Background and aims: Copeptin, a biomarker for arginine-vasopressin (AVP) activation may improve prognostication in patients with decompensated cirrhosis (DC). We aimed to develop and validate a novel MELD-copeptin score for the prediction of liver-related events in DC patients.
Method: Copeptin levels were determined in consecutive patients with DC undergoing hepatic venous pressure gradient (HVPG) measurement at the Vienna Hepatic Hemodynamic Lab. According to inclusion time period, patients were subdivided into a derivation cohort (01/2017–12/2019; n = 150) and an internal validation cohort (12/2019–04/2023; n = 148). The results were validated in an external cohort including hospitalized patients with DC from Besancon (04/2008–06/2009; n = 125) and patients with acute decompensation (AD) included in the CANONIC study (03/2011–12/2011; n = 646). The MELD-copeptin score was developed with coefficients derived from a competing risk regression model for the prediction of acute-on-chronic liver failure (ACLF) and of liver-related death. Liver transplantation was considered as a competing event. The prognostic utility of copeptin for ACLF and liver-related death (LRD) was investigated by calculating time-dependent areas under the receiver-operating characteristic curve (AUROCs).
Results: The multivariate competing risk regression model revealed copeptin (asHR: 1.45; 95%CI: 1–09–1.93; p = 0.011) and MELD-Na (asHR: 1.07; 95%CI: 1.01–1.13; p = 0.028) as independent risk factors for LRD in the derivation cohort. With these coefficients, the following score was created:.
MELD-copeptin = 0.0637 * MELD-Na + 0.3718 * log (copeptin [pmol/L]). In the internal validation cohort, the MELD-copeptin score showed excellent accuracy for the prediction of LRD at 6 months (AUROC 0.777) and 1 year (AUROC 0.784) of follow-up, while the MELD-Na yielded lower AUROCs (6 months: 0.673; 1 year: 0.661). Similarly, in the external validation cohort, the MELD-copeptin score consistently provided higher AUROCs for the prediction of ACLF (6 months: 0.803 vs. 0.726; 1 year: 0.827 vs. 0.755) and LRD (6 months: 0.765 vs. 0.748; 1 year: 0.761 vs. 0.747) compared to MELD-Na.
Conclusion: The developed and validated MELD-copeptin score shows excellent accuracy for the prediction of ACLF and LRD in patients with DC and refines prognostication as compared to MELD-Na.

WED-231
Ultrasound muscular thickness-based model to identify sarcopenia in patients with portal hypertension (PH): a cross-sectional single-center observational study

Martina Lucà[1], Giulia Tosetti[1], Valentina Cardone[2], Argiento Lorenzo[2], Sofia Ridolfo[2], Edoardo Acquati[2], Cicchetti Francesco[3], Xhepa Edon[3], Matilde Pavan[3], Chiara Grilli[3], Pierpaolo Buondetti[4], Alessio Angileri[4], Simona Stella[5], Gianpaolo Carrafiello[6], Pietro Lampertico[7]. *[1]Division of Gastroenterology and Hepatology, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]Division of Gastroenterology and Hepatology, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, University of Milan, Milan, Italy; [3]Diagnostic and Interventional Radiology Department, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, University of Milan, Milan, Italy; [4]Diagnostic and Interventional Radiology Department, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [5]Occupational Health Unit, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [6]Diagnostic and Interventional Radiology Department, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Division of Radiology, Department of Health Science, University of Milan, Milan, Italy; [7]Division of Gastroenterology and Hepatology, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, CRC "A. M. and A. Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy*
Email: martina.luca@policlinico.mi.it

Background and aims: Sarcopenia is a frequent complication of cirrhosis (40–70%) and is an independent prognostic factor of worse outcome. Currently, CT scan is the gold standard to identify this condition, but new user friendly and reliable non-invasive screening tools are needed.
Method: This single center prospective study includes consecutive outpatients with portal hypertension and abdominal CT who underwent US assessment of biceps brachii (BB), rectus abdominis (RA), rectus femoris (RF) and thigh muscle (TM), performed by two blinded trained investigators. The sum of both-side muscle thickness was adjusted for height obtaining an index (mm/m). Sarcopenia was defined using CT by L3-SMI cut-offs prosed by EASL/AASLD. Association between sarcopenia and US parameters, anthropometric, clinical, biochemical and nutritional data was assessed.
Results: 103 patients were enrolled (median age 61 ys, 63% men, 84% cirrhotic, median BMI 25,7 kg/m^2). Prevalence of sarcopenia was high among both cirrhotic and non-cirrhotic portal hypertension patients (54.1% vs 61.5%, p = ns), without statistically significant difference between women and men.
Among US measurements and anthropometric data, RF index and BMI showed the best inverse-correlation with sarcopenia with an OR of 0.79 (95% CI: 0.69–0.91, p < 0.01) and 0.80 (95% CI: 0.63–0.91, p < 0.01), respectively. Based on these findings, a gender specific integrated model to identify sarcopenia was proposed with best results among cirrhotic men and women overall where BMI threshold of 28 and 23.9 kg/m^2 and RF index of 14.8 and 13.4 mm/m showed the highest positive (73% and 78%) and negative (81% and 74%) predictive value, with a ROC of 0.81 and 0.80 respectively. Moreover, US muscular measurements showed high intra/inter-operator reliability.
Conclusion: US can be a bedside, non-invasive and reproducible tool to assess muscle thickness with a good capability in a model with BMI to discriminate patients with sarcopenia.

WED-232
Assessing portal hypertension with endoscopic ultrasound portal pressure gradient (eus-ppg): clinical correlations and procedural outcomes

Francesco Martini[1], Lucia Salvi[1], Giulia Scandali[1], Chiara Scorzoni[1], Daniele Balducci[1], Marco Marzioni[1], Luca Maroni[1], Antonio Benedetti[1], Giuseppe Tarantino[1]. *[1]Università Politecnica delle Marche, Clinic of Gastroenterology, Hepatology and Endoscopy, Ancona, Italy*
Email: martinifrancesco319@gmail.com

Background and aims: Portal hypertension (PH) is a critical complication in chronic liver diseases, notably cirrhosis, and often precedes severe outcomes. Recent advancements have introduced endoscopic ultrasound-guided PPG (EUS-PPG) as a method for directly measuring the portal pressure gradient, potentially overcoming the limitations of traditional indirect measures like the hepatic venous pressure gradient (HVPG). This prospective study aims to evaluate the technical success, safety, and correlation of EUS-PPG with clinical and laboratory indicators of portal hypertension.

Method: The study involved a cohort of patients with suspected or confirmed PH who underwent EUS-PPG using a linear echoendoscope, a 25G fine needle aspiration needle, and a compact manometer with non-compressible tubing. All procedures were performed by the same operator under conscious sedation. For each patient, at least three measurements were taken in the portal vein and three in the hepatic vein or retrohepatic inferior vena cava, with the gradient calculated as the difference between the means of these measurements. Clinical and laboratory data were collected for each patient to assess potential correlations with EUS-PPG values.
Results: A total of 32 patients underwent EUS-PPG. Descriptive analysis of demographic, clinical, and laboratory characteristics, as well as procedural details, is provided in supplemental data. Technical success was achieved in 100% of cases, with only minor complications (9%), such as mild post-procedural abdominal pain. For statistical analysis, a Student's t-test was conducted to compare PPG values between patients with a low probability versus a high probability of PH (defined as the presence of one specific sign of PH or, in its absence, at least two non-specific signs of PH). Results showed significantly higher PPG values in the high-probability group (p 0.0011). Spearman's correlation analysis was performed to evaluate the association between EUS-PPG values and portal hypertension severity, defined as the sum of specific and non-specific signs of PH. This analysis revealed a positive correlation, with an increase in PPG associated with greater PH severity (Spearman's p = 0.6283, p = 0.0003). Similarly, Spearman's correlation was used to assess the relationship between EUS-PPG values and platelet count, liver stiffness, and spleen stiffness. An inverse correlation was observed between PPG and platelet count (p = –0.5323, p = 0.0030), while positive correlations were found with liver stiffness (p = 0.6320, p = 0.0028) and spleen stiffness (p = 0.5812, p = 0.0231).
Conclusion: EUS-PPG demonstrated high technical success and safety in evaluating PH, with meaningful correlations between PPG values and clinical and laboratory indicators of PH severity. These findings support the potential of EUS-PPG as a valuable tool in the direct assessment of portal hypertension, warranting further studies to confirm its clinical applicability.

WED-237
Development and validation of a novel fibrosis digital pathology biomarker to predict portal pressure in patients with MASH cirrhosis

Louis Petitjean[1], Mathieu Petitjean[1], Naga Chalasani, Pol Boudes[2], Khurram Jamil[2]. [1]*PharmaNest Inc., Princeton, United States;* [2]*Galectin Therapeutics, Norcross, United States*
Email: louis.petitjean@pharmanest.com

Background and aims: Primary outcomes in MASH cirrhosis trials include hepatic venous pressure gradient (HVPG), liver histology, and clinical events. Current histologic methods to evaluate liver fibrosis have significant limitations and few data are available regarding their correlation with portal pressure. Using Artificial Intelligence, we report on the development and validation of a continuous fibrosis Digital Pathology score for the prediction of HVPG in patients with compensated MASH cirrhosis and portal hypertension (PH).
Method: The study is based on 164 patients from a belapectin Phase 2 study (NCT 04365868). Patients with PH (HVPG >6 mm Hg) had paired measurements of HVPG and liver histology one year apart. 103 patients had clinically significant PH (HVPG>10 mmHg). Fibrosis was evaluated from Masson's Trichrome stained biopsies scanned at 40X. Quantitative image analysis (FibroNest™) was performed to extract single-fiber quantitative traits (qFTs, N = 336) from the fibrosis composition, morphometric and architectural histological phenotypes. The qFT dataset was mined to identify qFTs that would exhibit a significant (p < 0.05) and meaningful (>20%) relative difference (group average) between a subgroup of 60 patients (training set) with low (4.5–7 mmHg, n = 30) and high HVPG (17.5–23 mmHg, n = 30). Such qFT are assembled into a normalized (0–10 range) fibrosis-based HVPG predictive composite score (HVPG-PS) Composite Score (PBC-FCS). The performance of the HVPG-PCS was then evaluated on 302 images.
Results: From the training dataset, the HVPG-PCS achieved an AUROC of 0.88 to predict Severe HVPG, with a Youden's Index of 0.633 for a HVPG-PCS cutoff score of 4.2. Validation against the entire cohort (n = 302) reduced the AUROC to 0.649 and Youden's Index to 0.244. However, distinguishing low HVPG (<7.5 mmHg, n = 53) from high HVPG (>15.5 mmHg, n = 73) improved the AUROC to 0.754 with a Sensitivity or True Positive Rate (resp. Specify, True Negative rate) of 69% (resp. 56%) for a cutoff of 4.2.
Conclusion: In patients with MASH cirrhosis and PH, our digital pathology AI method exhibits a moderate performance to predict PH but could potentially discriminate between patients with low or very high HVPG.

WED-238
ANT at discharge can predicts further development of overt hepatic encephalopathy after elective TIPS placement

Mélisande Jorus[1], Charlotte Bouzbib[1], Charles Roux[1], Nicolas Weiss[1], Philippe Sultanik[2], Lyès Kheloufi[2], Paul Primard[1], Sarah Mouri[2], Dominique Thabut[1], Marika Rudler[3]. [1]*APHP, Hôpital de la Pitié-Salpêtrière, Paris, France;* [2]*APHP, Hôpital de la Pitié-Salpêtrière, Paris, France;* [3]*APHP, Paris, France*
Email: marika_rudler@yahoo.fr

Background and aims: Overt hepatic encephalopathy (OHE) is the most feared complication after transjugular intrahepatic portosystemic (TIPS) placement. Accurate tools for the prediction of OHE after TIPS are still missing. Minimal HE is a risk factor for OHE, and can be screened thanks to the animal naming test (ANT). One previously published study suggested that ANT, evaluated before TIPS and at different time points after TIPS, had limited predictive value for predicting OHE after TIPS. We aimed to validate this result in an independent cohort of patients.
Method: We prospectively screened patients that were candidates for elective TIPS placement. ANT (1 minute) was evaluated on the day of TIPS placement, at discharge, and then at 1, 3 and 6 months after TIPS.
Results: 88 consecutive patients were included (men 81.8%, age 60 years, cause of cirrhosis MASH/ALD/MetALD/other in 15/41/24/20%, MELD score 11.8, Child-Pugh B/C in 76/6%, TIPS indication ascites/secondary prophylaxis/pre surgery in 62/19/14%, previous OHE in 21.6%, lactulose in 35.2%, rifaximin in 69.3%). Median ANT was 20 (16–25) and 41/88 (46.4%) of patients had a score <20. A poor negative correlation was found between MELD score and ANT before TIPS (ρ = –0.22; r2 = 0.024; p = 0.04). During follow-up, ANT was not statistically modified, neither at discharge, nor at 1, 3 or 6 months. Overall, 29/88 (32.9%) patients developed OHE in a mean delay of 54 days. In multivariate analysis, independent factors associated with further development of OHE were age (HR = 1.04, 95% CI [1; 1.09], p = 0.04), baseline ammonia (HR = 1.01, 95% CI [1; 1.02], p = 0.003), and ANT at discharge (HR = 0.86, 95% CI [0.79; 0.95], p = 0.001), but not ANT before TIPS (HR = 0.95, 95% CI[0.95; 1.01], p = 0.10).
Conclusion: We confirmed that pre-TIPS ANT was not predictive of further OHE in our series of patients treated with elective TIPS. However, ANT at discharge may be useful to early identify patients at higher risk of OHE after TIPS, in whom prophylaxis could be intensified and liver transplantation discussed.

WED-239
Prognostic performance of MELD variants and CLIF-C AD in 958 patients with cirrhosis and ascites

Email: nikolaj.christian.torp@rsyd.dk

Background and aims: MELD scores and CLIF-C AD are used to predict mortality in cirrhosis. While MELD scores primarily reflect liver disease severity, CLIF-C AD derived in hospitalized patients also incorporate white blood cells (WBC) as a marker of systemic inflammation. The relative accuracy of these scores in predicting 3-month and 6-month mortality following first hepatic decompensation remains unclear. We aimed to compare the prognostic performance of baseline and longitudinal MELD, MELD-Na, MELD 3.0 and CLIF-C AD in cirrhosis patients with index decompensation by ascites.
Method: We collected data from four centers in Austria, Italy and Denmark between 2003 and 2024. Patients were enrolled if they presented with overt ascites (grade 2 or 3) as their single index decompensation. From baseline through first 6 months, we longitudinally assessed up to 6,896 laboratory data points. Follow-up included data on further decompensation, ACLF, liver transplantation (LT) and death. Predictive performance at 3- and 6-months was assessed using baseline and longitudinal Cox regression models, adjusting for age, sex, ascites grade and etiological cure. Discrimination was evaluated by Harrell's C.
Results: A total of 958 patients (mean age 57 ± 12 years; 66% men; 56% alcohol-related cirrhosis) were included with 47% and 53% presenting with grade 2 and 3 ascites, respectively. Baseline median MELD was 14 (IQR: 11–18), MELD-Na 15 (IQR: 11–20), MELD 3.0 16 (IQR: 12–20) and CLIF-C AD 52 (IQR: 46–57). Mortality and LT rates were 5%/1% at 3 months and 10%/2% at 6 months. Baseline models predicted 3-month mortality ($p < 0.001$), with Harrell's C-statistic of 0.741 (MELD), 0.735 (MELD-Na), 0.760 (MELD 3.0), and 0.765 (CLIF-C AD). Similarly, models reflected 6-month mortality ($p < 0.001$) but with lower discrimination (C-statistic: 0.707–0.735). Considering longitudinal changes of these models improved the discriminative ability for 3-month and 6-month mortality, being highest for CLIF-C AD (3/6 months: 0.834/0.810). In landmark analyses including 3-month laboratory value dynamics, prognostic prediction from landmark to 6-month follow-up improved for MELD scores (C-statistic: 0.736/0.747/0.755 for MELD/MELD-Na/MELD 3.0) but not CLIF-C AD (C-statistic: 0.703). Systemic inflammation marker CRP predicted 3-month mortality (aHR = 1.063, 95% CI: 1.011–1.117, $p = 0.016$), independently of baseline MELD 3.0, age, sex, ascites grade and etiological cure. In contrast, WBC did not ($p = 0.109$). A model combining dynamics of MELD 3.0 and CRP showed the best prediction of 3-month mortality (C-statistic: 0.830).
Conclusion: MELD scores and CLIF-C AD exhibit comparable discrimination of 3-month and 6-month mortality in patients with cirrhosis and an index decompensation of ascites. Longitudinal evaluation of models provides better discrimination, suggesting improved prediction by monitoring model dynamics over time. Incorporation of systemic inflammation markers, such as CRP, into future MELD variants may enhance prediction.

