to any other dual immunosuppressive regimen (N = 244, mean age [SD] 48.98 years [13.30]).
Conclusion: This study comprehensively estimated the global burden of SLD related LT, revealing that de novo and recurrence of NAFLD/NASH post-LT are highly prevalent which is affected by metabolic dysfunctions. In 3D cultured human liver organoids mTOR inhibitors could ameliorate steatosis which was cross-sectionally validated in our LT cohort. Our findings call for awareness of this post-LT complication and support further investigating the possible protective effects of mTOR inhibitors on steatosis.

Background and aims: Metabolic dysfunction-associated steatohepatitis (MASH) is underdiagnosed, which can lead to an underestimation of health care resource utilization (HCRU) for this rapidly growing patient group. Here, we aimed to compare HCRU of patients in Swedish routine clinical care with a formal MASH diagnosis with

patients at high- and low risk of MASH based on the validated Fibrotic NASH Index (FNI).
Method: This study is based on registry data from primary- and secondary care (2010–2020) in Stockholm, Sweden. Healthcare-seeking patients with available liver biochemistry were categorized as high- or low-risk for fibrotic MASH based on the first FNI score (low risk: FNI < 0.1, high risk: FNI ≥ 0.33 and cardiometabolic risk factor (s)), or as MASH-diagnosed (ICD-10 K75.8 in specialist care). Patients with liver diseases other than MASH were excluded. Annualized HCRU was measured after index (first diagnosis or FNI score) and was stratified by reason for visit (major adverse liver outcome [MALO] or major adverse cardiovascular event [MACE]).
Results: In total, 101,166 patients with a FNI score (43,557 at high risk and 57,609 at low risk) and 141 diagnosed patients were included and followed for, on average, 4.4 years (range: 0.01–10.8 years). Patients with a diagnosis and high risk had more hospitalizations (total and MALO/MACE-related), longer length of stay, as well as more specialist visits and liver-related lab tests, compared to those at low risk. The mean/median for hospitalization occurrences (total) was 4.1/0.36, 1.6/0.36 and 0.64/0 for diagnosed, high-risk and low-risk patients, respectively (p for all comparisons <0.001). For MALO- and MACE-related hospitalizations, the corresponding numbers were 2.0/0, 0.0068/0 and 0.00026/0 (MALO; p for all <0.001) and 0.0070/0, 0.24/0, 0.080/0 (MACE; p for all <0.033). The mean/median length of stay was 64/18, 19/4.9 and 13/3.3 (p for all <0.001), the number of visits to a hepatology/gastroenterology clinic was 3.7/0.69, 0.070/0 and 0.037/0 (p for all <0.001), and the number of AST and ALT tests was 19/3.7, 6.1/1.9 and 3.8/1.6 (p for all <0.001), respectively. Finally, the number of primary care visits was 6.1/0, 7.2/2.4 and 4.6/2.1 (p for all <0.001). Out of all diagnosed patients, 38% had cirrhosis at index, compared to only 0.3% and 0.1% of patients at high and low risk, respectively. Sub-group analyses revealed similar differences in HCRU between groups after exclusion of patients with cirrhosis at baseline.
Conclusion: The higher HCRU across all types of visits for diagnosed- and high-risk patients indicate a high future burden on the health care system for this growing patient group, pointing to an urgent need for treatment preventing progression to cirrhosis.

FRI-202

Health-Related Quality of Life (HRQL) assessments in a 52-Week, double-blind, randomized, placebo-controlled phase 3 study of Resmetirom (MGL-3196) in patients with non-alcoholic steatohepatitis (NASH) and fibrosis (MAESTRO-NASH)

Zobair Younossi[1,2], Maria Stepanova[3,4], Andrei Racila[4,5], Linda Henry[5,6], Keith Miller[7], Dominic Labriola[7], Rebecca Taub[7], Fatema Nader[5,8,9]. *[1]The Global NASH Council, Washington, United States; [2]Beatty Liver and Obesity Research Program, Inova Health System, Falls Church, VA, United States; [3]The Global Nash Council, Washington DC, United States; [4]Beatty Liver and Obesity Research Program, Falls Church, United States; [5]The Global NASH Council, Washington DC, United States; [6]Beatty Liver and Obesity Research Program, Falls Church, United States; [7]Madrigal Pharmaceuticals, West Conshohocken, United States; [8]Beatty Liver and Obesity Program, Falls Church, United States; [9]Center for Outcomes Research in Liver Disease, Washington DC, United States*
Email: zobair.younossi@cldq.org

Background and aims: NASH, recently renamed as Metabolic Dysfunction-Associated Steatohepatitis (MASH), is highly prevalent liver disease and associated with adverse clinical outcomes and impaired HRQL. Resmetirom is a selective thyroid hormone receptor-β agonist that leads to improvement of fibrosis and resolution of NASH. The aim was to assess HRQL in NASH patients treated with resmetirom.
Method: Non-cirrhotic NASH patients with confirmed or suspected fibrosis were enrolled in a 52-week double-blind randomized placebo-controlled Phase 3 clinical trial with serial biopsy assessments (MAESTRO-NASH, NCT03900429). HRQL was assessed using Chronic Liver Disease Questionnaire-NASH (CLDQ-NASH; 6 domains and score range 1–7) and Liver Disease Quality of Life (LDQOL; 17 domains and score range 0–100) at baseline, week 24, and week 52. Changes in HRQL scores from subjects' own baseline scores were evaluated in patients receiving resmetirom vs. placebo and compared between subjects with vs. without biopsy response defined as meeting the study histologic end point (improvement of histologic fibrosis without worsening of NASH or resolution of NASH without worsening of fibrosis via in-window baseline/week 52 paired biopsies). Minimally clinically important Difference (MCID) in HRQL scores were defined as previously published.
Results: 966 mITT patients were included (57 ± 11 years, 44% male, 67% type 2 diabetes; 60% baseline fibrosis stage F3, 33% F2, 5% F1b, 84% NAS ≥ 5). Of those, 323 received resmetirom 100 mg, 322 resmetirom 80 mg, and 321 placebo. By weeks 24 and 52, patients receiving both doses of resmetirom experienced improvement of HRQL scores from baseline levels in Worry domain of CLDQ-NASH (mean +0.21 to +0.24, p < 0.05). At week 52, subjects who met the histologic end point after treatment with resmetirom (100 mg and 80 mg pooled) experienced improvement in several HRQL domains: Worry (WO) of CLDQ-NASH +0.46 (41% met MCID), Role Emotional (RE) of LDQOL +3.0 (28% met MCID), Health Distress (HD) of LDQOL +8.1 (38% MCID), Stigma (ST) of LDQOL +3.5 (39% MCID), and total LDQOL +2.2 (35% MCID) (all p < 0.05). Similar improvements in these HRQL domains were observed in biopsy responders from 100 mg and 80 mg resmetirom when groups were studied separately, contrasted by no improvements in both the placebo group and resmetirom biopsy non-responders. In other domains of LDQOL and CLDQ-NASH, MCID was met by 22–41% of resmetirom responders. Biopsy responders with baseline F3 had similar or more pronounced improvements of HRQL (WO +0.57 in F3 vs. +0.32 in F1b/F2, RE +3.6 vs. +1.7, HD +8.8 vs. +7.6, ST +2.9 vs. +5.2, total LDQOL +2.3 vs. +2.5) in comparison to those responders with baseline stage of F2 or F1b.
Conclusion: Patients with NASH who achieve improvement of fibrosis or resolution of NASH with resmetirom experience significant improvements in multiple domains of HRQL by the end of 52-week-long treatment.

FRI-203

Validation of optimal liver biopsy size for reliable quantitation of fibrosis severity in different areas and structures of liver lobule using second harmonic generation microscopy with artificial intelligence analyses

Nikolai V. Naoumov[1], Yayun Ren[2], Elaine Chng[2], Kutbuddin Akbary[2], Dean Tai[2], Jonathan Fallowfield[3], Timothy Kendall[3], David E Kleiner[4], Arun J. Sanyal[5]. *[1]Royal College of Physicians, London, United Kingdom; [2]HistoIndex Pte Ltd, Singapore, Singapore; [3]Institute for Regeneration and Repair, University of Edinburgh, Edinburgh, United Kingdom; [4]National Cancer Institute, Bethesda, MD, United States; [5]Division of Gastroenterology, Hepatology and Nutrition, Department of Internal Medicine, Virginia Commonwealth University, Richmond, VA, United States*
Email: nikolainaoumov@yahoo.com

Background and aims: Liver fibrosis is a key prognostic determinant for clinical outcomes in patients with metabolic dysfunction-associated steatohepatitis (MASH) and a key end point for clinical trials in MASH. Adequate size of liver specimens is essential for accurate histopathology examination to avoid sampling variability due to heterogeneity of fibrosis, sampling error, or distorted architecture of liver lobules and their anatomical structures. Digital pathology is increasingly used in MASH trials and provides greater sensitivity and precision in determining fibrosis dynamics, however, the influence of sample size on fibrosis quantitation using this technology and the agreement with pathologist's staging is poorly defined. The present study aimed to systematically evaluate the impact of liver specimen size on digital qFibrosis readouts.

Method: Wedge biopsies (n = 100) were obtained from liver resections or explants with 20 specimens for each pathologist's determined NASH-CRN fibrosis stage F0 to F4. Unstained sections were examined by Second Harmonic Generation/Two Photon Excitation Fluorescence (SHG/TPEF) microscopy with artificial intelligence (AI) software HistoHepa©. The severity of liver fibrosis was determined by analyzing 184 fibrosis parameters in portal tract (PT), periportal (PP, zone 1), perisinusoidal (PS, zone 2), pericentral (PC, zone 3) and central vein (CV) regions. Virtual needle biopsies were examined from each specimen with a fixed width of 0.9 mm and varying length from 5 to 30 mm. qFibrosis was determined individually for each virtual biopsy specimen and key parameters included the number of PT and CV; % fibrosis area in PT and CV; % fibrosis area in PP, PS and PC (zone 1, 2 and 3) of the liver lobule.
Results: qFibrosis assessment of wedge biopsies showed excellent concordance with NASH-CRN stages ($r = 0.92$; $p < 0.001$). The qFibrosis Coefficient of Variation (CoV) in virtual biopsies was very low for the number of PT-[median (lower quartiles, upper quartiles)]-0.17 (0.12, 0.24), or for % fibrosis in PT area-0.19 (0.13, 0.29), but highest for % fibrosis in CV area 0.50 (0.33, 0.74). Fibrosis assessment in different zones showed the CoV of 0.15 (0.10, 0.20), 0.09 (0.06, 0.14) and 0.35 (0.24, 0.53) for PP (zone 1), PS (zone 2) and PC (zone 3), respectively. Liver specimens with 10 mm length had on average 10 PTs and 5 CVs. The CoV progressively decreased in longer specimens and was consistently <0.2 for all parameters in biopsies longer than 20 mm.
Conclusion: qFibrosis readouts provide a standardized and highly reproducible assessment of liver fibrosis. The Coefficient of Variation is lower for PT and higher for CV-related parameters, indicating that portal tracts are less prone to sampling variability. qFibrosis assessment reduces errors due to sampling variability by precise and reproducible quantification of features with a higher Coefficient of Variation.

FRI-206-YI

Prevalence and severity of steatotic liver disease in 3, 123 at-risk individuals from the background population

Camilla Dalby Hansen[1], Johanne Kragh Hansen[1], Mads Israelsen[1], Peter Andersen[1], Laura Pikkupera[2], Katrine Lindvig[1], Maria Kjærgaard[1], Helle Schnefeld[1], Sara Stinson[2], Julie Tellerup[1], Maria Fogt[1], Nikolaj Torp[1], Katrine Tholstrup Bech[1], Katrine Thorhauge[1], Stine Johansen[1], Ida Ziegler Spedtsberg[1], Emil Deleuran Hansen[1], Ida Falk Villesen[1], Torben Hansen[2], Aleksander Krag[1], Maja Thiele[1]. *[1]Department of Gastroenterology and Hepatology, Odense University Hospital, Odense, Denmark; [2]Center for Basic Metabolic Research, University of Copenhagen, Copenhagen, Denmark*
Email: camilla.dalby.hansen@rsyd.dk

Background and aims: Characterization of the prevalence and severity for the newly defined steatotic liver disease (SLD) categories represent a significant knowledge gap. Our objective was to investigate the prevalence of SLD in the background population with either cardiometabolic or alcohol risk factors. Additionally, we aimed to explore the severity of disease and evaluate the impact of previous alcohol intake on individuals with metabolic dysfunction-associated steatotic liver disease (MASLD).
Method: We conducted a cross-sectional population based study. Participants were recruited based on either 1) cardiometabolic risk defined as BMI ≥ 30 or type 2 diabetes without excessive alcohol consumption, or 2) alcohol as a risk factor defined as a history of excessive alcohol consumption exceeding 24 g/day (W) and 36 g/day (M) for ≥5 years. We performed same-day assessments including liver stiffness measurements (LSM), controlled attenuation parameter (CAP) and cardiometabolic risk profiling. We used a validated CAP cut-off of ≥248 dB/m as marker of liver steatosis and LSM as a marker of liver disease severity.
Results: We included 3123 at-risk individuals; 1599 with cardiometabolic risk and 1524 with alcohol risk. In the cardiometabolic risk group 1239 (77%) had SLD of whom 1174 (95%) were categorized as MASLD and 56 (5%) as MetALD. In the alcohol risk group 996 (63%) had SLD of whom 431 (45%) were categorised as MASLD, 347 (36%) as MetALD and 188 (19%) as ALD. The prevalence of LSM ≥ 8 kPa were 0.2% in those without SLD (n = 2), 13% in MASLD (n = 211), 12% in MetALD (n = 46) and 24% in ALD (n = 48). The prevalence of LSM ≥ 12 kPa were 0% in those without SLD (n = 0), 5% in MASLD (n = 73), 5% in MetALD (n = 18) and 13% in ALD (n = 25). Compared to individuals without SLD, the odds ratio of LSM ≥ 8 kPa was 68.2 in MASLD (16.9 to 275; $p < 0.0001$), 59.4 in MetALD (14.3 to 245; $p < 0.0001$) and 147.4 in ALD (35.45 to 613; $p < 0.0001$). In individuals with MASLD a previous alcohol intake of ≥50 g/d (W)/≥60 g/d (M) associated with LSM ≥ 12 kPa (OR = 1.82 (1.02 to 3.26; P = 0.044)), whereas 20–50 g/d (W)/30–60 g/d (M) did not associate with LSM ≥ 12 kPa (OR = 0.90 (0.40 to 2.01; P = 0.792). Furthermore, a previous excessive alcohol intake of ≥20 years associated with LSM ≥ 12 kPa in individuals with MASLD (OR = 2.09 (1.11 to 3.95; P = 0.023), whereas a previous excessive alcohol intake from 5 to 20 years did not (OR = 1.00 (0.51 to 1.95); P = 0.993)).
Conclusion: Our study reveals a 77% prevalence of SLD in individuals with metabolic risk factors and a 63% prevalence in those with alcohol risk factors. The severity of SLD, as indicated by LSM ≥8 kPa, demonstrated rates of 13% in MASLD, 12% in MetALD, and 24% in ALD. Significantly, our findings highlight the impact of long-term and excess alcohol intake on liver disease severity among patients initially classified as MASLD. Our study suggests that the nomenclature for SLD should incorporate historical alcohol intake.

FRI-207-YI

Sarcopenia in metabolic-dysfunction associated steatotic liver disease (MASLD): unraveling its role in cardiovascular damage

Annalisa Cespiati[1,2], Rosa Lombardi[2,3], Giordano Sigon[2,4], Floriana Santomenna[2,3], Matteo Carlomagno[2], Margaux Couffon[4], Beatrice Martino[4], Jian Huang[4], Daniel Smith[2,3], Giuseppina Pisano[3], Giovanna Oberti[3], Roberta Forlano[4], Pinelopi Manousou[4], Salvatore Petta[5], Anna Ludovica Fracanzani[2,3]. *[1]SC Medicina ad Indirizzo Metabolico, Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy; [2]Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy; [3]SC Medicina ad Indirizzo Metabolico, Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milan, Italy; [4]Liver Unit, Division of Digestive Diseases, Department of Metabolism, Digestion and Reproduction, Faculty of Medicine, Imperial College, London, United Kingdom; [5]Section of Gastroenterology and Hepatology, PROMISE, University of Palermo, Palermo, Italy*
Email: annalisa.cespiati@unimi.it

Background and aims: Patients with MASLD are prone to sarcopenia with the complication rate and severity increasing as fibrosis progresses. MASLD is also associated with subclinical and clinical cardiovascular disease (CVD). However, the impact of sarcopenia on CVD in MASLD patients is undefined. Aims: to assess the impact of sarcopenia and metabolic comorbidities on CVD in a multicentric cohort of MASLD patients.
Method: We included consecutive patients with MASLD followed up in specialised hepatology clinics in Milan, Palermo, and London. Sarcopenia was defined as a skeletal muscle mass/height^2 ≤10.75/≤6.75 kg/m^2 (males/females) by bioimpedance. CVD was defined as presence of carotid plaques on Doppler-US. High and very high CV risk was defined by the scores specified for each patient outlined in the ESC 2021 guidelines.
Results: 876 MASLD patients were enrolled, with prevalence of sarcopenia at 34%. Mean BMI was 30 ± 5 kg/m^2 (44% with BMI≥30 kg/m^2), mean age 52 ± 12 years, while 62% were male, 43% had hypertension, 29% type-2 diabetes. Overall, 35% (307) patients had

carotid plaque, 60% (526) had high and 12% (105) very high CV risk. Sarcopenic patients were more frequently male (90 vs 48%, p < 0.001), had lower BMI (27.3 vs 31.6 kg/m^2, p < 0.001) and waist circumference (WC) (101 vs 107 cm, p = 0.003) compared to non-sarcopenic. There was no difference in terms of prevalence of age (51 vs 52 years, p = 0.6), severe steatosis (62% vs 66%, p = 0.19), carotid plaques (33% vs 36%, p = 0.4), and high/very high CV risk (73% vs 71%, p = 0.14). On multivariate analysis (adjusted for age, sex, and factors associated with sarcopenia on univariate analysis) sarcopenia was independently associated with lower BMI (OR 0.6, CI 95% 0.5–0.7, p < 0.001), lower waist circumference (OR 0.9, CI 95% 0.8–0.94, p < 0.001), male gender (OR 14.2, CI 95% 8.4–24, p < 0.001), and age (OR 1.02, CI 95% 1.01–1.04, p = 0.003). Analyzing different metabolic subgroups, in diabetic patients, prevalence of carotid plaques was higher in sarcopenic vs non-sarcopenic (56% vs 30%, p = 0.04). In hypertensive patients, sarcopenia remained an independent risk factor for carotid plaques (OR 1.9, CI 95% 1.05–3.5, p = 0.03) and high/very high CV risk (OR 3.0, CI 95% 1.2–7.2, p = 0.01) in multivariate analysis adjusted for age, sex, diabetes, dyslipidemia, smoke and BMI, whereas in non-diabetic subjects for high/very high CV risk (OR 1.44, CI 95% 1.1–2.1, p = 0.04).

Conclusion: MASLD patients, particularly non-obese and male, have a high prevalence of sarcopenia. Despite lower BMI, sarcopenic patients exhibit a similar extent of hepatic steatosis and CVD compared to those without sarcopenia. For those with additional metabolic risk factors like diabetes and hypertension, the risk of CVD is aggravated by sarcopenia. A prompt evaluation and treatment of sarcopenia could prevent the onset of CVD, particularly if hypertensive.

FRI-208

qBallooning: AI-based ballooned hepatocyte detection and quantification by second harmonic generation/two photon excitation microscopy

Email: Dean.Tai@histoindex.com

Background and aims: Presence of ballooned hepatocytes (BH) differentiates between metabolic dysfunction-associated steatotic liver (MASL) and metabolic dysfunction-associated steatohepatitis (MASH). The development of qBallooning (qB), an artificial intelligence (AI)-based method for ballooned hepatocytes detection and quantification using Second Harmonic Generation and Two-Photon Excitation images, is useful for pathological diagnosis and feature extraction. This study describes the development and performances of qB algorithm.

Method: A total of 9 expert pathologists conducted three rounds of readings with a total of 95 images (n = 30, 30, 35). qB annotated each of the BH in these images and the pathologists reviewed each individual BH afterwards. The pathologists labelled each BH with a yes or no to show if they agreed with qB. qB was further improved during these three rounds, and the new qB was used for the next round of reading throughout the process. The final qB determined BH by overlapping cells detected in both raw and 90°-rotated images. The performance of qB was defined as agreement of at least 5 pathologists, and the definition of the positive diagnostic criteria for MASH was established when ≥5 BH were identified in each image.

Results: At the individual cell level, qB exhibited a true positive (TP) of 55% and false positive (FP) of 8%, with BH concurrence from a minimum of 5 pathologists. When we used concurrence from a minimum of 3 pathologists, performance metrics improved TP to 89% but with a higher FP of 42%. On the diagnostic level, a diagnosis of no ballooning (defined as <5 BH) achieved a 100% TP and 0% FP with agreement from over 5 pathologists.

Conclusion: The study's findings have implications in MASH drug trial context, specifically in the patient inclusion and efficacy evaluation phases. In the patient inclusion phase, employing qB for AI annotation of BH can assist pathologists to achieve a higher consistency on ballooning grade 0 diagnosis. This approach can potentially reduce screening failure rates for clinical trial inclusion. During the efficacy evaluation phase of MASH drug trials, AI annotation on BH can assist pathologists in reviewing and eliminating falsely identified cells. Additionally, utilizing the algorithm's performance metrics (55% TP and 8% FP) with agreement from at least 5 pathologists, the relative change from baseline in the number of BH per unit area can be measured and quantified thus providing an additional tool to assess changes in disease activity.

FRI-209

Differential prevalence and prognostic value of metabolic syndrome components among metabolic-dysfunction associated steatotic liver disease (MASLD) patients

Jesse Pustjens[1], Laurens van Kleef[1], Harry L.A. Janssen[1,2], Robert J. de Knegt[1], Willem Pieter Brouwer[1]. *[1]Department of Gastroenterology and Hepatology, Erasmus MC University Medical Centre, Rotterdam, Netherlands; [2]Toronto Centre for Liver Disease, Toronto General Hospital, University Health Network, Toronto, Canada*
Email: j.pustjens@erasmusmc.nl

Background and aims: Metabolic-dysfunction associated steatotic liver disease (MASLD) is increasingly prevalent in the general population and a growing global health concern. This study aims to describe the cardiometabolic burden of the MASLD population and identify those at highest risk of adverse outcomes and all-cause mortality.
Method: We analysed individuals with MASLD enrolled in the National Health and Nutrition Survey (NHANES) III (N = 3, 628) and NHANES 2017–2020 (N = 2, 618) studies. MASLD was defined according to the clinical practice guidelines. Hepatic steatosis was assessed by ultrasonography and controlled attenuation parameter (CAP). The primary end points were all-cause mortality and liver stiffness measured by Fibroscan. Significant liver fibrosis was defined as a liver stiffness measurement (LSM) of ≥8 KiloPascal (kPa). Cox regression models were adjusted for age, sex, race, marital status, education, and smoking, and results were stratified according to three age groups (20–40, 40–60, 60–80).
Results: Among the total NHANES III MASLD population (median age = 48 [36–62], 44.8% males), 65% had ≥3 cardiometabolic disorders. Most frequent were obesity (89.1%), (pre)diabetes (66.6%) and hypo-HDL (54.7%). During a median follow-up of 22.3 [16.9–24.2] years, 1, 405 deaths occurred. Hypertension (aHR 1.42, 95% CI 1.26; 1.61), (pre-)diabetes (aHR 1.28, 95%CI 1.09; 1.49), and hypertriglyceridemia (aHR 1.19 95% CI 1.05; 1.34) were the strongest predictors of all-cause mortality. Consistent results were obtained in the NHANES 2017–2020 cohort for the association of cardiometabolic factors and liver fibrosis among the MASLD population. Here, an increased waist circumference (OR 3.45, 95% CI 1.44; 8.25), (pre)diabetes (OR 1.90, 95% CI 1.44; 2.25) and hypertension (aHR 1.84, 95% CI 1.40; 2.43) showed the strongest associations with liver fibrosis.
Conclusion: MASLD patients vary greatly in their cardiometabolic burden and consequently, in their prognosis and risk for significant liver fibrosis. These results highlight MASLD as a disease spectrum rather than a single disease entity, necessitating an individualized treatment approach, also for novel therapeutic regimens assessed in clinical trials.

FRI-210

Increased risk of cancers in metabolic dysfunction-associated steatotic liver disease and MetALD

Yewan Park[1], Jooyi Jung[2], Gi-Ae Kim[1]. *[1]Department of Internal Medicine, College of Medicine, Kyung Hee University Hospital, Kyung Hee University, Seoul, Korea, Rep. of South; [2]Department of Biostatistics, Korea University, Seoul, Korea, Rep. of South*
Email: antiankle@naver.com

Background and aims: Cancer is one of the most common causes of death in non-alcoholic fatty liver disease (NAFLD). With metabolic dysfunction-associated steatotic liver disease (MASLD) now recognized as a replacement of NAFLD and the introduction of a new category of MASLD with increased alcohol intake (MetALD), this study aims to explore the associated cancer risks under this revised nomenclature.
Method: This nationwide cohort study included 3, 596, 709 participants who underwent a health check-up in 2011 in South Korea. Steatotic liver disease (SLD) was defined as a fatty liver index ≥30. Participants were categorized into four exclusive groups: MASLD, MetALD, other combination etiology, and no SLD. To estimate the cause-specific adjusted hazard ratios (aHRs) for cancer risk, Cox proportional hazards regression was employed.
Results: Over 34 million person-years, 285, 845 participants (7.9%) developed cancers. Compared with no SLD, MASLD (aHR, 1.02; 95% CI, 1.01 –1.03), MetALD (aHR, 1.06; 95% CI, 1.04–1.08), and other combination etiology (aHR, 1.38; 95% CI, 1.35–1.40) were associated with an increased risk of all cancer. The risk of liver cancer increased in the order of no SLD, MASLD (aHR, 1.17; 95% CI, 1.12–1.22), MetALD (aHR, 1.50; 95% CI, 1.40–1.60), and other combination etiology (aHR, 5.21; 95% CI, 4.97–5.45). Compared with no SLD, MASLD (aHR, 1.13; 95% CI, 1.11–1.15), MetALD (aHR, 1.30; 95% CI, 1.26–1.34), and other combination etiology (aHR, 1.27; 95% CI, 1.23–1.31) had increased risk of gastrointestinal cancer such as the esophagus, stomach, colorectal, pancreas, and biliary cancer. Compared with no SLD, MASLD (aHR, 1.07; 95% CI, 1.04–1.10) and other combination etiology (aHR, 1.13; 95% CI, 1.07–1.20) had a higher risk of lung cancer. Little difference was observed in the risk of hormone-sensitive cancer.
Conclusion: This study showed the newly suggested MASLD and MetALD have an increased risk of all cancers, particularly liver and gastrointestinal cancer. The findings suggest that modifying MASLD and alcohol consumption can serve as a preventative strategy against cancer risk.

Email: asoriac@clinic.cat

Background and aims: Patients with metabolic associated steatosis liver disease (MASLD) frequently have (15–30%) positive autoantibodies (Ab). Preliminary data suggest that the presence of serologic and histological characteristics of autoimmune hepatitis (AIH) in MASLD patients may increase cirrhosis development and decompensation. The aim of this study was to assess the presence of AIH characteristics in MASLD patients and determine their role in disease prognosis.
Method: Retrospective multicenter cohort study (Spanish HEPAMET register) including patients ≥18 years with histologic diagnosis of MASLD and at least 1 year of follow-up. Patients with hepatocarcinoma and other concomitant liver diseases were excluded. The presence of Ab ≥ 1/40 (ANA, ASMA), gamma globulins (IgG ≥ 12 mg/dl or Gg ≥ 18%) and histological features of AIH (interface hepatitis

and/or moderate-severe portal inflammation) were assessed and their relationship with prognosis was analyzed.
Results: Out of the 651 patients in HEPAMET registry, 463 had autoimmune serologies available and 316 had histology assessment of AIH features and therefore were analyzed. Median age of 58 years (IQR 51–64), 48% women, BMI 33.2 kg/m^2 (IQR 29.7–37.1), liver stiffness 11.4kPa (IQR 9–16.9) and CAP 330 dB/m (IQR 300–363). After a median follow-up of 10.9 years (IQR 7.5–15, 5), 145 (31%) patients had liver cirrhosis, 49 (11%) hepatic decompensation, 4 (1%) underwent a liver transplantation and 26 (6%) died. Two hundred and sixty-five (36%) had elevated IgG/Gg, 217 (47%) positive Ab (172–37%- ANA and 121–26%- ASMA) and 93 (20%) had concomitant positive Ab and high Gg/IgG levels. Eighty-two patients (18%) had histological features of AIH. Of those, 54 (12%) had elevated IgG/Gg or positive Ab, and 25 (5.4%) met all three criteria. The presence of any serologic criteria of AIH (in combination or alone) increased the risk of cirrhosis (OR 2.4; CI95%, 1.64–3.68; p < 0.001 for positive Ab and OR 2.8; CI 95%; 1.7–4.5; p < 0.001 for positive Ab with elevated Gg/IgG), decompensation (OR 3.9; CI95%; 2.1–7.3; p < 0.001 for positive Ab and OR 5.9; CI95%; 2.8–12.6; p < 0.001 for positive Ab with elevated Gg/IgG) and death (OR 2.6; CI95%; 1.1–6.1; p = 0.016 for positive Ab with elevated Gg/IgG). Patients with isolated histological features of AIH had higher liver stiffness (13 vs 8.2kPa; p = 0.01) and increased risk of death (OR 5.4; CI95%; 1–9–15.4; p = 0.004), but only those with positive serologic tests (Ab + IgG/gg) on top of histological AIH had increased risk of cirrhosis (OR 2.5; CI95%; 1.08–5.7; p = 0.027) and decompensation (OR 3.55; CI95%; 1.42–8.86; p = 0.004).
Conclusion: The presence of AIH serological markers is frequent in MASLD patients and is associated with an increased risk of cirrhosis development, decompensation and death. Assessing the presence of AIH features in patients with MASLD could help to identify a subgroup of patients with worse prognosis.