WED-240

External validation of prognostic scores for post-TIPS mortality in a contemporary, australian cohort

Nirbaanjot Walia[1], Oliver Nilsen[1], Ernest Cheung[2], Jon Abdelmalak[1], Jacqueline Fraser[1], Adam Testro[1]. [1]*Gastroenterology and Liver Transplant Unit, Austin Health, Melbourne, Australia;* [2]*Department of Radiology, Austin Health, Melbourne, Australia*
Email: nirbaanwalia@gmail.com

Background and aims: Post-Transjugular Intrahepatic Portosystemic Shunt (TIPS) mortality remains a critical concern, necessitating accurate prognostic tools. Established scoring systems such as MELD and MELD-Na, and newer models such as the Modified TIPS-Score (MOTS) and Freiburg index of post-TIPS survival (FIPS) score have shown potential in refining risk stratification. Given the evolving trends in cirrhosis aetiologies in recent years, these models require ongoing validation in new cohorts. The aim of this study was to externally validate existing tools in predicting 30- and 90-day mortality after TIPS.
Method: This retrospective study conducted at Austin Hospital, Victoria, Australia included 117 patients undergoing TIPS procedures with at least 90-days follow-up. Prognostic scores were calculated using pre-TIPS clinical and laboratory data. Discriminative performance was assessed using Area Under the Receiver Operating Characteristic Curve (AUC). Prognostic accuracy was assessed at established cut-offs for MELD ≥18, MELD-Na ≥20, MOTS >1, FIPS ≥0.92.
Results: Indications for TIPS included ascites and/or hepatic hydrothorax (n = 66, 56.4%), variceal haemorrhage (n = 40, 34.2%), Budd-Chiari syndrome (n = 7, 6.0%) and other (n = 4, 3.4%). A total of 13 (11.1%) and 21 patients (18.0%) had died by 30- and 90- days, respectively. MELD displayed the best discriminative performance for 30-day mortality (AUC = 0.82), followed by MOTS (0.80), FIPS (0.76) and MELD-Na (0.73). MELD was also the best discriminator for 90-day mortality (AUC = 0.77), followed by FIPS (0.76), MOTS (0.75) and MELD-Na (0.69). With respect to prognostic accuracy for 30- and 90-day mortality, FIPS ≥ 0.92 had excellent specificities (94 and 95%, respectively) and negative predictive values (94% and 88%, respectively). These values were slightly better than those for MOTS, and marginally better still for MELD. MELD-Na performed worst. All scoring tools performed moderate-to-poorly with respect to sensitivity and positive predictive value at these thresholds. Kaplan-Meier curves revealed significant survival differences between groups stratified by the established cut-offs for each scoring tool.
Conclusion: Traditional scoring tools such as the MELD, and the newer MOTS and FIPS, demonstrate robust discriminative performance for 30- and 90-day mortality prediction, and consistently outperform MELD-Na. Further research is required to establish the optimal risk thresholds for these tools and support these findings.

WED-241

Changes in spleen stiffness as assessed via vibration-controlled transient elastography at 100 Hz reflect acute hepatic venous pressure gradient response to i.v. propranolol: a european multicenter study

Paul Thöne[1], Dario Saltini[2], Joana Calvão[3], Lorenz Balcar, Tomas Guasconi[2], Georg Semmler, Albert Friedrich Stättermayer[1], Michael Trauner, Thomas Reiberger, José Presa[3], Filippo Schepis[2], Mattias Mandorfer, Mathias Jachs. [1]*Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria, Vienna Hepatic Hemodynamic Lab, Department of Medicine III, Medical University of Vienna, Vienna, Austria, Clinical Research Group MOTION, Medical University of Vienna, Vienna, Austria, Vienna, Austria;* [2]*Severe Liver Diseases Unit (M.E.C.), Department of Medical Specialties, Azienda Ospedaliero-Universitaria di Modena, University of Modena and Reggio Emilia, Modena, Italy., Modena, Italy;* [3]*Liver Unit-CHTMAD, Vila Real, Portugal., Vila Real, Portugal*
Email: paul.thoene@meduniwien.ac.at

Background and aims: Acute hepatic venous pressure gradient (HVPG) response to i.v. propranolol is a predictive (potential treatment benefit) and well-established prognostic (direct endpoints) biomarker in patients with cirrhosis and clinically significant portal hypertension (CSPH). While LSM by vibration-controlled transient elastography is incapable of monitoring non-selective beta blocker (NSBB)-induced changes in HVPG, SSM by repurposing the 50 Hz LSM probe has shown promising data. However, this technique was limited by a high technical failure rate, which is overcome by SSM at 100 Hz (SSM-100 Hz). This Baveno Cooperation study aimed at investigating the value of SSM-100 Hz for the non-invasive diagnosis of acute HVPG-responders to i.v. propranolol.
Method: Patients who underwent paired HVPG and SSM-100 Hz measurements pre/post i.v. propranolol application at one of the three contributing expert centers between 2019 and 2024 were included into this cohort study. HVPG-response was defined as ≥10%-decrease in HVPG upon propranolol infusion (0.15 mg/kg body weight).
Results: A total of 94 patients (63.8% males, 36.2% females, mean age: 56.5 ± 12.6 years, BMI: 29.1 ± 22.8) were included. Most patients had ALD/metALD (59.6%) or MASLD (11.7%). Varices were present in 58.5% of patients, and 54.3% had already developed decompensated cirrhosis (ascites present in n = 40 patients). The mean HVPG was 17.4 ± 4.1 mmHg before and 15.7 ± 4.2 mmHg after NSBB administration. There was a mean decrease of 1.7 ± 1.7 mmHg (paired t-test: $p < 0.001$), and 43 (45.7%) patients achieved HVPG-response. Meanwhile, SSM decreased by 10.5 ± 19.2 kPa ($p < 0.001$), which corresponds to a relative decrease of 12.6 ± 25.6%. HVPG-responders showed a mean decrease in SSM of 16.6 ± 16.4 kPa ($p < 0.001$), while in HVPG-nonresponders, no significant change in SSM was noted upon i.v. propranolol (mean decrease: 5.4 ± 20.0 kPa, $p = 0.060$). The between-group difference in relative SSM change attained statistical significance (HVPG-responders: – 22.8 ± 18.7% vs. HVPG-nonresponders: –4.0 ± 27.6%, unpaired t-test: $p < 0.001$). Individual relative changes in SSM and HVPG showed a moderate correlation (Pearson's ρ: 0.345, $p < 0.001$). SSM yielded an area under the receiver operating characteristics curve (AUC) of 0.717 (95% CI: 0.614–0.820, $p < 0.001$) for HVPG-response.
Conclusion: Our multicenter study indicates that dynamics in SSM-100 Hz upon i.v. propranolol administration reflect those of HVPG. Thus, SSM-100 Hz may be used a non-invasive surrogate for the HVPG-lowering effect of medical therapies, which has important implications for clinical drug development.

WED-242
The Impact of lactulose on the gut microbiome and barrier function in patients with decompensated cirrhosis

Patricia Bloom[1], Krishna Rao[1], Vincent B. Young[1], Anna Lok[1].
[1]*University of Michigan, Ann Arbor, United States*
Email: ppbloom@med.umich.edu

Background and aims: Lactulose reverses and prevents HE but its precise mechanism of action remains uncertain. We hypothesize that lactulose increases abundance of beneficial gut bacteria, increases butyrate production, and thus improves gut barrier function. Therefore, we evaluated the impact of lactulose on gut microbiome composition, function, and intestinal permeability in patients at risk of HE.
Method: We enrolled consecutive patients with Childs Pugh Class B or C cirrhosis presenting for outpatient upper endoscopy, excluding patients with recent non-rifaximin antibiotic use or alcohol use. We obtained duodenal tissue biopsies, stool samples, and dietary recalls. Composition of the duodenal mucosal and stool microbiota was determined via 16S rRNA sequencing. Stool butyrate was measured via liquid chromatography. Epithelial permeability was assessed by transepithelial electrical resistance (TEER). Analysis of molecular variance (AMOVA) of Yue and Clayton dissimilarity index compared microbiota community structure between groups. Wilcoxon rank sum tests compared continuous variables between groups.
Results: We enrolled 47 patients, aged 60 (IQR 49, 69) years, 27 (57%) male, 19 (40%) MASLD and 26 (55%) alcohol-related cirrhosis, Child Pugh score 9 (IQR 8,10) and MELD 14 (IQR 11, 16). 24 (51%) had a history of overt HE. 12 patients were on lactulose alone, 18 on lactulose and rifaximin, 2 on rifaximin alone, and 15 on neither. Patients in the 3 largest treatment groups (lactulose alone, lactulose and rifaximin, and neither) had distinct stool microbiomes (3-way AMOVA, $P < 0.001$; each two-way comparison $P < 0.01$), as well as distinct duodenal microbiomes (3-way AMOVA, $P = 0.02$). In LEfSe analysis, 33 stool taxa and 6 duodenal mucosal taxa differed significantly between the 3 treatment groups. Patients on lactulose had higher fecal abundance of *Bifidobacterium* (known butyrate producer).
Stool butyrate concentration was greater in patients on lactulose (± rifaximin) than in patients on no HE medications (11 nmol/mg [IQR 6, 17] vs. 5 [IQR 3, 11], $P = 0.03$). Stool butyrate concentration was numerically greater in the sub-group on lactulose alone than the patients on no HE medications (12 nmol/mg [IQR 11,15] vs. 5 [IQR 3, 11], $P = 0.14$). Duodenal TEER was greater (less permeable) in patients on lactulose alone (21 Ω/cm^2 [IQR 15, 24]) compared to patients on neither HE medication (16 Ω/cm^2 [IQR 12, 20], $P = 0.28$). In logistic regression, total dietary fiber did not account for increased *Bifidobacterium*, stool butyrate, or duodenal TEER in the lactulose group.
Conclusion: In patients with decompensated cirrhosis, lactulose was associated with a distinct mucosal and stool microbiome, separate from rifaximin's influence. Lactulose was associated with greater *Bifidobacteria* abundance, higher stool butyrate and a trend towards less intestinal permeability (higher TEER). This work suggests a possible under-explored mechanism of action of lactulose and warrants further evaluation.

WED-243
Association between body mass index and adverse outcomes in patients with compensated cirrhosis

Ahmed Ibrahim[1], Abhinav Rao[1], Don Rockey[1]. [1]*Medical University of South Carolina, Charleston, United States*
Email: ibrahima@musc.edu

Background and aims: The relationship between an elevated BMI in cirrhotic patients and decompensating events remains controversial and requires further investigation. Here, we evaluated the association between BMI levels and the risk of developing esophageal varices, ascites, or variceal bleeding.
Method: We conducted a retrospective cohort analysis, using TriNetX's large administrative dataset including 115,676,318 patients from 66 US healthcare organizations. We examined patients ≥18 years old, with compensated cirrhosis, but without a prior history of esophageal varices or ascites. Based on BMI range, patients were classified into four BMI categories (normal (BMI 18.5–25), overweight (BMI 25–30), grade 1 obesity (BMI 30–35), grade 2–3 obesity (BMI ≥35)). Patients were matched only for age and sex. The development of esophageal varices, ascites, and variceal bleeding was compared across the different groups, using the normal BMI group as a reference. The international Classification of diseases ninth/tenth version (ICD-9/ICD-10) codes were used to identify patients with cirrhosis (ICD-10: K74; K74.6; K70.3) and associated portal hypertensive complications (ICD-10: R18; K76.82; I85.11, I85.01). TriNetX Analytics Platform built-in functions (R, version 4.0) were used for data analysis, including propensity score matching, HR's and 95% CI's.
Results: A total of 423,536 patients with compensated cirrhosis were identified, including 129,804 with normal weight, 169,024 overweight patients, 146,545 with grade 1 obesity, and 111,389 with grade 2–3 obesity. After propensity score matching, the cohorts were comparable in age and gender distribution (mean [SD] age, 59 [13] years old; 41% women). The likelihood of having metabolic syndrome

abnormalities increased in proportion to the severity of increase in BMI. Additionally, the likelihood of developing MASH increased concomitantly with BMI. There were no differences in AST, ALT, total bilirubin, or INR in the different weight groups. The risk of developing a portal hypertension related cirrhosis decompensating event (esophageal varices, ascites, or variceal bleeding) and the risk of all-cause mortality increased in patients with a BMI≥ 25 and those with grade 1 obesity ($P < 0.05$). However, they all decreased slightly in patients with grade 2–3 obesity.
Conclusion: There appears to be a direct relationship between BMI and the risk of developing decompensating events in patients who are overweight and have grade 1 obesity. However, the increase in risk appears to be small (though significant), and peaks at the grade 1 obesity level.

WED-244
Evaluation of the Baveno VII criteria for predicting liver-related events in patients with advanced chronic liver disease – a single centre retrospective study
Steven Trinh[1], Qing Fang[1], Estelle Sultana[1], Kimberley Eu[2], Alice Comsa[2], Emily Schembri[2], Stephen Bloom[1,2], Rohit Sawhney[1,2]. [1]*Eastern Health, Box Hill, Australia;* [2]*Eastern Health Clinical School, Monash University, Box Hill, Australia*
Email: steventr.7@gmail.com

Background and aims: Patients with advanced chronic liver disease (ACLD) are at risk of complications of decompensation, primarily related to clinically significant portal hypertension (CSPH). The Baveno VII guidelines proposed criteria using transient elastography (TE) and platelet count (plts) to assist in the diagnosis and prognostication of patients with compensated ACLD (cACLD) at higher risk. The aim of this study was to evaluate the Baveno VII criteria in identifying patients at risk and predicting subsequent liver-related outcomes in a retrospective analysis.
Method: Adult patients undergoing TE in a single tertiary centre for chronic liver disease were retrospectively reviewed. Demographic data, baseline and follow up liver stiffness measurements (LSM), and clinical and laboratory parameters within 3 months of LSMs were collected. Patients were categorised using the Baveno VII 'rule of 5s' as follows: LSM <10 kPa (stage 1 – cACLD excluded), LSM between 10 and 15 kPa with plts $<150 \times 10^9$/L (stage 2 – possible CSPH), LSM between 15 and 20 kPa with plts $<110 \times 10^9$/L (stage 3 – assumed cACLD), LSM between 20 and 25 kPa with plts $<150 \times 10^9$/L (stage 4 – assumed cACLD), and LSM >25 kPa (stage 5 – definitive cACLD). Liver-related events (LREs) including hospital admissions for decompensation with ascites, hepatic encephalopathy or variceal bleeding were recorded. Patients were excluded for suboptimal TE quality (success rate <60%, interquartile range/median ratio >0.3), if incomplete associated clinical/laboratory data or if <18 months of documented follow up.
Results: 1035 patients with chronic liver disease who underwent TE were analysed. The mean age was 49.7 years and 45.1% were female. The most common aetiologies were hepatitis B (53%), hepatitis C (25.1%), metabolic dysfunction-associated steatotic liver disease (21.2%) and alcohol-related liver disease (10.1%). The median LSM at baseline was 5.6 kPa; 75.6% of patients were in stage 1, 10.9% in stage 2, 3.7% in stage 3, 3.0% in stage 4 and 6.9% in stage 5. During follow up, 95 patients developed LREs and the optimal LSM cut-off to predict LREs was 16.4 kPa (AUROC = 0.82). There was a stepwise increase in odds ratio (OR) for developing LREs with each Baveno VII stage progression (comparing to stage 1, stage 2 OR 5.5, stage 3 OR 8.0, stage 4 OR 20.2, stage 5 OR 88.6; $p < 0.001$). The Baveno VII criteria demonstrated utility in both excluding patients at low risk (stage 1 cACLD and those not meeting stage 2 criteria; sensitivity = 90.9%, specificity = 76.3%) and identifying patients at risk of LREs (stages 2–5 cACLD: sensitivity = 81.1%, specificity = 81.3%).
Conclusion: The Baveno VII criteria using non-invasive tools demonstrated excellent utility in risk stratification for patients with cACLD. Further study will aim to validate these findings and determine the application of this model to guide patient management and improve outcomes.