Email: davidmmaa@gmail.com

Background and aims: Both metabolic dysfunction and alcohol consumption cause steatotic liver disease (SLD). Current definition of metabolic dysfunction-associated SLD (MASLD) allows 140–210 g/week of alcohol intake. We assessed the impact of different levels of alcohol consumption on the prevalence of significant fibrosis in MASLD.
Method: Population-based study with transient elastography (FibroScan®) data from participants in Spain (derivation) and U.S. (validation) cohorts. Controlled attenuation parameter (CAP ≥ 275 dB/m) identified SLD. At least one metabolic comorbidity was required to define MASLD. The FAST score was used to identify significant fibrosis. Low alcohol consumption was defined as an average of 5–9 drinks/week, and moderate consumption as 10–14 and 10–21 drinks/week for female and males respectively.
Results: The derivation cohort included 6, 738 adults, of whom 33% had MASLD. Among them, 9% reported low and 14% moderate consumption. Prevalence of significant fibrosis was 14%. In the multivariable analysis, both low (OR = 1.72, 95%CI 1.10–2.69) and moderate (OR = 3.89, 95%CI 2.83–5.35) consumption were independently associated with significant fibrosis. A dose-dependent supra-additive interaction was observed between the number of drinks/week and major metabolic comorbidities (obesity, diabetes, dyslipidemia), with detrimental effect at any level of daily alcohol consumption. The validation cohort included 4, 218 participants, 40% MASLD and 13% with significant fibrosis. Among the U.S. population, 39% reported low and 31% moderate consumption. This cohort validated the substantial increase of significant fibrosis in patients with 2/3 major metabolic comorbidities and joint low-to-moderate consumption.
Conclusion: Low-to-moderate alcohol intake is commonly seen in MASLD and increases the risk of advanced disease as compared with minimal consumption.

FRI-214

Risk of non-alcoholic steatohepatitis disease progression to more severe liver disease in medicare patients

Jesse Fishman[1], Yestle Kim[1], Joe Medicis[1], Matthew Davis[2], Dominic Nunag[2], Robert G. Gish[3]. *[1]Madrigal Pharmaceuticals, Inc., West Conshohocken, United States; [2]Medicus Economics, LLC, Milton, United States; [3]Robert G Gish Consultants LLC, La Jolla, United States*
Email: jfishman@madrigalpharma.com

Background and aims: Non-alcoholic steatohepatitis (NASH), or metabolic dysfunction-associated steatohepatitis (MASH), is a severe form of metabolic dysfunction-associated liver disease (MASLD). NASH may progress to more advanced liver disease associated with increased mortality, but progression risk and timing have not been well characterized among older adults. This study aimed to estimate risk of NASH disease progression and mortality for Medicare patients.
Method: Patients with NASH (ICD-10: K75.81) in 100% Medicare fee-for-service claims (2015–2021) were required to be ≥66 years at index diagnosis, have continuous enrollment for ≥12 months prior to and ≥6 months following index (unless death), and have no evidence of other causes of liver disease. Diagnoses within 90 days were used to categorize patient-time into five severity states: NASH without advanced liver disease, compensated cirrhosis (CC), decompensated cirrhosis (DCC), hepatocellular carcinoma (HCC), or liver transplant (LT). Survival analyses of disease progression and mortality were conducted for each state overall and by year of progression (Y1–5). Cox proportional hazards models assessed baseline risk factors associated with progression and mortality.
Results: Mean age and follow-up were 72.2 and 2.8 years in 14, 806 patients (N = 12, 990 NASH; 1, 899 CC; 997 DCC; 209 HCC; 140 LT). NASH patients had an annual progression rate of 3%-12% and mortality rates of 2%–12% for Y1–5. CC patients had the highest progression rates (11%–37% for Y1–5) but lower mortality rates (6%–26% for Y1–5) than more severe states. Relative to CC, DCC patients had lower progression rates (3%–18% for Y1–5) but substantially higher mortality rates (41%–76% for Y1–5). HCC patients had low rates of disease progression (2%–4% for Y1–5), but the highest rates of death (41%–85% for Y1–5). LT had mortality rates of 7%-33% in Y1–5. Delayed progression from NASH was associated with lower mortality risk; the 5-year mortality rate of Y2 progressors (32%) was 26% lower than the mortality rate of Y1 progressors (43%). This trend continued

for those who progressed in Y3, Y4, Y5, and non-progressors, with 5-year mortality rates of 28%, 18%, 18%, and 12%, respectively. Risk factors varied by state, but older patients and those with previous nursing home use, congestive heart failure, coagulopathy, fluid and electrolyte disorders, or unexplained weight loss faced increased risk of progression or death.

Conclusion: NASH patients have a high risk of disease progression associated with increased mortality rates. The association between unexplained weight loss and progression should be further explored as anti-obesity medications and other strategies are used more broadly. Slower disease progression is associated with lower rates of mortality, suggesting that therapies that can delay or prevent NASH progression may reduce morbidity and mortality.

FRI-215-YI

MASL-B registry: results from a european cohort of patients with chronic hepatitis B and metabolic dysfunction-associated steatotic liver disease

Email: r.forlano@imperial.ac.uk

Background and aims: Chronic hepatitis B (CHB) and metabolic-dysfunction associated steatotic liver disease (MASLD) are commonly observed together, with the prevalence and course of disease being debatable. We explored prevalence and risk factors for MASLD with or without fibrosis in patients with CHB in Europe. We also examined the performance of non-invasive markers (NIM).

Method: This multicenter, cross-sectional study included all consecutive CHB patients in 19 liver centers-5 European countries (UK, Italy, Spain, Greece, France). CHB was defined as presence of Hepatitis B surface antigen for at least 6 months. MASLD was defined based on ultrasound, histology or CAP ≥ 275 dB/m, in presence of at least one metabolic factor. Advanced fibrosis was defined as LSM ≥ 8 kPa in those with MASLD or LSM ≥ 9 kPa in those without MASLD. When histology was available, significant fibrosis was F ≥ 2, advanced fibrosis F ≥ 3 and cirrhosis F ≥ 5 (Ishak). A survey on standard of care for CHB patients with MASLD was circulated.

Results: 1410 CHB patients were included; median age 53 (43–65) years, BMI 25.5 (22–28) kg/m^2. 62% were White Caucasian, 16% East Asian, 11.2% African or Afro-Caribbean, 5.6% South Asian.

Among centers, 70% screened for MASLD all CHB patients, while 30% only those with metabolic syndrome. 50% used imaging, LFTs plus fibroscan, while only 10% serum NIM. Finally, 90% followed same treatment indication as those with CHB only. MASLD prevalence was 32% (465/1410) based on US, 25% (270/1069) on CAP, 49% (151/304) on biopsy. BMI (OR 1.1, 95%CI: 1.14–1.25, p < 0.001), ALT (OR 2.7, 95% CI: 1.02–7.67, p = 0.04), ferritin (OR 1.7, 95%CI: 1.09–2.78, p = 0.02) and history of T2DM (OR 2.1, 95%CI: 1.09–4.47, p = 0.03) predicted MASLD. In those with MASLD, prevalence of advanced fibrosis was 32% (193/598), with age (OR 1.03, 95%CI:1.01–1.05, p = 0.002), AST (OR 7.8, 95% CI:1.03–63.55, p = 0.04), PLT (OR 1, 95%CI:1–1, p = 0.02), insulin treatment (OR 4.2, 95%CI:1.21–16.8, p = 0.02)and long-term antivirals (OR 4.1, 95%CI:2.33–7.66, p < 0.001) as predictors for advanced fibrosis. In those without MASLD, advanced fibrosis prevalence was 38%. Overall, 304 (304/1410 = 21%) patients had biopsy. FIB-4 and LSM performed similarly at predicting significant (185/304 = 61%) (AUROC 0.64 vs 0.62, deLong test p = 0.7) and advanced fibrosis (115/304 = 38%) (AUROC 0.64 vs 0.64, deLong test p = 0.9). PPV for FIB-4 and LSM for significant and advanced fibrosis remained modest, while NPV for cirrhosis were 93–95%. The AUROC for CAP predicting steatosis was 0.56 (95%CI:0.48–0.65, p = 0.01).

Conclusion: In this large European cohort, MASLD and fibrosis were highly prevalent among CHB patients, mirroring host rather than virus-related factors. Biomarkers performed poorly in predicting fibrosis in patients with CHB and MASLD. These results may inform dedicated policies for screening CHB patients for liver disease due to MASLD.

Paik[1,11,13]. *[1]The Global NASH Council, Washington DC, United States; [2]Beatty Liver and Obesity Research Program, Falls Church, United States; [3]Barcelona Institute of Global Health (IS Global), University of Barcelona, Barcelona, Spain; [4]CUNY Graduate School of Public Health and Health Policy (CUNY SPH), New York City, United States; [5]Mayo Clinic, Department of Gastroenterology and Hepatology, Rochestor, United States; [6]University of Florida, Division of Endocrinology, Diabetes, and Metabolism, Gainesville, United States; [7]Universitatsmedizin, Department of Hepatology and Gastroenterology, Berlin, Germany; [8]Heinrich Heine University, Department of Endocrinology and Diabetology, Medical Faculty and University Hospital Dusseldorf, Dussledorf, Germany; [9]Heinrich Heine University, Institute for Clinical Diabetology, German Diabetes Center, Leibniz Center for Diabetes Research, Dusseldorf, Germany; [10]Saarland University Medical Center, Department of Internal Medicine II, Homburg, Germany; [11]Center for Outcomes Research in Liver Disease, Washington DC, United States; [12]Center for Outcomes Research in Liver Disease, Falls Church, United States; [13]Beatty Liver and Research Program, Falls Church, United States*
Email: zobair.younossi@cldq.org

Background and aims: MASH is not only responsible for morbidity and mortality but also significant economic burden. As management strategies are developed, there will be an opportunity to reduce the growing burden of MASH. Our aim was to model the economic burden (direct-medical and societal costs) of MASH in the US.
Method: A Markov Model estimated the burden of MASH in the US. Both MASH prevalent cases in the US (2020) (3.93% or 9.91 million cases) and new (incident) cases (2021: 0.39% or 1.0 million cases to 2040: 0.58% or 1.62 million cases) were considered. Data were sourced from US population projections (2020–2040), National Health and Nutrition Examination (NHANES), National Vital Statistics System (NVSS), global burden of disease (GBD), Scientific Registry of Transplant Recipients (SRTR) data, the Global NASH Registries (GNR) and systematic reviews. Incidence rates were calculated by calibrating against US prevalence rate with the assumption that trends of MASLD in the past decade will continue. Annual all-causes, liver- and cardiovascular-specific mortality were estimated by using NHANES data with 27 years follow-up. The disease states and mortality status were updated over 20-years. Transition probabilities across health states and deaths were updated from our published models, meta-analyses, and calibration. Societal costs were based on the estimated work productivity loss by using WPAI scores from the GNR, US Census Bureau, and the literature. The projections are based on a 3-year moving average trend. Future costs are inflated by +3.5%.
Results: Over the next 2 decades, the model estimates that the cases of NASH, advanced liver disease (F3, compensated cirrhosis, and decompensated cirrhosis) and liver deaths among adults (+18 years) will increase by +81.8% (2021: 4.18% or 10.49 million cases to 2040: 7.61% or 21.04 million cases), +48.4% (2021: 12.28% of MASH or 1.29 million cases to 2040: 13.09% of MASH or 2.75 million cases), and +158% (2021: 6.74 per 100, 000 general population or 16, 891 cases to 2040: 13.1%, 17.37 per 100, 000 or 48, 045), respectively. From 2021 to 2040, total annual direct and societal cost of MASH is expected to increase from $24.26 billion and $48.33 billion to $121.44 billion and $180.69 billion. If the prevalence of MASH is assumed to be lower (1.97%), total annual direct and societal cost for MASH will increase from $13.95 billion and $27.36 billion to $108.85 billion and $164.20 billion. If the prevalence of MASH is assumed to be higher (5.90%), the expected total annual directed and societal cost will increase from $32.74 Billion and $96.17 billion to $385.38 and $775.05.
Conclusion: The economic burden of MASH is expected to grow substantially over the next 2 decades. Cost-effective algorithms should be used to identify high-risk MASH patients and the newly developed treatment/management strategies must be adopted to reduce the future economic burden of MASH.

Email: 94jimenezalba@gmail.com

Background and aims: There is lack of a consensus definition and data on frequency of recompensation in MASLD cirrhosis. The aim of this study was to evaluate the incidence and factors associated with recompensation and/or improvement in liver function in decompensated MASLD cirrhosis.
Method: Retrospective study in 4 Catalonian university hospitals (Spain). Individuals with MASLD cirrhosis were enrolled at their initial decompensating event (ascites, hepatic encephalopathy, spontaneous bacterial peritonitis and portal hypertension-related bleeding) and followed until death, liver transplantation or last recorded follow-up. Baseline characteristics were collected. The primary end point was a composite of recompensation, defined as sustained absence of clinical decompensation for >1year without specific treatment, and improved and maintained liver function (albumin, bilirubin and INR resulting in Child-Pugh A and/or MELD < 10). Survival analyses were conducted by Kaplan-Meier method. A multivariate analysis of predictors of the primary end point was carried out with variables of the univariate analysis ($p < 0.10$).
Results: 98 patients were included (mean age 64 ± 10 yrs, 57% males). 63% had obesity, 34% overweight, 66% arterial hypertension, 75% type 2 diabetes, and 47% dyslipidemia. Most patients had Child-Pugh B score (68%), 31% Child-Pugh A, and 1 patient Child-Pugh C (1%). Mean (SD) MELD score was 10 ± 3.1. After a mean follow-up of 32 ± 31 mths, a total of 392 acute decompensation events were recorded (81% ascites, 64% HE, 33% bleeding, and 13% SBP). 65% patients experienced ≥2 episodes, 58% patients died and 15% undergone LT. Most deaths were attributed to liver-related events (45% liver failure, 21% hepatocellular carcinoma) while <10% were related to cardiovascular events. During the follow-up period, 15% of patients experienced persistent improvement in liver function, 45% of surviving patients maintained clinical compensation with specific treatment. Only one patient met the fully recompensation criteria. In the univariate analysis, no significant association was found between metabolic risk factors and primary end point, while alcohol consumption and smoking at first decompensation were associated, yet the multivariate analysis did not show significant association with the likelihood of recompensation. At 3-year follow-up, 3 Child-Pugh A patients (10%) and 4 Child-Pugh B patients (6%) exhibited sustained improvement in hepatic function. At 10-year follow-up, 40% and 20% of alive Child-Pugh A and B patients exhibited sustained liver function improvement.
Conclusion: Hepatic recompensation in decompensated MASLD cirrhosis seems very infrequent, possibly due to uncontrolled or unresolved etiology. However, sustained improvement in liver function is achieved in 15% of patients. Further studies are needed to clearly define recompensation criteria in MASLD.

FRI-220-YI

The unrecognised burden of pruritus in metabolic dysfunction associated steatotic liver disease

Nasir Hussain[1,2], Usha Gungabissoon[3], Linda Casillas[4], Sumanta Mukherjee[4], Andrea Ribeiro[5], Megan McLaughlin[4], Philip N. Newsome[1,2], Matthew Armstrong[1], Palak J. Trivedi[1,2].
[1]*National Institute for Health Research, Biomedical Research Centre, Birmingham, United Kingdom;* [2]*University of Birmingham, Birmingham, United Kingdom;* [3]*GSK, London, United Kingdom;* [4]*GSK, Collegeville, PA, United States;* [5]*GSK, Madrid, United States*
Email: nxh100@student.bham.ac.uk

Background and aims: Pruritus is a recognised symptom of cholestasis. However, the prevalence and impact on quality of life (QoL) in metabolic dysfunction associated steatotic liver disease (MASLD) has not been evaluated. We conducted a prospective observational study across a UK tertiary centre to (A) quantify the prevalence of pruritus (B) determine factors associated with pruritus intensity and (C) determine the impact of pruritus on health related QoL in patients (pts) with MASLD.
Method: Adults with MASLD were invited to complete specific itch severity and QoL questionnaires during routine outpatient visits; specifically, 5D-itch, itch numerical rating scale (NRS), chronic liver disease questionnaire (CLDQ) and EuroQol-5 Dimension 5 level (EQ-5D 5L). QoL assessments were undertaken at baseline and week 48, alongside paired clinical and laboratory data capture. Interim results pertaining to baseline readouts are presented herein. Autoimmune hepatitis, chronic hepatitis B and healthy volunteers served as control groups (each n = 50).
Results: Between Feb 2022 and Aug 2023 we recruited 200 pts with MASLD (115 men; 139 with diabetes mellitus; median age: 60y; median MELD score: 7; and median transient elastography score: 11.0 kPa). Overall, 66 pts were stratified as having no/early fibrosis (elastography <8.0 kPa and/or liver biopsy stage F0-F2), 47 with advanced fibrosis (biopsy F3), 66 with cirrhosis, and 21 as fibrosis unclassified. At baseline, 99 pts (49.5%) reported pruritus to any degree (median 5D-itch: 8.5 vs 5.0 in all control groups, $p < 0.001$), with 62 pts (31%) reporting moderate-severe pruritus (NRS ≥ 4). In the MASLD group, median 5D-itch scores were greater in women (10.0 vs 7.0 in men; $p = 0.04$) and those with more advanced disease (6.0 in no/early fibrosis, 8.0 in advanced fibrosis, and 10.0 in those with cirrhosis; $p = 0.04$). Conversely, individuals taking metformin reported lower itch scores (median 5D-itch: 5.0 vs 10.0 for those not on metformin; $p = 0.03$). 5D-itch scores had moderate positive correlations with body mass index ($r = 0.30$, $p < 0.01$) and serum autotaxin values ($r = 0.33$, $p = 0.02$), weak positive correlations with serum bile acid values ($r = 0.17$, p 0.03), and negatively correlated with serum albumin ($r = -0.24$, $p < 0.01$). No significant correlations were seen for 5D-itch and serum ALT, ALP, gGT or bilirubin. Pruritus severity associated with worse quality of life, with median CLDQ scores in those with no, mild, moderate, and severe itch on NRS of 5.6, 5.1, 4.1 and 3.7, respectively. In turn, median EQ-5D-5L scores for no, mild, moderate, and severe itch were 0.80, 0.77, 0.68 and 0.33, respectively.
Conclusion: One in 3 MASLD pts experience moderate to severe itch, with greater symptom severity in those with advanced fibrosis. Long-term follow-up capturing variability in itch over time, efficacy of anti-cholestatic agents, and factors influencing its persistence are ongoing.

FRI-221

Prevalence and mortality of the spectrum of steatotic liver disease (SLD) in the US populations

Email: zobair.younossi@cldq.org

Background and aims: The multi-society process to re-name non-alcoholic fatty liver disease led to the creation a new nomenclature. In this context, SLD and its subtypes has provided an opportunity to better assess the interaction of metabolic dysfunction (MetD) with different types of liver diseases. Our aim was to assess the prevalence and mortality of the spectrum of SLD in the U.S.
Method: Data for adults (20–74 years) from the National Health and Nutrition Examination Survey III linked with mortality (follow-up 2019) was utilized. SLD was determined as presence of hepatic steatosis by ultrasound. Definitions of different types of SLD were based on the multi-society consensus. Prevalence and mortality of each subtype of SLD were determined. Multivariable cox regression model with appropriate sample weights was used to investigate factors associated with mortality.
Results: Of 13, 260 adults from NHANES III [mean age 42.9 years; 49.2% male; 76.1% white, 10.7% Black, and 5.4% Mexican American, 7.7% other], 80.8% had at least one cardiometabolic risk (CMR) (65.5% High BMI/WC, 30.7% High Glucose/H1C, 32.1% High Blood pressure, 30.3% High Triglycerides, and 39.1% Low HDL-cholesterol). The following age-adjusted prevalence rates were noted among U.S. adults: SLD (34.3%); metabolic dysfunction-associated steatotic liver disease (MASLD) (25.7%); MetALD (0.62%); ALD with or without MetD (3.03% and 0.20%); viral hepatitis with or without MetD (0.86% and 0.20%); cryptogenic SLD with or without MetD (0.40% and 3.26%); other liver diseases without SLD (9.47%). After a median follow-up of 22.8 years [274, 485 person-years (PY)], the highest mortality rate (per 1, 000 PY) was observed for cryptogenic SLD with MetD (26.73), followed by viral hepatitis with MetD (26.08), ALD with MetD (23.34), MetALD (22.31), MASLD (19.34) and liver diseases without SLD (14.16). Socio-demographic-adjusted model showed that viral hepatitis with MetD had the highest mortality risk (Hazard Ratio [HR] = 3.51 [95% confidence interval, 2.12–5.82]) followed by cryptogenic SLD with MetD (HR = 2.10 [1.36–3.25]), MetALD (HR = 1.76 [1.28–2.42]) and MASLD (HR = 1.19 [1.09–1.29]), while other SLDs without MetD had no significant mortality risk.
Conclusion: Among the spectrum of SLD, MASLD is the most common subtype of SLD while cryptogenic SLD is associated with highest mortality rates. Presence of MetD increases the risk of mortality in different subtypes of SLD (Met-Viral Hepatitis, Met-Cryptogenic SLD, MetALD and MASLD) suggesting the dual impact of both MetD and other liver disease (ALD and Viral Hepatitis) in driving mortality.

FRI-222-YI

A prospective assessment of disease progression impact on patient-reported outcomes in metabolic dysfunction-associated steatotic liver disease

Ian P. O'Connor[1], Brent A. Neuschwander-Tetri[2], Philip N. Newsome[3], Andrea Mospan[4], Heather Morris[4], Cheryl Schoen[4], A. Sidney Barritt Iv[5], Arun J. Sanyal[1]. [1]*Stravitz-Sanyal Institute for Liver Disease and Metabolic Health at VCU School of Medicine, Richmond, United States;* [2]*Saint Louis University, St. Louis, United States;* [3]*University of Birmingham, Birmingham, United Kingdom;* [4]*Target RWE, Durham, United States;* [5]*UNC Liver Center, University of North Carolina, Chapel Hill, United States*
Email: ian.oconnor@vcuhealth.org

Background and aims: Metabolic dysfunction associated-steatotic liver disease and steatohepatitis (MASLD and MASH respectively) are major causes of liver-related morbidity and mortality. While several studies have reported clinical event rates in patients with MASLD,

there is a paucity of data on the impact of progression to cirrhosis on patient reported outcomes (PRO) and health related quality of life (HRQOL). The aim of this study was to perform a prospective, cross-sectional analysis of MASLD-specific PRO in patients with MASLD in a real-world setting.

Method: A prospective analysis of the NASH-CHECK PRO in the real-world TARGET-NASH observational longitudinal ongoing cohort in patients enrolled in the United States at academic and community sites was performed from 2021 to 2023. PRO and HRQOL were evaluated in a subset of participants using the NASH-CHECK instrument (version 1.0) that was developed and validated per regulatory guidance. MASLD was defined per the TARGET-NASH definitions using available biopsy, imaging, and clinical criteria as described previously. Three categories of patients were compared using previously published and validated case-definitions: (1) MASL, (2) MASH, (3) MASH cirrhosis. NASH-CHECK has 6 symptom scale scores and three additional HRQOL scores; each has a score of 0–10 with higher scores indicating greater impairment. Scores across classes were compared using ANOVA. A p value < 0.05 was considered significant.

Results: Data from 801 participants with a completed NASH-CHECK PRO and MASLD were obtained (n = 249, 296, 256 for MASL, MASH, and MASH cirrhosis respectively). Median age was 62, 61% female, 81% Non-Hispanic White, 7% Non-Hispanic Black, 7% Hispanic/Latino, 65% obese (BMI ≥ 30), 22% cardiovascular disease, 80% hypertension, 61% type 2 diabetes, 72% dyslipidemia, median follow-up 68 months. Significant differences were noted between MASL, MASH, and MASH cirrhosis: $p < 0.001$ for itchy skin, activity limitation, emotional impact, social impact; $p = 0.011$ for fatigue; $p = 0.018$ for cognitive impact. Scores for those with MASH cirrhosis were significantly higher than MASL and MASH for all domains except abdominal pain, abdominal bloating, and sleep.

Conclusion: In a real-world clinical setting, the recently validated MASLD-specific PRO measure instrument, NASH-CHECK, demonstrated significantly worse scores in patients with MASH cirrhosis vs those with MASL or MASH in 6 out of 9 domains.

FRI-223

Cost-effectiveness of one-time screening for advanced hepatic fibrosis using FIB-4 based two-step algorithm in the general population

Eileen Yoon[1], Jihyun An[2], Ha Il Kim[3], Joo Hyun Sohn[3], Bo-Kyeong Kang[4], Eun Chul Jang[5], Huiyul Park[6], Hye-Lin Kim[7], Sang Bong Ahn[8], Joo Hyun Oh[9], Dae Won Jun[10]. *[1]Department of Internal Medicine, Hanyang University, Seoul, Korea, Rep. of South; [2]Department of Internal Medicine, Hanyang University, Guri, Korea, Rep. of South; [3]Department of Internal Medicine, Hanyang University College of Medicine, Guri, Korea, Rep. of South; [4]Department of Radiology, Hanyang University College of Medicine, Seoul, Korea, Rep. of South; [5]Department of Occupational and Environmental Medicine, Soonchunhyang University College of Medicine, Chun An, Korea, Rep. of South; [6]Department of Family Medicine, Myoungji Hospital, Hanyang University College of Medicine, Goyangsi, Korea, Rep. of South; [7]College of Pharmacy, Sahmyook University, Seoul, Korea, Rep. of South; [8]Department of Internal Medicine, Nowon Eulji Medical Center, Eulji University, College of Medicine, Seoul, Korea, Rep. of South; [9]Department of Internal Medicine, Nowon Eulji Medical Center, Eulji University, College of Medicine, Seoul, Korea, Rep. of South; [10]Department of Internal Medicine, Hanyang University College of Medicine, Seoul, Korea, Rep. of South*
Email: noshin@hanyang.ac.kr

Background and aims: There is currently inadequate evidence supporting one-time screening and intensive lifestyle modification for advanced fibrosis in the general population. Therefore, this study is designed to assess the cost-effectiveness of a screening strategy utilizing the FIB-4 test followed by vibration-controlled transient elastography (VCTE) for identifying advanced hepatic fibrosis within the general United States population.

Method: We constructed a combined model of the decision tree model and Markov model to compare expected costs and quality-adjusted life-years (QALYs) between 'screening' and 'no screening' groups from healthcare system perspectives. Cardiovascular disease (CVD) conditions, which have the potential combined with advanced hepatic fibrosis, were also incorporated into the model. Patients diagnosed with advanced fibrosis in the screening group were given intensive lifestyle intervention (ILI). The incremental cost-effectiveness ratio (ICER) was calculated for a 30-year horizon.

Results: ICERs of one-time screening for advanced hepatic fibrosis using FIB-4 based two-step algorithm in the general population in their 40 s was $69, 242 per QALY, respectively, which was under the $100, 000, regarded as an ICER threshold in the US, indicating that screening is cost-effective. However, those before their 30 s and after 60 s exceeded the threshold. The most influential parameters on cost-effectiveness were the ILI success rate and duration of ILI. If the success rate of ILI drops to less than 28% (as fibrosis regression rate, 14.1%), cost-effectiveness was disappeared.

Conclusion: Screening for detecting advanced hepatic fibrosis using FIB-4 based two-step algorithm followed by ILI was cost-effective in the general population with 40 s.

FRI-224

Intramyocellular lipids are associated with insulin resistance in metabolic dysfunction-associated steatotic liver disease

Guillaume Henin[1,2], Maxime Nachit[2], Harmen Reyngoudt[3], Etienne Danse[4], Pierre Trefois[4], Frank Peeters[4], Salomé Declerck[2], Stéphanie André-Dumont[1], Alexis Goffaux[2], Benjamin Marty[3], Isabelle Leclercq[2], Audrey Loumaye[5], Nicolas Lanthier[1,2]. *[1]Service d'Hépato-gastroentérologie, Cliniques universitaires Saint-Luc, UCLouvain, Brussels, Belgium; [2]Laboratory of Hepatogastroenterology, Institut de Recherche Expérimentale et Clinique, UCLouvain, Brussels, Belgium; [3]Institute of Myology, Neuromuscular Investigation Center, NMR laboratory, Paris, France; [4]Service de Radiologie, Cliniques universitaires Saint-Luc, UCLouvain, Brussels, Belgium; [5]Service d'Endocrinologie, diabétologie et nutrition, Cliniques universitaires Saint-Luc, UCLouvain, Brussels, Belgium*
Email: nicolas.lanthier@saintluc.uclouvain.be

Background and aims: Insulin resistance is considered an indicator of the severity of MASLD. In this context, the role of skeletal muscle fat and its intra- or extra-myocellular localisation on insulin sensitivity remains debated. The aim of this study is to assess muscle lipid content and cellular localisation using proton-magnetic resonance spectroscopy (^{1}H-MRS) and its relationship with insulin resistance in a cohort of MASLD subjects.