WED-245
Personalized biomarkers scores outperform established scores in the short- and long-term prediction of hepatocellular carcinoma and decompensation
Rosina Maria Critelli[1], Fabiola Milosa[1], Davide Guido[2], Grazia Serino[2], Filippo Schepis[1], Gianluigi Giannelli[2], Erica Villa[1]. [1]*University of Modena and Reggio Emilia, Modena, Italy;* [2]*IRCCS Saverio de Bellis, Castellana Grotte (Bari), Italy*
Email: erica.villa@unimore.it

Background and aims: Predicting the two main complications of compensated advanced chronic liver disease (cACLD) – hepatocellular carcinoma (HCC) and decompensation - is crucial for improving prognosis. We tested various combinations of serum biomarkers to predict HCC and decompensation at 5- and 10-year in a cohort of cACLD patients, of any etiology and compared the results to the established GALAD, aMAP, and EPOD scores.
Method: From 2011 to 2018, we prospectively recruited 545 patients with cACLD. At enrollment, we analyzed 28 serum biomarkers related to inflammation, immunity, metabolism, coagulation, and angiogenesis (Ella ELISA,Bio-Techne). Based on the most effective combinations in the Cox models, we developed personalized biomarker scores (BioMscores) tailored for each condition and specific subgroups categorized by sex and etiology (viral, MAFLD/MASH, alcohol). Additionally, we calculated GALAD, aMAP, and EPOD scores and assessed their predictive capability for HCC and decompensation, versus the BioMscores using Cox proportional hazard regression models and the AUROC method.
Results: Patients were followed for a median of 3.60 and 5.58 years at 5 and 10 years, respectively. We observed 92 incident HCC cases (16.9%). For the entire HCC cohort, a combination of 9 biomarkers linked to inflammation, IGF-1 transport and uptake, and cellular response to hypoxia outperformed GALAD and aMAP (BioMscore HR 4.700, $p < 0.001$; GALAD: HR 1.307, $p < 0.001$; aMAP HR 0.997, p = NS). Notably, BioMscores differed significantly between subgroups, with males and MAFLD/MASH patients showing more inflammation, and females showing more hypoxia-linked biomarkers. GALAD and aMAP did not havepredictive ability in MAFLD/MASH, while BioMscore did (HR1.929, $p < 0.001$). For decompensation, BioMscores revealed inflammation- and angiogenesis-linked biomarkers in all subgroups except females, who lacked inflammatory biomarkers. BioMscore for the entire group had the same predictive ability as EPOD but greatly outperformed it in males, females, and etiology subgroups. EPOD failed to predict decompensation in MAFLD/MASH, while BioMscore did (HR 4.455, p = .002).
Conclusion: HCC and decompensation displayed significantly different risk profiles: HCC was more closely linked to inflammation, while decompensation was associated with coagulation and angiogenesis. Males predominantly exhibited inflammation-associated biomarkers, whereas females were more likely to have markers related to hypoxia and angiogenesis. Notably, personalized scores significantly outperformed traditional ones in predicting both conditions, achieving a higher degree of accuracy across all subgroups.

Long-term outcomes of patients with porto-sinusoidal vascular liver disorder. A single-centre 10 year-follow-up study
Sanchit Sharma[1], Neil Rajoriya[1], Samagra Agarwal[2], Faisal Khan[3], Dhiraj Tripathi[1,4]. [1]*Liver Unit, Queen Elizabeth Hospital, Birmingham, United Kingdom;* [2]*Department of Gastroenterology, All India Institute of Medical Sciences, New Delhi, India;* [3]*Department of Gastroenterology, Good Hope Hospital, Birmingham, United Kingdom;* [4]*Institute of*

Immunology and Immunotherapy, University of Birmingham, Birmingham, United Kingdom
Email: dtripathi@bham.ac.uk

Background and aims: Porto-sinusoidal vascular disorder(PSVD) is a recently described entity with a paucity of data on its natural history. We studied the clinical, histological characteristics and liver related outcomes in patients with PSVD from a single center.
Method: In this single-center, retrospective study(1998–2023), baseline descriptive characteristics and outcomes such as transplant free survival, new onset decompensation such as variceal bleeding, ascites and incidence of portal vein thrombosis (PVT) were evaluated in patients diagnosed with PSVD using VALDIG criteria. Predictors of survival were identified using a machine learning algorithm(Boruta).
Results: A total of 80 patients were included, with a mean age of 44 years and 38% females. At diagnosis, 45% (n = 36) patients had a history of portal hypertension related complications: 24%(n = 24) had variceal bleed and 20% (n = 16) had ascites. Signs of portal hypertension were present in 70% (n = 56) patients. Six (7.8%) patients had PVT at baseline. Median hepatic venous pressure gradient (HVPG) (n = 25) was 11 (5–12) mmHg. Median duration of follow-up was 78 (27–132) months. The cumulative 5-year and 10-year incidence of new onset variceal bleed was 15.4% and 21.8% respectively. New onset/worsening ascites developed in 21.6% and 35% of patients at 5-year and 10-year respectively and cumulative incidence of PVT at 5-years and 10-years was 15.9% and 21% respectively. Nine patients (11.8%) underwent liver transplant and 23 patients (29%) died during follow-up. Sixteen patients (20%) underwent trans jugular intrahepatic portosystemic shunt insertion. Transplant free survival at 5 year and 10 years was 70.5% and 60.7% respectively. A model combining histological variables (incomplete septal fibrosis, nodular regenerative hyperplasia), serum bilirubin and PVT at presentation could predict survival with optimism corrected C-statistics of 0.755.
Conclusion: This natural history study with the longest reported follow-up of PSVD describes the long-term outcomes with 60% transplant free survival at 10 years. Baseline liver dysfunction, presence of PVT and certain histological features could predict the prognosis in the present cohort.

WED-247
Targeted nutrition intervention improves frailty and quality of life in patients with liver cirrhosis

Saniya Khan[1,2], Sara Sansoni[1,2], Lucia Lapenna[1,2], Simone Di Cola[1,2], Manuela Merli[1,2]. [1]*Sapienza University, Rome, Italy;* [2]*Policlinico Universitario Umberto 1, Rome, Italy*
Email: manuela.merli@uniroma1.it

Background and aims: Inadequate food intake is one of the major contributors to malnutrition in decompensated liver cirrhosis patients, and addressing this issue can significantly enhance their clinical outcomes. Malnutrition is closely linked to frailty and sarcopenia, both modifiable with targeted interventions. This study aimed to evaluate the impact of 16-week nutritional intervention on the liver frailty index (LFI) and health-related quality of life (HRQOL) in patients with cirrhosis.
Method: In this clinical trial, patients with liver cirrhosis attending the portal hypertension clinic at Policlinico Umberto I were enrolled for dietary intervention according to EASL guidelines for nutrition in chronic liver disease, if meeting inclusion (age 18–70 years, CTP ≤ 10, clinically stable) and exclusion criteria (patients already on a diet program or high protein supplements, patients with server co-morbidities, chronic or recurrent hepatic encephalopathy, or patients who refused to participate). Data on clinical parameters, dietary intake, HRQOL, LFI, and anthropometry were recorded at baseline and post-intervention. Dietary intake was analysed to calculate energy intake (kcal/kg body weight/day) and protein intake (g/kg body weight/day). Paired t test was performed using SPSS software (version 28.0.1.1).
Results: Thirty-five patients (age – 56.5 ± 11.2 years; male - 73.3%; etiology : alcohol - 46.6%, MASLD – 26.7%, viral – 26.7%; MELD – 9.2 ± 2.3; MELD-Na – 10.3 ± 2.8; CTP – 5.6 ± 0.7) have been enrolled, with 15 completing the 16-week follow up. Significant improvement was observed in hand grip strength (23.8 ± 12.1 kg vs. 27.1 ± 10.8 kg, p = 0.002) and chair sit-ups (15.6 ± 6.3 secs vs. 12.4 ± 3.8 secs, p = 0.04) after the dietary intervention. LFI also showed significant improvement (4.5 ± 0.7 vs. 3.9 ± 0.5, p < 0.001). Additionally, HRQOL, as measured by the chronic liver disease questionnaire (CLDQ) score, improved significantly (2.5 ± 0.9 vs. 3 ± 0.7, p = 0.025). Energy intake (kcal/kg BW/ day) also increased but did not reach statistical significance (24.2 ± 7.5 vs. 26.2 ± 3.5, p = 0.4). Moreover, protein intake significantly improved from 0.9 ± 0.3 g/kg BW/day to 1.3 ± 0.1 g/kg BW/ day (p < 0.001). Other measures, including body weight, body mass index (BMI), triceps skinfold thickness (TSF), mid-arm muscle circumference (MAMC), and mid-arm muscular area (MAMA), remained comparable between baseline and 16-week follow-up.
Conclusion: The preliminary results indicate that a dietary intervention in cirrhotic patients can significantly improve physical performance, and health-related quality of life. These findings underscore the potential of nutritional strategies to enhance clinical outcomes in this patient group. Future studies should explore long-term adherence and broader applications of such interventions.

WED-248
CT-based clinically significant portal hypertension: predicting complications in HCC hepatectomy

Subin Heo[1], Boryeong Jeong[2], Seung Soo Lee[1], Eun Sun Choi[1]. [1]*Asan Medical Center, Seoul, Korea, Rep. of South;* [2]*Severance Hospital, Yonsei University College of Medicine, Seoul, Korea, Rep. of South*
Email: subin7131@gmail.com

Background and aims: The role of CT-based clinically significant portal hypertension (CSPH) assessed using deep-learning algorithm in predicting short-term and long-term liver-related complications following hepatic resection has not been evaluated.
Method: This retrospective study included patients with advanced chronic liver disease (ACLD) who underwent partial hepatectomy for hepatocellular carcinoma (HCC) with BCLC stage 0 or A between 2017 and 2018. The presence of CT-based CSPH was evaluated in preoperative contrast-enhanced CT, which included splenomegaly determined by deep learning-based spleen volume measurements with personalized reference thresholds, and the presence of at least one of esophagogastric varix, spontaneous portosystemic shunt, or ascites. We performed multivariable logistic regression and competing risk analysis to evaluate the association of CT-based CSPH with liver-related outcomes. The primary endpoint was severe post-hepatectomy liver failure (PHLF), as defined by International Study Group of Liver Surgery. Secondary endpoints were the occurrence of hepatic decompensation and liver-related death or liver transplantation. Additionally, CT-based CSPH was applied to two well-known PHLF prediction models (Citterio's algorithm and Wang's model), and their performance was compared with that when applying the conventional surrogate CSPH assessment (presence of esophageogastric varix at endoscopy or coexistence of splenomegaly and a platelet count < $100 \times 10^3/\mu L$).
Results: A total of 593 patients (mean age, 57.9 years ± 9.3; 460 male) were included in the study. Severe PHLF occurred in 41 patients (6.9%). The presence of CT-based CSPH was a significant independent predictor for the occurrence of severe PHLF (odds ratio 7.672, 95% confidence interval [CI] 3.209–18.346). The performance of both Citterio's algorithm and Wang's model significantly improved when using the CT-based CSPH criteria compared to the conventional method (AUC 0.724 vs. 0.694, p = 0.036, and AUC 0.854 vs 0.830, p = 0.011, respectively). CT-based CSPH was also a significant predictor for long-term hepatic decompensation (hazard ratio [HR] 4.518, 95%

CI 1.868–10.929) and liver-related death or transplantation (HR 2.756, 95% CI 1.315–5.773).
Conclusion: The presence of CT-based CSPH predicts short-term and long-term liver related outcomes following partial hepatectomy for HCC in ACLD.

WED-253-YI
Endoscopic ultrasound-guided therapies versus standard and modified balloon-occluded retrograde transvenous obliteration for management of fundal varices – a multicentric propensity-matched analysis

Suprabhat Giri[1], Ranjan Patel[2], Radhika Chavan[3], Bhavik Shah[4], Jimmy Narayan[5], Jimil Shah[6], Taraprasad Tripathy[2], Sushant Babbar[7], Lalit Garg[8], Rozil Gandhi[9], Karan Anandpara[10], Swati Das[1], Manjit Kanungo[5], Girish Kumar Pati[5], Hemanta Nayak[2], Manas Kumar Panigrahi[2], Preetam Nath[1], Saroj Kanta Sahu[1], Dibyalochan Praharaj[1], Bipadabhanjan Mallick[1], Sarat Panigrahi[1], Sanjay Rajput[3], Manoj Sahoo[1], Anil Anand[1]. *[1]Kalinga Institute of Medical Sciences, Bhubaneswar, India; [2]All India Institute of Medical Sciences, Bhubaneswar, India; [3]Ansh Clinic, Ahmedabad, India; [4]Shree Narayana Hospital, MediGenix Hospital, Raipur, India; [5]IMS and SUM Hospital, Bhubaneswar, India; [6]Postgraduate Institute of Medical Education and Research, Chandigarh, India; [7]Dayanand Medical College and Hospital, Ludhiana, India; [8]Santokba Durlabhji Memorial Hospital, Jaipur, India; [9]Sushrut Hospital, Ahmedabad, India; [10]Heart and Vascular Superspecialty Hospitals, Mumbai, India*
Email: supg19167@gmail.com

Background and aims: Balloon-occluded retrograde transvenous obliteration (BRTO) or its modifications are viable options for managing fundal varices. Endoscopic ultrasound (EUS) guided glue injection with or without coil is an alternate option. Due to the scarcity of data comparing these two modalities, the present study compared the outcome of EUS-guided therapies and BRTO for managing fundal varices.
Method: We retrospectively analyzed the data of patients with fundal varices undergoing EUS-guided intervention or BRTO from ten tertiary care centers in India, and both groups were compared after propensity matching. The study's primary outcome was the incidence of variceal bleeding within 1 year. The secondary outcomes included procedure-related adverse events (AEs), variceal obliteration, reintervention, and mortality within 1 year.
Results: A total of 167 patients (EUS-guided intervention: 108, BRTO: 59) were included in the analysis, of which 59 patients were included in each group after propensity matching. The incidence of variceal bleeding (15.3% vs. 13.6%, p = 0.793) within 1 year was comparable between the EUS and BRTO groups. Procedure-related AEs, primarily new onset or worsening of ascites, were higher in the BRTO group. The incidence of variceal obliteration at 4 weeks was comparable between groups (83.1% vs. 91.5%, p = 0.167). The need for reintervention within 1 year of the index procedure (30.5% vs. 22.0%, p = 0.296) was comparable between the EUS and BRTO. However, the need for reintervention for GVs was higher in the EUS group (28.8% vs. 5.1%, p = 0.001), and the need for reintervention for esophageal varices (EVs) was higher in the BRTO group (16.9% vs. 1.7%, p = 0.008).
Conclusion: EUS-guided therapy offers a safer alternative with comparable efficacy to BRTO for managing fundal varices. The need for reintervention for GVs was higher in the EUS group, while the incidence of AEs and reintervention for EVs was higher in the BRTO group.

WED-254
Deeplearning allows prediction of portal hypertension from liver biopsies

Email: thomas.sorz-nechay@meduniwien.ac.at

Background and aims: Portal hypertension (PH) arises due to profound architectural changes of the liver parenchyma not only limited to fibrosis. Measurement of the hepatic venous pressure gradient (HVPG) represents the diagnostic gold-standard for PH. We employed state of the art deep learning methods to predict HVPG and PH from liver biopsies (LB).
Method: Patients with liver disease were included when both LB and HVPG measurement were performed within ± 3 months. Patients with liver cancer or post liver transplantation were excluded. Hematoxylin-eosin-stained LB specimens were digitized at high resolution (40x, 0.137 mm/px). Whole slide images were downscaled to 1.14 m/px and tessellated into tiles sized 224 × 224px. Feature extraction was performed using two pretrained foundation models: CTransPath (CTrP) and UNI. We performed 4-fold cross validation with attention-based multiple instance learning (attMIL) to train classifiers that predict clinically significant PH (CSPH: HVPG≥10 mmHg) and severe PH (SPH: HVPG≥16 mmHg). Performance was evaluated using AUROC. Further, we trained attMIL regression models with 3-fold cross validation to predict the HVPG value directly, followed by Pearson's r coefficient evaluation.
Results: A total of 160 patients (n = 108, 67.5% showing F4 cirrhosis on LB) were included, the main etiologies were alcohol-related (n = 52, 32.5%) and metabolic dysfunction-associated steatotic liver disease (n = 37, 23.1%). The median HVPG was 15mmHg (IQR = 8mmHg) and 128 (80%) and 77 (48.1%), respectively, had CSPH and SPH. Direct HVPG prediction using CTrP features yielded an average r value of 0.12, with the best performing model reaching an r of 0.29 (p = 0.033). Models trained on UNI features outperformed CTrP models with an average r of 0.40, with the most accurate model reaching an r of 0.51 (p < 0.001). For prediction of CSPH, AUROC analysis revealed an average area under the curve (AUC) of 0.78 ± 0.08 when trained on CTrP features, whereas training on UNI features yielded an AUC of 0.79 ± 0.02. The best performing models using CTrP or UNI features had AUCs of 0.82 and 0.81, respectively. Prediction of SPH had worse overall performance, with an average AUC of 0.68 ± 0.20 with CTrP features and an average AUC of 0.72 ± 0.03 with UNI features. However, the best performing model trained on CTrP features had an AUC of 0.83 for predicting SPH, while the best UNI features-trained model remained with an AUC 0.73. Explainability analysis revealed that both models allocate high attention weights to tiles containing excess fibrosis and immune cell infiltrates.
Conclusion: Deep learning approaches allow prediction of CSPH from LBs to facilitate prognostication in patients with liver disease. Predictive value for SPH was worse, potentially explained by pronounced extrahepatic factors contributing to SPH. The current model for direct estimation of the HVPG value requires further refinement.

WED-255

Three-dimensional computed tomography angiography-based computational fluid dynamics simulation for noninvasive assessment of portal hypertension in patients with cirrhosis

Yang Tai[1], Yue Qiu[2], Ying Li[1], Zhidong Wang[1], Huan Tong[1], Bo Wei[1], Hao Wu[1]. [1]*Department of gastroenterology and hepatology, west china hospital, sichuan university, Chengdu, China;* [2]*West china biomedical big data center, west china hospital, sichuan university, Chengdu, China*
Email: tyscu@foxmail.com

Background and aims: Portal hypertension (PH) is a severe consequence of chronic liver diseases and is responsible for the main clinical complications of liver cirrhosis. The accurate assessment of portal pressure for cirrhosis patients would aid in risk stratification and improve clinical management. Although measurement of hepatic venous pressure gradient (HVPG) remains the gold standard for diagnosing and evaluating PH, the technical difficulty, invasiveness, and low feasibility of multiple measurements restrict its widespread clinic application. This study aims to demonstrate the feasibility of the combination of three-dimensional computed tomography angiography angiography (3D-CTA) with computational fluid dynamics (CFD) for noninvasive portal pressure assessment in patients with cirrhosis.
Method: A total of 40 cirrhotic patients with PH receiving transjugular intrahepatic portosystemic shunt (TIPS) treatment were retrospectively included. All patients received HVPG and portosystemic pressure gradient (PPG) measurements during the interventional procedure. The preoperative imaging from abdominal contrast-enhanced CT and hemodynamic parameters from color Doppler ultrasound were collected. Patient-specific 3D geometries of the portal venous system and the entire hepatic region were reconstructed. Virtual HVPG (vHVPG) and virtual PPG (vPPG) were noninvasively measured in CFD simulation by considering the liver region as porous media to account for the patient-specific intrahepatic resistance.
Results: A porous media model with porous diameter of 120 μm was considered as the most appropriate model to present the simulation results. vPPG derived from CFD analysis was in great agreement with clinical measured data (17.2 ± 2.3 mmHg vs. 16.3 ± 2.0 mmHg). Validation of the numerical method was performed by post-TIPS PPG measurement (10.1 ± 1.8 mmHg vs. 9.3 ± 1.4 mmHg). vHVPG was significantly correlated with vPPG ($R = 0.7499$, $p < 0.0001$), with an accuracy to distinguish clinically significant portal hypertension (CSPH) as high as 92%. However, PH severity classification was underestimated for 36% patients, especially for patients with hepatic venous collateral formation and presinusoidal portal venous occlusion.
Conclusion: A patient-specific 3D-CTA based CFD simulation for noninvasive portal pressure assessment has been established. This computational model shows favourable performance for evaluating PH in patients with cirrhosis and might guide clinical decisions. HVPG is a relatively reliable diagnostic method for PH when PPG cannot be directly measured. For patients who have clinical symptoms of PH but their HVPG are within a normal range, numerical evaluation of PPG with CFD is an optional method for their diagnosis.

WED-256

Multiparametric ultrasound for the prediction of the outcomes of endoscopic ligation of esophageal varices

Valentin Calvez[1], Raffaele Borriello[1], Giorgo Esposto[1], Irene Mignini[1], Maria Elena Ainora[1], Linda Galasso[1], Antonio Gasbarrini[1], Maria Assunta Zocco[1]. [1]*Fondazione Policlinico Universitario "A. Gemelli" IRCCS, Catholic University of Rome, Department of Translational Medicine and Surgery, Rome, Italy*
Email: valentino.calvez@gmail.com

Background and aims: Endoscopic Variceal Band Ligation (EVBL) is a cornerstone in the prophylaxis of esophageal variceal bleeding in cirrhotic patients. However, in most cases, a single EVBL session does not completely eradicate esophageal varices, necessitating a control endoscopy after 2–4 weeks to assess eradication or the need for further ligation. Currently, there are no noninvasive tools available to predict the outcome of EVBL. This study aimed to identify noninvasive predictors of variceal eradication after EVBL using multiparametric ultrasound.
Method: We prospectively enrolled consecutive cirrhotic patients intolerant to or with contraindications to beta-blockers, undergoing EVBL for bleeding prophylaxis. Before the procedure(T0), patients underwent abdominal ultrasound with liver and spleen 2D-ShearWave Elastography and Dynamic Contrast-Enhanced Ultrasound (D-CEUS) with time-intensity curve analysis using VueBox® software, with two regions of interest: liver parenchyma and portal vein. After 1 month(T1), the same exams were repeated before control endoscopy to confirm variceal eradication, defined as either complete absence of varices or residual varices not requiring further ligation. Percentage changes in D-CEUS parameters between T0 and T1 were calculated as $[(T1 - T0)/T0] \times 100$. Logistic regression analyses were performed to evaluate predictors of variceal eradication.
Results: Forty-one patients were included (mean age 63 ± 7.5 years; 75.6% male). After EVBL at T0, 28 patients (68.3%) achieved variceal eradication, while 13(31.7%) required a second ligation at T1. Patients who achieved eradication showed a significant reduction in spleen stiffness (SS) at T1 compared to T0 (39 kPa vs. 52.5 kPa; $p = 0.014$). Logistic regression analyses identified a reduction in spleen stiffness as a predictor of eradication (OR: 1.156, $p = 0.033$). Additionally, changes in D-CEUS parameters between T0 and T1 were predictive of eradication. Regarding the liver parenchyma, the percentage increase in Mean Linear Amplitude Unit (MeanLinAU; OR: 0.92, $p < 0.001$), peak enhancement (PE; OR: 0.905, $p = 0.003$), and area under the curve (AUC; OR: 0.957, $p = 0.009$) were significant predictors. Similarly, for the portal vein, the percentage increase in MeanLinAU (OR: 0.92, $p = 0.009$), PE (OR: 0.947, $p = 0.003$), and AUC (OR: 0.947, $p = 0.006$) also predicted variceal eradication.
Conclusion: Our study demonstrated that reduction in SS and changes in D-CEUS parameters are reliable noninvasive predictors of variceal eradication after EVBL.

WED-257-YI

Long-term albumin treatment improves outcomes in patients with cirrhosis and ascites

Valeria Santori[1,2], Marta Tonon[1], Lorenz Balcar[3,4], Nikolaj Torp[2,5], Enrico Pompili[6,7], Lucie Simonis[3,4], Cecilie Løbel[2,5], Roberta Gagliardi[1], Jan Embacher[3,4], Mads Israelsen[2,5], Antonio Accetta[1], Christian Sebesta[3,4], Stine Johansen[2,5], Leonie Hafner[3,4], Michael Trauner[3,4], Mattias Mandorfer[3,4], Thomas Reiberger[3,4,4], Aleksander Krag[2,5], Paolo Caraceni[6,7], Paolo Angeli[1], Salvatore Piano[1], Georg Semmler[2,3,4,5]. Email: salvatore.piano@unipd.it

Background and aims: While the ANSWER trial has demonstrated improved survival with long-term albumin treatment in patients with ascites, a benefit was not observed in some other studies. Study design, heterogeneity in study cohorts and albumin dose have been hypothesized to explain these discrepancies. We aimed to assess the

effects of long-term albumin treatment – administered in a real-life outpatient setting – on liver-related mortality in cirrhosis patients with ascites.
Method: 878 cirrhosis patients with ascites as index decompensation between 2003–2024 from four tertiary care centers in Europe were included. 106 patients (11.7%) receiving long-term (i.e., more than > 30 days) i.v. albumin therapy. Patients were characterized from time of albumin treatment initiation or first decompensation. We performed inverse probability of treatment weighting (IPTW) adjusting for age, sex, MELD-Na and etiologic cure to account for differences in disease severity in multivariable cox regression analyses of liver-related mortality.
Results: The main patient characteristics were balanced between patients receiving long-term albumin [ivALB (+)] and those w/o albumin treatment [ivALB(-)]: median age: 60.2 vs 56.9 years (p = 0.008) and MELD-Na 14 vs 15 (p = 0.231). Median ivALB(+) treatment dose was 40 grams per week (mostly 20% 200 mL) and patients were treated for 11.1 (IQR: 5.0–20.3) months. During a median follow-up of 46.5/36.4 months in ivALB(-)/ivALB(+) patients, 44.4%/35.9% died including 39.0%/27.2% liver-related deaths, and 12.3%/17.5% underwent liver transplantation (LT). Incidence of liver-related mortality at 36 months was 38.8% in the ivALB(-) vs. 34.4% in the ivALB(+) patients (log-rank p = 0.100). Cox proportional hazards regression with IPTW for ivALB(+) treatment showed that next to age (aHR per year: 1.04 [95%CI: 1.02–1.06]; p < 0.001), MELD-Na (aHR per point: 1.07 [95%CI: 1.04–1.10]; p < 0.001), female sex (aHR: 0.58 [95%CI: 0.42–0.81]; p = 0.001) and etiologic cure (aHR: 0.56 [95%CI: 0.36–0.88]; p = 0.012) - long-term ivALB(+) therapy was associated with significantly reduced risk of liver-related death (aHR: 0.65 [95%CI: 0.42–0.99]; p = 0.048).
Conclusion: Acknowledging the limitations related to retrospective design and non-standardized treatment schedules, long-term ivALB (+) treatment significantly reduced liver-related mortality in our cohort of cirrhosis patients with ascites.

WED-258
TIPS for portal hypertensive gastropathy bleeding reduces further decompensation and mortality

Zeyu Wang[1], Markus Kimmann[1], Johannes Chang[2], Juliana Goediker[1], Silvia Letmathe[1], Jörn Arne Meier[1], Feras Sanoubara[1], Sara Noemi Reinartz Groba[1], Franziska Weppelmann[1], Christian Jansen[2], Carsten Meyer[3], Michael Köhler[4], Jonel Trebicka[1], Michael Praktiknjo[1]. *[1]Department of Medicine B, University Hospital Münster, Münster, Germany; [2]Department of Medicine I, University Hospital Bonn, Bonn, Germany; [3]Department of Diagnostic and Interventional Radiology, University Hospital Bonn, Bonn, Germany; [4]Department of Radiology, University Hospital Münster, Münster, Germany*
Email: michael.praktiknjo@ukmuenster.de

Background and aims: Portal hypertensive gastropathy (PHG) is the second leading cause of gastrointestinal bleeding after gastroesophageal varices, affecting 20–80% of patients with liver cirrhosis. Current guidelines recommend non-selective beta-blockers (NSBBs) as the first-line treatment. For PHG patients who are transfusion-dependent and unresponsive to NSBBs or endoscopic therapy, transjugular intrahepatic portosystemic shunt (TIPS) is suggested as an alternative treatment. However, there is a lack of evidence supporting the efficacy of TIPS in improving long-term outcomes, such as further decompensation.
Method: In this retrospective, multicenter study, patients with PHG-related bleeding (32% rebleeding) treated with TIPS were 1:1 propensity score matched (PSM) to patients receiving SOC. Of a total of 110 patients (n = 28 treated with TIPS), 50 patients could be matched: TIPS (n = 25) and SOC (n = 25). Primary outcome was further decompensation. Secondary outcomes included mortality and rebleeding rates. Further decompensation was defined as the new occurrence or worsening of ascites, variceal bleeding, hepatic encephalopathy, jaundice, spontaneous bacterial peritonitis (SBP), or hepatorenal syndrome (HRS). Follow-up was 1 year.
Results: TIPS showed significantly lower rates of further decompensation (TIPS: 15% vs. SOC: 25%, p = 0.027), especially in terms of ascites (HR 0.064, 95% CI: 0.008–0.305, p = 0.002) and hepatic encephalopathy (HR 0.308, 95% CI: 0.122–0.775, p = 0.012), compared to the SOC group. Cox regression analysis indicated a trend towards improved survival in the TIPS group (HR: 0.55, 95% CI: 0.18–1.68, p = 0.3). TIPS group showed a trend for lower rebleeding rates (p = 0.343).
Conclusion: The clinical use of TIPS for PHG-related bleeding significantly reduces further decompensation, is associated with improved survival, and trends toward lower rates of rebleeding within one year.