Method: MASLD patients were prospectively recruited based on the co-existence of liver steatosis measured by a controlled attenuation-parameter (CAP) above 251 dB/m and at least one cardiometabolic risk factor. Type 2 diabetes was defined by the intake of hypoglycemic drugs. Insulin resistance was estimated in non-diabetic patients using the homeostatic model assessment of insulin resistance (HOMA-IR). Intra (IMCL) and extramyocellular lipids (EMCL) were measured in vivo using ^{1}H-MRS. Single voxel ^{1}H-MRS was performed on a 3-Tesla Signa Premier scanner (GE healthcare) on tibialis anterior (TA) and soleus using a PRESS-sequence (voxel size $10 \times 10 \times 15$ mm^3, TE = 27 ms, TR = 1500 ms, 8 averages). JMRUI software, including the AMARES algorithm was used to quantify IMCL and EMCL on non-water suppressed spectra.

Results: 54 MASLD patients were included. 32 patients were male (59%), with a mean age of 54 years (range: 19–75). 27 patients were diabetic (50%). Mean BMI was 35 (range: 24–60). Mean waist circumference was 118 cm (range: 89–160). Mean CAP and liver elasticity were 342 dB/m (range: 242–400) and 14.8 kPa (range: 3.6–35). In the entire cohort, mean TA lipid content was 0.6% for IMCL (range: 0.1–1.5) and 1.8% (0.3–6.8) for EMCL ($p < 0.05$). Mean soleus

lipid content was 0.8% for IMCL (range: 0.2–2.1) and 4.4% for EMCL (range: 0.3–10.9) ($p < 0.05$). In non-diabetic patients, mean fasting glycaemia was 103 mg/dl (range: 76–126) and mean HOMA-IR was 8 (range: 1.7–26). The HOMA-IR index was positively correlated to IMCL content in the TA ($r = 0.63$, $p = 0.017$) but no correlation was found with EMCL content or with soleus fat content (IMCL and EMCL). Diabetic patients had a higher IMCL content in the soleus compared to non-diabetic patients (0.9% versus 0.6%; $p = 0.02$). No difference was highlighted for the EMCL content of soleus (4.1% versus 4.7%; $p > 0.05$) or for IMCL for TA (0.55% versus 0.7%; $p > 0.05$) between diabetic and non-diabetic patients.

Conclusion: The majority of skeletal muscle lipids are extramyocellular. However, IMCL but not EMCL content assessed by ^{1}H-MRS positively correlates with insulin resistance assessed by the HOMA-IR index in non-diabetic MASLD patients. This observation is reinforced by the IMCL content in diabetic patients being significantly higher compared to non-diabetic patients. This observation highlights a link between IMCL, systemic insulin resistance and type 2 diabetes in MASLD.

FRI-225

Novel digital pathology adequacy score benchmarks the performance of pre-analytical method for digital pathology and AI end-to-end tissue assays

Louis Petitjean[1], Li Chen[2], Adi Lightstone[2], Nathan Aist[2]. *[1]PharmaNest, Inc, Princeton, United States; [2]PharmaNest Inc, Princeton, United States*
Email: louis.petitjean@pharmanest.com

Background and aims: The control and monitoring of pre-analytical conditions is key to minimize the noise and variability of Digital Pathology read-outs in the context of Artificial-enabled Digital Pathology tissue assay used for the assessment of liver biopsies. While modern AI algorithms can compensate for most sources of noise (FibroNest, doi: 10.1111/liv.15768), additional opportunities can be addressed for large studies. Inspired by the definition of Adequacy for tissue biopsies, we report the development, validation, and results of a Digital Biopsy Adequacy (DBA) score as a Key Performance Indicator (KPI) to measure liver biopsy pre-analytical quality.

Method: The BDA score is a normalized composite score (1 to 10) to evaluate a digital pathology image along three dimensions and 24 features including (i) Biopsy tissue and glass slide processing (11 features such as area of the biopsy, tissue rupture, folding artifacts) (ii) staining quality (7 features including over or under staining, rinsing artefacts) and (iii) digital scanning (6 features including out-of-focus areas, scanning stripes). The score is based on a point-based method where defects have different penalty weights, such as one single defect can significantly affect the overall score. The method is consistent with the August 2021 FDA Guidance to Industry and Technical Specifications for Submission of Clinical Trials Data Sets for Treatment of NASH, Bio specimen Findings (BS) domain. Digital Pathology images are classified as Non-Adequate ($DBA < 5$), Minimally Acceptable ($5 < DBA < 8$) and Acceptable ($BDA > 8$). We report aggregated DBA results for N = 5227 Digital images processed since 2020 from 13 Phase 2 and 3 MASH studies.

Results: From one operator scoring 385 images and a second independent operator scoring a random subset of 99 images, the Intra-Class Correlation (ICC) is 0.876 ("excellent," Cichetti, 1994) and the Linear Correlation is 0.889 ("good," Koo and Li, 2016). We observe significantly different Not Acceptable ratios (Min 0%, Mean 8%, Median 6% Std 10% Max 41%) and Acceptable Ratios (35%, 71%, 79%, 19%, 97%) across studies. The main toot causes for non and minimal adequacy are overstaining, sectioning and folding artefacts, which can be resolved by basic quality control procedures and rework. Best in class performers demonstrate non-acceptable images can be fully avoided.

Conclusion: The use of a KPI for pre-analytical quality in a Digital Pathology end-to-end tissue assay has the potential to significantly improve the Digital Pathology Images used in MASH studies. The industry benchmark (13 studies, 5227 images) demonstrates that defect rates (not-acceptable biopsies) can be realistically expected to be below 3% and that the rate of fully adequate digital images be above 80%. This KPI should be used to incentivize some pre-analytical laboratories to implement basic Quality Assurance and rework processes.

FRI-226

The impact of light to moderate alcohol consumption on liver and cardiovascular damage in metabolic-dysfunction associated steatotic liver disease

Rosa Lombardi[1], Felice Cinque[1], Andrea Dalbeni[2], Annalisa Cespiati[1], Floriana Santomenna[1], Jaqueline Currà[1], Daniel Smith[1], Erika Fatta[1], Cristina Bertelli[1], Giuseppina Pisano[1], Edoardo Pulixi[1], Anna Mantovani[2], Mirko Zoncapè[2], David Sacerdoti[2], Anna Ludovica Fracanzani[1]. *[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico of Milan, University of the Study of Milan, Milan, Italy; [2]University of Verona and University and Hospital Trust (AOUI) of Verona, Verona, Italy*
Email: rosalombardi@hotmail.it

Background and aims: Metabolic-dysfunction associated steatotic liver disease (MASLD) and met-ALD are both characterized by hepatic fat and metabolic alterations without other causes of liver disease but the amount of daily alcohol consumption in their definition differs (0–30/0–20 die vs 30–60/20–50 g/die male/female). MASLD and met-ALD expose patients to progressive liver disease and increased cardiovascular (CV) risk, however the impact of the amount of alcohol in this setting needs to be elucidated. Aim: to evaluate the impact of light alcohol consumption in MASLD on the hepatic and CV damage in a multicentric cohort of steatotic patients with metabolic alterations as compared to total abstinence and met-ALD

Method: 729 patients with ultrasound (US) proven steatosis (mean age 52 ± 12 years, 77% male) without other causes of liver disease were enrolled and classified according to their drinking habits as abstainers (0 g/die) and light consumers in MASLD (<30/20 g/die male/female) or met-ALD (30–60/20–50 g/day male/female). Steatosis was graded by US, hepatic fibrosis diagnosed by LSM > 8.0 kPa at Fibroscan, CVD by carotid US (cIMT > 0.9 mm, plaques) and echocardiography (systolic and diastolic function, epicardial adipose tissue EAT > 7.5/9.5 mm M/F).

Results: 397 (54%) were no alcohol consumers (NAC-MASLD), 290 (40%) light alcohol consumers (LAC-MASLD) and 42 (6%) met-ALD. Considering LAC-MASLD vs NAC-MASLD, there was no difference in the severity of liver disease (severe US steatosis 22% vs 16% $p = 0.06$, LSM > 8 kpa 9% vs 9%, $p = 0.89$). Conversely, LAC had a significantly lower prevalence of cIMT > 0.9 mm compared to NAC (18% vs 28%, $p = 0.005$) and resulted an independent protective factor for increased cIMT (adjusted for age, sex, active smoking, T2DM, hypertension, dyslipidemia, overweight; OR 0.58, CI 95% 0.36–0.93). No difference in other CV parameters was observed. Considering LAC-MASLD vs met-ALD, the latter had significantly higher LSM values (6.4 ± 3.2 vs 5.4 ± 2.2, $p = 0.02$) despite a not significantly different prevalence of LSM > 8 kPa (19% vs 9%, $p = 0.10$). Met-ALD vs LAC-MASLD had a significantly higher prevalence of carotid plaques (55% vs 30%, $p = 0.003$) and resulted an independent risk factor for carotid plaques (adjusted for sex, active smoking, T2DM, hypertension, dyslipidemia, overweight, statins use; OR 2.01, CI 95% 1.00–4.12). Conversely, there was no difference in the prevalence of severe US steatosis or other CV parameters.

Conclusion: Light alcohol consumption in middle-aged MASLD patients appears to protect against early atherosclerosis without exhibiting more severe liver disease compared to abteiners. However, when alcohol consumption increases up to the level of met-ALD, the cardiovascular protection is hampered and alcohol becomes harmful also for the liver.

FRI-227

Impact of antidiabetic medications on adverse liver outcomes in patients with type 2 diabetes mellitus: independent and interactive effects

Sherlot Juan Song[1], Vincent Wai-Sun Wong[1], Grace Lai-Hung Wong[1], Terry Cheuk-Fung Yip[1]. [1]*Medical Data Analytics Centre (MDAC), Department of Medicine and Therapeutics, The Chinese University of Hong Kong, Institute of Digestive Disease, Faculty of Medicine, The Chinese University of Hong Kong, HK, Hong Kong*
Email: 1155169298@link.cuhk.edu.hk

Background and aims: The impact of antidiabetic medications on liver-related events (LRE) among patients with type 2 diabetes mellitus (T2DM) remains unclear. This study aimed to investigate the independent and interactive effects of antidiabetic medications on the hazards of LRE in patients with T2DM.
Method: This territory-wide retrospective study included adult patients diagnosed with T2DM between January 2007 and December 2021 in Hong Kong. Patients with chronic viral hepatitis, excessive alcohol use, other metabolic and autoimmune liver diseases, malignancies, and pre-existing LRE were excluded. The primary end point was LRE, defined as hepatic decompensation or the development of hepatocellular carcinoma. A cause-specific hazard model was used to calculate hazards ratios (HR) with 95% confidence intervals (CI), with LRE as the event of interest. Time-dependent analysis and interaction analysis were employed to investigate the effects of medications on LRE. LRE-free survival probability was predicted based on combinations of medications with significant interaction.
Results: A total of 575, 000 patients with T2DM (mean age 61.9 years; 52.3% males) were included with a median follow-up duration of 6.2 years. 4882 patients developed LRE during the follow-up period. Statin (HR: 0.59, 0.55–0.63), metformin (HR: 0.89, 0.83–0.96), Inhibitors of dipeptidyl peptidase 4 (DPP-4 inhibitors) (HR: 0.85, 0.79–0.93) and sodium-glucose cotransporter-2 inhibitors (HR: 0.70, 0.62–0.78) were all associated with decreased hazards of LRE, while insulin (HR: 1.83, 1.72–1.95) and sulfonylureas (HR: 1.20, 1.13–1.29) increased the risk of LRE. A significant synergistic effect between DPP-4 inhibitors and stain was observed (p value < 0.05). The incidence rate of LRE among patients receiving DPP-4 inhibitors but not statins was 1.341 cases per 1000 person-years, compared with 1.169 cases per 1000 person-years in those receiving both medications.
Conclusion: Antidiabetic medications have varied impact on hazards of LRE. A synergistic interaction was indicated between statin and DPP-4 inhibitors to lower the risk of LRE among patients with T2DM.
This study was supported by Health and Medical Research Fund of Health Bureau of HKSAR Government (Reference number:19202141).

FRI-230-YI

Prevalence and predictors of steatotic liver disease and significant liver fibrosis in an integrated hepatological and non-hepatological healthcare pathway model: preliminary results from a prospective cohort of a tertiary center

Background and aims: An integrated healthcare pathway model for metabolic-dysfunction associated steatotic liver disease (MASLD) is recommended for a comprehensive evaluation of the metabolic health. In this prospective study we aimed to assess prevalence and predictors of steatotic liver disease (SLD) and significant liver fibrosis (SLF) in consecutive patients first referred for type 2 diabetes mellitus (T2DM) or SLD in two different settings (diabetology and hepatology clinics) of the "AOU Città della Salute e della Scienza di Torino" University Hospital.
Method: All patients underwent vibration-controlled transient elastography for liver stiffness measurement (LSM) and controlled attenuation parameter (CAP), and echocardiography with speckle tracking analysis. SLD was defined by CAP > 247 dB/m. SLF was defined by LSM > 7 kPa. Diastolic dysfunction was defined by mitral E/E' ratio>9 and systolic dysfunction by left ventricular global longitudinal strain (GLS) > –18.
Results: 544 patients (59% in the liver clinic group [LCG] and 41% in the diabetes clinic group [DCG]) were enrolled. In the LCG all patients fulfilled the criteria for MASLD; prevalence of T2DM and obesity were 21.8% and 42.7%; 4.7% were referred to the DCG for first diagnosed or decompensated T2DM. Median LSM was 5.1 [4.6–6.3] kPa and SLF was detected in 17.8% of cases. In the DCG prevalence of obesity was 52.0% and median LSM was 4.9 [4.1–5.9] kPa. SLD was present in 67.7% of cases, of which 59.6% MASLD, 1.3% ALD (alcohol-related liver disease) and 6.7% metALD. SLF was detected in 13.5% of cases, which were referred to the LCG for hepatological evaluation. A known cardiovascular disease (CVD) was found in 9.7% and 50.2% of patients in the LCG and DCG, respectively. A high Framingham risk score (>20%) was detected in 12.9% in the LCG and 1.3% in the DCG. Prevalence of diastolic and systolic dysfunctions in those without CVD were 27.4% and 18.2% in the LCG and 8.9% and 3.6% in the DCG. In the LCG, Body Mass Index (BMI) and T2DM were the strongest predictors of SLF (aOR 1.13[95%CI 1.06–1.21], p = 0.0002 and 5.66 [95% CI 2.64–12.07], p < 0.001). In the DCG, only transaminases were independent predictors of SLF (aOR 1.11 [95%CI 1.04–1.19], p = 0.001), while BMI was the only predictor of SLD (aOR 1.09 [95%CI 1.03–1.16], p = 0.001).
Conclusion: Two thirds of SLD in the non-hepatology setting are due to MASLD and associated with BMI. Prevalence of SLF is similar in hepatology and non-hepatology settings, but presence of T2DM results in the strongest association independent of other metabolic risk factors. A higher prevalence of pre-clinical CVD is detected in the hepatology setting by advanced echocardiography, consistent with a higher 10-year risk of CVD-related mortality. This study was funded by the Italian Ministry for Education, University and Research (MIUR) under the programme 'Dipartimenti di Eccellenza 2018–2022' Project code D15D18000410001.

Background and aims: Moderate alcohol intake in patients with metabolic dysfunction-associated steatotic liver disease (MASLD) may increase their severity. Met-ALD has been recently defined as metabolic dysfunction associated with moderate alcohol intake of 140/210 g to 350/420 g per week in females and males respectively. There is no data on the effect of alcohol intake less than the moderate amount on the severity of liver disease in patients with MASLD. The aim of the study was to assess the effect of alcohol intake less than the moderate amount on the severity of liver disease in patients with MASLD.
Method: In an on-going real-life Indian Consortium on MASLD study, interim data across 31 centres over 4.5 years (n = 6963) was analysed to compare the severity of non-invasive tests (NITs) namely, aspartate aminotransferase-to-platelet ratio index (APRI), Fibrosis-4 (FIB-4) and FibroScan-AST (FAST) scores among total alcohol abstainers of alcohol Vs those taking <140 g/week alcohol intake within the cohort of MASLD. The study had ethical approval at respective centres and all patients gave an informed consent.
Results: Out of total of 6963 patients [males:61.2%, age:45.8 (32–52)], 5622 (81%) were total abstainers and 1341 (19%) were taking alcohol <140 g/week. Data on the metabolic syndrome, APRI, FIB-4, FAST score and LSM was available in 6097 (87%), 6963 (100%), 2640 (38%), and 2644 (38%) patients. There was no difference in the prevalence of metabolic syndrome amongst the two groups. Total abstainers had significantly lower mean APRI [0.63 ± 0.85 Vs 0.72 ± 0.77, p = 0.03], FAST [0.41 ± 0.24 Vs 0.44 ± 0.22, p = 0.04] and LSM scores (9.43 ± 8.3 Vs 11.7 ± 24.4, p = 0.001) scores than those with alcohol intake with no difference in mean FIB-4 score [1.64 ± 1.87 Vs 1.64 ± 1.87, p = 0.251] among the two groups.
Conclusion: In patients with MASLD, non-significant alcohol use may be associated with severe liver disease in comparison to those with complete abstainers.

FRI-232

In Patients with Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD), Clinically Significant Pruritus is Associated with High Serum Bile Acid (BA) Level and Advanced Fibrosis (AF)

Zobair Younossi[1,2], James M. Estep[1,3], Sean Felix[1], Brian Lam[1,3], Sumanta Mukherjee[4], Brandon Swift[5], Linda Casillas[4], Andrea Ribeiro[6], Jake Hunnicutt[4], Megan McLaughlin[4], Andrei Racila[1,3], Fatema Nader[1,3,7], Maria Stepanova[1,3,7]. *[1]Beatty Liver and Obesity Research Program, Inova Health System, Falls Church, VA, United States; [2]The Global NASH Council, Washington, United States; [3]The Global NASH Council, Washington, DC, United States; [4]GSK, Collegeville, PA, United States; [5]GSK, Durham, NC, United States; [6]GSK, Madrid, Spain; [7]Center for Outcomes Research in Liver Diseases, Washington, DC, United States*
Email: zobair.younossi@cldq.org

Background and aims: Elevated serum BA are associated with pruritus in cholestatic liver diseases. We aimed to assess the associations of serum BA with clinically significant (CS)-pruritus in patients with MASLD.
Method: We used previously collected frozen fasting serum samples and simultaneously collected data (including CLDQ) from patients with MASLD. Patients with viral hepatitis (B, C) and healthy blood donors were used as controls. The diagnosis of non-alcoholic steatohepatitis (NASH), also known as Metabolic Dysfunction-Associated Steatohepatitis (MASH), was based on liver biopsy. Serum was used to measure BA levels using Diazyme Total Bile Acids Assay kit. High BA level was defined as ≥5.9 µmol/L. Significant fibrosis (SF) was defined as histologic stages 2–4 or liver stiffness by transient elastography >8 kPa, and advanced fibrosis (AF) was defined as histologic stages 3–4 or liver stiffness >10 kPa. Pruritus was assessed using the itch item of CLDQ (frequency of itch over the past 2 weeks; score from 1 (all the time) to 7 (none of the time), CS-pruritus defined as ≤4.
Results: This cross-sectional study included 651 subjects: MASLD (N = 497) including MASH/NASH (N = 88), viral hepatitis B and C (VH, N = 98) and healthy controls (N = 56). Across the diagnostic groups, VH patients had the highest BA levels with the lowest levels in healthy controls (p < 0.0001 across groups). There were no differences in the prevalence of CS-pruritus across these groups (p = 0.63). The correlation of higher BA with more itch (lower itch scores) was only seen in MASLD (r = –0.15, p = 0.0006) with stronger correlations according to histologic severity (MASH/NASH: r = –0.23, p = 0.029; SF: r = –0.30, p = 0.0005; AF: r = –0.43, p = 0.0001). Patients with MASH/NASH had higher levels of BA (7.3 ± 11.2 vs. 3.9 ± 5.3 µmol/L in non-MASH MASLD) and 34/88 (39%) vs. 95/409 (23%) met high BA criteria (p < 0.05). Furthermore, MASLD patients with SF and AF had even higher serum BA levels (SF vs no SF: 6.6 ± 10.2 vs. 3.6 ± 4.8 µmol/L, high BA 43/130 (33%) vs. 70/334 (21%), p < 0.01; AF vs no AF: 8.1 ± 11.7 vs. 3.7 ± 5.2 µmol/L, high BA 27/74 (37%) vs. 86/390 (22%), p < 0.01). MASLD/NAFLD and its subgroups with high BA had more CS-pruritus, and this pattern was more pronounced in patients with greater disease severity (CS-pruritus with high BA vs. those without high BA in all MASLD: 25% vs. 17%; in NASH/MASH 30% vs. 13%; in SF: 33% vs. 12%; in AF: 41% vs. 8%; all p ≤ 0.05). In multivariable logistic regressions adjusted for age, sex, obesity, and type 2 diabetes (T2D), having high BA was an independent predictor of CS-pruritus in MASLD patients with SF [OR = 3.48 (1.37–8.84) (p = 0.009)] and AF [OR = 7.29 (1.95–27.32) (p = 0.003)]. Notably, associations of T2D and obesity with CS-pruritus were not significant (all p > 0.10).
Conclusion: High serum BA level is associated with pruritus in MASH. High BA is an independent predictor of pruritus in MASLD, especially those with advanced fibrosis.

FRI-233

Cardiovascular disease burden in patients with and without metabolic dysfunction-associated steatohepatitis: data from the unCoVer-MASH longitudinal cohort study

Elisabetta Bugianesi[1], Anurag Mehta[2], Kamal Kant Mangla[3], Abhishek Shankar Chandramouli[4], Katrine Grau[3], Niels Krarup[3], Ahsan Shoeb Patel[3]. [1]*Department of Medical Sciences, University of Turin, Turin, Italy;* [2]*VCU Health Pauley Heart Center, Richmond, VA, United States;* [3]*Novo Nordisk A/S, Søborg, Denmark;* [4]*Novo Nordisk Service Center India Pvt Ltd, Bangalore, India*
Email: elisabetta.bugianesi@unito.it

Background and aims: Metabolic dysfunction-associated steatohepatitis (MASH) is linked to increased risk of cardiovascular (CV) disease (CVD), but many aspects of CVD burden in patients with MASH remain unknown. Particularly, data on the clinical burden of CVD and specific CV events in patients with MASH vs those without MASH are limited. This real-world study aimed to assess CVD burden in patients with and without MASH.
Method: Patients with MASH were identified using the International Classification of Diseases code for non-alcoholic steatohepatitis (K75.81) from October 2015-June 2022, using data from a federated network (TriNetX). Index date was defined as the date of first MASH diagnosis. Exclusion criteria were viral hepatitis, alcohol use disorder, chronic liver diseases other than MASH or metabolic dysfunction-associated steatotic liver disease, cirrhosis, decompensated MASH, hepatocellular carcinoma and human immunodeficiency virus. Patients with MASH were matched 1:1 to patients without MASH based on demographics (sex, age, year of start/end of insurance enrolment, and insurance scheme). Outcomes were CVD prevalence (assessed up to 1 year prior to index) and risk of CV events (s) during follow-up (index date to end of enrolment, death or study end) amongst patients with no history of respective CV event (s) at baseline. For CV risk, cumulative incidence was plotted using Aalen-Johansen curves after adjusting for competing risk of non-CV death. Incidence rate (IR) was calculated per 100 person-years (PY) and hazard ratios (HR) were calculated using Cox proportional hazard models (crude and adjusted for CV risk factors [age, sex, type 2 diabetes (T2D), chronic kidney disease (CKD), obesity, hyperlipidaemia and hypertension]).
Results: In total, 9, 642 patients (4, 821 with MASH; 4, 821 without MASH) were included. In both groups, mean (standard deviation) age was 50.8 (13.2) years and 58.5% were women. Compared with those without MASH, more patients with MASH had hypertension (58% vs 31%), hyperlipidaemia (57% vs 30%), obesity (45% vs 17%), T2D (41% vs 14%) and CKD (6% vs 3%) at baseline. Prevalence of any CVD was higher in patients with MASH than without MASH (23% vs 12%), as was risk of any CV event (IR: 11.1 vs 4.5 per 100 PY; crude HR [95% confidence interval]: 2.72 [2.30, 3.22], $p < 0.0001$; adjusted HR: 2.27 [1.95, 2.66], $p < 0.0001$). Similar results were seen for individual CV events, namely ischaemic heart disease (IR: 5.3 vs 2.3), cerebrovascular disease (IR: 4.4 vs 2.1), atherosclerosis (IR: 3.9 vs 1.8), and heart failure (IR: 3.2 vs 1.5).
Conclusion: CVD prevalence at baseline and risk of CV events during follow-up were significantly higher in patients with non-cirrhotic MASH compared with matched controls without MASH in a real-world cohort. These data provide additional evidence of the association between MASH and CVD, and complement a previous analysis of the unCoVer-MASH study.

FRI-234

Association between the duration of comorbidities and steatotic liver disease

Ha Il Kim[1], Hyunji Sang[2], Jihyun An[3], Eileen Yoon[3], Dae Won Jun[3], Joo Hyun Sohn[4]. [1]*Hanyang University Guri Hospital, Guri, Korea, Rep. of South;* [2]*Kyung Hee University Hospital, Seoul, Korea, Rep. of South;* [3]*Hanyang University College of Medicine, Seoul, Korea, Rep. of South;* [4]*Hanyang University College of Medicine, Seoul, Korea, Rep. of South*
Email: mondosewan@gmail.com

Background and aims: Steatotic liver disease (SLD) is a major cause of chronic liver disease. Previous studies have been reported that SLD interacts with various comorbidities and linked with their outcome. However, there is a paucity of studies on how the duration of the comorbidities is related to SLD development and mortality. We examined the association between comorbidity duration and SLD, focusing on disease-predicting variables and mortality rates.
Method: Data from 12, 262 patients aged ≥20 years in the 2010 and 2015 Korea National Health and Nutrition Examination Survey were analyzed. Ten comorbidities (hypertension, diabetes mellitus [DM], dyslipidemia, stroke, myocardial infarction [MI], angina pectoris, asthma, chronic obstructive lung disease [COPD], chronic kidney disease [CKD], and depression) were categorized by duration. We investigated the association between presence SLD and the duration of comorbidity by using association rule mining and logistic regression analysis. Survival analysis was conducted using Cox regression analysis.
Results: Among the 2, 757 SLD cases and 9, 505 non-SLD cases analyzed, shorter durations of DM, MI, CKD, and COPD were associated with a higher proportion in SLD cases, while hypertension, dyslipidemia, stroke, and depression exhibited a lower proportion. Association rule mining highlighted the significance of shorter durations of DM and dyslipidemia, and longer durations of hypertension in predicting SLD. In multivariate logistic regression analysis, DM with a duration ≤1year showed a notably elevated odds ratio (11.53, CI 9.09–14.63). Multivariate Cox regression analysis for survival revealed that longer durations of hypertension and DM were associated with increased hazard ratios beyond 10 years (hazard ratio [HR] 2.222, HR 2.11, respectively). Cardiovascular disease duration ≤5years and lung disease duration >5 years demonstrated significant hazard ratios (HR 2.486, HR 2.382, respectively). Cardiovascular-related survival showed similar patterns, with longer HTN and shorter cardiovascular disease durations linked to higher risks. The higher FIB-4, longer HTN, and DM durations are independently associated with cancer-related survival.
Conclusion: This suggests that a comprehensive risk stratification should be undertaken, considering the duration of comorbidities, for both the identification of SLD and the assessment of their prognostic significance when they are detected.

FRI-235

Causes of death, mortality rates, and the role of socio-demographic risk factors and biomarkers in metabolic dysfunction-associated steatohepatitis mortality in more than 18, 000 real world patients from the United States

Jörn M Schattenberg[1], Claudio Sartini[2], Ronald Herrera[2], Mireia Raluy[3], Mark Yates[4], Ramy Younes[5]. [1]*Department of Medicine II, Saarland University Medical Center, Homburg, Germany;* [2]*Boehringer Ingelheim International GmbH, Global Epidemiology and Real-World Evidence, Ingelheim, Germany;* [3]*Evidera, Data Analytics, Borlänge, Sweden;* [4]*Evidera, Data Analytics, London, United Kingdom;* [5]*Boehringer Ingelheim International GmbH, Medicine, Cardio Metabolism and Respiratory, Ingelheim, Germany*
Email: joern.schattenberg@uks.eu

Background and aims: To reduce mortality risks in patients with metabolic dysfunction-associated steatohepatitis (MASH) it is critical to have a better disease understanding in real-world populations. Limitations of past studies were small sample size, point in time of

data collection, being single center, biopsy based, or broad focus on steatotic liver disease. This study investigates mortality rates, causes of death, and the role of socio-demographic risk factors and biomarkers that could be associated with mortality in a large real-world MASH population.

Method: Retrospective cohort study (2016–2021 years) using Optum Market Clarity (linked claims and electronic health records, EHRs) from the United States. MASH was defined by the first ICD10 diagnosis code (K75.81 Non-alcoholic steatohepatitis) recorded during the study period, presence of AST, ALT and platelets tests carried out 3 months prior/after diagnosis, and absence of diseases prior/at diagnosis, such as alcoholic/chronic liver diseases. Risk factors included age, sex, race, region, comorbidities, FIB-4 fibrosis score and routinely collected biomarkers such as LDL cholesterol, Triglycerides, eGFR, and HbA1c. The associations between risk factors and mortality were estimated using multivariate survival models. To contextualize findings, crude mortality rates were calculated in the subgroup of MASH patients with BMI ≥ 25 and type 2 diabetes (T2D) and in a group of patients in Optum with BMI ≥ 25 who did not report any liver diseases or T2D.