WED-259
Limited value of liver frailty index to predict symptom control after insertion of a transjugular intrahepatic portosystemic shunt

Jonna Friederike Zimmermann[1], Martin Kabelitz[1], Sophia Geißelbrecht[1], Anja Tiede[1,2], Jim Benjamin Mauz[1], Simon Johannes Gairing[3,4], Christian Labenz[3,4], Heiner Wedemeyer[1,2,5], Matti Peperhove[6], Benjamin Maasoumy[1,2,5], Lisa Sandmann[1,2,5]. *[1]Department of Gastroenterology, Hepatology, Infectious Diseases and Endocrinology, Hannover Medical School, Hannover, Germany; [2]German Center for Infection Research (DZIF), Hannover/Braunschweig, Germany; [3]Department of Internal Medicine I, University Medical Center of the Johannes Gutenberg-University, Mainz, Germany; [4]Cirrhosis Center Mainz (CCM), University Medical Center of the Johannes Gutenberg-University, Mainz, Germany; [5]Excellence Cluster RESIST, Excellence Initiative Hannover Medical School, Hannover, Germany; [6]Department of Diagnostic and Interventional Radiology, Hannover Medical School, Hannover, Germany*
Email: zimmermann.jonna@mh-hannover.de

Background and aims: Both sarcopenia and frailty are associated with a reduced quality of life and an increased risk for decompensating events in patients with liver cirrhosis. As prevalence of frailty is high among patients with liver cirrhosis eligible for insertion of a transjugular intrahepatic portosystemic shunt (TIPS), the aim of this study was to investigate the impact of frailty pre-TIPS on symptom control post-TIPS.
Method: From 07/2019 to 04/2024, 220 consecutive patients who underwent TIPS insertion at Hannover Medical School were prospectively enrolled. Structured follow-up (FU) was performed one, three, six and 12 months after TIPS insertion, followed by annual visits. Frailty was assessed using the Liver Frailty Index (LFI) categorizing patients into “robust,” “pre-frail” and “frail.” Morbidity post-TIPS was evaluated by applying modified Baveno VII criteria at the respective FU visits with “first decompensation” (FiD) and “further decompensation” (FuD) defined according to the Baveno VII criteria, and modified early (mER) and sustained recompensation (mSR) as absence of decompensating events 3 and 12 months after TIPS, respectively, while maintaining HE prophylaxis and diuretics. Statistical analyses were performed using competing risk analysis (liver transplantation/death as competing events), chi-squared tests and logistic regression.
Results: A total of 87 patients qualified for final analysis after excluding cases with insufficient baseline data on LFI, hepatocellular carcinoma outside Milan, Budd-Chiari syndrome or absence of cirrhosis. Patients were predominantly male (60%) with a median MELD and Freiburg index of post-TIPS survival (FIPS) of 12 (IQR 9–15) and −0.12 (IQR −0.79–0,34), respectively. Before TIPS, 40% (35/87) of patients were classified as “frail,” 54% (47/87) as “pre-frail” and 6% (5/87) as “robust.” Proportions of patients achieving mER and mSR post-TIPS were comparable between frail and robust/pre-frail patients pre-TIPS (mER: p = 0.824; mSR: p = 0.882). In univariable competing risk analysis, frailty status pre-TIPS was neither associated with FiD (HR 0.94, 95%CI 0.53–1.66, p = 0.83) nor FuD (HR 0.97, 95% CI 0.46–2.03, p = 0.93) after TIPS. Additionally, no significant association between

frailty status and any decompensating event after TIPS was detected (HR 1.04, 95% CI 0.59–1.84, p = 0.89). In contrast, a higher FIPS pre-TIPS was associated with a higher incidence of FuD after TIPS (HR 1.50, 95% CI 1.04–2.17, p = 0.031) independent of frailty (aHR 1.52, CI 95% 1.04–2.21, p = 0.031).
Conclusion: Frailty diagnosed by LFI before TIPS was not associated with symptom control stratified according to Baveno VII criteria after TIPS.

Fibrosis – Stellate cell biology

TOP-053
The mechanisms of transcription factor ZEB2 in regulating hepatic stellate cell activation and liver fibrosis
Qianwen Zhao, Fajuan Rui[1], Jie Li[1]. [1]*Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, China*
Email: lijier@sina.com

Background and aims: The pathogenesis of liver fibrosis is highly complex, with the persistent activation of hepatic stellate cells (HSCs) being a critical driver of its initiation and progression. The transcription factor E-box binding zinc finger protein 2 (ZEB2) has been shown to regulate fibrosis in organs such as the kidney and lung. However, its specific regulatory mechanisms in liver fibrosis remain poorly understood. This study aims to elucidate the role of ZEB2 in HSC activation and its mechanisms in liver fibrosis.
Method: Human HSC line LX-2 cells were stimulated with transforming growth factor β (TGF-β), and ZEB2 protein expression was suppressed using Zeb2 siRNA to assess its regulatory effect on liver fibrosis. A mouse liver fibrosis model was established via bile duct ligation (BDL) and a choline-deficient amino acid (CDAA) diet. One week prior to fibrosis induction, mice were tail-vein injected with AAV6-shZeb2 driven by the Postn promoter to achieve HSC-specific knockdown of Zeb2. The impact of Zeb2 knockdown on liver fibrosis progression was evaluated. RNA-seq and ATAC-seq analyses were employed to identify ZEB2 target genes and further elucidate its molecular mechanisms.
Results: In vitro, TGF-β stimulation significantly upregulated both mRNA and protein levels of Zeb2 in LX-2 cells. Zeb2 knockdown markedly suppressed the expression of pro-fibrotic genes such as α-SMA, Postn, and Col1a1. In vivo, compared with control mice injected with AAV6-shControl (shc-BDL and shc-CDAA), HSC-specific Zeb2 knockdown in BDL (shZeb2-BDL) and CDAA (shZeb2-CDAA) mice resulted in significantly lower expression of pro-fibrotic genes and reduced serum levels of liver injury markers ALT and AST. Masson's trichrome and Sirius red staining confirmed decreased extracellular collagen deposition in shZeb2-BDL and shZeb2-CDAA mice. RNA-seq and ATAC-seq analyses revealed that ZEB2 enhances HSC activation by suppressing TGF-β receptor 3 (TGFBR3), thereby amplifying the responsiveness of TGFBR1 and TGFBR2 to TGF-β signaling.
Conclusion: Targeting ZEB2 in HSCs effectively prevents the onset and progression of liver fibrosis and alleviates liver injury in mice. Thus, ZEB2 may serve as a potential therapeutic target for liver fibrosis.

TOP-054
Single cell fixed RNA-seq revealed HSCLMCD1+LIMK2+ is a driver of liver fibrosis by modulating SMAD3-AKT-PRAS40-4EBP1
Pham Minh Duc[1], Le Thi Thanh Thuy[2], Hoang Hai[1], Nguyen Thi Ha[1], Hideki Fujii[1], Norifumi Kawada[1]. [1]*Department of Hepatology, Osaka Metropolitan University, Osaka, Japan;* [2]*Department of Global Education and Medical Sciences, Osaka Metropolitan University, Osaka, Japan*
Email: kawadanori@omu.ac.jp

Background and aims: Single-Cell Fixed RNA Profiling (FLEX) is an innovative technique that enables the analysis of RNA expression at single-cell resolution from frozen tissues. This study aimed to leverage FLEX technology to investigate human and experimental models of cirrhosis progression and regression, with the goal of identifying novel therapeutic targets for antifibrotic treatments.
Method: Thioacetamide (TAA) was administered intraperitoneally to mice at escalating doses ranging from 50 to 400 mg/kg over a 10-week period to induce liver fibrosis, while control mice received saline. Regression of liver fibrosis was assessed two weeks after TAA cessation. Frozen liver tissues from both mice and human samples were fixed, dissociated into single cells, and analyzed via single-cell RNA sequencing (scRNA-seq). Molecular analyses, including immunoblotting, immunohistochemistry, gene silencing, overexpression studies, and human phosphokinase arrays, were employed to validate findings.
Results: Using FLEX, approximately 40,000 liver cells were analyzed, providing high-resolution transcriptomic data and enabling classification into 10 major cell types. In cirrhotic livers, hepatocyte and LSECs populations were reduced by 30–50%, whereas hepatic stellate cells (HSCs) increased by 150% compared to healthy livers. Transcription factor analysis revealed that regressed HSCs exhibited reduced expression of SMAD3 and FOSL1, alongside increased expression of TP53, ETV4, SP1, SP3, GATA2, and GATA3. Notably, LIM-domain-related genes, including LIMA1, LIMK2, PDLIM2, PDLIM5, PDLIM7, FHL2, FHL3, and LMCD1, were significantly upregulated in cirrhotic HSCs from both mouse and human samples but were downregulated during fibrosis regression. Functional studies demonstrated that silencing LMCD1 or LIMK2 attenuated HSC activation, whereas overexpression of LMCD1 strongly enhanced HSC activation via the SMAD3-AKT-PRAS40-4EBP1 pathway. Specific inhibition using AZD8055 mitigated HSC activation, both spontaneously and under TGF-β stimulation, and significantly reduced the phosphorylation of 16/39 proteins implicated in HSC activation, including CREB, c-JUN, TP53, WNK1, GSK3B, STAT2/3, HSP27/60, and RSK1/2/3. Importantly, LMCD1 was prominently expressed in fibrotic regions of patients with metabolic-associated steatotic liver disease (MASLD) and colocalized with α-SMA and vimentin. Furthermore, LMCD1 expression strongly correlated with fibrosis severity, with an area under the receiver operating characteristic (AUROC) curve of 0.92 (95% CI: 0.76–1; p = 0.006) for predicting advanced fibrosis.
Conclusion: This study highlights previously unrecognized molecular and cellular dynamics of HSCs, identifying LMCD1 and LIMK2 as promising therapeutic targets for antifibrotic interventions.

Bortezomib improves advanced fibrosis by selectively inducing stellate cell apoptosis via downregulation of LGALS2 and CDH3 expression
Ling Wu[1,2], Yingjie Ai[1,2], Shiyao Chen[1,3], Detlef Schuppan[2,4], Feng Li[1,3]. [1]*Zhongshan Hospital, Fudan University, Shanghai, China;* [2]*Institute of Translational Immunology and Research Center for Immunotherapy, University Medical Center, Johannes Gutenberg University, Mainz, Germany, Mainz, Germany;* [3]*Minhang Hospital, Fudan University, Shanghai, China;* [4]*Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, United States*
Email: 20111210043@fudan.edu.cn

Background and aims: Bortezomib (B), a proteasome inhibitor, has been shown to attenuate fibrosis in organs other than the liver. We aimed to evaluate the efficacy of B in ameliorating advanced parenchymal and biliary liver fibrosis in rats and the potential underlying mechanisms.

Method: Advanced liver fibrosis was induced in rats by intraperitoneal injection of thioacetamide (TAA) for 12 weeks or bile duct ligation (BDL) for 3 weeks. Rats were then divided into 3 groups: intravenous injection of B at 0.1 mg/kg in PBS (BL), 0.15 mg/kg in PBS (BH) (defined and calculated from the literature) and PBS alone twice a week for 3 weeks each (fibrotic controls, FC). Age-matched untreated rats served as normal controls (NC). Portal venous pressure (HVPG) was measured before sacrifice. Potential toxicity of B was assessed by hepatic and renal function parameters, hepatic inflammation and fibrosis by HE and Masson's staining, liver collagen content via quantification of hydroxyproline, and fibrosis-related gene and protein expression by RT-qPCR and Western blot. Livers were subjected to NGS analysis and differentially expressed genes (DEGs) were analyzed as fold changes vs controls (greater than 1.5 fold and p-value <0.05). Target genes were enriched from genes that were equally regulated in rats with TAA-induced and BDL-induced fibrosis. Apoptosis was detected in vivo (TUNEL staining) and in vitro (flow cytometry).
Results: After B treatment, HVPG decreased, although p-values did not reach statistical significance in the two fibrosis models. B decreased ALT and AST in both fibrosis models, and serum creatinine and bilirubin levels remained unchanged, indicating a beneficial effect of B on liver function without apparent hepatic or renal toxicity. Liver collagen content and Masson's staining showed a significant reduction in fibrosis. DEG analysis showed that LGALS2 (Galectin-2) and CDH3 (p-Cadherin) were overlapping genes that were prominently upregulated in mice with advanced fibrosis but downregulated after B treatment at two different concentrations. TUNEL assay labeled more apoptotic cells in liver sections from B-treated groups in both models at the doses selected, with prominent signals in hepatic stellate cells, but not hepatocytes.
Conclusion: A narrow dose range of B induces apoptosis of activated HSC in vitro and in vivo through enhanced LGALS2 and CDH3 expression and has a prominent antifibrotic potential in parenchymal and biliary fibrosis.

THU-036-YI

Integrating spatial lipidomics with imaging mass cytometry: a novel approach for metabolic profiling of liver fibrosis

Aleksandra Gruevska[1], Elena Perpinan[2], Robert D. Goldin[1], Mark R. Thursz[1], Matthew Hoare[3], Niloufar Safinia[2], Joram Posma[1], Zoe Hall[1]. *[1]Department of Metabolism, Digestion and Reproduction, Imperial College London, London, United Kingdom; [2]Department of Inflammation Biology, Institute of Liver Studies, School of Immunology and Microbial Sciences, James Black Centre, King's College London, London, United Kingdom; [3]Early Cancer Institute, University of Cambridge, Cambridge, United Kingdom*
Email: zoe.hall@imperial.ac.uk

Background and aims: During steatotic liver disease (SLD), lipid deposition, inflammation, and fibrosis progress heterogeneously across the hepatic tissue, making whole tissue analyses an approximation. It is therefore crucial to employ approaches that retain spatial information to fully characterize the fibrotic niche. The aim of this study is to establish a link between key lipids and different cells within the fibrotic regions, with potential implications for novel therapeutics.
Method: We performed spatial lipidomics using mass spectrometry imaging (MSI) on human SLD-related cirrhotic tissue sections (n = 8). To establish a link between the dysregulated lipid metabolism with different cell types, we performed imaging mass cytometry (IMC) for highly multiplex localisation of 16 protein markers on a subset of adjacent tissue sections (n = 4). Individual IMC channels and MSI single ion images were then co-registered and spatial correlation between lipids and cellular markers was assessed using the Matthews Correlation Coefficient (MCC). MSI was also performed on tissue slices from MASLD patients across various fibrosis stages (F0-F2, n = 9). To test if manipulating lipid metabolism could serve as a potential anti-fibrotic strategy, we targeted sphingolipid metabolic pathways in stimulated LX-2 cells (immortalized hepatic stellate cells cell line; n = 5) and measured alpha-SMA protein expression by western blot.
Results: MSI analysis showed that lipid metabolism is dysregulated spatially, with sphingomyelin (SM)34:1 being one of the top increased lipids in the fibrotic regions. IMC analysis showed that 11 markers were significantly increased in fibrosis, whereas 2 were increased in parenchyma. Next, we co-registered MSI and IMC images and we found that SM(34:1) was highly correlated with alpha-SMA, vimentin and collagen (MCC >0.54). Similar to the cirrhotic samples, SM(34:1) was increased in fibrotic regions in MASLD tissue sections, showing that sphingolipid metabolism is altered in the early stages of LF, when the potential for reversibility is greater. *In vitro*, we inhibited sphingolipid metabolism pathways in activated HSCs, as these cells are key players in driving fibrogenesis. In TGF-beta activated LX-2 cells, inhibition of de novo synthesis of ceramides with myriocin and fumonisin B1 and inhibition of the ceramide salvage pathway with D-PDMP and miglustat, significantly decreased alpha-SMA protein levels.
Conclusion: Overall, this innovative spatial multi-omics approach suggests cell type-specific mechanisms of LF involving sphingolipid metabolic pathways. These results show that sphingolipid metabolic pathways are modifiable targets, which may have potential as an anti-fibrotic therapeutic strategy.