Results: 18, 710 MASH patients (mean age 44 years, 54% female, 80% white, 95% with BMI ≥ 25, 52% with T2D) had been followed-up (FU) for 6.5 years after diagnosis (mean FU = 3 years): 1465 patients died (70% from cardiovascular disease (CVD) and 17% from liver-related causes). The mortality rate was 25 per 1000 persons-year (py). African Americans (vs white) and South residents (vs North-East) had higher all-cause mortality rates [Hazard ratios (HRs) of 1.33 and 1.45 respectively]. A decrease in eGFR of 10 ml/min/1.73 m² and having 3 or more comorbidities (vs none) were also associated with increased mortality (HRs of 1.21 and 1.93 respectively). The mortality rate was 31 per 1000 py in MASH with BMI ≥ 25 and T2D (5 times higher than those with BMI ≥ 25 without liver diseases/diabetes).

Conclusion: CVD risk reduction in patients with MASH will be crucial to improve outcomes. Mortality rates are especially high in MASH patients who are overweight/obese and living with T2D. In addition, racial differences in MASH mortality were observed: African Americans and South residents were at increased risk; this may be due to less access to health care. Also, the eGFR-mortality association signaled that kidney and renal disease prevention is important. This is the largest and most comprehensive study on MASH mortality using claims and EHRs.

FRI-236-YI

Racial disparities in incidence of cirrhosis and extrahepatic manifestations in metabolic dysfunction-associated steatotic liver disease

Majd Aboona[1], Leith Ghani[1], Pooja Rangan[1], Vincent Chen[2], Cheng Han Ng[3], Daniel Huang[4], Mark Muthiah[5], Donghee Kim[6], Moises Nevah Rubin[7,8], Ma Ai Thanda Han[1,9], Michael Fallon[1,9], Karn Wijarnpreecha[1,9,10]. *[1]University of Arizona College of Medicine-Phoenix, Phoenix, United States; [2]University of Michigan Health System, Ann Arbor, United States; [3]Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore; [4]National University Hospital, Singapore, Singapore; [5]National University Health System, Singapore, Singapore, [6]Stanford University School of Medicine, Stanford, United States; [7]University of Arizona College of Medicine Phoenix, Phoenix, United States; [8]Banner University Medical Center, Phoenix, United States; [9]Banner University Medical Center, Phoenix, United States; [10]BIO5 Institute, University of Arizona College of Medicine-Phoenix, Phoenix, United States*
Email: aboona@arizona.edu

Background and aims: Metabolic Dysfunction-associated Steatotic Liver Disease (MASLD) has increased in prevalence in recent years. Data regarding the new cardiometabolic criteria of MASLD, especially in diverse patient population are limited. We conducted a study to estimate the incidence of MASLD and its complications in an ethnically diverse population.

Method: We conducted a multicenter study on MASLD patients seen at the Banner Health System, representing hospitals across Arizona, California, and Colorado, and the University of Michigan Health System from 2012 to June 2023 using ICD codes and natural language processing. We excluded patients with other causes of liver disease, underweight, baseline decompensated cirrhosis, baseline cancer diagnosis, prior bariatric surgery, or missing data on race, BMI, aspartate and alanine aminotransferase, and platelet. Patients who met 1/5 cardiometabolic criteria including BMI > 25 (BMI > 23 in Asians), hypertension, DM, dyslipidemia, or hypertriglyceridemia were included in the study. The primary outcomes are mortality, the incidence of any cardiovascular disease, cirrhosis, liver-related events (ascites, hepatic encephalopathy, variceal bleeding), type 2 diabetes mellitus, any cancer, and major adverse cardiac events (MACE) among racial groups.

Results: We included 51, 625 MASLD patients in the cohort. 67.38 % were Non-Hispanic White, 21.57 % Hispanic, 4.93 % African-American, 1.46 % Native American/Alaskan Native (NA), and 1.96 % Asian/Pacific Islanders. Compared to Non-Hispanic White patients, Hispanic patients had a higher mortality (Hazard ratio (HR) 1.19; 95 % Confidence Interval (CI), 1.01–1.40; p value, 0.03) and higher incidence of cirrhosis (HR 1.23; 95 % CI, 1.03–1.45; p value, 0.02). Furthermore, compared to Non-Hispanic White patients, NA patients had a higher mortality (HR 2.18; 95 % CI, 1.39–3.41; p value, < 0.01), higher incidence of liver-related events (HR 1.83; 95 % CI, 1.01–3.32; p value, 0.047), and higher incidence of MACE (HR 1.36; 95 % CI, 1.07–1.74; p value, 0.01).

Conclusion: In this population-based cohort of patients with MASLD, Hispanic patients had higher risk of mortality and cirrhosis despite controlling for other variables. Furthermore, NA had a higher risk mortality, liver related events, and MACE. Attention to racial disparities and cardiac risk stratification is warranted in patients with MASLD, particularly in the NA population.

FRI-237

Natural history of lean and non-lean metabolic dysfunction associated steatotic liver disease

Shun-ichi Wakabayashi[1], Nobuharu Tamaki[2], Takefumi Kimura[1], Takeji Umemura[1], Masayuki Kurosaki[2]. *[1]Shinshu University School of Medicine, Department of Gastroenterology and Hepatology, Matsumoto, Japan; [2]Department of Gastroenterology and Hepatology, Musashino Red Cross Hospital, Musashino-shi, Tokyo, Japan*
Email: shun_1@me.com

Background and aims: The prognosis of lean metabolic dysfunction-associated steatotic liver disease (MASLD) has not been clear due to some conflicting evidence. This study aimed to clarify the prognosis of lean MASLD by conducting a comprehensive analysis of a vast Asian cohort.

Method: This study used a nationwide, population-based database and analyzed 2.9 million patients. The primary end points were liver-related events (LREs) and cardiovascular events (CVEs) in patients with lean MASLD, non-lean MASLD, and normal liver control groups.

Results: The median observation period was 4.2 years. The 5-year incidence of LREs in the lean MASLD, non-lean MASLD, and normal liver control groups were 0.065%, 0.039%, and 0.006%, respectively. The LRE risk of lean MASLD was significantly higher than that of normal liver control (adjusted hazard ratio [aHR]: 5.94, 95% confidence interval [CI], 3.95–8.92) but comparable to that of non-lean MASLD (aHR: 1.35, 95% CI, 0.87–2.08). By contrast, for CVEs, the non-lean MASLD group exhibited a higher 5-year cumulative incidence rate (0.779%) than the lean MASLD (0.600%) and normal liver control (0.254 %) groups. The lean MASLD group had a reduced risk of CVEs compared with the non-lean MASLD group (aHR, 0.73; 95% CI, 0.64–0.84), and comparable risk of CVEs to the normal liver control group (aHR, 0.99; 95% CI, 0.88–1.12).

Conclusion: Lean MASLD has a similar LRE risk and a lower CVE risk to non-lean MASLD. Therefore, follow-up and treatment strategies should be tailored to the specific MASLD condition.

Histological and clinical disease progression in patients with metabolic dysfunction-associated steatotic liver disease using paired liver biopsy

Merve Ekelik[1], Dilara Turan Gökçe[2], Mesut Gumussoy[3], Saba Kiremitçi[1], Emin Bodakçi[4], Volkan Yılmaz[1], Sevınc Tugce Karayel[1], Serkan Duman[5], Zeynep Melekoğlu Ellik[6], Abdullah Mübin Özercan[7], Ramazan Erdem Er[1], Fatih Karakaya[1], Hale Gokcan[1], Atilla Elhan[1], Berna Savas[1], Murat Törüner[1], Ramazan Idilman[1]. *[1]Ankara University Faculty of Medicine, Ankara, Turkey; [2]Ankara Bilkent Şehir Hastanesi, Ankara, Turkey; [3]Gaziantep Şehitkamil Devlet Hastanesi, Gaziantep, Turkey; [4]Gaziantep Ersin Arslan Eğitim ve Araştırma Hastanesi, Gaziantep, Turkey; [5]Mersin Toros Devlet Hastanesi, Mersin, Turkey; [6]Karaman Eğitim ve Araştırma Hastanesi, Karaman, Turkey; [7]Fırat University Faculty of Medicine, Elazığ, Turkey*
Email: mervekelik@gmail.com

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a dynamic disease. Therefore, the aims of the present study were to assess the histological evolution of patients with MASLD using paired liver biopsies-, to identify the factors associated with fibrosis and clinical disease progression, and to determine the relationship between histological progression and clinical disease outcomes.
Method: This was a single-center study. A total of 114 patients with MASLD who had at least two liver biopsies more than one year apart between January 2001 and December 2021 were included in the analysis.
Results: The median interval between the two biopsies was 46 months (IQR:49.2 months). From the baseline to the follow-up biopsy, 44% of patients showed histological progression. Fibrosis progressed in 28 patients, regressed in 21, and showed no change in 65 patients. The proportion of MASH increased from 83% to 90%, with 95% of the MASH patients remaining MASH and 70% of the MASL patients fulfilling the MASH criteria at the follow-up biopsy. Logistic regression showed no baseline characteristics associated with fibrosis progression. Notably, histological progression was more common in patients with MASL than in patients with MASH (p = 0.002). Among the patients with MASL exhibiting histological progression, 87% had lobular inflammation at baseline. During the median follow-up period of 10 years, half of the patients with MASLD showed clinical disease progression, with 73% having MASH at baseline. Ten patients with MASLD developed new-onset cirrhosis. New-onset DM developed in 31% of the 91 patients who did not have DM at baseline, hypertension developed in 25% of the 73 patients without hypertension at baseline, and hyperlipidemia developed in 55% of the 38 patients without hyperlipidemia at baseline. Notably, no metabolic abnormality developed in MASL patients who maintained MASL status at the follow-up biopsy. Multivariable logistic regression showed baseline hypertension (Odds Ratio [OR]: 2.611, p = 0.024) and high serum ALT levels (OR: 2.815, p = 0.049) were predictors of clinical disease progression in patients with MASLD.
Conclusion: In conclusion, patients with MASLD, both patients with MASL and patients with MASH, exhibit disease progression. Hypertension and abnormal liver injury tests at baseline are predictors of clinical disease progression in patients with MASLD.

FRI-239

An inference model of risk factors for liver-related complications among patients with type 2 diabetes mellitus

Sherlot Juan Song[1], Vincent Wai-Sun Wong[1], Grace Lai-Hung Wong[1], Terry Cheuk-Fung Yip[1]. *[1]Medical Data Analytics Centre (MDAC), Department of Medicine and Therapeutics, The Chinese University of Hong Kong, Institute of Digestive Disease, Faculty of Medicine, The Chinese University of Hong Kong, HK, Hong Kong*
Email: 1155169298@link.cuhk.edu.hk

Background and aims: Data on the prognostic risk factors of liver-related complications among patients with type 2 diabetes mellitus (T2DM) remains limited. This study aims to construct an inference model to explain risk factors associated with adverse liver outcomes.
Method: This territory-wide retrospective study included 575, 000 adult patients with the diagnosis of T2DM between January 2007 and December 2021 in Hong Kong. Patients with chronic viral hepatitis, excessive alcohol use, other metabolic and autoimmune liver diseases, malignancies, and liver-related events (LRE) before T2DM diagnosis were excluded. The primary end point was LRE, defined as hepatic decompensation or the development of hepatocellular carcinoma. Cause-specific hazard model was fitted in competing risk analysis considering LRE as the event of interest. Restricted cubic spline analysis was used for the non-linear effects of clinical parameters on LRE.
Results: 575, 000 patients with T2DM were included (mean age 61.9 years; 52.3% males). 4887 patients reached the outcome of LRE. 0.05% patients had cirrhosis at baseline, while 0.3% patients presented with compensated cirrhosis over the follow-up. Old age (1.028, 1.025–1.031), male gender (1.19, 1.12–1.26), presence of compensated cirrhosis (3.30, 3.07–3.56) were all associated with an increase in the hazards of LRE, and compensated cirrhosis had the highest estimated hazard ratios among all covariates. Hypertension (1.21, 1.11–1.31) and dyslipidemia (1.14, 1.07–1.21) at diagnosis also heightened the risks of LRE. High albumin (0.977, 0.972–0.982) showed protective effect, while total bilirubin (1.005, 1.004–1.006), international normalized ratio (1.12, 1.08–1.17) and creatinine (1.002, 1.002–1.002) increased hazards of LRE. Both platelet count and hemoglobin A1c (HbA1c) demonstrated a U-shaped relationship with LREs, with the highest risk observed in patients with extreme values of the two parameters.
Conclusion: Compensated cirrhosis had the highest estimated hazard ratios for LRE among patients with T2DM. Bipolar extreme levels of platelet and HbA1c heightened the risk of LRE and warrants extra clinical attention in the management of T2DM.

FRI-242

Redefining the relationship: the diminished correlation between MASLD and CKD after accounting for diabetes or insulin resistance

Tianyuan Yang[1], JingYa Yin[2], Yang Bingqing[2], Qi Wang[3]. *[1]Center of Liver Diseases, Beijing Ditan Hospital, Capital Medical University, Beijing, China; [2]Center of Liver Diseases, Beijing Ditan Hospital, Capital Medical University, Beijing, China; [3]Center of Liver Diseases, Beijing Ditan Hospital, Capital Medical University, Beijing Key Laboratory of Emerging Infectious Diseases, Institute of infectious diseases, Beijing, China*
Email: tyy66303@gmail.com

Background and aims: Non-Alcoholic Fatty Liver Disease (NAFLD) is widely regarded as a multisystem condition. Previous studies suggest an independent association between NAFLD and the incidence of CKD. Herein, we explore whether metabolic dysfunction-associated steatotic liver disease (MASLD), as newly defined, is independently associated with CKD after adjusting for five cardiovascular metabolic factors and other covariates.
Method: Analysis included 6567 non-pregnant adult participants from NHANES 2017 to 2020. Fibroscan with controlled attenuation parameter was used to define steatotic liver disease (CAP more than

248 dB/m). Stages of CKD were defined according to the KDIGO guidelines. Insulin resistance was defined by HOMA-IR value of more than 2.69. Weighted logistic regression models were utilized to elucidate the correlation between MASLD, covariates, and CKD. Subgroup analyses were performed to evaluate the impact of five cardiovascular metabolic factors, insulin resistance, on the MASLD-CKD association.

Results: Univariate regression analysis revealed that MASLD is significantly linked to a risk of CKD. Further analysis using model 6 (adjustments for age, sex, cardiovascular metabolic factors), the relation was still statistically significant (OR 1.32 95% CI 1.03–1.69 p = 0.031). Model 7, expanding on Model 6 by including diabetes among its covariates, indicated that the relationship did not significance. Incorporating insulin resistance as a categorical variable in the Model 8 altered the findings: the association between MASLD and CKD remained non-significant (OR 1.00 95% CI 0.73–1.38 p = 0.981), yet insulin resistance itself was significantly linked to CKD. Introduction of an interaction term between insulin resistance and MASLD into the model was statistically significant (OR 2.02 95% CI 1.05–3.89 p = 0.037). Faceted bar chart presented the predicted probabilities of CKD across different age and genders, showing that MASLD did not statistically affect CKD risk in the absence of insulin resistance. The presence of insulin resistance significantly increased the likelihood of CKD in those with MASLD compared to those without. Subgroup analyses showed that the associations between MASLD and CKD varied across different subgroups. The analyses identified insulin resistance (p = 0.02) as potential modifiers of the MASLD-CKD association. For those without insulin resistance, impact of MASLD on CKD risk is not significant (OR 0.69 95% CI 0.42–1.12 p = 0.124), in contrast to its significant effect in those with insulin resistance (OR 1.44 95% CI 1.03–2.23 p = 0.046).

Conclusion: Although the prevalence of CKD is higher in patients with MASLD, MASLD does not have an independent association with CKD after adjusting for diabetes or insulin resistance. Therefore, in the community management of comorbid MASLD and CKD, the focus should still be placed on the treatment of diabetes.

FRI-243

Echocardiography-based markers of subclinical cardiac dysfunction in patients with MASLD and preserved ejection fraction: prospective data from the Turin cohort

Kamela Gjini[1], Angelo Armandi[1], Alessandro Andreis[2,3], Matteo Bellettini[2,3], Irene Poggiolini[1], Gabriele Castelnuovo[1], Gian Paolo Caviglia[1], Chiara Rosso[1], Nuria Pérez Diaz del Campo[1], Marta Guariglia[1], Davide Giuseppe Ribaldone[1], Giorgio Maria Saracco[1], Davide Castagno[2,3], Alberto Milan[4], Fabrizio Amato[1], Martina Marano[1], Gaetano De Ferrari[2,3], Elisabetta Bugianesi[1]. *[1]Division of Gastroenterology and Hepatology, Department of Medical Sciences, University of Turin, Turin, Italy; [2]Division of Cardiology, Department of Medical Sciences, Città della Salute e della Scienza di Torino University Hospital, Turin, Italy; [3]Advanced Cardiovascular Echocardiography Unit, Cardiovascular and Thoracic Department, Città della Salute e della Scienza di Torino University Hospital, Turin, Italy; [4]Hypertension Unit, Department of Medical Sciences, Città della Salute e della Scienza di Torino University Hospital, Turin, Italy*
Email: angelo.armandi@unito.it

Background and aims: Individuals with Metabolic dysfunction-Associated Steatotic Liver Disease (MASLD) have abnormal myocardial energy metabolism and reduced coronary functional capacity, even in the absence of risk factors for cardiovascular disease (CVD), potentially associated with cardiac fibrosis and heart failure. We aimed to evaluate diastolic and systolic function in MASLD individuals with preserved ejection fraction.

Method: We prospectively enrolled patients with ultrasound-diagnosed MASLD and without overt CVD undergoing screening echocardiography (Philips, Andover, US) including speckle tracking analysis for myocardial fiber deformation (strain) in all four cardiac chambers. Significant diastolic dysfunction was defined as mitral E/E' ratio >9, while systolic dysfunction was defined by left ventricular global longitudinal strain (GLS) >−18%. Significant liver fibrosis (SLF) was non-invasively assessed by either FIB-4 score >1.3 or liver stiffness measurement (LSM) >7 kPa by transient elastography. Severe liver steatosis was defined by Controlled Attenuation Parameter (CAP) >300 dB/m.

Results: A total of 94 patients were included (median age 53.0 [44.5–62.5] years, male sex 43.2%). SLF was detected in 20.0% by FIB-4 and in 14.9% by LSM. Severe steatosis was present in 53.8% of cases. FIB-4 values were significantly higher in patients with diastolic (p = 0.008) and systolic (p = 0.006) dysfunction. In patients with SLF by either FIB-4 or LSM we found lower absolute values of left atrium reservoir strain (indirect marker of reduced compliance) (p = 0.027 and p = 0.021, respectively), lower values of left atrium conduit strain (indirect marker of impaired passive emptying) (p = 0.020 and p = 0.0003) and lower values of right atrium reservoir strain (p = 0.011 and p = 0.007). Patients with severe steatosis had increased epicardial fat tissue deposition (p = 0.020). In a multiple stepwise logistic regression model including type 2 diabetes (T2D), obesity, arterial hypertension, dyslipidemia, male sex and SLF by FIB-4, both SLF and T2D were significantly associated with diastolic dysfunction.

Conclusion: MASLD patients with SLF and without overt CVD have impaired pre-clinical markers of cardiac dysfunction. Increased FIB-4 is associated with diastolic dysfunction independently of major CVD risk factors. *The research was supported by the Italian Ministry for Education, University and Research (MIUR) under the programme "Dipartimenti di Eccellenza 2018–2022" Project code D15D18000410001.*

Barriers and motivators for implementation of lifestyle changes in a large population with MASLD

Sharon Oude Veldhuis[1,2], Stans Drossaert[2], Marjolein den Ouden[1,3], Lisette van Gemert-Pijnen[2], Maureen Guichelaar[4]. *[1]Saxion University of Applied Sciences, Enschede, Netherlands; [2]University of Twente, Enschede, Netherlands; [3]Regional Community College of Twente, Hengelo, Netherlands; [4]Medisch Spectrum Twente, Enschede, Netherlands*
Email: l.s.derksen@saxion.nl

Background and aims: Long-term improvements in lifestyle changes has been shown possible in only a minority of patients with MASLD. This study explored the barriers and motivators in MASLD patients to implement (long-term) lifestyle changes.

Method: A quantitative survey (with some open-ended questions) was distributed via two Dutch patient organizations. The survey included questions about comorbidities, attempts to change lifestyle, motivators and barriers for lifestyle changes, information provision and information needs. The data was analyzed using descriptive statistics.

Results: The survey was completed by 449 MASLD patients (81% female, mean/SD age 56 ± 11 years, BMI 30 ± 5 kg/m^2). Patients experienced a high rate of comorbidities, including diabetes mellitus (n = 98, 22%), and cardiovascular disease (n = 83, 19%). Almost half of the patients (n = 210, 47%) experienced joint problems. Sixty-three percent of patients (n = 283) self-reported their stage of disease of which 16% reported fibrosis/cirrhosis. The majority of patients attempted lifestyle changes (n = 365, 81%), including dietary changes to support weight loss (n = 320, 71%). A low percentage of participants succeeded in permanently changing their diet (n = 174, 39%), exercise pattern (n = 159, 35%) and weight reduction (n = 90, 20%). Most frequently mentioned motivators for lifestyle changes were symptoms of MASLD and/or comorbidities (n = 92, 20%), desire to live a long and healthy life (n = 76, 17%), and discomfort from being overweight (n = 65, 14%). Barriers to implement lifestyle changes were lack of knowledge about MASLD-related topics (n = 122, 27%), stress (n = 116, 26%), and lack of motivation (n = 97, 22%). Information

about MASLD was mainly provided by a gastroenterologist (n = 210, 47%) and general practitioner (n = 123, 27%). Less than 20% of participants indicated they had received sufficient information about MASLD-related topics. About 72–90% of patients would like to receive more information on almost all MASLD-related topics including disease specifics and self-management options.
Conclusion: Key reasons to attempt lifestyle changes, in a large population of MASLD patients, included motivation to improve discomfort and comorbidities related to obesity and MASLD. Although the majority of respondents attempted lifestyle changes, only a minority of them were able to sustain long-term improvements (~20% permanent weight loss). Lack of knowledge about MASLD and self-management were key barriers to improve lifestyle in the long-term. Our study supports ongoing efforts to increase patient's knowledge about MASLD and its treatment in order to sustain (long-term) lifestyle changes.

FRI-245
Longitudinal follow-up of Fib-4 in patients at risk of steatotic liver disease (SLD) receiving low-dose Methotrexate treatment (LD-MTX): results from the CIRT randomized placebo-controlled Trial in 4769 patients

Vincent Di Martino[1], Jing Cui[2], Delphine Weil-Verhoeven[3], Daniel Solomon[4]. [1]*CHU Besançon, INSERM UMR 1098 Right, Besançon;* [2]*Harvard Medical scool, Brigham and Women's Hospital, Boston, United States;* [3]*CHU Besançon, INSERM UMR 1098 Right, Besançon, France;* [4]*Harvard Medical School, Brigham and Women's Hospita, Boston, United States*
Email: vdimartino@chu-besancon.fr

Background and aims: It seems well established that low-dose methotrexate (LD-MTX), even when administered over the long term, is unable to induce liver fibrosis per se, but the question of whether LD-MTX could worsen SLD and promote fibrosing SLD in at-risk patients remains unanswered so far. The aim of this retrospective study was to report the course of Fib-4 scores in patients included in the CIRT trial, a randomized placebo-controlled trial testing the prevention of cardiovascular events in patients with coronary artery disease by LD-MTX administration (15 to 20 mg/week; Ridker et al, NEJM 2019; NCT 01594333).
Method: Among the 4786 patients included in the CIRT trial, biochemical data enabled calculation of Fib-4 score every 3 months in 4769 patients (2381 in the LD-MTX group; 2388 in the placebo group) for up to 5 years of follow-up. MTX was temporarily discontinued in the event of AST or ALT>2 ULN, until values were <1.5 ULN. All patients received folic acid supplementation (1 mg/d). Using a mixed model (type 3 test), we tested whether subjects on LD-MTX had a higher Fib-4 score at study visits, taking into account different MTX dosages, metabolic syndrome, and gender.
Results: Baseline patients characteristics were similar in the two groups (81% males; median age = 65 years, BMI = 32.3 kg/m²; 67% diabetic; 62% alcohol-free; 86% under statins; median Fib-4 = 1.29). On inclusion, 46.5% of patients had a Fib-4 above the alert threshold (>1.3 or >2 depending on age <or >65 years), and 6.5% had a Fib-4 score >2.67. Seven patients developed cirrhosis during follow-up (six in the LD-MTX group; one in the placebo group; NS), of whom only two had baseline Fib-4 > 2.67. In multivariate analysis adjusted for gender and the presence of metabolic syndrome, Fib-4 was slightly but significantly higher in the placebo group (+0.042; 95% CI:0.001–0.075; p = 0.015).
Conclusion: Under the usual conditions of administration and monitoring, LD-MTX is not associated with an increased risk of hepatic fibrosis in patients with coronary artery disease presumed to be at risk of SLD.

FRI-246
Effect of antidiabetics on the risk of hepatocellular carcinoma in patients with diabetes and metabolic dysfunction-associated steatotic liver disease

Han Ah Lee[1], Hwi Young Kim[1], Yeon Seok Seo[2], Sang Hoon Ahn[3], Seung Up Kim[3]. [1]*Ewha Womans University College of Medicine, Seoul, Korea, Rep. of South;* [2]*Korea University College of Medicine, Seoul, Korea, Rep. of South;* [3]*Yonsei University College of Medicine, Seoul, Korea, Rep. of South*
Email: amelia86@naver.com

Background and aims: Diabetes is a significant risk factor for the development of hepatocellular carcinoma (HCC). In this retrospective cohort study, we investigated the effects of antidiabetic drugs on the risk of HCC development in patients with diabetes and metabolic dysfunction-associated steatotic liver disease (MASLD).
Method: From 2004 to 2018, patients with diabetes and MASLD were selected from three tertiary academic institutes in South Korea. The patients were followed from the date of MASLD diagnosis until HCC diagnosis, death, or last follow-up. Independent predictors of HCC development were investigated using landmark Cox proportional hazard models.
Results: In total, 4, 024 patients with diabetes and MASLD were identified. Their median age was 56.0 years, and 2, 184 (54.3%) were male. A total of 3, 370 (83.7%) patients received antidiabetics (oral antidiabetic drugs [OADs] in 2, 581 and insulin-based therapy in 789), whereas the remaining 16.3% of patients received no antidiabetics. During a median follow-up of 5.1 years, 269 (6.7%) patients developed HCC. The multivariate analysis showed that liver cirrhosis, a fibrosis-4 Index ≥1.45, male sex, older age, obesity, hypertension, dyslipidemia, lower albumin level, diabetes complications, longer duration of diabetes, and the type of antidiabetics were significantly associated with an increased risk for HCC (all p < 0.05). No treatment and OAD therapy had comparable risks for HCC, whereas insulin-based therapy was associated with an increased risk for HCC compared to no treatment (hazard ratio [HR] = 1.739, 95% confidence interval [CI] 1.047–2.888) and OAD therapy (HR = 1.717, 95% CI 1.242–2.372) (all p < 0.05). Metformin-based therapy was associated with a reduced risk for HCC in the entire study population (HR = 0.713, 95% CI 0.522–0.973) and in a subgroup of patients receiving OAD therapy (HR = 0.362, 95% CI 0.205–0.640) (all p < 0.05). Metformin-based therapy decreased the risk for HCC in both patients who received OAD monotherapy (HR = 0.148, 95% CI 0.044–0.503) and those who received dual OAD therapy (HR = 0.448, 95% CI 0.200–0.986). However, in patients receiving insulin-based therapy, the combination of metformin treatment did not reduce the risk for HCC compared to insulin monotherapy or combined treatment of insulin and OADs other than metformin.
Conclusion: Metformin use decreased the incidence of HCC in patients with diabetes and MASLD. Careful consideration regarding the choice of antidiabetic drugs is needed for HCC prevention in such patients.

FRI-247
Association of plasma magnesium with MASH and cirrhosis: combined data from multiple therapeutic trials including more than 10, 000 patients

Stephen A. Harrison[1], Julie Dubourg[2], Vlad Ratziu[3], Jörn M. Schattenberg[4], Naim Alkhouri[5], Mazen Noureddin[6], Michael Charlton[7]. [1]*Radcliffe Department of Medicine, University of Oxford, Oxford, United Kingdom;* [2]*Summit Clinical Research, San Antonio, United States;* [3]*Sorbonne Université, Institute for Cardiometabolism and Nutrition, Hospital Pitié-Salpêtrière, INSERM UMRS 1138 CRC, Paris, France;* [4]*Saarland University Medical Center, Homburg, Germany;* [5]*Arizona Liver Health, Phoenix, United States;* [6]*Houston Research Institute, Houston, United States;* [7]*University of Chicago, Chicago, United States*
Email: jdubourg@summitclinicalresearch.com

Background and aims: Insulin resistance is considered a key driver of metabolic dysfunction-associated steatotic liver disease (MASLD)/ metabolic dysfunction-associated steatohepatitis (MASH) pathogenesis. Magnesium has an important role in insulin and glucose homeostasis. We aimed to investigate the association between plasma magnesium and MASLD.
Method: Using combined screening data from 10 industry-funded MASH phase 2 trials, we examined patients with biopsy-proven MASLD/MASH and available magnesium levels. Univariate and multivariate logistic regressions were performed to predict histological severity.
Results: 2, 696 patients with available data were included in this analysis. Mean age was 55.0 years (SD: 11.5) and 58% were female. 60% of the patients had MASH, 40% had advanced fibrosis (F3-F4) and 14% had cirrhosis (F4). In univariate analysis, magnesium concentration was associated with advanced fibrosis (Odds Ratio: 0.19, 95% CI: 0.13–0.27), cirrhosis (Odds Ratio: 0.17, 95% CI: 0.10–0.27), hepatocyte ballooning (Odds Ratio: 0.23, 95% CI: 0.15–0.33), and inflammation (Odds Ratio: 0.29, 95% CI: 0.12–0.66). Plasma magnesium concentration was not associated with the presence of steatosis. After adjustment on age, liver enzymes, FIB-4, platelet, HbA1c, magnesium concentration remained independently associated with advanced fibrosis (Odds Ratio: 0.31, 95% CI: 0.20–0.49), cirrhosis (Odds Ratio: 0.28, 95% CI: 0.15–0.59), hepatocyte ballooning (Odds Ratio: 0.40, 95% CI: 0.26–0.63), and inflammation (Odds Ratio: 0.36, 95% CI: 0.14–0.89). Plasma magnesium concentration was significantly lower in patients with cirrhosis (1.96 mg/dL SD 0.23) compared to patients without significant fibrosis (F0-F1) (2.07 mg/dL SD 0.20).
Conclusion: Plasma magnesium was independently and inversely associated with MASH severity. Further studies are warranted to understand this association and mechanistic link.

FRI-248-YI

The impact of baseline sarcopenia, over time, on liver and cardiovascular damage in patients with metabolic-dysfunction associated steatotic liver disease (MASLD): a prospective study

Floriana Santomenna[1,2], Annalisa Cespiati[1,2], Matteo Carlomagno[2], Giovanna Oberti[1], Edoardo Pulixi[1], Jaqueline Currà[1,2], Daniel Smith[1,2], Rosa Lombardi[1,2], Erika Fatta[1], Cristina Bertelli[1], Giuseppina Pisano[1], Anna Ludovica Fracanzani[1,2]. *[1]SC Medicina ad Indirizzo Metabolico, Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico of Milan, Milan, Italy; [2]Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy*
Email: floriana.santomenna@unimi.it

Background and aims: Sarcopenia, defined as the loss of muscle mass, is linked to metabolic comorbidities, connecting to steatotic liver disease and cardiovascular damage (CVD). The impact of sarcopenia on liver and CVD progression over time is not well understood. The aim of this study was to evaluate the impact of baseline sarcopenia on liver and CVD progression after 5 years in non-cirrhotic ultrasound (US) proven metabolic dysfunction-associated liver disease (MASLD) patients.
Method: 180 patients (63% male, mean age 51 ± 10 years) were enrolled. Sarcopenia was defined as skeletal muscle mass/height^2 ≤10.7/7.5 kg/m^2 in men/women by bioimpedance analysis. CVD was assessed by carotid plaques at US, liver fibrosis and steatosis by liver stiffness measurement (LSM) and controlled attenuation parameter (CAP), respectively. After 5 years, liver disease and CVD severity were reassessed.
Results: At baseline 45% were sarcopenic, 35% obese, 39% hypertensive, 26% dyslipidemic and 13% diabetic. Sarcopenic patients compared to non-sarcopenic had lower BMI (26.6 vs 31.1, p < 0.001), lower waist circumference (97 vs 105, p < 0.001), lower LSM (4.5 vs 5.1, p = 0.02), and lower CAP values (p = 0.004), but similar prevalence of carotid plaques (p = 0.9). No differences were seen regarding age (p = 0.99) and gender (p = 0.09). At 5 years of follow-up, despite lifestyle modifications, in sarcopenic patients the mean BMI (26.6 vs 26.5, p = 0.17), LSM (4.5 vs 4.8, p = 0.97), and CAP (281 vs 285, p = 0.29) did not significantly change, while they experienced an increase in carotid plaque (28% vs 53%, p = 0.002). Conversely, non-sarcopenic patients showed amelioration in mean BMI (31.1 vs 30.1, p = 0.02), and LSM (5.1 vs 4.6, p = 0.01), and a decrease in carotid plaques (8% vs 3%, p = 0.02) compared with sarcopenic ones. Patients with sarcopenia at baseline, showed less improvement in mean LSM (-0.1 vs −1.1 kPa, p = 0.04) than non-sarcopenic patients, with no differences in delta BMI (0.1 vs −0.6 kg/m2, p = 0.18) and delta CAP (−3 vs −5 dB/m, p = 0.7). At multivariate analysis, adjusted for sex, age, and factors associated with sarcopenia at univariate analysis, sarcopenia at baseline remained associated with delta LSM (OR 1.86, p = 0.04), irrespective of confounders.
Conclusion: In non-cirrhotic MASLD patients, the presence of sarcopenia at baseline reduces over time, despite lifestyle intervention, the chance of improvement in liver damage and promotes worsening of cardiovascular damage. These findings should prompt us to screen all patients at diagnosis of MASLD for the presence of sarcopenia.

FRI-249

Association between uric acid concentration and MASH: combined data from multiple therapeutic trials including more than 10, 000 patients

Stephen A. Harrison[1], Julie Dubourg[2], Vlad Ratziu[3], Jörn M. Schattenberg[4], Naim Alkhouri[5], Mazen Noureddin[6], Michael Charlton[7]. *[1]Radcliffe Department of Medicine, University of Oxford, Oxford, United Kingdom; [2]Summit Clinical Research, San Antonio, United States; [3]Sorbonne Université, Institute for Cardiometabolism and Nutrition, Hospital Pitié-Salpêtrière, INSERM UMRS 1138 CRC, Paris, France; [4]Saarland University Medical Center, Homburg, Germany; [5]Arizona Liver Health, Phoenix, United States; [6]Houston Research Institute, Houstom, United States; [7]University of Chicago, Chicago, United States*
Email: jdubourg@summitclinicalresearch.com

Background and aims: Uric acid is considered the ultimate product of purine metabolism and is associated with cardiovascular disease. We aimed to investigate the association between uric acid and metabolic dysfunction-associated steatotic liver disease (MASLD)/ metabolic dysfunction-associated steatohepatitis (MASH).
Method: Using combined screening data from 10 industry-funded MASH phase 2 trials, we examined patients with biopsy-proven MASLD/MASH and available uric acid levels. Univariate and multivariate logistic regressions were performed to predict histological severity.
Results: 2, 880 patients with available data were included in this analysis. Mean age was 55.1 years (SD: 11.3) and 60% were female. 62% of the patients had MASH, 41% had advanced fibrosis (F3-F4) and 14% had cirrhosis (F4). In univariate analysis, uric acid concentration was inversely associated with advanced fibrosis (Odds Ratio: 0.88, 95% CI: 0.84–0.93), cirrhosis (Odds Ratio: 0.85, 95% CI: 0.79–0.92), hepatocyte ballooning (Odds Ratio: 0.93, 95% CI: 0.89–0.98), and steatosis (Odds Ratio: 1.25, 95% CI: 1.11–1.41). Uric acid concentration was not associated with the presence of inflammation. After adjustment on age, liver enzymes, HbA1c, and triglycerides, uric acid concentration remained independently associated with steatosis (Odds Ratio: 1.22, 95% CI: 1.03–1.44). After adjustment on age, liver enzymes, FIB-4, platelet, HbA1c, uric acid concentration remained independently associated with advanced fibrosis (Odds Ratio: 0.93, 95% CI: 0.87–0.98), cirrhosis (Odds Ratio: 0.91, 95% CI: 0.84–0.99), but was not associated anymore with hepatocyte ballooning. Uric acid concentration was significantly higher in patients with steatosis (5.9 mg/dL SD 1.4) compared to patients without steatosis (5.5 mg/dL SD 1.5).
Conclusion: Uric acid was independently associated with steatosis while it was independenly inversely associated with the presence of advanced fibrosis. Further studies are warranted to understand this association and mechanistic link.

FRI-250

An intergenerational study of the prevalence and cardiometabolic significance of steatotic liver disease in adults in the Raine Study

Oyekoya Ayonrinde[1,2,3], Leon Adams[1], Trevor Mori[1], Phillip Melton[1,4], John Olynyk[2,3], Marilyn Zelesco[2], Andrea Mould[5], James Fiori[2], Lawrence Beilin[1], Girish Dwivedi[1,2], Frank Sanfilippo[1], Christopher Welman[2]. [1]*The University of Western Australia, Perth, Australia;* [2]*Fiona Stanley Hospital, Murdoch, Australia;* [3]*Curtin University, Bentley, Australia;* [4]*University of Tasmania, Hobart, Australia;* [5]*Fiona Stanley Hospital, Perth, Australia*
Email: oyekoya.ayonrinde@uwa.edu.au

Background and aims: Steatotic liver disease (SLD) is the most common chronic liver disease globally. SLD is associated with increased risk of cardiometabolic disorders. We aimed to compare the prevalence and metabolic significance of SLD in two generations of adults participating in the Raine Study, a longitudinal cohort study.
Method: Middle-aged adults (Gen1) and their adult offspring (Gen2) participating in a cross-sectional follow-up of the Raine Study in Australia, had liver assessments using controlled attenuation parameter (CAP) with transient elastography (TE), anthropometry, and fasting blood tests. SLD was defined by CAP ≥ 275 dB/m, grade 3 steatosis as CAP ≥ 331 dB/m, and significant liver fibrosis as liver stiffness measurement (LSM) ≥ 8.0 kPa. Associations between liver and cardiometabolic characteristics were sought.
Results: The cohort comprised 331 Gen1 adults (63% female) with mean (SD) age 60 (7) and 252 Gen2 adults aged 33 (6) years (46% female). SLD was diagnosed in 26% Gen1s vs. 19% Gen2 s (p = 0.05). Among Gen1s 24% had metabolic dysfunction-associated steatotic liver disease (MASLD), 1% metabolic plus alcohol-related liver disease (MetALD) and 1% alcohol-related liver disease (ALD). Gen2s had 16% MASLD, 0% MetALD and 2% ALD. In both Gen1 and Gen2 mean [SD] body weight (92.6[19.5] kg vs. 76.3[15.3] kg), body mass index (31.3 [6.2] kg/m^2 vs. 26.2[4.5] kg/m^2), waist (104.8[13.5] cm vs. 89.8 [12.7] cm, CAP (315[33] dB/m vs. 213[38] dB/m) were higher in those with SLD compared with those without SLD, p < 0.05 for all. Mean serum glucose (5.2[1.3] mmol/L vs. 4.7[0.8] mmol/L), alanine aminotransferase (40.9[30.6] IU vs. 28.2[13.9] IU), remnant lipoprotein cholesterol (RLP-C) (0.65[0.30] mmol/L vs. 0.49[0.24] mmol/L), and median[IQR] homeostasis model for insulin resistance (1.9[1.2–2.9] vs. 1.1[0.8–1.6]) were higher in those with SLD, p < 0.05 for all. Compared with Gen2s, Gen1s had a higher prevalence of central obesity (78% vs. 55%, p < 0.001), type 2 diabetes mellitus (T2DM) (6.2% vs. 1.3%, p = 0.004), impaired fasting glucose or T2DM (IFG/T2DM) (16.3% vs. 2.2%, p < 0.001), and significant hepatic fibrosis (4.7% vs. 1.2%, p = 0.03), but a similar prevalence of grade 3 hepatic steatosis (6.3% vs. 6.5%, p = 0.94). Using multivariable logistic regression analyses, grade 3 steatosis (OR 8.14, 95% CI 2.73–24.31), central obesity (OR 4.47, 95% CI 1.27–15.81), and RLP-C (OR 5.27, 95% CI 1.71–16.21) were associated with IFG/T2DM after adjusting for age, sex and LSM in the Gen1s. In the Gen2s, grade 3 steatosis (OR 12.51, 95% CI 1.40–111.72), but not waist, RLP-C, sex, age or LSM, was associated with IFG/T2DM.
Conclusion: The prevalence of SLD and suspected liver fibrosis was higher in middle-aged than in younger adults. Severe hepatic steatosis with or without central adiposity increases the likelihood of a diagnosis of IFG/T2DM. Liver fibrosis was not significantly associated with IFG/T2DM.

FRI-251-YI

Hepatic steatosis contributes to cognitive impairment in patients with metabolic dysfunction-associated steatotic liver disease and/or type 2 diabetes-mellitus

Nuria Pérez Diaz del Campo[1], Arianna Ferro[1], Gabriele Castelnuovo[1], Gian Paolo Caviglia[1], Chiara Rosso[1], Marta Guariglia[1], Eleonora Dileo[1], Angelo Armandi[1,2], Francesca Saba[1], Giorgio Maria Saracco[1,3], Federica Barutta[4], Guglielmo Beccuti[1], Gabriella Gruden[4], Elisabetta Bugianesi[1,3]. Email: nuria.perezdiazdelcampo@unito.it

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) coexists with multiple comorbidities such as obesity, type 2 diabetes mellitus (T2DM), and metabolic syndrome, all contributing to impaired vascular function and thus worsening cognitive impairment. However, the biological mechanism underlying the association between MASLD and cognitive dysfunction has not yet been elucidated. In this study, we aimed to assess the impact of hepatic steatosis on cognitive impairment in patients with MASLD and T2DM.
Method: A total of 601 patients diagnosed with MASLD and/or T2DM underwent evaluation of liver stiffness by transient elastography and liver steatosis by controlled attenuation parameter (CAP) (Fibroscan®530, Echosens). According to the established cut-off, a CAP value ≥300 dB/m was used to identify severe steatosis (S3). The cognitive function was assessed by the Repeatable battery for assessment of neuropsychological status (RBANS); the questionnaire evaluates the overall cognitive function and five subdomains assessing immediate memory, visuospatial and constructional function, language function, attention and delayed memory. Score values <90 points were indicative of cognitive impairment.
Results: Overall, the median age was 59 years (range 51–65) and 58.6% of patients were male. Impaired overall cognitive function was observed in 288 (47.9 %) patients (median score value 91, 78–107), with the most prevalent deficit in attention (n = 130; 78.4 %), followed by immediate memory (n = 295; 49.1 %), language function (n = 289; 48.1%), visuospatial and constructional function (n = 230; 38.3 %), and delayed memory (n = 225, 37.4 %). 278 subjects (46.3 %) had severe steatosis and showed increased liver stiffness, AST, ALT, GGT and triglycerides levels compared to those with CAp < 300 (p < 0.001 for all). Moreover, patients with severe steatosis showed a higher prevalence of overall cognitive as compared to patients with CAp < 300 dB/m (p = 0.015). At logistic regression analyses severe steatosis was significantly associated with cognitive impairment (OR = 1.41, 95 % CI 1.0; 1.9; p = 0.048) along with arterial hypertension (p = 0.023) and independently from sex, body mass index, diabetes, dyslipidaemia and obstructive sleep apnoea.
Conclusion: Our results suggest that severe hepatic steatosis is associated with cognitive impairment. Other comorbidities such as arterial hypertension may contribute to cognitive deterioration. Further longitudinal and interventional studies with a careful cognitive profile are needed to replicate these results. *This research has been supported by the Italian Ministry for Education, University and Research (MIUR) under the programme "Dipartimenti di Eccellenza 2018–2022" Project code D15D18000410001.*

FRI-254

Global prevalence, clinical characteristics, histology and outcomes of PNPLA3 I148M variant in metabolic dysfunction-associated steatotic liver disease: a systematic review and meta-analysis

Matheus Souza[1], Ivanna Diaz[2], Lubna Al-Sharif[3], Cristiane Villela-Nogueira[1], Alessandro Mantovani[4]. [1]*Federal University of Rio de Janeiro, Rio de Janeiro, Brazil;* [2]*Suny Downstate Health Sciences University, New York, United States;* [3]*An-Najah National University, Nablus, Palestine;* [4]*University and Azienda Ospedaliera Universitaria Integrata of Verona, Verona, Italy*
Email: matheushenrique.gs@hotmail.com

Background and aims: *PNPLA3* rs738409 variant is a risk factor for onset and progression of metabolic dysfunction-associated steatotic liver disease (MASLD). We performed a systematic review and meta-

analysis to assess the global prevalence, clinical and histological characteristics, and long-term outcomes of the *PNPLA3* variant in MASLD.

Method: We searched PubMed and Embase up to December 2023 for observational studies of *PNPLA3* genotyped adults (≥18 years) with MASLD. Proportions were pooled using a generalised linear mixed model. Continuous and dichotomous variables were analysed using random effects modelling. Primary outcome was the minor allele frequency of the G allele [MAF (G)] of the rs738409 at *PNPLA3* in MASLD patients. Secondary outcomes were comparisons of clinical, histological and long-term outcomes of *PNPLA3* variant versus *PNPLA3* CC. We also performed subgroup, meta-regression and sensitivity analyses. Publication bias was assessed using funnel plots, Egger's test and trim-and-fill analysis.

Results: A total of 112 studies (113, 786 MASLD subjects) were included. We found an overall MAF (G) of 0.45 (95%CI 0.43;0.48, I^2 = 97.9%). After adjustment for publication bias, a more conservative MAF (G) estimate of 0.39 (95%CI 0.36;0.42, I^2 = 98.4%) was obtained. This allele frequency varied significantly worldwide, with the highest MAF (G) in the Latin America (0.63 95%CI 0.52;0.72, I^2 = 96.2%) and East Asian (0.50, 95%CI 0.47;0.53, I^2 = 95.0%) regions, and the lowest in Europe (0.38, 95%CI 0.34;0.41, I^2 = 96.3%). Notably, no African countries were identified. Patients with *PNPLA3* variant had lower values of WC (CG: MD −2.18 cm, 95%CI −3.12;−1.23, I^2 = 0%/GG: MD −2.30 cm, 95%CI −4.36;−0.24, I^2 = 57.4%) and TG (CG: MD −12.04 mg/dL, 95%CI −22.17;−1.90, I^2 = 50.2%/GG: MD −21.32 mg/dL, 95%CI −39.91;−2.73, I^2 = 91.4%), and higher AST (CG: MD 2.83 U/L, 95%CI 0.99;4.68, I^2 = 63.2%/GG: MD 5.76 U/L, 95%CI 4.17; 7.35, I^2 = 66.9%) and ALT (CG: MD 5.99 U/L, 95%CI 2.57;9.42, I^2 = 60.9%/GG: MD 11.40 U/L, 95%CI 7.99; 14.81, I^2 = 73.2%) levels compared to *PNPLA3* CC. Similarly, we observed that *PNPLA3* variant carriers had higher histological severity and odds of advanced stages of MASLD. *PNPLA3* GG carriers had an increased risk of overall mortality, liver-related events and mortality, and cirrhosis. In addition, our univariable meta-regressions showed the influence of adiposity, age and diabetes mellitus on some *PNPLA3* expression parameters.

Conclusion: This study reveals the global pattern of *PNPLA3* prevalence and its clinical, histological and outcomes implications in MASLD. Our findings underscore the importance of *PNPLA3* genotyping in clinical trials and advocate for personalized medicine approaches. Further research is needed on genetic epidemiology for underrepresented populations, challenges of incorporating genotyping into clinical practice, and gene-environment interactions.

FRI-255

Modeling the burden of steatotic liver disease and its subcategories in people living with HIV in Germany

Maurice Michel[1,2], Angelo Armandi[1,3], Diana Granz[1,2], Katharina Bayer[1,2], Leonard Kaps[1,4], Wolfgang Maximilian Kremer[2], Christian Labenz[1,2], Peter R. Galle[1,2], Daniel Grimm[2], Jörn M. Schattenberg[1,4]. [1]*Metabolic Liver Research Program, I. Department of Medicine, University Medical Centre Mainz, Mainz, Germany;* [2]*I, Department of Medicine, University Medical Centre Mainz, Mainz, Germany;* [3]*Division of Gastroenterology and Hepatology, Department of Medical Sciences, University of Turin, Turin, Italy;* [4]*Department of Internal Medicine II, Saarland University Medical Centre, Homburg, Germany*
Email: maurice.michel@icloud.com

Background and aims: People living with HIV (PLWH) show a high prevalence of metabolic comorbidities and other partially overlapping liver-related risk factors, including co-infections with hepatitis B (HBV) and hepatitis C (HCV) virus, which increase the risk of steatotic liver disease (SLD) and liver fibrosis, leading to worse outcomes. However, the disease burden of SLD, its different subcategories, and associated risk factors in PLWH under antiretroviral therapy according to the new nomenclature on SLD remain to be determined.

Method: In this prospectively enrolling cohort study, participants with an HIV infection were non-invasively screened using vibration-controlled transient elastography (VCTE) for SLD (controlled attenuation parameter [CAP] ≥ 248 dB/m) and fibrosis (liver stiffness measurement [LSM] ≥ 8 kPa). The subcategories of SLD, including metabolic dysfunction-associated steatotic liver disease (MASLD), MASLD and increased alcohol intake (MetALD), alcohol-associated liver disease (ALD), and associated cardiometabolic criteria were defined according to the recently published new nomenclature on SLD. The Fibroscan-AST (FAST) score was used to identify those with metabolic-dysfunction associated steatohepatitis (MASH) and significant fibrosis, using a cut-off ≥0.67. Uni- and multivariable logistic regression analysis was used to determine predictors of SLD.

Results: In the entire cohort of 325 participants, 71.4% were male and the median age was 51 (41; 58) years. The median HIV disease duration was 12 (5; 20) years and the majority had a CD4 cell count ≥500/μL (70.2%). A history of HBV and HCV was detected in 19.4% (n = 63) and 5.8% (n = 19), respectively. Median BMI (kg/m²) was 25.3 (22.5; 28.5), and 17.5% (n = 57) were obese (BMI ≥30 kg/m²). Insulin resistance was detected in 24.3% (n = 79). The overall prevalence of SLD was 50.8% (n = 165), with MASLD (42.8%, n = 139) showing the highest prevalence as compared to either MetALD (2.5%, n = 8) or ALD (0.9%, n = 3). Of those with MASLD, 23.7% (n = 33) had a history of HBV or HCV coinfection (MASLD-viral). Cryptogenic or other causes (viral, undefined due to missing data) of SLD were identified in 4.3% (n = 14). Metabolic comorbidities were overall more prevalent in participants with SLD. Liver fibrosis and MASH were detected in 5.8% (n = 19) and 1.8% (n = 6), respectively, in those with MASLD. On multivariable analysis, the cardiometabolic criterion with a BMI ≥25 kg/m² or a waist circumference ≥94/80 cm (male/female) was associated with the highest risk of SLD (OR 5.2, 95% CI 2.6–10.6, p < 0.001). In turn, HIV-related parameters showed no effect on the risk of SLD.

Conclusion: The burden of SLD and especially MASLD is high in PLWH in Germany. Screening for SLD, fibrosis, and associated metabolic comorbidities may reduce the burden of liver disease in PLWH and identify those at higher risk of liver disease progression.

FRI-256-YI

Patients with metabolic-associated steatotic liver disease and portal hypertension have different skeletal muscle and adipose tissue mass than patients with other causes of cirrhosis

Ikram Abow-Mohamed[1], Philip Wong[1], Marc Deschenes[1], Giada Sebastiani[1], Tatiana Cabrera[1], Louis-Martin Boucher[1], David Valenti[2], Ali Bessissow[1], Amine Benmassaoud[1]. [1]*McGill University Health Centre (MUHC), Montreal, Canada,* [2]*McGill University Health Centre (MUHC), montreal, Canada*
Email: ikram.abow-mohamed@mail.mcgill.ca

Background and aims: Low muscle mass has been associated with mortality in patients with cirrhosis. The impact of the etiology of liver disease on this association remains unknown especially following the new formal classifications of patients with metabolic-associated steatotic liver disease (MASLD). We aimed to compare the body composition of patients with or without pure MASLD when HVPG ≥ 10 mmHg.

Method: This retrospective cohort study conducted at the McGill University Health Centre included adults with cirrhosis and Hepatic Venous Pressure Gradient (HVPG) between 2012 and 2022. Total skeletal muscle index (SMI), and subcutaneous and visceral adipose tissue indices (SATI, VATI) at the 3rd lumbar vertebrae were measured at the time of HVPG using computed tomography images and CoreSlicer, for body composition analysis. We compared the body composition of patients with or without MASLD. Variables associated with MASLD were assessed using univariate and multivariate logistic regression analyses reporting adjusted odds ratio (aOR) with a 95% confidence interval (CI).

Results: Overall 99 patients were included (mean age: 58.8years, male gender 61.6%, MASLD 36.4%, clinically significant portal

hypertension: 66.7%, decompensated liver disease: 60.2%, Child-Pugh score A/B/C: 27.8%/45.4%/26.8%, Model for End-stage liver disease [MELD]: 15.6). Patients with MASLD had less decompensated liver disease (42.9% vs 69.8%, p = 0.01), and lower MELD score (13.2 vs 16.9, p = 0.002), but had similar age, gender, and HVPG than patients without MASLD. Patients with MASLD had higher SMI (51.9 cm2/m2 vs 45.0 cm2/m2, p = 0.008), SATI (94.2 cm2/m2 vs 54.2 cm2/m2, p < 0.001), and VATI (79.5 cm2/m2 vs 52.7 cm2/m2, p = 0.001) compared to patients without MASLD. In univariate logistic regression analysis, when HVPG ≥ 10 mmHg, patients with MASLD were associated with higher SMI (OR1.08, 95% CI 1.02–1.13), SATI (OR1.04, 95% CI 1.01–1.04) and VATI (OR1.02, 95% CI 1.01–1.04) compared to non-MASLD. After adjusting for age, and prior decompensation, when HVPG ≥ 10 mmHg, higher SMI (aOR1.08, 95% CI 1.02–1.15), SATI (aOR1.02, 95% CI 1.01–1.04) and VATI (aOR1.02, 95% CI 1.01–1.04) remained independently associated with patients with MASLD compared to non-MASLD. These associations remained true when adjusted for age and MELD score instead.

Conclusion: In our single-center cohort, after adjusting for confounders, patients with MASLD had different body composition characteristics than patients without MASLD including higher muscle mass.

FRI-257

Metabolic dysfunction associated steatohepatitis (MASH) disease progression phenotyping features based on medical claims

Magda Berberova[1], Petar Nikolov[2], Deepa Kumar[2], Liuqiang Lu[3].
[1]ICON plc, Leopardstown, Dublin 18, Ireland, Dublin, Ireland; [2]ICON plc, Dublin 18, Ireland, Ireland; [3]ICON plc, Leopardstown, Dublin 18, Ireland, Dublin 18, Ireland, Ireland
Email: magda.berberova@iconplc.com

Background and aims: To define and assess the phenotype of progressing MASH in comparison to the general United States (US) MASH population in regards of the medical claims features and diagnoses reported.

Method: ICON's US medical and prescription longitudinal anonymised records data was leveraged for this analysis of newly diagnosed MASH patients [OCT2018-SEP2020] to collect age, gender and observed conditions information. New diagnoses were confirmed by the absence of MASH and cirrhosis-related conditions records in the two years prior to the MASH diagnosis. For eligible population, disease progression and pace were determined based on the development of cirrhosis-related conditions within three years of MASH diagnosis, categorizing them as Fast Progressors v. Other. Descriptive statistics, significance tests (p value<0.05) of findings specific parameters/morbidities and speed of progression are performed.

Results: A total of 38 823 individual records have been identified with newly diagnosed MASH followed up for 3 years, based on the above criteria, within them a subpopulation of 5993 cases (15%) meeting the Fast progression definition. More than half of the total population are females, and females gender is significantly higher in the Fast progressors. Mean age is also significantly higher in the Fast progressors (61.3 ± 13.1) compared to the rest (53.7 ± 14.2). Between the most frequent co-morbidities significantly more presented in the Fast progressors are the type 2 diabetes mellitus (40% v 28%) and dyslipidaemia (40% v 37%), followed by anaemia (16% v 9%), coronary artery disease (12% v 7%) and heart failure (5% v 1%), all p values < 0.05. Leading body system affected in the Fast progressors with significant magnitude of difference to the rest of MASH population are assessed as well.

Conclusion: Around 15% of the total MASH population shows disease progression-related medical features diagnosed within a 3 years follow-up period after the initial MASH diagnosis. The Fast progressor phenotype is more frequently female, higher mean age between 55 and 75 years, with a diagnosed cardiovascular or renal co-morbidities, a drug use and dependence records, respiratory morbidities (sleep apnoea), circulatory and endocrinology disease states. Within the most frequent metabolic syndrome related co-morbidities the arterial hypertension and type 2 diabetes are significantly higher in the Fast progressors, similarly like the sleep apnoea, osteoarthritis, depression, anaemia and shortness of bread. We would consider the above features of the MASH phenotype as potential markers of higher medical attention for treatment and prevention within the MASH-related medical care.

FRI-258

Pruritus is frequent, burdensome, and persistent in metabolic dysfunction-associated steatohepatitis (MASH) and primary biliary cholangitis (PBC): a 6-month longitudinal study

Usha Gungabissoon[1], Jake Hunnicutt[2], Eleanor McDermott[3], Andrew Lovley[4], Monica Frazer[4], Kaitlin LaGasse[4], Mark Kosinski[4], Kristen McCausland[4], Anna Halliday[1], Ashleigh McGirr[5], Helen T. Smith[1], Gideon M. Hirschfield[6], Palak J. Trivedi[7]. *[1]GSK, London, United Kingdom; [2]GSK, Collegeville, PA, United States; [3]GSK, Stevenage, United Kingdom; [4]QualityMetric Incorporated, LLC, Johnston, RI, United States; [5]GSK, Mississauga, ON, Canada; [6]Toronto Centre for Liver Disease, University of Toronto, Toronto, ON, Canada; [7]University of Birmingham, Birmingham, United Kingdom*
Email: usha.2.gungabissoon@gsk.com

Background and aims: Pruritus is a symptom typically associated with cholestasis. However, the burden of pruritus in non-cholestatic liver disorders has not been systematically evaluated. This online, longitudinal, patient (pt)-reported outcome (PRO) study sought to characterise pruritus over 6 months in pts with a range of chronic liver diseases (CLDs). Here, we analyse pruritus in pts with MASH and present these data in the context of PBC-an archetypal chronic cholestatic disease.

Method: Adults with CLDs including MASH or PBC residing in the USA, UK, Canada or Germany were recruited via pt advocacy groups, healthcare provider referral or other methods. Pts were screened online for study eligibility, which included pruritus (reported using worst itch numerical rating scale [WI-NRS] with a 3-month recall) and a confirmed diagnosis of liver disease (via physician note, medical records etc.). Pruritus of extrahepatic origin or prior liver transplant were exclusion criteria. Validated PRO measures including WI-NRS (2-week recall) and 5-D itch, as well as items developed specifically for the study were completed at baseline, 3 and 6 months. In this analysis, pt experience, frequency, impact and persistence of pruritus were examined in pts with MASH or PBC.