THU-037

Lycorine reduces liver fibrosis by inactivating hepatic stellate cells (HSCs) in mouse models of metabolic dysfunction-associated steatohepatitis (MASH)

Alma Diaz Ruiz de Zarate[1], Marlene Kohlhepp[1], Jana Hundertmark[1], Lukas Geisler[1], Joeri Lambrecht[1], Thomas Thum[2], Frank Tacke[1], Tobias Puengel[1]. *[1]Department of Hepatology & Gastroenterology, Charité - Universitätsmedizin Berlin, Campus Virchow-Klinikum and Campus Charité Mitte, Berlin, Germany, Berlin, Germany; [2]Institute of Molecular and Translational Therapeutic Strategies (IMTTS), IFB-Tx, Hannover Medical School, Hannover, Germany, Department of Cardiology and Angiology, Hannover Medical School, Hannover, Germany, National Heart and Lung Institute, Imperial College London, UK, Hannover, Germany*
Email: alma.de-zarate@charite.de

Background and aims: In the context of metabolic dysfunction-associated steatotic liver disease (MASLD), metabolic damage leads to the release of profibrogenic mediators that activate and transdifferentiate hepatic stellate cells (HSCs) into myofibroblasts, the primary source of extracellular matrix. The stage of liver fibrosis is a critical risk factor correlating with disease-associated morbidity and mortality in patients with metabolic dysfunction-associated steatohepatitis (MASH), making it a key target for pharmacological strategies in the treatment of MASH and liver fibrosis. We investigated the efficacy of the compound Lycorine and its derivative, both of which have demonstrated promising preclinical effects in myocardial fibrosis, for the treatment of MASH and liver fibrosis in a murine model.
Objectives: To evaluate the antifibrotic potential of Lycorine and its derivative in the treatment of MASH and liver fibrosis.
Method: The efficacy of Lycorine and its derivative was analyzed in five different models using male C57BL/6J wild-type mice. These included chronic toxic injury induced by CCl4 (6 weeks), advanced liver fibrosis induced by a choline-deficient high-fat diet (CDAHFD; 8 or 10 weeks), and mild liver fibrosis induced by a Western diet (WD; 8 weeks). In the fibrosis models (CCl4 and CDAHFD), short (2 weeks) and long (4 weeks) treatment intervals were evaluated. Additionally, the impact of Lycorine on HSC activation and metabolism was studied in vitro using primary murine cells.
Results: Lycorine inhibited the activation of primary murine HSCs in a dose-dependent manner in vitro. Therapeutic administration of Lycorine reduced inflammatory processes and improved

steatohepatitis and liver fibrosis in independent murine models (CCl4 and CDAHFD). The Lycorine derivative exhibited greater potency in promoting fibrosis regression, with antifibrotic effects of both compounds showing trends correlating with dose and treatment duration. In the model of mild fibrosis (WD), reduced liver damage was observed.
Conclusion: Lycorine directly inhibits the activation of matrix-producing HSCs, representing a novel and promising compound with anti-inflammatory and antifibrotic effects for the treatment of MASH and liver fibrosis.

THU-038
Patients with chronic liver disease present elevated plasma levels of peptidylprolyl isomerase C associated with the degree of fibrosis
Cristina Benavides[1,2], Isabel Fuster-Martínez[1,2], Ana Benedicto[1,2], Fernando Solano[1,3], Joan Tosca[4], Cristina Montón[4], Douglas Maya-Miles[5,6], Javier Ampuero[5,6,7,8], Manuel Romero-Gómez[5,6,7,8], Susana Rovira-Llopis[2,9], Victor M. Víctor[2,6,9], Juan V. Email: ana.blas@uv.es

Background and aims: Various members of the cyclophilin family have been associated with the pathogenesis of metabolic dysfunction-associated liver disease (MASLD), but there is scarce information on peptidylprolyl isomerase C (PPIC), whose gene expression has been increased in the liver of animal models and patients with chronic liver disease (CLD). We aimed to characterize the association between PPIC levels and the progression of CLD.
Method: PPIC expression was evaluated by Western Blot in in vitro liver injury models (LX2 cells and human primary hepatic stellate cells treated with 2.5 ng/μL TGF-β, 48 h; Hep3B cells with fatty acid overload, 48 h) and in vivo (livers of C57BL/6J mice treated with CCl_4). Plasma PPIC levels (pg/mL) were determined by ELISA in: 1) a cohort composed of healthy controls (N = 18) and patients with CLD of mixed origin (N = 46) from the Hospital Clínico Universitario of Valencia; 2) a cohort of 149 patients with MASLD from the Hospital Universitario Virgen del Rocío (Seville) and; 3) a cohort with healthy controls (N = 21) and patients with type II diabetes mellitus (N = 38) from the Hospital Dr. Peset-FISABIO (Valencia).
Results: PPIC protein expression was significantly increased in LX2 cells incubated with TGF-β and in liver tissue of CCl_4-treated mice, and showed an increasing trend in the other preclinical models. The determination of PPIC levels in plasma showed: 1) a general increase in patients with CLD of mixed etiology compared to controls (237.5 [202.2–279.2] vs 116.9 [100.7–133], $p \leq 0.0001$); 2) a positive correlation with age ($r = 0.22$, $p \leq 0.01$), indirect [FIB-4 ($r = 0.20$) and VCTE ($r = 0.21$), $p \leq 0.05$] and direct parameters [histological degree of liver fibrosis ($r = 0.22$, $p \leq 0.01$)] and glycemia ($r = 0.21$, $p \leq 0.05$), an inverse association with parameters related to cholesterol levels [total cholesterol ($r = -0.20$), HDL ($r = -19.3$), and LDL ($r = -0.21$), $p \leq 0.05$] and liver function [albumin ($r = -0.24$, $p \leq 0.05$)] in patients with MASLD, and an association with significant fibrosis (F0–F1 149.4 [129.9–168.8] vs F2–F4 196.4 [170.3–222.6], $p \leq 0.01$), which remained significant after correcting for the rest of the variables associated with fibrosis using logistic regression ($p \leq 0.05$); 3) elevated plasma levels of PPIC only in those diabetic patients with high FIB-4 (≥1.45) compared to controls (169.6 [136–203.2] vs 88 [59.6–116.3], $p \leq 0.01$).
Conclusion: PPIC levels in liver and plasma of patients increase in CLD, regardless of its etiology. The increase in plasma PPIC correlates positively with the degree of fibrosis and FIB-4. These results suggest that PPIC could be a therapeutic target for the treatment of liver fibrosis and a marker of the progression of CLD, although more data are needed to clarify the role of this cyclophilin in liver disease.

THU-039
Sex differences in aging rates and superoxide dismutase activity in patients with metabolic dysfunction-associated steatotic liver disease: implications for fibrosis risk
Olena Kolesnikova[1], Anastasiia Radchenko[1], Olga Zaprovalna[1], Vilena Chupina[2]. *[1]L.T.Malaya Therapy National Institute of the National Academy of Medical Sciences of Ukraine, Kharkiv, Ukraine; [2]Kharkiv National Medical University, Kharkiv, Ukraine*
Email: anastasha.radchenko@gmail.com

Background and aims: Gender differences, among other factors, determine the specifics of the course of metabolic dysfunction-associated steatotic liver disease (MASLD), but differences in aging rates (ARs) remain underexplored. Oxidative stress is a key pathogenic mechanism both in aging and steatohepatitis development. Superoxide dismutase (SOD) is the primary antioxidant enzyme, with its activity potentially influenced by gender. This study aimed to evaluate sex-related differences in ARs and SOD activity in patients with MASLD, with a focus on fibrosis risk (FR).
Method: The study included 52 men (53.1 [44.7; 59.5] years) and 48 women (54.5 [47.9; 59.5] years) with MASLD, divided into age-matched subgroups based on FR (FIB-4): low (<1.3) (men 71%, women 58%) and moderate (1.3–2.67). A control group of young adults (n = 24, 25.2 [23.7; 28.5] years) was similarly matched by sex. Phenotypic age (PA) and AR were evaluated using the method by M. Levine et al. (2018), total SOD activity was determined via colorimetric analysis.
Results: Patients with MASLD demonstrated differences in PA, body mass index, WHR, ALT, glycosylated hemoglobin, HOMA-IR, total cholesterol, triglycerides, low-density lipoprotein cholesterol, UA, glomerular filtration rate (GFR), albumin, C-reactive protein, FIB-4, and SOD levels ($p < 0.05$) across both sexes compared to controls. Notable differences ($p < 0.05$) also included in men elevated AST, ALT/ALP, and AST to platelet ratio index (ARPI) ($p = 0.020$); and in women variations in body fat percentage (FAT), muscle percentage (MUS), and ALP. ARs in MASLD patients correlated with visceral fat levels in both men ($p = 0.037$) and women ($p = 0.036$). Within the subgroups categorized by FIB-4, men exhibited lower FAT ($p < 0.001$) but higher ALT/ALP and ARPI levels ($p < 0.05$) compared to women. Men with low FR also showed higher MUS ($p = 0.0001$), GFR ($p = 0.008$), lower HOMA-IR ($p = 0.003$), but higher WHR ($p = 0.0001$), ALT ($p = 0.049$), indirect bilirubin ($p = 0.007$), UA ($p = 0.008$), gamma-glutamyl transferase ($p = 0.003$), and SOD ($p = 0.047$), along with lower HDL-C levels ($p = 0.012$). In the moderate FR subgroup, additional differences were only noted in total protein levels ($p = 0.028$). Importantly, men with moderate FR had significantly higher ARs than women ($p = 0.043$).
Conclusion: Men with MASLD and moderate FR exhibit accelerated aging compared to women, potentially due to cardiometabolic differences that emerge even at low FR. To prevent premature aging and MASLD progression in men, it is essential to address abdominal obesity, HDL-C levels, and liver dysfunction. In women, monitoring for postmenopausal insulin resistance and renal filtration impairment is critical. Increased antioxidant defense via SOD likely acts as a compensatory mechanism in men with low FR.

THU-040

Efficacy of CRV431 and Semaglutide on liver fibrosis in a mouse model of MASH

Asha Goodman[1]. [1]*The Scripps Research Institute, San Diego, United States*
Email: asham@scripps.edu

Background and aims: Metabolic dysfunction-associated steatohepatitis (MASH) is a severe form of metabolic dysfunction-associated steatotic liver disease (MASLD), characterized by hepatic inflammation and fibrosis that can progress to cirrhosis and liver failure. CRV431, a cyclophilin inhibitor, has demonstrated antifibrotic effects in previous studies, while semaglutide, a GLP-1 receptor agonist, has shown potential therapeutic benefits in metabolic disorders. This study aimed to evaluate the efficacy of CRV431, semaglutide, and their combination on hepatic fibrosis in a MASH mouse model.
Method: Male mice were divided into several treatment groups: healthy controls at baseline (n = 4), MASH model at baseline (n = 4), MASH model treated with vehicle for five weeks (n = 2), MASH model treated with CRV431 for five weeks (n = 2), MASH model treated with semaglutide for five weeks (n = 4), MASH model treated with both CRV431 and semaglutide for five weeks (n = 4), and healthy controls after five weeks (n = 4). Liver fibrosis was quantified by measuring the fibrosis percentage area from histological sections. One-way ANOVA was performed to compare group means, followed by post-hoc tests using the Benjamini, Krieger, and Yekutieli procedure to control the false discovery rate. Statistical significance was set at $P < 0.05$.
Results: A significant difference among group means was observed ($F(6,17) = 2.728$, $P = 0.0482$, $R^2 = 0.4905$). The mean fibrosis percentage areas were: healthy controls at baseline, 12.31% ± 4.49%; MASH model at baseline, 16.00% ± 4.49%; vehicle-treated MASH model after five weeks, 16.00% ± 6.50%; CRV431-treated MASH model after five weeks, 10.83% ± 6.50%; semaglutide-treated MASH model after five weeks, 17.55% ± 4.49%; combination-treated MASH model after five weeks, 18.17% ± 4.49%; and healthy controls after five weeks, 12.31% ± 4.49%. CRV431 treatment resulted in the lowest mean fibrosis area among the treatment groups. Compared to the vehicle-treated group, CRV431-treated mice showed a reduced fibrosis area (mean difference: 5.17%, $t = 1.627$, $P = 0.1221$). Although this difference did not reach statistical significance, CRV431 demonstrated the greatest impact on reducing hepatic fibrosis. Semaglutide did not significantly reduce fibrosis compared to the vehicle-treated group (mean difference: 1.55%, $t = 0.565$, $P = 0.5796$).
Conclusion: CRV431 showed the most substantial reduction in hepatic fibrosis among the treatments tested, aligning with historical observations of its antifibrotic efficacy in liver disease models. The absence of a synergistic effect and the higher fibrosis levels in the combination-treated group suggest possible antagonistic interactions between CRV431 and semaglutide, potentially diminishing the therapeutic benefits of CRV431 when used concurrently with semaglutide.

Investigating the role of Fn14 in metabolic associated steatohepatitis: effects on fibrosis, inflammation, and proliferation in a mouse model

Anouk Oldenburger[1], Henning Hvid[2], Elisabeth Galsgaard[3], Matilde Smærup Leth[3], Anna-Marie Finger[4], Helene Lykkegaard[4], Nicole Spiegelman[5], Bina Albuquerque[5], Morten Fog-Tonnesen[6]. [1]*Obesity & Liver Biology, Novo Nordisk, Måløv, Denmark;* [2]*Pathology & Imaging, Novo Nordisk, Måløv, Denmark;* [3]*Global Translation, Novo Nordisk, Måløv, Denmark;* [4]*Liver Biology, Novo Nordisk, Måløv, Denmark;* [5]*RNA Pharmacology, Novo Nordisk, Cambridge, Massachusetts, United States;* [6]*Liver Biology, Novo Nordisk, Måløv, Denmark*
Email: auog@novonordisk.com

Background and aims: Metabolic associated steatohepatitis (MASH) is a fatty liver disease with inflammation and fibrosis. Improved understanding of the underlying disease mechanisms is needed for development of new treatments. Elevated fibroblast growth factor-inducible 14 (Fn14) levels are seen in advanced fibrosis stages. Fn14, expressed in stellate cells, hepatocytes, and cholangiocytes, is a receptor for TNF-like weak inducer of apoptosis (TWEAK). It is involved in hepatocyte proliferation, regeneration, pro-inflammatory cytokine expression, and fibrosis. Additionally, soluble Fn14, generated via proteolytic cleavage in the blood, plays a role in inflammatory responses. We hypothesized that knockdown of Fn14 in hepatocytes with an investigational Fn14 siRNA would have an improved effect on MASH and fibrosis.
Method: Male wildtype mice were fed either a chow diet (Altromin 1324) or a choline-deficient high-fat diet (CDHFD) (Research Diets, A06071302) for 4 weeks. CDHFD-fed mice then received either a vehicle or GalNAc conjugated siRNA targeting Fn14 (GalXC-Fn14) (weekly at 0.1 mg/kg or 5 mg/kg) for 8 more weeks (n = 16). Body weight was monitored throughout. Terminal plasma (ALT, AST) and liver samples were collected. MASH-related parameters were assessed via histology (HE, CD45, Ki67, αSMA, PSR staining) or bulk liver mRNA sequencing.
Results: GalXC-Fn14 treatment led to a dose-dependent reduction of Fn14 expression in liver and plasma. High dose treatment showed 58% and 72% inhibition after one week, with further reductions over time. Fn14 reduction was hepatocyte-specific, with corresponding decreases in soluble Fn14. ALT and AST levels induced by CDHFD were unaffected. GalXC-Fn14 reduces Pro collagen III in plasma and a trend to a decrease in COL3A mRNA at the low dose, though no effect on hepatic collagen was observed via PSR staining. High dose GalXC-Fn14 induced Growth differentiation factor 15 (GDF15) expression, involved in various biological processes, including inflammation. While high dose GalXC-Fn14 reduced steatosis, it increased inflammation. Bulk liver sequencing revealed limited gene changes with Fn14 GalXC, increasing inflammation (e.g., Trim12c and Timd2) and reducing proliferation (e.g., Ptprt and Usp21).
Conclusion: Fn14 is critically involved in MASH, indicated by elevated Fn14 levels in liver and plasma of MASH patients. However, knockdown of Fn14 in hepatocytes had minimal effect on fibrosis, but reduced steatosis, exacerbated inflammation and reduced proliferation. This could indicate absence of Fn14 disrupts regenerative processes, potentially enhancing inflammation. The mechanism behind the apparent beneficial effect of reduced steatosis in the CDAHFD mouse model is unknown. Balancing the favorable effects on steatosis against adverse impacts on proliferation and inflammation complicates therapeutic use of Fn14 reduction in MASH patients. Further research is essential to fully understand Fn14's role in proliferation and inflammation in MASH.