Results: Among 97 pts with MASH and 174 with PBC who were screened for this study, 69% and 49% reported any pruritus (WI-NRS score ≥1, 3-month recall), respectively. At baseline, eligible pts in the MASH cohort (N = 61) were younger than those with PBC (N = 80) (mean [SD] 54.0 [9.9] vs 57.1 [10.6] years) and more often men (44% vs 11%). Overall, 49% of pts with MASH reported moderate-to-severe pruritus (NRS score ≥4) on the WI-NRS (2-week recall) compared with 64% in the PBC group. Both cohorts used similar terms to describe their pruritus: 'deep' (64/68%), 'urgent' (59/58%), 'scratching does not help' (46/51%) and 'relentless' (44/45%). Mean (SD) 5-D itch total score indicated moderate pruritus in both cohorts; but was significantly lower in MASH than PBC (12.0 [3.2] vs 13.5 [3.9]; p < 0.05). Additionally, mean (SD) disability (2.5 [1.2] vs 3.1 [1.3]) and distribution domain scores (1.9 [0.9] vs 2.3 [1.2]) were lower in MASH vs PBC (both p < 0.05). The duration, degree and direction domain scores were similar between cohorts. Longitudinal analyses revealed pruritus, especially moderate-to-severe, recorded on WI-NRS (2-week recall), was largely consistent over 6 months of follow-up; in MASH, 49% of pts had moderate-severe pruritus at baseline, 56% at 6 months, while in PBC, 64% had moderate-severe pruritus at both baseline and 6 months.

Conclusion: Our results show that pruritus in MASH is common, burdensome and persists over time.
In both MASH and PBC, moderate-severe pruritus was frequent, pts used similar language to describe pruritus, and itch impact was comparable across many 5-D itch domains.
Funding: GSK (209971).

FRI-259

A real-life multidisciplinary clinic approach for the management of metabolic dysfunction associated steatotic liver disease

Raluca Pais[1,2], Thomas Maurel[3], Pascal Lebray[4], Luminita Bonyhay[4], Charlotte Bouzbib[4], Stephanie Combet[5], Marika Rudler[6], Dominique Thabut[7], Vlad Ratziu[2,8]. *[1]Sorbonne University, Assistance Publique-Hôpitaux de Paris, Pitié Salpetriere Hospital, Foundation for Innovation in cardiometabolism and Nutrition (IHU-ICAN), Paris, France; [2]Foundation for Innovation in Cardiometabolism and Nutrition (IHU-ICAN), Paris, France; [3]Assistance Publique Hopitaux de Paris, Pitié Salpetriere Hospital, Paris, France; [4]Assitance Publique Hopitaux de Paris, Pitié Salpetriere Hospital, Paris, France; [5]Foundation for Innovation in Cardiometabolism and Nutrition (IHU-ICAN), Paris, France; [6]Sorbonne University, Brain Liver Pitié-Salpêtrière (BLIPS) study group, Assistance Publique-Hôpitaux de Paris, Pitié Salpetriere Hospital, Paris, France; [7]Sorbonne University, Brain Liver Pitié-Salpêtrière (BLIPS) study group, Assistance Publique-Hôpitaux de Paris, Pitié Salpetriere Hospital, Paris, France; [8]Sorbonne University, Assistance Publique-Hôpitaux de Paris, Pitié Salpetriere Hospital, Paris, France*
Email: raluca.pais@aphp.fr

Background and aims: Metabolic dysfunction associated steatotic liver disease (MASLD) is associated with the metabolic syndrome, type 2 diabetes (T2D), dyslipidemia and cardiovascular (CV) complications. Therefore integrated multidisciplinary clinics (MDCs) for diagnosis and management are preferable to siloed approaches. We aimed to investigate the effectiveness of MDCs for the management of MASLD using surrogate markers of liver injury and CV risk.
Method: Real-life prospectively collected data of patients with known or newly diagnosed MASLD referred to a MDCs with comprehensive hepatological (liver stiffness measurement, (LSM), by vibration controlled transient elastography and shear-wave elastography), metabolic and CV risk assessment (coronary calcium score, CAC), dietetic counseling, patients' education program (PEP) and questionnaires to assess disease awareness.
Results: 381 pts were prospectively included between 2019–2023, 288 with previously established and 93 with a newly diagnosed MASLD; 56% males, mean age 59 ± 11 yrs, mean BMI 32.3 ± 5.7 kg/m^2. 48% T2D, 53% high blood pressure (HBP), 50% dyslipidemia and 12% known coronary artery disease (CAD); 11% had cirrhosis and 25% were F3 by either liver biopsy (LB) or LSM. Following evaluation in the MDCs, 19% of pts were newly diagnosed with T2D or prediabetes, 30% of pts without known CAD had high to moderate CV risk (19% had CAC ≥ 300 and 11% had CAC of 100–300 Agatston UI); 58% had insufficiently controlled LDLc and needed statin dose adjustment) and 14% were initiated on statins. Among patients with newly diagnosed MASLD, 44% had T2D, 54% had HBP, 46% had dyslipidemia, 10% had known CAD; 12% had cirrhosis and 25% F3 fibrosis. Following MDCs, 25% were prescribed LB; 20% were diagnosed with CAD and 26% were seen by a cardiologist for treatment adjustment; 20% were diagnosed T2D or prediabetes; 20% were initiated on statins. Disease awareness was low in 52% of pts: 62% of pts were not aware of the risk factors to develop MASLD; However, 75% of pts believed that MASLD can progress to cirrhosis and 48% expressed anxiety in relation to the MASLD diagnosis. Mean follow-up was 9 ± 5 months. 53% of pts lost weight (mean weight loss, WL = 5 ± 4.7 kg): ≤5% in 65%; 5%–10% in 24%; ≥10 in 11%. 14% of patients had stable weight and 33% gained weight (3 ± 2.5 kg). During follow-up there was a significant reduction in ALT ($p < 0.001$), GGT ($p = 0.027$), fasting insulin ($p = 0.05$) and liver fat content assessed by CAP (0.035). 65% of pts entered a PEP; they had significant WL and reduction in ALT, lipids (total cholesterol and LDLc) and steatosis. There was no significant variation in WL, LFT and lipid parameters in patients without PEP.
Conclusion: MDC models can be effectively implemented in real-life settings with substantial benefit for the diagnosis of hepatic, metabolic and CV comorbidities. Implementation of PEP results in hepatic, metabolic and CV risk improvement.

FRI-260

Diagnosed prevalence of cardio-renal diseases, mental health disorders, sleep apnea, cancer, and mortality rates in more than 18, 000 patients with metabolic dysfunction-associated steatohepatitis with and without cirrhosis from the United States

Jörn M. Schattenberg[1], Claudio Sartini[2], Ronald Herrera[2], Mireia Raluy[3], Mark Yates[4], Ramy Younes[5]. *[1]Saarland University Medical Center, Homburg, Germany; [2]Boehringer Ingelheim International GmbH, Global Epidemiology and Real-World Evidence, Ingelheim, Germany; [3]Evidera, Data Analytics, Borlänge, Sweden; [4]Evidera, Data Analytics, London, United Kingdom; [5]Boehringer Ingelheim International GmbH, Medicine, Cardio Metabolism and Respiratory, Ingelheim, Germany*
Email: joern.schattenberg@uks.eu

Background and aims: The disease burden of metabolic dysfunction-associated steatohepatitis (MASH) extends beyond the liver, impacting especially the cardio-renal system. The prevalence of co-existing diseases in patients with MASH at different disease stages, such as sleep apnea, mental health disorders, and cancer, is not fully understood. This study uses ICD codes to compare the diagnosed prevalence of comorbidities across the disease spectrum including in patients with no evidence of cirrhosis (NC), with compensated cirrhosis (CC), and with decompensated cirrhosis (DC) in the real world setting. We hypothesized that patients with MASH and DC have higher prevalence of comorbidities and that mortality rates were similar in comparison with prior biopsy-based studies.
Method: Retrospective cohort study (2016–2021 years) using Optum Market Clarity (linked claims and electronic health records) from the United States. MASH was defined by the first ICD10 diagnosis code (K75.81 Non-alcoholic steatohepatitis) recorded during the study period, presence of AST, ALT and platelets tests carried out 3 months prior/after diagnosis, and absence of diseases prior/at diagnosis, such as alcoholic, or other chronic liver diseases. Codes for cirrhosis and decompensation were used to classify NC, CC, and DC. Both ICD and National Drug Codes were used to assess comorbidities prevalence at/or prior to MASH diagnosis. Mortality incidence rates were estimated in each sub-group.
Results: 18, 710 MASH patients were included (mean age 44 years, 95% with BMI ≥25 and 52% with diabetes, 73% NC, 9% CC, and 18% DC). In patients with MASH DC vs NC, the prevalence of sleep apnea, heart failure, renal disease, chronic kidney disease, hematological malignancies, and dementia was 38% vs 33%, 32% vs 10%, 31% vs 11%, 28% vs 9%, 16% vs 10%, and 5% vs 1% respectively. Mental health disorders were highly prevalent in all patients (39–43% for anxiety, while 37–41% and 15–19% used at least once anti-depressant and anti-psychotic drugs respectively). In patients with DC, CC, and NC the all-cause mortality incident rate per 1000 person-year was 113, 35, and 8 respectively. 1465 patients died: liver-related causes were responsible for 20%, 14% and 6% of the deaths in MASH DC, CC, and NC.
Conclusion: Patients with MASH live with several comorbidities beyond known metabolic diseases. Patients with DC had higher comorbidities prevalence and remarkably higher all-cause and liver-related mortality rates. Our mortality rates estimations were in line with prior biopsy-based studies: as there is no standard set of ICD codes to define MASH by disease stage, these findings i) contribute to the current debate about consensus of ICD codes that could be the reference standard in the real world studies to classify MASH NC, CC, and DC and ii) inform clinical trials study designs, where inclusion/exclusion criteria for some comorbidities could be applied.

FRI-261-YI

Steatotic liver disease predicts cardiovascular disease and advanced liver fibrosis: a community-dwelling cohort study with 20-year follow-up

Hun Jee Choe[1], Joon Ho Moon[2], Won Kim[3], Bo Kyung Koo[3], Nam H. Cho[4], Young Ho So[5], Yong Jin Jung[6]. *[1]Hallym University Dongtan Sacred Heart Hospital, Hwaseong-si, Gyeonggi-do, Korea, Rep. of South; [2]Seoul National University Bundang Hospital, Seongnam, Gyeonggi-do, Korea, Rep. of South; [3]Seoul National University College of Medicine, Seoul, Korea, Rep. of South; [4]Ajou University School of Medicine, Suwon, Gyeonggi-do, Korea, Rep. of South; [5]Seoul National University College of Medicine, Department of Radiology, SMG-SNU Boramae Medical Center, Seoul, Korea, Rep. of South; [6]Seoul National University College of Medicine, Department of Internal Medicine, SMG-SNU Boramae Medical Center, Seoul, Korea, Rep. of South*
Email: hunjeechoe@snu.ac.kr

Background and aims: Steatotic liver disease (SLD) has emerged as new nomenclature to increase awareness and reflect the pathophysiology of the disease better. We investigated the risk of advanced fibrosis and cardiovascular disease (CVD) in SLD using data derived from a Korean prospective cohort.
Method: We defined SLD using the fatty liver index (FLI) and identified advanced fibrosis with the age-adjusted Fibrosis-4 Index. SLD was further subcategorized into metabolic dysfunction-associated SLD (MASLD), MASLD with increased alcohol intake (MetALD), and alcohol-associated liver disease (ALD).
Results: The Ansung-Ansan cohort of the Korean Genome and Epidemiology study, following 9, 497 participants from 2002 to 2020, included 3, 642 (38.3%) with MASLD, 424 (4.5%) with MetALD, and 207 (2.1%) with ALD. During the median follow-up of 17.5 years, CVD risk was higher in those with MASLD (hazard ratio [HR], 1.27; 95% confidence interval [CI], 1.12–1.45; $p < 0.001$), MetALD (HR, 1.88; 95% CI, 1.33–2.65; $p < 0.001$), and ALD (HR, 1.95; 95%CI, 1.01–3.77; $p < 0.001$) than in those without SLD, after adjusting for conventional risk factors. Notably, the CVD risk was higher in the MetALD than in the MASLD group ($p = 0.027$). In the MASLD group, the number of cardiometabolic risk factors (CMRFs) correlated positively with CVD risk (HR, 1.34; 95%CI, 1.24–1.45; $p < 0.001$ for trend). Among the CMRFs, hypertension (HR, 1.94; 95%CI, 1.63–2.31; $p < 0.001$) was the predominant contributor to CVD. The MASLD (HR, 1.39; 95%CI, 1.25–1.55; $p < 0.001$), MetALD (HR, 1.75; 95%CI, 1.38–2.23; $p < 0.001$), and ALD (HR, 2.00; 95%CI, 1.30–3.07; $p = 0.002$) groups had a higher risk of advanced fibrosis than did the non-SLD group ($p < 0.001$ for trend).
Conclusion: Our study provides new insight into hepatic and cardiovascular outcomes related to SLD subtypes. A progressive increase in CVD risk was found from MASLD to MetALD. The SLD subcategories, considering CMRFs and alcohol intake, outperformed traditional fatty liver categorizations in predicting CVD risk. The proposed SLD terminology could impact clinical practice, warranting further exploration of the heterogeneity of clinical outcomes among SLD subtypes.

FRI-262

Liver Fibrosis in Metabolic Dysfunction-Associated Steatotic Liver Disease is Independently Associated with Reduced Kidney Function

Gres Karim[1], Carolina Villarroel[2], Dewan Giri[3], Ilan Weisberg[1], Amreen Dinani[4]. *[1]New York Presbyterian Brooklyn Methodist Hospital, New York, United States; [2]Mount Sinai Beth Israel, New York, United States; [3]Mount Sinai Beth Israel, New York, United States; [4]Duke University Hospital, Durham, United States*
Email: karimgres@gmail.com

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) and chronic kidney disease (CKD) share several phenotypic characteristics, such as type 2 diabetes (T2DM), obesity and hypertension (HTN). Presence of metabolic syndrome, dysbiosis, and unhealthy diets have been postulated as mechanisms linking MASLD and CKD. The aim of this study is to explore the association and risk factors between MASLD and CKD in a cohort of patients with obesity, a population at high risk for developing both MASLD and CKD.
Method: Patients with obesity (defined as body mass index [BMI] >30 kg/m2) and MASLD (ICD-10 codes K76.0 and K75.8) were identified using electronic medical record (EMR) at a tertiary care clinic between 06/2019 to 06/2020. Demographics, ethnicity, medical conditions, markers of liver inflammation and synthetic function were recorded. To assess the health of renal function, glomerular filtration rates (GFR) were recorded. Fibrosis Index 4 (FIB4) was calculated to determine the degree of liver fibrosis. Univariate analysis was performed using t-tests for continuous variables and chi-square or Fisher's exact tests for categorical variables. Multivariate analysis and adjustment for confounders was performed using generalized linear models including linear regression.
Results: A total of 546 patients with MASLD were identified from a cohort of patients with obesity. Majority were female (58.6%), mean age 56 years (SD 12.7), and mean BMI 35.7 kg/m2 (SD 5.49). Hispanics constituted 24%, 15.2% were black and 37.9% were white. Approximately half (49.6%) had HTN and 34.9% had T2DM. Age ($p < 0.001$), ALT ($p = 0.01$), albumin ($p = 0.011$) and FIB4 ($p = 0.005$) were associated with changes in GFR in univariate analysis. In univariate linear regression, reducing GFR was associated with higher FIB4 (effect size [beta] of one-unit increase in GFR on FIB4 = −0.013, $p < 0.001$). In multivariate linear regression, T2DM was independently associated with increased liver fibrosis (effect size of T2DM on FIB4 = 0.387925, $p < 0.02$). After adjustment for T2DM, the relationship between GFR and FIB4 was maintained (beta −0.012, $p < 0.001$). HTN did not significantly change the relationship between GFR and FIB4 in this model ($p > 0.5$). When compared to white race, only patients of black race had a lower FIB4 (effect size of black race on FIB4 = −0.442 compared to white race, $p < 0.05$). Adjusting for race did not alter the underlying relationship between GFR and FIB4.
Conclusion: MASLD is independently associated with reduced kidney function in obese patients. Black race was associated with lower FIB4. Our analysis revealed an inverse relationship between liver fibrosis and GFR which needs to be further explored.

FRI-263

Severity of hepatic steatosis measured with controlled attenuation parameter as a determinant of carotid atherosclerosis in the Raine Study

Oyekoya Ayonrinde[1,2,3], Leon Adams[1], Marilyn Zelesco[2], Christopher Welman[2], Trevor Mori[1], Phillip Melton[1,4], Andrea Mould[2], Lawrence Beilin[1], James Fiori[2], Girish Dwivedi[1,2], Frank Sanfilippo[1], John Olynyk[2,3]. *[1]The University of Western Australia, Perth, Australia; [2]Fiona Stanley Hospital, Murdoch, Australia; [3]Curtin University, Bentley, Australia; [4]University of Tasmania, Hobart, Australia*
Email: oyekoya.ayonrinde@uwa.edu.au

Background and aims: Atherosclerotic cardiovascular disease (ASCVD) is a leading cause of morbidity and mortality in people with steatotic liver disease (SLD). We aimed to examine associations between the severity of SLD and carotid intima media thickness (cIMT) as a measure of carotid atherosclerosis.
Method: Middle-aged adults participating in a cross-sectional follow-up of the longitudinal Raine study in Perth, Australia, had comprehensive liver assessments using controlled attenuation parameter (CAP) with transient elastography (TE), anthropometry, fasting blood tests, blood pressure and carotid artery ultrasound. SLD was defined by CAP ≥ 275 dB/m and grade 3 steatosis as CAP ≥ 331 dB/m. cIMT ≥ 1.0 mm was considered to represent carotid atherosclerosis. The sonographers were blinded to the results of the CAP and TE assessments. We examined the relationship between the severity of hepatic steatosis, cardiometabolic risk factors and cIMT.
Results: Three hundred and thirty-one predominantly Caucasian adults with mean (SD) age 60 (7) years had liver assessments. During

the same attendance, 132 also had a B-mode carotid artery ultrasound. Overall, 26% had SLD (38% male and 22% female, p = 0.45), 6.3% grade 3 hepatic steatosis (8.5% male and 5.0% female), while 25% had carotid atherosclerosis (39% male and 16% female, p = 0.006). Those with carotid atherosclerosis were older (66.1 [5.9] vs. 63.7 [5.2] years), had higher body weight (87.0[13.7] vs. 76.3 [14.6] kg), waist circumference (102.7[12.0] vs. 94.2[13.5] cm), body mass index (29.8[4.6] vs. 27.7[4.0] kg/m2), and more severe hepatic steatosis (CAP 261[56] vs 240[45] dB/m), p < 0.05 for all. Furthermore, a finding of carotid atherosclerosis was associated with higher serum glucose (5.5[1.7] vs. 5.0[0.8] mmol/L), lower high density lipoprotein cholesterol (1.4[0.4] vs. 1.5[0.4] mmol/L) but similar low density lipoprotein cholesterol (3.1[1.2] vs. 3.2[1.0]) mmol/L and remnant lipoprotein cholesterol (0.6[0.3] vs. 0.5[0.3] mmol/L). Using multivariable logistic regression analysis, older age (OR 1.11, 95% CI 1.01–1.22, p = 0.003), a diagnosis of grade 3 hepatic steatosis (OR 9.14, 95% CI 1.23–67.83, p = 0.03) and male sex (OR 3.31, 95% CI 1.25–8.76, p = 0.02) were associated with carotid atherosclerosis after adjusting for a diagnosis of type 2 diabetes mellitus (OR 3.99, 95%CI 0.83–19.14, p = 0.08), central obesity (OR 2.67, 95%CI 0.74–9.59, p = 0.13), remnant lipoprotein cholesterol (OR 3.12, 95%CI 0.63–15.52, p = 0.16), and liver stiffness measurement (OR 1.07, 95%CI 0.69–1.66, p = 0.61).

Conclusion: Severe hepatic steatosis is associated with increased risk of ASCVD, after adjusting for liver fibrosis and traditional cardiovascular risk factors of obesity, atherogenic dyslipidaemia and type 2 diabetes mellitus. Less severe hepatic steatosis did not appear to increase the risk of ASCVD.

FRI-266-YI

Temporal trends in the profile of non-alcoholic fatty liver disease: a decadal experience

Prajna Anirvan[1], Chitta Ranjan Khatua[2], Preetam Nath[3], Sanjib Kar[4], Manas Kumar Panigrahi[5], Shivaram Prasad Singh[1]. *[1]Kalinga Gastroenterology Foundation, Cuttack, India; [2]MKCG Medical College and Hospital, Berhampur, India; [3]Kalinga Institute of Medical Sciences, Bhubaneswar, India; [4]Indian Institute of Gastroenterology and Hepatology, Cuttack, India; [5]All India Institute of Medical Sciences, Bhubaneswar, India*

Email: spsingh.cuttack@gmail.com

Background and aims: The world is seeing an unprecedented burden of non-alcoholic fatty liver disease (NAFLD)-almost one in three people have NAFLD. Of late, there has also been a change in the nomenclature of NAFLD and this has generated a lot of interest among clinicians and patients regarding the pathophysiology, management and other clinical aspects of this entity. India harbours a huge chunk of the world's NAFLD population; however, studies evaluating temporal shifts in the profile of these patients are few. The aim of this study was to compare two separate cohorts of patients-one from 2022 to 2023 and the other from 2013 to 2014.

Method: 1537 NAFLD patients (628 belonging to the 2022–23 cohort and 909 belonging to the 2013–14 cohort) were included in this retrospective study. Anthropometric and biochemical parameters of the two groups were compared. Comparison of liver fibrosis by transient elastography was carried out between the two groups.

Results: The mean age of the subjects in both the cohorts was comparable (43.71 ± 11.01 years in the 2022–23 cohort vs 43.53 ± 11.56 years in the 2013–14 cohort). Males predominated in both the cohorts although the proportion was higher in the 2022–23 cohort (79% vs 70.9%, p < 0.001). The mean BMI between the two groups was comparable. However, a greater proportion of patients in the 2013–14 cohort had lean NAFLD (13.31% vs 12.4%, p < 0.05). The proportion of patients with diabetes mellitus was greater in the 2013–14 cohort (21.25% vs 14.35%, p < 0.001), while the proportion of subjects with hypertension was comparable between the two cohorts. The mean AST and ALT levels were significantly higher in the 2022–23 cohort (ALT, 36.31 ± 23.14 U/L vs 29.98 ± 2.10 U/L, p < 0.001; AST, 32.65 ± 17.68 U/L vs 26.40 ± 13.50 U/L, p < 0.001) although the proportion of patients with elevated liver enzymes was higher in the 2013–14 cohort (18.04% vs 14.79%, p < 0.05). The proportion of subjects with insulin resistance (HOMA-IR >2) was slightly higher in the 2013–14 cohort (55.25% vs 54.89%, p < 0.05). The proportion of patients with significant fibrosis (≥F2) was greater in the 2022–23 cohort compared to the earlier cohort (29.9% vs 21.78%, p < 0.001)

Conclusion: The results of this study conclusively show that compared to a decade ago, the prevalence of significant fibrosis has markedly increased in NAFLD patients. While there have been some shifts in the anthropological and biochemical parameters, the marked increase in the proportion of patients with significant fibrosis deserves immediate attention.

FRI-267

Regional fibrosis progression analysed by digital pathology with artificial intelligence is associated with renal dysfunction

Dan-Qin Sun[1,2,3], Jia-Qi Shen[1,2,3], Xiao-Fei Tong[4], Yangyang Li[5], Giovanni Targher[6], Yayun Ren[7], Haiyang Yuan[8], Chris D. Byrne[9], Hong You[4], Ming-Hua Zheng[8,10]. *[1]Urologic Nephrology Center, Jiangnan University Medical Center, Wuxi, China; [2]Affiliated Wuxi Clinical College of Nantong University, Wuxi, China; [3]Wuxi No.2 People's Hospital, Wuxi, China; [4]Liver Research Center, Beijing Friendship Hospital, Beijing Key Laboratory of Translational Medicine on Liver Cirrhosis, National Clinical Research Center of Digestive Diseases, Capital Medical University, Beijing, China; [5]Key Laboratory of Diagnosis and Treatment for the Development of Chronic Liver Disease in Zhejiang Province, Wenzhou, China; [6]Section of Endocrinology, Diabetes and Metabolism, Department of Medicine, Azienda Ospedaliera Universitaria Integrata Verona, Verona, Italy; [7]HistoIndex Pte Ltd, Singapore, Singapore; [8]MAFLD Research Center, Department of Hepatology, the First Affiliated Hospital of Wenzhou Medical University, Wenzhou, China; [9]Southampton National Institute for Health and Care Research Biomedical Research Centre, University Hospital Southampton and University of Southampton, Southampton General Hospital, Southampton, United Kingdom; [10]Key Laboratory of Diagnosis and Treatment for The Development of Chronic Liver Disease in Zhejiang Province, Wenzhou, China*

Email: sundanqin126@126.com

Background and aims: An association between liver fibrosis and kidney dysfunction in metabolic dysfunction-associated fatty liver disease (MAFLD) patients has recently been demonstrated. However, an analysis of hepatic lobule fibrosis progression and kidney function decline in MAFLD has not been undertake. The second harmonic generation/two-photon excitation fluorescence (SHG/TPEF) microscopy with artificial intelligence analyses can provide automated quantitative assessment of liver fibrosis (qFibrosis) across the liver lobule. In this study, we aimed to discover the potential relationship between the progression of liver fibrosis and kidney function for MAFLD patients using qFibrosis assessment.

Method: In this longitudinal cohort study, formalin-fixed sections from 58 paired liver biopsies were enrolled with completed a 28-month followed up. Total 184 fibrosis parameters were quantified in 5 liver regions, including portal tract (PT), peri-portal (PP), zone 2, peri-central (PC) and central vein (CV), and qFibrosis continuous (qFC) values were generated for all samples based on 10 fibrosis parameters using qFibrosis assessment. Liver fibrosis progression (LF+) and regression (LF-) was defined as qFC changes of at least a 20% relative difference, and kidney function decline (or improvement) were defined as eGFR changes of at least a 2% relative difference during the 28-month follow-up period. The two-tailed Wilcoxon rank-sum test and the Spearman nonparametric method were performed to test the independence of associations between liver fibrosis and eGFR.

Results: There was no significant difference in liver fibrosis stage and eGFR at the first and second liver biopsy. However, after 28-month follow-up, eGFR values declined in the LF+ group compared to baseline eGFR. Moreover, eGFR change in LF+ group evaluated by qFibrosis was greater than that in LF- group (p = 0.043). In addition,

compared with peri-portal area, zone 2 and portal tract area, kidney function decline was significantly correlated with fibrosis changes in the central vein region and peri-central region. Regional qFibrosis parameters were also able to differentiate kidney injury (%CVDis, AUC:0.737, P = 0.003; #ThinStrCVDis, AUC:0.791, P = 0.000; StrLengthCVDis, AUC:0.743, P = 0.003).
Conclusion: Regional qFibrosis assessment by digital pathology with artificial intelligence can demonstrate specific liver lobular changes that are associated with kidney dysfunction. Further study of specific liver injury in MAFLD and renal dysfunction is required.

FRI-268
MASH not NASH: A contemporary study of the impact of cardiac arrythmias
Charles Yang[1], Trinava Roy[1], Brian Blair[1], Lucy Joo[1], C. J. Foster[1].
[1]*Jefferson Health New Jersey, Cherry Hill, United States*
Email: cxy206@jefferson.edu

Background and aims: Limited data exists specifically looking at metabolic dysfunction-associated steatohepatitis (MASH), formerly known as non-alcoholic steatohepatitis (NASH), and cardiac arrythmias. We sought to examine the national inpatient sample database to describe in-hospital outcomes among these patients.
Method: The National Inpatient Sample (NIS) Database was analyzed for the years 2019 and 2020. The NIS was searched for hospitalizations of adult patients greater than 18 years-old with MASH with and without a concomitant diagnosis of atrial fibrillation, atrial flutter, supraventricular tachycardia or ventricular tachycardia. Multivariate logistics were used to adjust for confounders. The primary outcome was inpatient mortality. Secondary outcomes were hospital length of stay (LOS), and total hospital charges (TOTHCG).
Results: This study included 237, 215 patients with MASH, of which 40, 275 (16.9%) patients were diagnosed with atrial fibrillation, atrial flutter, supraventricular tachycardia or ventricular tachycardia. Multivariate regression showed that patients with both MASH and selected cardiac arrhythmias had higher inpatient mortality compared to those with MASH alone (OR 1.87, CI 1.67–2.09, p < 0.0001). It was also shown that MASH patients with selected cardiac arrhythmias pay significantly more total hospital charges $16, 108.80 (CI $13, 048.17-$19, 167.43, P < 0.001) with increased length of stay of 1.58 days (1.39–1.77, p < 0.0001).
Conclusion: This nationwide study evaluated the characteristics and outcomes of hospitalized patients with MASH and atrial fibrillation, atrial flutter, supraventricular tachycardia or ventricular tachycardia. Our work highlights longer hospital stays and increased inpatient mortality in this subset of patients. The role of inflammation in the context of cardiac arrhythmias needs elucidation. This relationship may inspire opportunities to screen for arrythmias that ultimately influence mortality. Further studies are needed on this particular population.