THU-042

Targeting metabolic dysfunction-associated steatohepatitis with microRNA therapeutics

Nicolina Sciaraffa[1], Annapaola Carreca[1], Claudia Coronnello[1], Annalisa Martorana[1], Gioacchin Iannolo[2], Stefania Bruno[3], Simone Scilabra[1], Massimo Pinzani[2], Pier Giulio Conaldi[2], Cinzia Chinnici[1]. [1]*Ri.MED Foundation, Palermo, Italy;* [2]*IRCCS ISMETT, Palermo, Italy;* [3]*University of Torino, Torino, Italy*
Email: cchinnici@fondazionerimed.com

Background and aims: Metabolic dysfunction-associated steatohepatitis (MASH) is a severe form of fatty liver characterized by chronic liver inflammation, hepatocyte injury, and mild to moderate fibrosis. If left untreated, MASH can progress to advanced fibrosis, cirrhosis, and hepatocellular carcinoma (HCC). MicroRNAs (miRNAs) have gained attention as promising multitarget therapeutics due to their ability to regulate multiple genes simultaneously, making them ideal candidates for treating complex diseases like MASH. This study aimed to identify miRNAs with therapeutic potential for MASH.
Method: Fibrosis was modeled using the human hepatic stellate cell line LX-2, activated with TGFbeta-1. Proteomic analysis of secretome

and cellular extracts using liquid chromatography-tandem mass spectrometry (LC-MS/MS) identified significantly upregulated "pro-fibrotic" proteins, which were inferred to predict miRNA-target interactions using two tools: the MicroRNA ENrichment TURned NETwork (experimentally validated interactions) and our miRNA Binding Site prediction database (integrating PITA, miRanda, and TargetScan algorithms). To validate these interactions, LX-2 cells were transfected with miRNA mimics, followed by activation with a combination of TGFbeta-1 and L-ascorbic acid, the latter a cofactor of prolyl 4-hydroxylase enzymes. Finally, gene silencing was conducted using small interfering RNA (siRNA) to corroborate the role of specific genes in the fibrotic process. The effects of miRNA mimics and gene silencing on target proteins and fibrosis-related markers were assessed by Western blot.

Results: Among the upregulated proteins found in activated LX-2 cells, the prolyl 4-hydroxylase subunit alpha 2 (*P4HA2*) gene was selected as a key therapeutic target due to its role in collagen fiber stabilization and its dysregulation in fibrotic conditions, such as biliary and pulmonary fibrosis. Target prediction analysis identified miR-9-5p, miR-30a-5p, miR-4640-5p, miR-4726-5p and miR-128-1-5p as potential regulators of *P4HA2*. Among these, only miR-9-5p significantly inhibited P4HA2 protein expression. Additionally, miR-9-5p downregulated TGFbeta-1i protein and maintained LX-2 cells in an inactivated state by preventing the upregulation of fibrosis markers such as COL1A1, FN1, and alpha-SMA, while reducing collagen secretion. Similarly, silencing *P4HA2* mitigated the expression of fibrosis markers, underscoring its role in fibrogenesis.

Conclusion: miR-9-5p mimic therapy shows promise in countering hepatic stellate cell activation in MASH by targeting *P4HA2* and *TGFbeta-1i* genes. Alternatively, silencing the *P4HA2* gene may represent a viable therapeutic approach with a lower risk of off-target effects. Ongoing experiments are focused on optimizing miRNA mimic delivery via nanoparticles for targeted liver therapy.

Nuclear factor I-B delays liver fibrosis by inhibiting chemokine ligand 5 transcription

Qianqian Chen[1], Zhiwen Fan[1], Nan Geng[1], Fajuan Rui[1], Wenjing Ni[1], Yue Huan[2], Junping Shi[3], Chao Wu[1], Shengxia Yin[1], Qianwen Zhao, Jie Li[4]. *[1]Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, China; [2]Jiangsu Key Laboratory of Oral Diseases, Jiangsu Province Engineering Research Center of Stomatological Translational Medicine, Department of General Dentistry Affiliated Hospital of Stomatology, Nanjing Medical University, Nanjing, China; [3]the Affiliated Hospital & Institute of Hepatology and Metabolic Disease, Hangzhou Normal University, HangZhou, China; [4]Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjingch, China*
Email: lijier@sina.com

Background and aims: Liver fibrosis is a vital pathophysiological process in various liver-related diseases, with hepatic stellate cells (HSCs) activation being crucial in its development. Reduced expression of nuclear factor I-B (NFIB) has been observed in patients with cirrhosis and liver fibrosis of mice models. This study aims to investigate whether restoring NFIB expression can alleviate liver fibrosis in mice and elucidate its potential mechanism.

Method: NFIB expression in HSCs was assessed in tissues from cirrhotic patients and liver fibrosis of mice models, by feeding a choline-deficient l-amino acid defined diet (CDAA) and carbon tetrachloride (CCl4) injection. The transcriptome was analyzed using RNA-sequencing. ChIP and luciferase reporter experiments were used to identify the potential target of NFIB during liver fibrosis.

Results: Our study demonstrates that NFIB expression is down-regulated at both the transcriptional and protein levels in human and mouse tissues. Overexpression of NFIB in HSCs inhibited the progression of CDAA and CCl4-induced liver fibrosis. Furthermore, NFIB overexpression in HSCs reduced activation of HSCs, decreased oxidative stress, and attenuated cell inflammation. RNA-seq analysis identified CCL5 as a key target of NFIB-induced changes in HSCs. During liver fibrosis, NFIB bound to the CCL5 promoter and suppressed CCL5 expression. Further analysis showed that the transcriptional inhibitory effect of NFIB on CCL5 was dependent on IRF3.

Conclusion: Our findings elucidate the mechanism of NFIB, and suggest that targeting the NFIB-IRF3-CCL5 axis could be a promising strategy for treating liver fibrosis.

THU-044

CCN5 promotes fibrogenic activation of hepatic stellate cells and serves as a biomarker for liver fibrosis

Yunhao Duan[1], Fan Ding[2], Xiaoli Chen[1], Wenrun Wu[1], Ji Fang[1], Jinjiang Pi[1], Jinnan Yue[1], Yuting Zhang[1], Hongda Li[1], Carolin V. Schneider, Kai Markus Schneider, Bin Zhou[3], Shougang Zhuang[4], Qi Zhang[1], Frank Tacke[5], Christian Trautwein[6], Lin Zhang[1], Jie Liu[1], Gang Zhao[2], Yuzhen Zhang[1]. *[1]State Key Laboratory of Cardiovascular Diseases and Medical Innovation Center, Research Center for Translational Medicine, Shanghai Heart Failure Research Center, Shanghai East Hospital, Tongji University School of Medicine, Shanghai, 200120, China, Shanghai, China; [2]Center of Gallstone Disease, Shanghai East Hospital, Tongji University School of Medicine, Institution of Gallstone Disease, Shanghai, 200120, China, Shanghai, China; [3]New Cornerstone Science Laboratory, Key Laboratory of Multi-Cell Systems, Shanghai Institute of Biochemistry and Cell Biology, Center for Excellence in Molecular Cell Science, Chinese Academy of Sciences, University of Chinese Academy of Science, Shanghai, China; [4]Department of Nephrology, Shanghai East Hospital, Tongji University School of Medicine, Shanghai, 200120, China, Shanghai, China; [5]Department of Hepatology and Gastroenterology, Charité-Universitätsmedizin Berlin, Augustenburger Platz 1, D-13353 Berlin, Germany, Berlin, Germany; [6]Leibniz Research Centre for Working Environment and Human Factors (IfADo), Ardeystr. 67, D-44139 Dortmund, Germany, Dortmund, Germany*
Email: zhao_gang7@126.com

Background and aims: Matricellular protein Cellular Communication Network Factor 5 (CCN5) has been implicated in organ fibrosis. This study aimed to investigate the relevance of CCN5 in hepatic stellate cell (HSC) activation crucial for liver fibrogenesis and to evaluate plasma CCN5 as liver fibrosis biomarker.

Method: CCN5 expression in liver and plasma was analyzed bioinformatically from public databases for association with liver fibrosis. Fibroblast-specific *Ccn5* loss- and gain-of-function mice were generated to evaluate the implications of Ccn5 on liver fibrogenesis, and mass spectrometry was conducted to identify CCN5 interacting proteins. Finally, human fibrotic liver and plasma samples were collected to validate CCN5 as the biomarker for liver fibrosis.

Results: CCN5 expression was nearly undetectable in quiescent HSCs but significantly increased in activated HSCs of CCl_4-induced mouse and human fibrotic livers of various etiology. Fibroblast-specific-*Ccn5* deletion mice exhibited reduced myofibroblast formation and ECM production hence inhibited liver fibrogenesis, while fibroblast-*Ccn5* overexpression promoted fibrosis progression. Mechanistically, CCN5 facilitated MOESIN phosphorylation and activated the downstream MRTF-A/SRF pathway, which promoted HSC activation triggering liver fibrosis progression. As a secreted protein, CCN5 plasma level was associated with liver diseases in the UKB population and our cohort demonstrated high diagnosis performance of plasma·CCN5 level for mild liver fibrosis that was superior to the classical tests. Finally, plasma CCN5 level exhibited a strong correlation with the degree of liver fibrosis, and its coefficient value was superior to FIB-4 index, PRO-C3 and MELD score.

Conclusion: CCN5 activates the MOESIN/MRTF-A/SRF pathway in HSCs promoting liver fibrosis progression and plasma CCN5 level is a novel biomarker for early detection and severity assessment of

fibrosis, providing an accurate non-invasive tool to monitor therapeutic outcome.

THU-045

Neo-epitope biomarkers for fibrogenesis and neutrophil activity predict liver-related events in advanced chronic hepatitis C infection

Emilie Skovgaard[1], Thomas Wiggers[1], Morten Karsdal[1], Diana Julie Leeming[1], Keyur Patel[2]. [1]*Nordic Bioscience, Herlev, Denmark;* [2]*University Health Network, Toronto, Canada*
Email: esk@nordicbio.com

Background and aims: Patients with untreated chronic hepatitis C (CHC) infection are at increased risk of developing a liver-related event. Despite the availability of simplified direct-acting antiviral therapy, the prevalence of CHC remains unchanged in many industrialized countries. Biomarkers that can predict which chronic liver disease patients with inflammatory injury are at greatest risk of developing a clinical outcome are required. In a well-characterized study population from The Hepatitis C Antiviral Long-Term Treatment Against Cirrhosis Trial (HALT-C) (ClinicalTrials.gov #NCT00006164), we investigated the incidence of liver-related outcomes in patients with hepatitis C virus (HCV) who were non-responders to prior interferon-based standard-of-care with either high or low active fibrogenesis, measured by PRO-C3, in combination with high or low neutrophil activity, measured by CPa9-HNE.
Method: In this study population, we measured serum concentrations of the fibrogenesis marker, nordicPRO-C3™ measuring type III collagen formation, and the neutrophil activity marker measuring human neutrophil elastase cleaved calprotectin, nordicCPa9-HNE™. The event-free survival probability over 1511 days was investigated between four groups with combination of high and low PRO-C3 (high >27.8 ng/mL > low) and CPa9-HNE (high >1850.5 ng/mL > low): 1) low PRO-C3 and low CPa9-HNE, 2) low PRO-C3 and high CPa9-HNE, 3) high PRO-C3 and high CPa9-HNE, 4) high PRO-C3 and low CPa9-HNE. The Cox proportional hazards model was used to evaluate differences between the event-free survival curves. Data provided by NIDDK CR, a program of the National Institute of Diabetes and Digestive and Kidney Diseases.
Results: Our study population included 339 CHC patients (62% with F3-F4) with a median age of 50 years (47–55), BMI of 29.4 (26.6–32.6), and 65% male. Eighty-nine patients (26%) had a liver-related event (related to decompensation and hepatocellular carcinoma). Patients were divided into four groups based on whether their baseline levels of PRO-C3 and CPa9-HNE were high or low. Among these groups, patients with high PRO-C3 and low CPa9-HNE had the lowest event-free survival rate, with 46.9% (95% CI: 30.4–63.5) remaining event-free after 1511 days. In contrast, patients with low PRO-C3 and high CPa9-HNE had the highest event-free survival rate, with 87.9% (95% CI: 73.5–100) remaining event-free after 1511 days. The difference in survival probability between these two groups was statistically significant ($p = 0.003$).
Conclusion: CHC patients with advanced fibrosis stage, high active fibrogenesis, and low neutrophil activity have a higher risk of developing liver-related events compared to low active fibrogenesis and high neutrophil activity baseline levels. These findings should be validated in other chronic liver diseases with pro-inflammatory activity to identify patients at higher risk of disease progression.

THU-046

Engineering liver fibrosis in a three-dimensional, extracellular matrix-hydrogel, ex-vivo disease model

Frederik Højberg Svejsø[1,2], Diana Julie Leeming[1], Morten Karsdal[1], Thomas Hartvig Lindkær Jensen[2,3], Christian Beltoft Brøchner[3], Alejandro Mayorca Guiliani[1]. [1]*Nordic Bioscience A/S, Herlev, Denmark;* [2]*Biotech Research and Innovation Centre, University of Copenhagen, Copenhagen, Denmark;* [3]*Department of Pathology, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark*
Email: frsv@nordicbio.com

Background and aims: The US Food and Drug Administration (FDA) has proposed to reduce reliance on animal models in drug development and promote preclinical models yielding physiologically relevant results. Modeling fibrosis requires replicating the mechano-chemical cues of the extracellular matrix (ECM), including binding sites, three-dimensionality and biomechanics. Here, we present a liver fibrosis model based on native, decellularized ECM with spatial and compositional integrity layered on a hydrogel of polyethylene glycol diacrylate (PEGDA) that provides tunable mechanical properties.
Method: Human liver from consenting donors and porcine liver was sliced at 250 µm thickness, decellularized to retain 3D ECM architecture, and adhered to a PEGDA hydrogel contained in a 48-well plate. PEGDA concentration was modulated to model healthy (~1–5 kPa) or fibrotic (~20–30 kPa) liver stiffness. Primary human hepatic stellate cells (HSCs) repopulated ECM-PEGDA constructs, cultured with medium enriched with transforming growth factor beta 1 (TGF-B1), tumor necrosis factor alpha (TNF-a), chemokine ligand 2 (CCL2), thymic stromal lymphopoietin (TSLP), and interleukin (IL)-1b, IL-4, IL-8, IL-13, and IL-33. In this proof-of-concept study, ECM formation was evaluated with fibrogenesis biomarkers nordicPRO-C1, nordicPRO-C3, and nordicPRO-C6, surrogates of collagens type I, III, and VI synthesis, respectively. The constructs were imaged with two-photon and confocal microscopy.
Results: At 7.5% PEGDA, mimicking healthy tissue, average levels of nordicPRO-C1, nordicPRO-C3, and nordicPRO-C6 on day 8 were measured at 255.87 ± 26.62 ng/mL, 13.73 ± 2.44 ng/mL, and 3.12 ± 0.51 ng/mL, respectively. By comparison, constructs with higher stiffness (15% PEGDA) demonstrated lower average concentrations of these markers on day 8, with values of 187.01 ± 88.29 ng/mL, 9.84 ± 4.64 ng/mL, and 2.65 ± 2.14 ng/mL, respectively. Over a 12-day stimulation period, nordicPRO-C3 levels increased gradually, with average concentrations of 10.55 ± 4.08 ng/mL, 13.73 ± 2.44 ng/mL, and 17.97 ± 4.35 ng/mL measured on days 4, 8, and 12, respectively. HSCs selectively colonize the ECM, with nuclei structure following interstitial matrix anatomy. Fluorescent labelling revealed alpha-smooth muscle actin (aSMA+) cytoskeleton in HSCs, suggesting HSC activation.
Conclusion: HSCs colonize human and porcine ECM and synthesize new ECM. Biochemical signaling induces ECM formation, while biomechanical properties regulate biomarker production, jointly simulating the fibrotic niche. Porcine ECM is anatomically similar to human ECM, readily available, and enables high-throughput modeling with no animals being sacrificed for model fabrication.