FRI-269
GH agonist use in MASLD: a systematic review and meta-analysis of randomised controlled trials
Islam Mohamed[1], Misha Gautam[1], Hazem Abosheiashaa[1], Sophia Hussain[1], Kopal Kumar[1], Anaya Kotak[1], Macy Baugh[1], Raabia Qureshi[1], Rawan Rajab[1], Laura Alba[1]. [1]*University of Missouri Kansas city, Kansas city, United States*
Email: islamh3255@gmail.com

Background and aims: Metabolic Dysfunction Associated Steatotic Liver Disease (MASLD) represents a complex clinical condition characterized by hepatic steatosis and metabolic dysregulation. MASLD poses significant health risks, including the development of insulin resistance, cardiovascular complications, and liver-related morbidity. Growth Hormone (GH) agonists have emerged as potential therapeutic agents, given their role in modulating metabolism, promoting lipolysis, and influencing insulin-like growth factor-1 (IGF-1) levels. However, the comprehensive efficacy outcomes of GH supplementation in MASLD remain incompletely understood. The primary aim of this study is to systematically evaluate the impact of GH agonist use on a range of clinical and biochemical parameters in MASLD patients.
Method: A systematic literature search across major databases identified randomized controlled trials (RCTs) investigating GH supplementation in MASLD patients. Inclusion criteria encompassed outcomes related to IGF-1 levels, BMI, hepatic fat fraction (relative and absolute), HbA1C, CRP levels, fasting serum glucose, lipid profiles, liver enzymes, and adverse events, with a focus on mean differences (MD), 95% confidence intervals (CI), and p values. Two reviewers independently extracted data, and quality assessment employed the Cochrane Risk of Bias tool. Meta-analyses, utilizing random-effects models and sensitivity analyses, were conducted to synthesize findings. Statistical significance was set at p < 0.05.
Results: GH supplementation resulted in a significant reduction in both relative (MD: −46.26, 95% CI [−71.52, −21.00], p = 0.0003) and absolute (MD: −5.15, 95% CI [−7.93, −2.37], p = 0.0003) hepatic fat fraction. No significant changes were observed in HbA1C, CRP levels, fasting serum glucose, BMI, triglycerides, and LDL-C. GH supplementation showed a significant reduction in ALT (MD: −5.97, 95% CI [−10.31, −1.62], p = 0.007) and GGT (MD: −16.18, 95% CI [−30.76, −1.59], p = 0.03) levels compared to placebo. No significant differences were observed in the incidence of arthralgia, myalgia, paresthesia, and injection site reactions between GH and placebo groups.
Conclusion: In summary, our meta-analysis highlights GH supplementation as a promising therapy for MASLD. GH agonists significantly reduced both absolute and relative hepatic fat fraction, indicating potential efficacy in addressing steatosis. Positive effects on liver enzymes, with significant reductions in ALT and GGT levels, were observed. GH agonists showed no significant adverse events compared to placebo, emphasizing their safety. However, further large-scale randomized controlled trials are essential to clarify the long-term effects, safety profile, and potential impact on measures like fibrosis in MASLD patients.

FRI-270-YI
Association of severity of metabolic dysfunction-associated steatotic liver disease with gut dysbiosis and shift in the metabolic function of the gut microbiota in people with HIV
Luz Ramos Ballesteros[1]. [1]*McGill University Health Centre, Montreal, Canada*
Email: luz.ramos@muhc.mcgill.ca

Background and aims: The progression of metabolic dysfunction-associated steatotic liver disease (MASLD) to its severe forms, including metabolic dysfunction-associated steatohepatitis (MASH) and liver fibrosis, might be attributed to a combination of lifestyle and genetic factors. Recently, several studies have emphasized gut microbial dysbiosis as a key driver in this process. However, the role of gut dysbiosis in people with HIV (PWH), a population with a complex MASLD pathogenesis and at risk for severe liver disease, is not known. We aimed to evaluate the association between gut dysbiosis and severe MASLD, that is, MASH and liver fibrosis, in a well-characterized population of PWH.
Method: Consecutive PWH from a prospective Cohort (LIVEr disease in HIV, LIVEHIV) underwent transient elastography with controlled attenuation parameter (CAP) and the measurement of serum cytokeratin-18, a biomarker of hepatocyte apoptosis used to diagnose MASH. All included patients had MASLD, defined as CAp >238 dB/m. Severe MASLD was defined as presence of MASH (cytokeratin-18 ≥130.5 U/L) and/or significant liver fibrosis (liver stiffness measurement ≥7.1 kPa). Taxonomic composition of gut microbiota was determined using 16S ribosomal RNA gene sequencing of stool samples. PICRUSt-based functional prediction was employed. Bacterial and functional differences were assessed using a

generalized linear model, with adjustment for age and sex as confounding factors, using a negative binomial distribution.
Results: 34 patients with MASLD were enrolled (mean age 52 years, 15% females, meanstiffness measurement 6.7 kPa, mean cytokeratin-18 184 U/L). Among them, 32% had severe MASLD. After adjusting for age and sex, liver health status (severe MASLD yes vs. no) explained 7% of the overall variation (r2 = 0.07, p = 0.09) in bacterial composition. Several genera were found to be significantly different between PWH with severe MASLD. Participants with severe MASLD had increases of genera *Eubacterium*, *Bacteroides*, *Roseburia*, *Ruminococcus*, *Slackia*, *Holdemanella*, *Bilophila* and decreases of *Alloprevotella*, *Paraprevotella*, *Prevotella*, *Olsenella*, *Oribacterium*, *Romboutsia*, *Desulfovibrio*, *Dialister*. In severe MASLD, functional analysis revealed increases in fatty acid degradation and flavonoid biosynthesis, and decreases in pyrimidine metabolism, steroid biosynthesis, folate biosynthesis, and alanine, aspartate, glutamate metabolism.
Conclusion: In HIV mono-infection, MASLD severity is associated with gut dysbiosis and a shift in metabolic function of the gut microbiota. Some of these taxa are similar to those associated with MASLD in HIV-negative populations. Thus, gut microbiota analysis adds information to classical predictors of MASLD severity and suggests novel metabolic targets for pre-/probiotics therapies.

Hepatitis C infection increases the risk of new-onset HTN and DM among patients with metabolic dysfunction-associated steatotic liver disease
Ping-Tsung Shih[1], Chin-I Shih[2], Kuan-Ta Wu[3], Meng-Hsuan Hsieh[3,4,5], Jeng-Fu Yang[3], Yi-Yu Chen[3], Wei-Lun Tsai[6,7], Wen-Chi Chen[6,7], Po-Cheng Liang[4], Yu-Ju Wei[4], Pei-Chien Tsai[4], Po-Yao Hsu[4], Ming-Yen Hsieh[4], Yi-Hung Lin[4], Tyng-Yuan Jang[4], Chih-Wen Wang[4,5], Ming-Lun Yeh[4,5], Chung-Feng Huang[4,5], Jee-Fu Huang[4,5], Chia-Yen Dai[4,5], Chi-Kung Ho[3], Wan-Long Chuang[4,5], Ming-Lung Yu[4,5,6]. *[1]Department of Internal Medicine, Kaohsiung Medical University Hospital, Kaohsiung, Taiwan; [2]Department of Medical Education and Department of Internal Medicine, Kaohsiung Veterans General Hospital, Kaohsiung, Taiwan; [3]Department of Preventive Medicine, and Health Management Center, Kaohsiung Medical University Hospital, Kaohsiung Medical University, Kaohsiung, Taiwan; [4]Hepatobiliary Division, Department of Internal Medicine and Hepatitis Center, Kaohsiung Medical University Hospital, Kaohsiung Medical University, Kaohsiung, Taiwan; [5]School of Medicine and Hepatitis Research Center, College of Medicine, and Center for Liquid Biopsy and Cohort Research, Kaohsiung Medical University, Kaohsiung, Taiwan; [6]School of Medicine and Doctoral Program of Clinical and Experimental Medicine, College of Medicine and Center of Excellence for Metabolic Associated Fatty Liver Disease, National Sun Yat-Sen University, Kaohsiung, Taiwan; [7]Division of Gastroenterology, Department of Internal Medicine, Kaohsiung Veterans General Hospital, Kaohsiung, Taiwan*
Email: ping289764@gmail.com

Background and aims: Steatotic liver disease (SLD) is associated with higher risks of hypertension (HTN) and diabetes mellitus (DM). A new nomenclature of SLD, metabolic dysfunction-associated steatotic liver disease (MASLD) has emerged recently. Besides, Taiwan is hyperendemic for chronic hepatitis B virus (HBV) and hepatitis C virus (HCV) infections. The interaction between MASLD and viral hepatitis on the risk of HTN and DM remains unclear. We conducted a retrospective cross-sectional and longitudinal cohort design to evaluate the role of viral hepatitis in the risk of co-existing and new-onset HTN and DM among patients with MASLD with and without viral hepatitis.
Method: The cross-sectional cohort consisted of 22, 493 adults with SLD who underwent health checkups at a tertiary hospital in Taiwan from 1999 to 2013. Of them, 17, 375 subjects with estimated glomerular filtration rate (eGFR) ≧30 ml/min/1.73 m^2, but without HTN and/or DM at baseline and within 1 year after enrollment were included as a longitudinal cohort (mean, 6.49 years for HTN; 6.85 years for DM). Both cohorts were divided into two groups, MASLD (SLD with at least one cardiometabolic risk factor [CMRF]) as the target group and simple SLD (SLD without CMRF) as the control group. The target group (MASLD) was further divided into three subgroups (NBNC-MASLD, HBV-MASLD, and HCV-MASLD), and the control group (simple SLD) was further divided into simple non-B, non-C (NBNC)-SLD, simple HBV-SLD, and simple HCV-SLD.
Results: In the cross-sectional cohort, HBV-MASLD, but not HCV-MASLD, had significantly lower risk of existing-HTN (adjusted odds ratio [aOR]/95% confidence interval [CI] 0.85/0.77–0.94) compared to those with NBNC-MASLD. The prevalence of existing DM did not differ among HBV-MASLD, HCV-MASLD and NBNC-MASLD. In the longitudinal cohort, 2, 084 (13.07%) subjects and 701 (4.40%) subjects developed new-onset HTN and DM, respectively (annual incidence, 20.05 and 6.36 per 1000 person-years; 10-year cumulative incidence, 19.80% and 6.98%, respectively). HCV-MASLD, but not HBV-MASLD, had significantly higher risks of new-onset HTN (adjusted hazard ratio [aHR]/95% CI: 1.46/1.12–1.92) and DM (aHR/95% CI: 1.81/1.22–2.68) than NBNC-MASLD did (annual incidence, 27.89, 20.7, and 19.7, respectively, for HTN and 12.69, 5.85 and 6.33, respectively, for DM per 1000 person-years). The new onset of HTN and DM did not differ among simple NBNC-SLD, simple HBV-SLD, and simple HCV-SLD subjects.
Conclusion: HCV, but not HBV, infection increased the risk of new-onset HTN and DM among patients with MASLD.

FRI-272
Steatotic liver disease with normal liver enzyme: clinical use of ultrasound attenuation method and share wave elastography
Shunsuke Sato[1], Hidehiko Kawai[2], Takuya Genda[1]. *[1]Juntendo University Shizuoka Hospital, Shizuoka, Japan; [2]Fuji Town Medical Center, Shizuoka, Japan*
Email: syusato@juntendo.ac.jp

Background and aims: Recently, steatotic liver disease (SLD) has emerged as the most common chronic liver disease in Japan. The Nara Declaration, proposed by the Japan Society of Hepatology in 2023, recommends that patients with elevated liver enzyme (ALT level of ≥30 IU/L) consult general physicians. However, its disease progression has been known, including patients with normal ALT test. Therefore, we investigated the clinical characteristics and diagnostic significance of SLD with normal ALT test using annual health checkup cohort.
Method: Among the 2, 448 patients who underwent a quantitative evaluation of steatosis (attenuation) and fibrosis (shear wave elastography) simultaneously using ARIETTA 850SE (Fujifilm Healthcare, Tokyo, JAPAN) in 2021, 2, 397 patients without obvious liver disease were enrolled. Based on previous studies, cut-off values for steatosis were S1 (0.62 dB/cm/MHz), S2 (0.67), and S3 (0.73) and cut-off values for fibrosis were F1 (1.26 KPa), F2 (1.51), and F3 (1.63).
Results: SLD was observed in 850 cases (35.5%). Among them, 599 cases (70.5%) had normal ALT value and 251 cases (29.5%) had elevated ALT value. The degree of steatosis was S1/S2/S3; 51.4/30.1/18.5% vs. 24.3/32.7/43.0% in the patients with normal and elevated ALT test, respectively. Patients with SLD and normal ALT test was less common in obesity (31.2 vs. 66.5%), hypertension (30.6 vs. 47.0%), dyslipidemia (57.8 vs. 77.7%), and diabetes (7.0 vs. 15.1%) ($p < 0.001$). The diagnostic ability of fatty liver index is good in patients with SLD and normal ALT test (AUROC 0.645, $p < 0.001$) and those with elevated ALT test (AUROC 0.708, $p < 0.001$). Conversely, the optimal cut-off value was 45 (sensitivity 66.9/specificity 64.3/PPV 71.8/NPV 80.9%) for patients with SLD and elevated ALT test and 15 (sensitivity 56.4/specificity 64.9/PPV 41.4/NPV) for those with normal ALT test. The degree of fibrosis was F0/F1/F2/F3; 73.6/20.2/4.2/2.2% vs. 53.0/32.7/6.0/8.4% in patients with SLD and normal and elevated ALT test, respectively. The ability of FIB-4 index to diagnose F2 or higher

fibrosis is good only in patients with SLD and elevated ALT test (AUROC; 0.773, p < 0.001), while its usefulness did not show in patients with SLD and normal ALT test (AUROC; 0.527, p = 0.598).
Conclusion: Approximately 70% of patients with SLD showed normal ALT test. Although mild hepatic steatosis was more common in SLD with normal ALT test, approximately 25% of them showed liver fibrosis. Since it is difficult to identify individuals with SLD and fibrosis; particularly, in normal ALT test, diagnosis using ultrasound measurement was considered important.

FRI-273-YI
Prevalence, characteristics and hepatic fibrosis burden of the different subtypes of steatotic liver disease among a cohort of Egyptian people living with HIV
Rahma Mohamed[1], Heba Omar[2], Naeema El Garhy[1], Ahmed Cordie[1], Hend Tamim[3], Zainab Masoud[3], Lamiaa Al Sehemy[1], Ammar Hatem[1], Reham Awad Awad[1], Mariam Ismail Abdelraouf[1], Aya M. Al-sharif[1], Mirella Sherif[1], Andrew Saweres[1], Remon Atef[1], Mohamed Nagy[1], Rania Hamza[3], Mona Salah Eldin Hamdy[3], Engy El Khateeb[3], Gamal Esmat[2]. *[1]Cairo University Hospitals HIV Clinic, Endemic medicine department, Cairo University Hospitals, Cairo, Egypt; [2]Endemic medicine department, Cairo University Hospitals, Cairo, Egypt; [3]Department of Clinical and Chemical Pathology, Cairo University Hospitals, Cairo, Egypt*
Email: ahmedcordie@gmail.com

Background and aims: A consensus was reached to change the nomenclature of non-alcoholic liver disease to steatotic liver disease (SLD), comprising different entities, including metabolic dysfunction-associated steatotic liver disease (MASLD), characterized by the presence of cardiometabolic risk factors (CMRF), met-ALD, which add to MASLD an excessive alcohol consumption, and cryptogenic SLD (cSLD). We aimed to determine the prevalence, clinical characteristics, and frequency of clinically significant fibrosis (CSF) within the SLD subgroups in a cohort of Egyptian people with HIV (PWH).
Method: A cross-sectional study included PWH attending Cairo University Hospital's HIV clinic from July 2022 to September 2023. Patients with viral hepatitis coinfections, alcohol use, or metabolic dysfunction (defined by having ≥1 CMRF) were allowed. CSF was defined as liver stiffness measurement >7.1 KPa, and SLD was defined as controlled attenuation parameter (CAP) ≥238 dB/m by transient elastography. Participants were categorized into five subgroups (No-SLD, cSLD, HCV-SLD, HCV+CMRF-SLD, and MASLD. A multivariate analysis was used to identify the predictors of steatosis and CSF.
Results: Of 531 participants, 77.4% were male, mean (SD) age 36 ± 10 years, 90.85% on integrase inhibitors-based antiretroviral therapy (ART), 62.2% were virally suppressed, 13.7% reported occasional alcohol intake, 14.8% cured of HCV and 79.6% had at least one CMRF. The prevalence of SLD was 31.8%, MASLD 23.9%, HCV/CMRF-SLD 4.7%, HCV-SLD 2.8%, cSLD 0.4%, and CSF 7.7%. None of them met the criteria for alcohol-related liver disease or metALD. Within MASLD subgroup, being overweight (OR 4.69, 95%CI, 2.52–8.71, p < 0.001) or having hypertension (OR 3, 95%CI, 0.99–9.17, p 0.05) were strongly associated with MASLD, followed by triglycerides >150 (OR 2.09, 95%CI (1.26–3.44, p 0.004) and age >35 years (OR 1.81, 95% CI (1.05–3.12, p 0.03). Meanwhile, male gender, intravenous drug use, glycated haemoglobin >5.7% and higher CAP reading were significantly associated with CSF (OR, 4.24, 5.37, 2.47, and 1, respectively), but being on ART was protective against having CSF (OR, 0.39, p = 0.03). Viral load suppression, CD 4 count and ART type did not affect MASLD risk.
Conclusion: MASLD was the dominant cause of SLD in PWH, with 79.6% of the total cohort having CMRF. Early diagnosis and proactive management of metabolic risk factors are crucial for mitigating the risk of MASLD and subsequent CSF among PWH.

FRI-274
Persistence of fatty liver index (FLI) ≥20 as a predictor for hepatocellular carcinoma (HCC) development in non-HBV/non-HCV infected population
Rachel Wen-Juei Jeng[1,2], Mei-Hung Pan[3], Yi-Chung Hsieh[1,2], Hwai-I Yang[3]. *[1]Chang Gung Memorial Hospital, Linkou Medical Center, Department of Gastroenterology and Hepatology, Taoyuan, Taiwan; [2]Chang Gung University, College of Medicine, Taoyuan, Taiwan; [3]Genomics Research Center, Academia Sinica, Taipei, Taiwan*
Email: hiyang@gate.sinica.edu.tw

Background and aims: The Fatty Liver Index (FLI) has been employed to exclude hepatic steatosis and is recognized as a factor for incident severe liver disease. However, it has not been thoroughly investigated whether longitudinal changes in FLI can predict hepatocellular carcinoma (HCC) development in the Taiwanese population without viral hepatitis infection.
Method: We enrolled participants from the Taiwan Biobank who tested seronegative for HBsAg and anti-HCV (NBNC). HCC diagnoses were validated through the Taiwan National Cancer Registry, with repeated measurements of body mass index, triglycerides, and liver biochemistry. Subjects were categorized based on their initial and follow-up FLI as follows: persistent lower than 20 (referent), initial <20 and increased to ≥20 (group 1), initial ≥20 and reduced to <20 (group 2), and persistent greater than 20 (group 3). Subjects who experienced an HCC event between the two visits were excluded. Time to the event was calculated from the second visit until the end of the follow-up period (December 31, 2020, as per the National Cancer Registry) or the occurrence of the event. Cox regression analysis was applied to identify the impact of longitudinal changes in FLI on the prediction of HCC.
Results: Among the 116, 269 NBNC subjects in the Taiwan Biobank, 28, 738 subjects had a second visit with repeated measurements, with a median interval duration of 3.9 (IQR: 3.1–3.8) years. These subjects had a mean age of 51, 35% male, 68% anti-HBcAb positive, 27% with type 2 DM, and 18 developed HCC during a median follow-up of 3.1 (IQR: 1.3–3.9) years. There were 13, 284, 2, 842, 1, 727, and 10, 885 subjects in groups 0, 1, 2, and 3, respectively. No HCC developed in group 1 patients. Univariate Cox regression analysis showed that persistent FLI >20 (group 3) is a factor for HCC development [crude hazard ratio (cHR): 4.0, P = 0.015], while group 2 (cHR: 1.8, P = 0.604) failed to achieve significance. After adjusting for anti-HBc serostatus, FIB-4, age, gender, and current alcohol consumption, persistent FLI >20 (group 3) remained the only independent risk factor for HCC development [persistent FLI < 20 as the referent, adjusted HR (aHR): 3.3, P = 0.042], while group 2 remained insignificant (aHR: 1.4, P = 0.752).
Conclusion: Persistence of FLI greater than 20 is identified as an independent risk factor for HCC development in NBNC subjects. Aggressive reduction of FLI may effectively mitigate their HCC risk.

FRI-275-YI
Liver fibrosis and Lipoprotein (a) levels in individuals with metabolic dysfunction
Sara Margarita[1], Chiara Macchi[2], Serena Pelusi[1], Cristiana Bianco[1], Giulia Periti[1], Jessica Rondena[1], Francesco Malvestiti[3], Daniele Prati[1], Massimiliano Ruscica[2], Luca Valenti[4]. *[1]Transfusion Medicine Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Milan, Italy; [2]Department of Pharmacological and Biomolecular Sciences, Università degli Studi di Milano, Milan, Italy; [3]Department of Pathophysiology and Transplantation, Università degli Studi di Milano, Milan, Italy; [4]Transfusion Medicine Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Department of Pathophysiology and Transplantation, Università degli Studi di Milano, Milan, Italy*
Email: sara.margarita@policlinico.mi.it

Background and aims: Metabolic-dysfunction associated steatotic liver disease (MASLD), characterized by the presence of liver fat and metabolic alterations, has progressively become the most common

chronic liver disease, and is associated with accelerated atherosclerosis. Circulating levels of Lipoprotein (a) (Lp (a)) is emerging as an independent cardiovascular (CV) risk factor and a target for novel therapeutic approaches. However, previous studies in small cohorts suggested that Lp (a) may be lower in patients with chronic advanced MASLD, but evidence is not yet conclusive. Aim of the study was to evaluate Lp (a) levels in a cohort of 728 individuals, consecutively enrolled in a primary prevention program for candidate blood donors in Milan, Italy, focused at the early diagnosis of hepatic and extrahepatic complications of MASLD (the Liver-Bible-2022 Biobank cohort).

Method: The study cohort included apparently healthy subjects, aged 40–65 in the presence of at least three criteria of metabolic dysfunction defining MASLD. Anthropometric data, lipid levels, transaminases and Lp (a) levels were available for all. Hepatic fibrosis and steatosis were non-invasively estimated by measurement of liver stiffness measurement (LSM) and controlled attenuation parameter (CAP) by FibroScan, while Lp (a) was measured by turbidimetric in vitro test and log transformed. Observational associations were performed by fitting data to generalized linear models. Binary outcomes were examined by fitting logistic regression models.

Results: Patients were mainly males (85%), mean age was 53 years, 361 showed CAP ≥ 275 dB/m (49%), 16 (2.2%) had LSM ≥ 8 kPa (>11.9 kPa in two). Of these, 326 subjects (44%) had hypercholesterolemia, only 62 (8%) were on lipid lowering therapy, while 122 (16%) showed increased Lp (a) levels, considering 75 nmol/L as threshold. Increased Lp (a) levels were associated with hypercholesterolemia (p = 0.02), while lower Lp (a) concentrations were observed in subjects with LSM above 11.9 kPa (p = 0.04), consistent with advanced fibrosis, irrespective of age, sex, use of lipid lowering treatment and overweight. Moreover, participants with lower Lp (a) displayed a trend towards higher ALT levels (p = 0.08) and showed an increased NASH score (p = 0.04), a non-invasive test taking into account insulin, albumin, AST and *PNPLA3* genotype for the estimation of MASH.

Conclusion: We confirm an association between severe liver fibrosis and lower circulating Lp (a) levels. Lp (a) may therefore not be reliable in evaluating CV risk in this subset of patients with increased predisposition to CV events.

FRI-278

The risk of cardiometabolic disease related to increasing amounts of liver fat above the cut-off of 5%

Gabrielle Alblas[1], Jeroen van der Velde[1], Maarten Tushuizen[1], J. Wouter Jukema[1], Hildo Lamb[1], Frits Rosendaal[1], Renée de Mutsert[1], Minneke Coenraad[2]. *[1]Leiden University Medical Center, Leiden, Netherlands; [2]Leiden University Medical Center, Leiden*
Email: g.alblas@lumc.nl

Background and aims: Metabolic dysfunction associated steatotic liver disease (MASLD), defined as liver fat content ≥5% and the presence of cardiometabolic criteria, is associated with an increased risk of type 2 diabetes and cardiovascular diseases. However, it remains unclear to what extent increasing amounts of liver fat above the cut-off of 5% are associated with more pronounced risks of cardiometabolic disease. We aimed to examine the association between increasing amounts of liver fat content and the risk of cardiometabolic diseases in a middle-aged population during a 10-years follow-up.

Method: In the Netherlands Epidemiology of Obesity study, a prospective cohort study with 10 years of follow-up, liver fat content was assessed using proton magnetic resonance spectroscopy in 1763 participants without pre-existing diabetes or cardiovascular diseases. Incident cardiometabolic diseases were collected via medical records. Cox regression was used to examine associations of MASLD, and of different categories of liver fat content with cardiometabolic diseases, adjusted for age, sex, education, ethnicity, alcohol consumption, physical activity and total body fat.

Results: The overall population had a mean (95% CI) age of 55 (55–56) years, BMI of 29.2 (29.0–29.4) kg/m^2, liver fat content of 8.1 (7.7–8.5)%. 50% were men, and 751 (43%) had MASLD. During 10 years of follow-up, 140 new cases of cardiometabolic diseases occurred, leading to an adjusted hazard ratio (HR, 95% CI)) of 2.2 (1.5–3.3) for those with MASLD as compared with those without MASLD. Compared with those who had a liver fat content between 0 and 2.5%, the adjusted HR for participants with liver fat content between 5 and 10% was 1.8 (1.0–3.2), for 10–15% 1.9 (1.0–3.7), for 15–20% 1.9 (0.9–3.9), for 20–25% 2.4 (1.1–5.2), for 25–30% it was 2.7 (1.2–7.2), and for those with liver fat content of 30% or more the HR was 3.4 (1.7–6.9).

Conclusion: Patients with MASLD have a two-fold increased risk of cardiometabolic disease. Increasing categories of liver fat content above the cut-off of 5% were not associated with strong risk increases. Future studies should reveal to what extent the presence of comorbidities in addition to hepatic steatosis increase the risk of cardiometabolic diseases.

FRI-279-YI

Platelet dynamics in metabolic patients with metabolic dysfunction-associated steatotic liver disease/steatohepatitis and liver cirrhosis

Mirko Zoncapè[1], Marco Castelli[2], David Sacerdoti[1], Pietro Minuz[2], Andrea Dalbeni[3]. *[1]Liver Unit, University of Verona and University and Hospital Trust (AOUI) of Verona, Verona, Italy; [2]Division of General Medicine C, Department of Medicine, University of Verona and University and Hospital Trust (AOUI) of Verona, Verona, Italy; [3]Liver Unit, University of Verona and University and Hospital Trust (AOUI) of Verona, Division of General Medicine C, Department of Medicine, University of Verona and University and Hospital Trust (AOUI) of Verona, Verona, Italy*
Email: mirko.zonky@yahoo.it

Background and aims: Metabolic dysfunction-Associated Steatotic Liver Disease (MASLD), affects about 30% globally, potentially leading to cirrhosis. Metabolic dysfunction-Associated Steatohepatitis (MASH) often involves platelets. Platelet roles in MASLD progression remain underexplored. Our aim was to verify the possible platelet contributions to MASLD/MASH genesis and in MASLD-related cirrhosis, compared to healthy subjects, investigating the activation state of platelets *in vitro* and *in vivo*.

Method: Patients with metabolic liver cirrhosis (Child-Pugh classes A/B), MASLD/MASH, and healthy volunteers without metabolic alterations were examined. Patients were diagnosed trough abdominal ultrasounds, TC, RM and liver biopsy, Fibroscan and other non-invasive test and scores were also used.

Microfluidic analysis assessed platelet adhesion on collagen, indicating pre-activation states and in vitro activation levels. Urinary 11-dehydro-thromboxane-B2 (11-TXB2) measured in vivo thromboxane A2 synthesis, indirectly assessing platelet activation in vivo. Platelet interaction with coagulation factors, specifically Factor VIII (FVIII) and von Willebrand Factor (vWF) activity, was explored through cross-mixing experiments.

Results: Among 66 participants, platelet count was significantly lower in cirrhotic patients compared to controls (p < 0.001). However, no differences were observed in platelet distribution width (PDW), mean platelet volume (MPV), or immature reticulate fraction (IRF) among the three groups. *In vitro* adhesion on collagen was higher in MASLD/MASH and cirrhosis (p < 0.01) compared to controls. 11-TXB2 levels were significantly elevated in cirrhotic patients compared to controls (p < 0.001). Higher levels of FVIII and vWF were observed in the platelet-poor plasma (PPP) of cirrhotic patients. Cross-mixing experiments indicated that elevated FVIII and vWF levels in cirrhotic patients were associated with these factors in PPP rather than a direct contribution from washed platelets.

Conclusion: MASLD and MASH patients showed normal platelet counts, but increased adhesion, suggesting pro-inflammatory and pro-fibrotic roles. In contrast, cirrhotic patients displayed reduced

platelet count, but increased adhesion function. They also exhibit significantly higher 11-TXB2 levels compared to controls, suggesting higher in-vivo platelet activation.

FRI-280

Dynamic of cardiometabolic components are highly correlated with the risk of hypertension and diabetes among patients with metabolic dysfunction-associated steatotic liver disease

Chin-I Shih[1], Ming-Lun Yeh[2], Kuan-Ta Wu[3], Meng-Hsuan Hsieh[3], Jeng-Fu Yang[3], Yi-Yu Chen[3], Wei-Lun Tsai[4], Wen-Chi Chen[5], Po-Cheng Liang[2], Yu-Ju Wei[3], Pei-Chien Tsai[3], Ya-Yun Cheng[6], Po-Yao Hsu[3], Ming-Yen Hsieh[3], Yi-Hung Lin[3], Tyng-Yuan Jang[3], Chih-Wen Wang[3], Chung-Feng Huang[3], Jee-Fu Huang[3], Chia-Yen Dai[3], Chi-Kung Ho[2], Wan-Long Chuang[3], Wei-Ting Chang[7], Ming-Lung Yu[6]. *[1]Department of Medical Education, Kaohsiung Veterans General Hospital, Kaohisiung, Taiwan; [2]Kaohsiung Medical University Hospital, Kaohsiung, Taiwan; [3]Kaohsiung Medical University Hospital, Kaohsiung, Taiwan; [4]Kaohsiung veterans general hospital, Kaohsiung, Taiwan; [5]Kaohsiung Veterans General Hospital, Kaohsiung, Taiwan; [6]National Sun Yat-sen University, Kaohsiung, Taiwan; [7]Chi-Mei Medical Center, Tainan, Taiwan*
Email: chini861018@gmail.com

Background and aims: Fatty liver disease (FLD) is associated with higher risks of hypertension (HTN) and diabetes mellitus (DM). A new nomenclature of FLD, metabolic dysfunction-associated steatotic liver disease (MASLD) was purposed recently. We conducted a retrospective cross-sectional and longitudinal study to evaluate the role of cardiometabolic risk factors (CMRF) in MASLD and non-steatotic liver disease (non-SLD) in the risk of new-onset HTN and DM.

Method: The cross-sectional cohort consisted of 32, 569 adults without hepatitis or significant alcohol consumption, who underwent health checkups at a tertiary hospital in Taiwan from 1999 to 2013. Of them, 27, 109 without HTN and/or DM at baseline and within 1 year after enrollment were included as a longitudinal cohort (mean, 6.28 years for HTN; 6.58 years for DM). Both cohorts were further divided into four groups (MASLD, Simple SLD, CMRF+ Non-SLD, and Healthy control) based on the presence of CMRF and the presence of hepatic steatosis assessed by ultrasound sonography.

Results: In the longitudinal cohort, 12, 620 subjects had MASLD, 1, 113 subjects had simple SLD, 8, 547 subjects had CMRF+ non-SLD, and 4, 829 subjects were healthy controls. MASLD subjects had significantly higher risks of new-onset HTN (adjusted hazard ratio [aHR]/CI: 1.89/1.73–2.07) and DM (aHR/CI: 8.24/6.22–10.92) compared to those with non-SLD. The presence of CMRF increased the risk of new-onset HTN in both SLD and non-SLD patients (aHR/CI: 6.45/3.94–10.57 and 10.71/7.78–14.74, respectively) and DM (aHR/CI: 15.38/3.83–61.78 and 9.66/2.35–39.71, respectively). The risk of new-onset HTN and DM significantly increased with the fulfilled number of cardiometabolic components (HTN: aHR/CI from 2.02/1.20–3.41 to 15.53/8.13–29.65 in one-component subjects to five-components subjects; DM: from 2.92/0.68–12.42 to 82.38/18.98–357.58). Resolved cardiometabolic dysfunction (CMD) during follow-up decreased the risk of HTN and/or DM.

Conclusion: Patients with MASLD are at high risk of prevalent and incident HTN and/or DM. The risk increases with the number of CMRF.

FRI-281

Metabolic steatosis in renal transplant recipients does not correlate with CVD, a retrospective cohort study

Pietro Torre[1], Carmine Secondulfo[2], Letizia Sangiovanni[1], Federica Belladonna[1], Mario Masarone[1], Giancarlo Bilancio[2], Marcello Persico[1]. *[1]Internal Medicine and Hepatology Division, Department of Medicine, Surgery and Dentistry, "Scuola Medica Salernitana", Baronissi (Salerno), Italy; [2]Nephrology Division, Department of Medicine, Surgery and Dentistry, "Scuola Medica Salernitana," University of Salerno, Baronissi (Salerno), Italy*
Email: pietrotorre90@gmail.com

Background and aims: Metabolic Associated Steatotic Liver Disease (MASLD) is among the main causes of chronic liver disease and is growing. Chronic Kidney Disease (CKD) has a global prevalence of between 8 and 16%, significantly increasing in recent years. This simultaneous increase is not surprising: both recognize common triggering causes, including obesity, diabetes mellitus, hypertension, dyslipidemia and metabolic syndrome. The prevalence of CKD in MASLD patients is between 4 and 40%. The severity of liver disease has been related to the progression of CKD which in turn can aggravate NAFLD by altering the intestinal barrier and microbiota, with the accumulation of uremic toxins and the modification of metabolism of glucocorticoids. To date, there is little data regarding the prevalence of steatosis in renal transplant recipients and how these alterations can modify the outcome of the renal transplant, and particularly the occurrence of CVD. Aims: Investigate the prevalence of steatosis in a population of kidney transplant patients. Evaluate if there is an association between prevalence of CVD and steatosis and its severity in these patients.

Method: 200 patients, followed-up in the Nephrology Unit of Salerno University Hospital, were enrolled after an informed consent. Demographical, clinical and laboratory data have been collected for each patient, as well as abdominal ultrasonography (US). Patients with steatosis underwent liver stiffness measurement and controlled attenuation parameter (CAP). Also, any history of active or inactive CVD was collected (myocardial infarction, angina, stroke). Data were analyzed with parametric and non-parametric tests when indicated, significance was given when a $p < 0.05$ in a two-tailed analysis was reached.

Results: Of the 200 kidney transplant patients, 69% were males, the mean age was 56.8 yrs. The median time of the kidney transplant was 15.88 years (range ±7, 5). Steatosis was present at the US in 45.5% of the patients, with a median CAP of 219 (208–237.5) and LS of 5.0 (4.3–5.2). Of those with steatosis, 11.1% (8 pts) were at risk of significant fibrosis (>8 Kpascal). The mean BMI was 26.9 ± 4.8 overall, with 28.5 ± 5.2 vs 25.5 ± 3.9 kg/m2 in patients with steatosis vs those without (p:0.0001). Metabolic syndrome was present in 30.8% of patients with steatosis vs 11.0% of those without (p:0.001). The prevalence of CVD among the overall population was of 14.5% with no differences between patients with and without steatosis (14.3 vs 14.7%). At a logistic binary regression CVD was correlated only with age and sex, but not with steatosis, BMI, LS, CAP and MS.

Conclusion: In a cohort of kidney transplant recipients, the prevalence of liver steatosis, as well as overweight and metabolic syndrome was higher than that of the general population. However, previous, or actual CVD did not seem to be correlated with the presence of metabolic steatosis and its causes.

FRI-282

Obese patients with sarcopenic obesity have a more severe metabolic phenotype and hepatic disease and exhibit less metabolic improvement after bariatric surgery

Vittoria Zambon Azevedo[1], Judith Aron-Wisnewsky[2], Raluca Pais[1], Jean Michel Oppert[2], Vlad Ratziu[2]. *[1]ICAN, Paris, France; [2]Sorbonne Université, Paris, France*
Email: vlad.ratziu@inserm.fr

Background and aims: Patients (pts) with obesity can have sarcopenia, i.e. reduced muscle mass with increased fat mass, however a precise and consensual definition for sarcopenic obesity (SO) is lacking and different definitions result in widely divergent prevalences. Using an AI-assisted unbiased clustering approach, we identified a body composition-based phenotype that distinguishes SO vs. non-SO patients (Clinical Nutrition ESPEN 2022, PMID 36513443). Here we aimed to externally validate the hepatic and metabolic clinical correlations of the SO phenotype in a population of morbidly obese pts undergoing bariatric surgery (BaS) and to

determine if weight loss patterns and metabolic improvement post-surgery differs between SO and non-SO pts.
Method: Pts who underwent BaS, per-operative liver biopsy and body composition assessment by dual-energy X-ray absorptiometry (DEXA) were included (n = 972) and 862 were reassessed 1-year post-surgery. Pts were categorized as having or not SO.
Results: At baseline, 207 (21.3%) pts were diagnosed with SO. They had worse metabolic and cardiovascular profiles than non-SO pts, with a higher prevalence of diabetes (48.8% vs. 37.3%), hypertension (61.8% vs. 44.2%), metabolic syndrome (77.3% vs. 65.4%) and sleep apnea (80.7% vs. 53.7%), all p values ≤ 0.003, and a higher proportion of android fat-mass (67.2 ± 5.0 % vs. 62.5 ± 6.6 %, p < 0.001). SO pts had higher grades of steatosis [≥S2: 64.2% vs. 47.3%], hepatocyte ballooning [≥1: 58.9% vs. 43.9%], portal inflammation [44.4% vs. 32.5%], and fibrosis stage [≥F3: 12.1% vs. 6.0%] than those non-SO (p < 0.01). At follow-up, the prevalence of SO was 11.0% and 170 pts no longer had SO. SO pts had a smaller % weight loss than non-SO pts (−31.9 ± 13.3 vs. −35.1 ± 12.2) whereas pts with persistent SO (N = 76) had the lowest % weight loss (23.8 ± 9.7). SO at baseline was associated with lower remission rates of comorbidities (diabetes 46% vs 62.2% in non-SO, p = 0.031; hypertension 21.4% vs 41.8% in non-SO, p = 0.004; metabolic syndrome 51.3% vs 72.4%, p < 0.001). ALT reduction was −12.3 ± 2.4 IU/L vs. −9.6 + 1.2 in SO vs non-SO pts, p = 0.037.
Conclusion: The SO diagnostic index identifies a population of pts with more severe metabolic and hepatic disease, with lower weight loss post-BaS and with lesser metabolic benefit from BaS.

FRI-283
Costs associated with non-alcoholic steatohepatitis disease progression in medicare patients
Jesse Fishman[1], Yestle Kim[1], Joe Medicis[1], Matthew Davis[2], Dominic Nunag[2], Robert G. Gish[3]. [1]*Madrigal Pharmaceuticals, Inc., West Conshohocken, United States;* [2]*Medicus Economics, LLC, Milton, United States;* [3]*Robert G Gish Consultants LLC, La Jolla, United States*
Email: jfishman@madrigalpharma.com

Background and aims: Non-alcoholic steatohepatitis (NASH), or metabolic dysfunction-associated steatohepatitis (MASH), is a severe form of non-alcoholic fatty liver disease (NAFLD) or metabolic dysfunctional associated steatotic liver disease (MASLD). NASH may progress to more advanced liver disease and is associated with high healthcare resource use (HRU); the risk of progression may be higher in older populations. Costs associated with progression are not well characterized in those ≥65 years of age. This study aimed to quantify HRU and costs associated with NASH progression in a Medicare population.
Method: Those diagnosed with NASH (ICD-10: K75.81) in 100% Medicare claims (2015–2021) were required to be ≥66 years at index (diagnosis), have continuous enrollment in Parts A, B, and D for ≥12 months prior to and ≥6 months following index (unless death), and have no evidence of other causes of liver disease. Diagnoses within 90 days were used to categorize patient-time into five baseline severity states: NASH, compensated cirrhosis (CC), decompensated cirrhosis (DCC), hepatocellular carcinoma (HCC), and liver transplant (LT). Annualized HRU and costs were calculated during the baseline and follow-up periods, and for the duration of each severity state. Follow-up period outcomes were stratified by occurrence and timing of progression.
Results: In 14, 806 unique patients, mean age and follow-up were 72.2 and 2.8 years (N = 12, 990 NASH; 1, 899 CC; 997 DCC; 209 HCC; 140 LT). Average annualized costs increased from baseline following diagnosis, generally scaling with severity: $16, 231 to $27, 044; $25, 122 to $57, 705; $40, 613 to $181, 036; $36, 549 to $165, 121, and $35, 626 to $108, 918 in NASH; CC; DCC; HCC; and LT; respectively. Adjusting for demographics, comorbidities, and baseline HRU, NASH and CC patients with subsequent progression to a more severe disease state (8% of NASH and 20% of CC patients) had significantly higher follow-up spending (1.6x for NASH and 1.7x for CC) than non-progressors (both p < 0.001). NASH and CC progressors were 2.8x and 6.1x more likely to experience inpatient hospitalization and 2.6x and 3.6x more likely to be in the top 20% of spenders, respectively, compared to non-progressors (both p < 0.001). Follow-up costs correlated with the time of progression. Within NASH, costs increased for earlier progression; year 1 progressors' costs ($50, 382) were 1.4×, 1.6×, 1.7×, and 2.2× more than year 2, 3, 4, and 5 progressors' costs, respectively. In CC, year 1 progressors' costs ($75, 599) were 1.3×, 1.8×, 2.0×, and 2.2× more than year 2, 3, 4, and 5 progressors' costs, respectively.
Conclusion: NASH progression is associated with higher costs that increase in more severe disease states. Slower progression is associated with lower costs, suggesting a potential benefit of interventions to delay or prevent progression for patients with NASH or CC.

FRI-284-YI
A plant-based diet for liver health: the protective role of vegetable fat on MASLD and other liver diesases
Simon Schophaus[1], Paul-Henry Koop[2], Jan Clusmann[1], Christian Trautwein[1], Kai Markus Schneider[1], Carolin V. Schneider[1]. [1]*RWTH Aachen University Medizinische Klinik III, Aachen, Germany;* [2]*RWTH Aachen University Medizinische Klinik 3, Aachen, Germany*
Email: sschophaus@ukaachen.de

Background and aims: The increasing prevalence of MASLD poses an enormous challenge for Western civilization. Previous research has highlighted the benefits of a vegan diet on MASLD, but the specific impacts of animal versus plant-based fats are not well understood. This study aims to explore their relative effects in relation to total fat consumption.
Method: Utilizing 24-hour dietary data from the UK Biobank (n > 210, 000), excluding individuals with pre-existing liver conditions, we analyzed the impact of higher proportions of animal and plant-based fats in total fat intake on ICD-10-coded liver diseases. Adjustments were made for age, sex, BMI, Townsend index, caloric, alcohol, and carbohydrate intake.
Results: A higher plant-based fat proportion was associated with reduced odds of ICD10-coded MASLD (OR = 0.643 (0.425–0.973), p = 0.037), liver diseases in general (OR = 0.740 (0.597–0.917), p = 0.006), and liver failure (OR = 0.258 (0.093–0.713), p = 0.009). In contrast, increased animal fat intake was associated with higher risks for these conditions (MASLD: OR = 1.555; liver diseases: OR = 1.352; liver failure: OR = 3.876). Cox-proportional hazard models indicated a decreased risk of death from overall (OR = 0.786) and digestive-disease (OR = 0.295) for higher plant-based fat consumption, versus increased risk with more animal fat (OR = 1.273 and OR = 3.393).
Conclusion: Our findings suggest that a higher ratio of plant-based fats in the diet may offer protective benefits against MASLD and related liver conditions, while increased consumption of animal fats appears to raise MASLD risk. These findings open new avenues for dietary interventions in liver disease prevention and underscore the power of plant-based choices for liver health.

FRI-285
Mendelian-randomization study revealed causal relationship between non-alcoholic fatty liver disease and osteoporosis/fractures
Wei Jiang[1], Xiong Pei[1], Qingmin Zeng[1], Yixian You[1], Lang Bai[1], Chang Hai Liu[1], Dongbo Wu[1], Hong Tang[1]. [1]*Center of Infectious Diseases, West China Hospital of Sichuan University, Chengdu, China*
Email: htang6198@hotmail.com

Background and aims: Observational studies have revealed patients with non-alcoholic fatty liver disease (NAFLD) had a higher risk of osteoporosis/fracture. However, due to the existing of reverse causality and confounding factors, whether NAFLD had a causal relationship with osteoporosis/fracture were still unclear. The

purpose of the current study was to examine the potential correlation between NAFLD and the risk of osteoporosis/fractures by using the Mendelian randomization (MR) study design.
Method: Publicly available genome-wide association studies (GWASs) were employed for univariable and multivariable mendelian randomization analyses (MR). GWASs for NAFLD were obtained from the FinnGen consortium. GWASs for bone mineral density (BMD) were derived from a large meta-analysis. To clarify whether the accompanying symptoms of NAFLD contributed to the increased risk of fracture, GWASs for obesity-related traits, liver function metrics, diabetes-related traits, and serum lipids metrics were used for causal inference. GWASs for fractures at different body sites were acquired from FinnGen consortium. Moreover, two additional GWASs of NAFLD were applied to examine the potential correlation between NAFLD and BMD. A range of sensitivity analysis methods were performed to ensure the reliability of the results. The Bonferroni-corrected significance level was applied.
Results: Causal association between NAFLD and reduced BMD using GWASs from FinnGen consortium were not observed. However, in replication GWAS 1, a suggestive relationship between fibrosis and femoral neck BMD (FN-BMD) were observed. In replication GWAS 2, a causal relationship between NAFLD and FN-BMD and a suggestive relationship between NAFLD and osteoporosis were obtained. Moreover, after univariate MR analysis, the genetically proxied body mass index (BMI), high-density lipoprotein (HDL) cholesterol and hip circumference increased the likelihood of lower limb fracture. Waist-to-hip decreased while glycated hemoglobin (HbA1C) and homeostasis model assessment-β (HOMA-B) increased forearm fracture risk. Reduced low-density lipoprotein (LDL) cholesterol and increased HbA1C resulted in a higher femur fracture. Alkaline phosphatase (ALP) predisposed to a rising risk of foot fracture. However, after multivariate MR (adjusting for BMI), all the relationship above became insignificant.
Conclusion: NAFLD caused reduced BMD and genetically predicted HDL, LDL, HbA1C, HOMA-B, ALP, hip circumference, and waist-to-hip causally increased the risk of fracture causally. And the causal relationships were potentially mediated by BMI, but larger GWASs studies were needed to verify.

FRI-286
Muscle function and walking time are associated with better quality of life in MASLD patients

Roberta Forlano[1], Thishana Kirupakaran[2], Margaux Couffon[2], Beatrice Martino[3], Giordano Sigon[3], Jian Huang[3], Benjamin H. Mullish[3], Michael Yee[4], Mark R. Thursz[3], Pinelopi Manousou[3]. *[1]Division of Digestive Diseases, Department of Metabolism, Digestion and Reproduction, Imperial college London, London, United Kingdom; [2]Division of Digestive Diseases, Department of Metabolism, Digestion and Reproduction, Imperial college london, London, United Kingdom; [3]Division of Digestive Diseases. Department of Metabolism, Digestion and Reproduction, Imperial College London, London, United Kingdom; [4]Department of Endocrinology, Imperial college NHS Trust, London, United Kingdom*
Email: r.forlano@imperial.ac.uk

Background and aims: Metabolic-dysfunction associated steatotic liver disease (MASLD) is an increasing cause of chronic liver disease worldwide, with lifestyle changes being the mainstay of treatment. Nevertheless, achieving physical activity, weight loss and well-being in this population remains challenging. Here, we aimed to explore the association between exercise and quality of life among MASLD patients.
Method: We included all consecutive MASLD patients, followed up at St Mary's Hospital, London, UK, between October 2022 and June 2023. Patients filled the 36-Item Short Form survey (SF36) for quality of life, which includes 8 domains exploring physical and mental components. They also filled International Physical Activity Questionnaire (IPAQ) for physical activity (PA). Patients were classified into inactive (total PA<600 MET*min/week), minimally/moderately active (total PA 600–3000 MET*min/week) and health-enhancing physical activity (HEPA, total PA>3000 MET*min/week). Muscle function was evaluated by 5 sit-to stand test (5-STS test) and handgrip strength (HST). Multivariate analysis (MVA) was corrected for socio-economic status and psychiatric comorbidity.
Results: In total, 138 patients were enrolled. Median age was 59 (45–67) years, while median BMI was 32.7 (28–36.6) kg/m^2. HEPA patients were significantly younger (55 vs 60 years, p = 0.025) and had better muscle mass (56.7 vs 55.6 kg, p = 0.024) and function (5-STS:12 vs 13.1 s, p = 0.007 and HST:27 vs 26 kg, p = 0.014). They also scored significantly higher for each of the SF36 domains. 41 (29%) patients showed good social functioning. These patients had better handgrip test (32.3 vs 13.7 kg, p = 0.03), longer walking (60 vs 45 min/week, p = 0.006), moderate (40 vs 5 min/week, p = 0.008) and vigorous exercise time (30 vs 5 min/week, p = 0.001). On MVA, handgrip strength (OR 1.058, 95%CI: 1.009–1.109, p = 0.02) and walking time (OR 1.005, 95%CI: 1.001–1.009) predicted better social functioning. 32 patients (32/138 = 23%) reported lower perception of bodily pain. These patients had higher handgrip test (32 vs 26 kg, p = 0.02), 5STS test (11.6 vs 13.2 s, p = 0.03) and were more frequently men (78 vs 58%, p = 0.008). On MVA, 5STS test (OR 0.98, 95%CI: 0.95–0.99, p = 0.05) predicted lower perception of bodily pain. Finally, 33 patients (32/138 = 24%) had good perception of general health. These were significantly older (63 vs 57 years, p = 0.01) and reported longer walking (90 vs 30 min/week, p = 0.001), moderate exercise (42.5 vs 5 min/week, p = 0.038) and vigorous exercise time (30 vs 0 min/week, p = 0.01). On MVA, age (OR 1.08, 95%CI: 1.02–1.14, p = 0.004) and walking time (OR 1.005, 95%CI: 1.001–1.01, p = 0.026) predicted better perception of general health.
Conclusion: Muscle function and walking time are associated with better quality of life in patients with MASLD. Specific lifestyle interventions should be offered to MASLD patients.

FRI-287
Increased risk of mortality in metabolic dysfunction-associated steatotic liver disease: a nationwide population-based cohort study

Seung Up Kim[1], Jae Seung Lee[2], Mi Na Kim[2], Hye Won Lee[2], Beom Kyung Kim[3], Jun Yong Park[2], Do Young Kim[2], Sang Hoon Ahn[4]. *[1]Yonsei university, Seoul, Korea, Rep. of South; [2]Yonsei University, Seoul, Korea, Rep. of South; [3]Yonsei University, Seoul, Korea, Rep. of South; [4]Yonsei Univesity, Seoul, Korea, Rep. of South*
Email: ksukorea@yuhs.ac

Background and aims: A new fatty liver disease nomenclature, steatotic liver disease (SLD) has been proposed; however, there are no data on clinical outcomes. We investigated the impact of SLD with metabolic dysfunction (MD; SLD-MD) on all-cause mortality.
Method: We evaluated nationally representative participants aged ≥19 years using data from the Korea National Health and Nutrition Examination Survey 2007–2015 and their linked death data through 2019. The presence of fatty liver disease was assessed by liver fat score and significant liver fibrosis was evaluated by the Fibrosis-4 Index. SLD-MD was categorized into three groups: metabolic dysfunction-associated steatotic liver disease (MASLD); metabolic alcoholic liver disease (MetALD); and SLD with other combination etiologies.
Results: Among 25, 888 individuals (11, 087 men and 14, 801 women, mean age 48.1 years), 1, 624 (6.3%) died during a mean follow-up period of 111.3 ± 33.5 months. Mortality risk was significantly higher in individuals with SLD-MD (hazard ratio [HR] = 1.41) than in those without (p < 0.001). Among the three groups, MASLD (HR = 1.38) and SLD with other combination etiologies (HR = 2.47) independently increased mortality risk (all $P < 0.001$). When individuals with SLD-MD had significant liver fibrosis or diabetes, mortality risk increased further (HR = 1.77 and 1.97, respectively; all $P < 0.001$). SLD-MD with both significant liver fibrosis and diabetes showed the highest mortality risk (HR = 2.50, $P < 0.001$).

Conclusion: SLD-MD is associated with a higher mortality risk. When SLD-MD was combined with significant liver fibrosis or diabetes, the mortality risk became much higher. Treatment strategies to reduce fibrotic burden and improve glycemic control in individuals with MASLD are needed.

Evaluation of ChatGPT as a counselling tool for Italian-speaking MASLD patients: assessment of accuracy, completeness and comprehensiveness

Nicola Pugliese[1], Davide Polverini[2], Rosa Lombardi[3], Grazia Pennisi[4], Federico Ravaioli[5], Angelo Armandi[6], Elena Buzzetti[7], Andrea Dalbeni[8], Antonio Liguori[9], Alessandro Mantovani[10], Rosanna Villani[11], Cesare Hassan[12], Luca Valenti[13], Luca Miele[14], Salvatore Petta[15], Giada Sebastiani[16], Alessio Aghemo[17]. *[1]Division of Internal Medicine and Hepatology, Department of Gastroenterology, IRCCS Humanitas Research Hospital, Rozzano (MI), Italy, Department of Biomedical Sciences, Humanitas University, Pieve Emanuele (MI), Italy, Milano, Italy; [2]Department of Biomedical Sciences, Humanitas University, Pieve Emanuele (MI), Italy, Milano, Italy; [3]Unit of Internal Medicine and Metabolic Disease, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico of Milan, Italy, Department of Pathophysiology and Transplantation, University of Milan, Italy, Milano, Italy; [4]Sezione di Gastroenterologia, Dipartimento Biomedico di Medicina Interna e Specialistica, Universita di Palermo, Palermo, Italy, Palermo, Italy; [5]University of Bologna, Bologna, Italy; [6]University of Turin, Turin, Italy; [7]University of Modena, Modena, Italy; [8]University and Azienda Ospedaliera Universitaria Integrata of Verona, Verona, Italy; [9]Università Cattolica del Sacro Cuore, Roma, Italy; [10]Department of Medicine, University and Azienda Ospedaliera Universitaria Integrata of Verona, Verona, Italy, Verona, Italy; [11]Centro C.U.R.E, Dept. of Medical and Surgical Sciences, University of Foggia, Foggia, Italy; [12]Humanitas University, Milano, MI, Italy; [13]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Università degli Studi di Milano, Milano, Italy; [14]Università Cattolica del S. Cuore, Roma, Italy; [15]Section of Gastroenterology and Hepatology, PROMISE, University of Palermo, Palermo, Italy, Palermo, Italy; [16]Division of Gastroenterology and Hepatology, McGill University Health Centre, Montreal, Canada, Montreal, Canada; [17]Humanitas University, Milano, Italy*
Email: nicola.pugliese@live.com

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a significant global public health concern and is expected to become the leading indication for liver transplantation in the coming decades. Chatbots, which utilize artificial intelligence (AI) to simulate conversations with users, could provide counselling and support to English-speaking patients with MASLD. In a recent study, we showed that while ChatGPT 3.5 is complete and comprehensive in answering MASLD-related questions, its accuracy is still suboptimal. Whether language plays a role in modifying these findings is unclear.
Method: We evaluated the accuracy, completeness and comprehensiveness of ChatGPT 3.5 in answering 15 pre-set questions about MASLD in Italian. The questions were grouped into three domains: specialist referral, physical activity, and dietary composition. ChatGPT responses were rated on a 6-point accuracy scale, a 3-point completeness scale, and a 3-point comprehensibility scale by 13 native Italian MASLD experts.
Results: The mean scores for accuracy and completeness were 4.57 ± 0.42 and 2.53 ± 0.51 respectively, with a mean score of 2.91 ± 0.07 for comprehensiveness. The domain of physical activity achieved the most elevated mean score of 4.82 ± 0.22 and 2.35 ± 0.11 for accuracy and completeness respectively, while the domain of specialist referral achieved the lowest mean score of 4.1 ± 0.44 and 1.66 ± 0.29 for accuracy and completeness respectively. The mean Kendall's coefficient of concordance for accuracy, completeness and comprehensiveness across all 15 questions was 0.524, 0.623 and 0.73 respectively. Age and academic role of the evaluators did not affect the scores. The scores were not significantly different from those reported in our previous study focusing on the English language.
Conclusion: We have shown that language does not affect the ability of ChatGPT to provide complete and understandable counselling for MASLD patients, however its accuracy remains suboptimal in certain domains. To ensure the trustworthiness of medical information provided by AI, the collaboration between healthcare professionals, patient associations and medical literature databases needs to be further improved.

FRI-291

Stigma in steatotic liver disease (SLD): a survey of patients from Saudi Arabia

Saleh Alqahtani[1], Khalid A. Alswat[2], Mohammad Mawardi[3], Faisal Sanai[4], Faisal Aba Alkhail[5], Saad Alghamdi[6], Waleed K. Al-Hamoudi[2], Fatema Nader[7], Maria Stepanova[7], Zobair Younossi[7]. *[1]Liver Transplant Center, King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia, Division of Gastroenterology and Hepatology, Johns Hopkins University, Baltimore, MD, United States; [2]Liver Disease Research Centre, College of Medicine, King Saud University, Riyadh, Saudi Arabia; [3]Department of Internal Medicine, King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia; [4]Gastroenterology Unit, Department of Medicine, King Abdulaziz Medical City, Jeddah, Saudi Arabia; [5]Department of Medicine, King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia; [6]Liver Transplant Center, King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia; [7]The Global NASH Council, Washington DC, United States, Center for Outcomes Research in Liver Diseases, Washington DC, United States*
Email: kalswat@ksu.edu.sa

Background and aims: Non-alcoholic fatty liver disease (NAFLD) and its progressive form non-alcoholic steatohepatitis (NASH) are part of the spectrum of SLD. The terms NAFLD/NASH may be associated with stigma. We aimed to understand stigma among NAFLD/NASH patients enrolled in Saudi Arabia (SA).
Method: Members of the Global NASH Council created a 68-item survey about patients' experience with NAFLD, history of stigma and discrimination due to the disease, various aspects of the disease burden (Liver Disease Burden instrument, 35 items in 7 domains), and perception of various diagnostic terms for NAFLD. We included only patients whose country of residence was SA.