THU-047-YI

Inhibition of Adipocyte triglyceride lipase (ATGL) reduces fibrosis and portal hypertension in murine CCl4 liver fibrosis

Henriette Horstmeier[1], Katharina Bonitz[2,3], Tanmoy Chakma[1], Vlad Taru[2], Thomas Sorz-Nechay[2,3], Nikolaus Michalitsch[2], Robert Brettner[1], Claudia Fuchs[1], Thomas Reiberger, Philipp Schwabl[1,2,3], Michael Trauner. [1]*Hans Popper Laboratory of Molecular Hepatology, Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria;* [2]*Christian Doppler Lab for Portal Hypertension and Liver Fibrosis, Medical University of Vienna, Vienna, Austria;* [3]*Center for Molecular Medicine (CeMM) of the Austrian Academy of Sciences, Vienna, Austria*
Email: henriette.horstmeier@meduniwien.ac.at

Background and aims: Immune cells orchestrate hepatic inflammation and fibrogenesis. Importantly, their intrinsic lipid metabolism is among their key phenotypic determinants in addition to the critical impact of lipotoxicity on hepatocellular injury. We investigated the role of lipolysis in liver fibrosis by studying adipocyte triglyceride lipase (ATGL) that cleaves triacyl glycerides stored in lipid droplets.

Hepatic ATGL deficiency promotes lipid accumulation but in turn, prevents lipotoxicity originating from lipolysis-derived intrahepatic free fatty acids (FFAs). Thus, targeting lipolysis via ATGL may represent a novel therapeutic approach in fibrosis.
Method: Liver fibrosis was induced in male C57BL/6 mice by administration of carbon tetrachloride (CCl_4; 3×/week, 2 ml/kg, oral gavage) for 8 weeks, while healthy control groups received olive oil (OO). Healthy and diseased mice were treated with an ATGL inhibitor (Atglistatin, 2 mmol/kg), via oral gavage (2×/day for 4 weeks; 200 µmol/kg, n = 10), and diet supplementation (2 mmol/kg chow diet for 8 weeks, n = 10), whereas the respective control groups (n = 10 each) received olive oil as vehicle control under pair-fed conditions. Hepatic collagen proportionate area (CPA) was assessed histologically and portal pressure measured invasively, while fibrogenic and inflammatory gene expression were quantified by qPCR and bulk tissue RNA sequencing. Hepatic immune cells were profiled using flow cytometry.
Results: ATGL-inhibition strongly improved features of liver fibrosis (CPA: 5,07 ± 1,16 vs. 3,09 ± 1,28%; p < 0,0002) and portal hypertension (7,94 ± 0,97 vs. 6,87 ± 0,62 mmHg; p = 0,004). This was accompanied by markedly reduced profibrogenic (*Col1a1, Acta2, Tgfb1, Timp1*) gene expression. Intrahepatic lipid accumulation was confirmed by histology supporting sufficient hepatic ATGL inhibition by Atglistatin. Moreover, Atglistatin remarkably increased liver to body weight ratio (4,915 ± 0,48 vs. 5,97 ± 0,49%) and induced a proinflammatory transcriptional signature (*Mcp1)*, suggesting inflammatory hepatic immune cell infiltration. In liver flow cytometry, this was predominantly reflected by a strongly increased abundance of $CD3^+$ T-cells - further identified as $CD8^+$ T-cells (14,32 ± 3,29% vs. 6,76 ± 1,58 of the $CD45^+$ population). The role of hepatic $CD8^+$ T-cells, promoted by Atglistatin treatment, will be functionally dissected *in vitro*.
Conclusion: Our data shows a protective role for Atglistatin in a model of toxic liver fibrosis. The underlying potential mechanism is a profound alteration of the liver immune cell niche and points towards a novel role for ATGL-driven lipolysis in T cell biology during fibrosis. Ongoing transcriptome sequencing and cytokine profiling will allow deciphering of our findings on lipase-mediated immunoregulation in liver fibrosis.

THU-048

Cell-type specific roles of TGF-β2 signaling in cholestatic liver disease progression and therapeutic targeting

Ida Harst[1], Seddik Hammad[2], Chenhao Tong[3], Jan Albin[4], Carolina De La Torre[5], Maria Reich[6], Verena Keitel-Anselmino[7], Thomas Weiss[8], Christoph Schramm[9], Trine Folseraas[10], Matthias Ebert[11], Steven Dooley[12], Nadia Meindl Beinker[13], Anne Dropmann[1]. *[1]2.Med. Email: anne.dropmann@medma.uni-heidelberg.de

Background and aims: In both healthy and diseased livers, TGF-β2 is predominantly expressed in cholangiocytes and proliferating bile ducts, with its expression upregulated in response to tissue damage and inflammation. However, the role of TGF-β2 and its downstream signaling pathways in the progression of liver disease remains poorly understood. This study investigates the expression dynamics of TGF-β2, identifies target cells, and analyzes signaling outcomes with cell-specific resolution in patients with primary sclerosing cholangitis (PSC) and cholangiocarcinoma (CCA).
Method: Liver tissues from PSC and CCA patients were analyzed through hematoxylin and eosin (HE) staining and immunohistochemistry (IHC). The localization of TGF-β2 and its receptor, TGFβR3, was determined using RNAscope. In silico analysis of three databases was conducted to identify upstream regulators of TGF-β2 expression, including transcription factors, cytokines, bile acids, and stressors, which were experimentally validated in the human cholangiocyte cell line MMNK1 at both mRNA and protein levels. Pharmacological inhibitors were used to target specific signaling pathways. Bulk RNA sequencing was performed on MMNK1 cells after TGF-β2 treatment at various time points.
Results: In PSC and CCA patients, TGFβR3 was primarily localized in non-parenchymal cells such as activated myofibroblasts and CD31-positive cells within periportal regions, as shown by co-staining analysis. In contrast, TGF-β2 was mainly expressed in cholangiocytes. Bioinformatic analysis of the TGF-β2 promoter revealed several candidate transcription factors, including CREB1, involved in its induction. Bile acids, such as lithocholic acid (LCA), and combinations of ursodeoxycholic acid (UCDA), chenodeoxycholic acid (CDA), and deoxycholic acid (DCA), induced TGF-β2 expression in cholangiocytes. Cellular stressors, such as hydrogen peroxide (H_2O_2), also upregulated TGF-β2 in MMNK1 cells. Inhibition of the farnesoid X receptor (FXR) with GW4064 attenuated TGF-β2 expression induced by LCA or H_2O_2 in MMNK1 cells. Furthermore, TGF-β2 stimulation in MMNK1 cells deregulated extracellular matrix (ECM) components, induced Smad3 phosphorylation, and modulated TGF-β signaling pathways. Spatial transcriptomics in PSC liver tissues further elucidated TGF-β2 signaling activation, providing insights into its role in disease progression.
Conclusion: This study offers a detailed cell type-specific analysis of TGF-β2 and TGFβR3 expression in PSC and CCA tissues. It identifies potential regulatory mechanisms and therapeutic targets to mitigate TGF-β2-driven disease progression, highlighting the inhibition of TGF-β2 expression as a promising strategy for therapeutic intervention.

Extracellular vesicle-dependent crosstalk between hepatic stellate cells and Kupffer cells promotes their mutual activation

Junyu Wang[1], Jia Li[1], Manon Buist-Homan[1], Martin Harmsen[1], Han Moshage[1]. *[1]University Medical Center Groningen, Groningen, Netherlands*
Email: j.wang03@umcg.nl

Background and aims: Hepatic fibrosis is characterized by activation of hepatic stellate cells (HSCs), resulting in excessive extracellular matrix (ECM) deposition by these cells. Chronic inflammation is the key driver of HSC activation in the liver. Kupffer cells (KCs), the liver-specific macrophages, play an important role in HSC activation. Although KCs can trigger HSC activation, this regulation is not exclusively one-way. Our study aims to explore the reciprocal interaction between HSCs and KCs, focusing on the role of extracellular vesicles (EVs) as mediators of this crosstalk.

Method: Primary HSCs and KCs were isolated from male Wistar rats. HSCs were co-cultured with KCs for 24 hours, and changes in inflammatory markers in KCs and activation markers in HSCs were evaluated. EVs derived from KCs, with or without lipopolysaccharide (LPS) stimulation, were administered to HSCs on day 1. LPS and the Toll-like receptor 4 (TLR4) inhibitor TAK-242 were used to investigate the intercellular communication in detail.
Results: Co-cultured HSCs and KCs exhibited mutual activation, demonstrated by elevated inflammatory markers in KCs and enhanced HSC activation. KCs-derived EVs induced similar activation, with LPS amplifying this bidirectional interaction. Inhibition of TLR4 signaling significantly reduced KC activation and slightly suppressed HSC activation, indicating the involvement of TLR4 signaling in this crosstalk.
Conclusion: HSCs and KCs engage in a positive feedback loop, facilitating mutual activation. This interaction is partly mediated by EVs, with LPS augmenting the effect. TLR4 signaling is partly involved in this reciprocal activation, highlighting its importance in the intercellular communication between liver-resident cells.

THU-050-YI
Dual inhibition of glutaminolysis and de novo amino acid synthesis underpins Pirfenidone's suppression of hepatic stellate cell activation
Jia Li[1], Li Wang[1], Manon Buist-Homan[1], Klaas Nico Faber[1], Han Moshage[1]. [1]*University Medical Center Groningen, Groningen, Netherlands*
Email: jiali9163@gmail.com

Background and aims: Activation of hepatic stellate cells (HSCs) from their quiescent state (qHSC) to activated myofibroblasts (aHSC) is a pivotal event in liver fibrosis, marked by excessive extracellular matrix (ECM) deposition. Metabolic reprogramming, particularly through glutaminolysis and de novo amino acid synthesis, has been identified as a critical driver of HSC activation. Pirfenidone (PFD) is known to inhibit HSC activation and fibrosis in rodent models, though its precise molecular mechanisms remain unclear. This study investigates the role of PFD in suppressing HSC activation by targeting key metabolic pathways.
Method: Primary HSCs were isolated from male Wistar rats and examined at distinct activation stages: qHSC (Day 1), intermediate activating HSC (Day 3), and fully activated aHSC (Day 7). Cells were treated with PFD (10–1000 nM) for 72 hours. LX-2 cells were activated with TGF-β (2.5 ng/mL) and treated with PFD (0.1–1000 μM) for 72 hours. Cellular activation markers and protein levels of key enzymes involved in glutaminolysis (glutaminase 1, GLS1) and de novo proline (pyrroline-5-carboxylate synthase, P5CS) and glycine (serine hydroxymethyltransferase 2, SHMT2) synthesis were analyzed.
Results: PFD exhibited dose-dependent inhibition of HSC and LX-2 cell proliferation and reduced protein expression of activation markers, with limited effect on transcriptional levels. Inhibition of glutaminolysis via glutamine deprivation or GLS1 inhibition (CB-839) was used as a control to confirm PFD's broader effects. PFD reduced GLS1 expression and simultaneously downregulated P5CS (proline biosynthesis) and SHMT2 (mitochondrial one-carbon metabolism) in an ATF4-dependent manner.
Conclusion: PFD effectively suppresses HSC activation by modulating metabolic reprogramming pathways, including glutaminolysis and amino acid metabolism, which are essential for collagen synthesis. These findings highlight PFD's potential as an anti-fibrotic agent and underscore the therapeutic promise of targeting metabolic reprogramming to reverse fibrosis in liver and other organs.

THU-055-YI
Novel natural killer cell immunotherapy through synthesized Neuroligin-4 peptides improved liver fibrosis
Johnny Amer[1], Baker Saffouri[1], Ahmad Salhab[1], Rifaat Safadi[1].
[1]*Hadassah Medical Organization, Liver Institute, Jerusalem, Israel*
Email: safadi@hadassah.org.il

Background and aims: NK cells lose their antifibrotic potential in advanced liver fibrosis, particularly in patients with non-alcoholic fatty liver disease (NAFLD). Neuroligin-4 (NLGN4) receptor was recently found to overexpress NK cells and influence their killing potentials in NAFLD patients with advanced liver fibrosis. NLGN4 and its ligand β-neurexin (β-NRXN) expressed on activated hepatic stellate cells (HSCs) were shown to exert a synergistic inhibitory effect on NK cells. β-NRXN overexpression in activated HSCs indicated its role in fibrogenesis. Herein, we developed newly synthesized NLGN4 peptides to assess their impact on NK cells and HSCs activities in an in vitro and in vivo liver fibrosis model.
Method: Three synthesized peptides were used and incubated for two hours at a concentration of 2,4,8 μg/ml with LX2 cells before co-culturing with NK cells obtained from NAFLD patients with F3/F4 scores for 24 hours. Flow cytometry assessed NK cell activity through CD107a, lysosomal-associated membrane protein-1, and LX2 activations through α-Smooth muscle actin. For the in vivo study, C57/Bl mice were injected with CCl_4-induced liver fibrosis (0.5 μl/g body weight) and synthesized peptides (8 μg/mice) twice a week for 6 weeks. Serum and livers were assessed for pro-inflammatory cytokines and histopathological staining, respectively.
Results: In an in vitro setting, HSCs pre-incubated with NLGN4 peptides reduced their activations (αSMA expressions 1.53 and 1.55-folds in peptide 1 and peptide 2, respectively, $P < 0.001$) with a further prominent reduction in αSMA expressions following incubations with NK cells (2.85 and 2.3-folds in peptide 1 and peptide 2, respectively, $P < 0.001$). Moreover, the studied peptides downregulated expressions of both NLGN4 and β-NRXN in liver extracts isolated from the CCl_4 liver fibrosis mice model. NLGN4 peptides showed delayed progressions of liver fibrosis by improving liver histological findings of inflammatory and fibrotic lesions and reducing liver injury enzymes (ALT). Fibrotic markers (αSMA, Collagen, CREB, and MMP4) were assessed via western blot. RT-PCR was also alleviated following treatment with peptides. These results were associated with elevated NK cell activations assessed by the CD107a and F-actin expressions through flow cytometry and confocal microscopy.
Conclusion: Interruption of NK/myofibroblast cellular synapse by targeting the NLGN4/β-NRXN axis with NLGN4 peptides achieved synergistic antifibrotic effects through (1) cytotoxic NK cells stimulation against myofibroblasts; either directly via NLGN4 inhibition and indirectly by blocking the NK inhibitor β-NRXN, (2) directly inhibit β-NRXN of myofibroblasts and decreased their activation. Thus, immunotherapy targeting the NLGN4/β-NRXN axis represents a novel immune therapeutic strategy in NK cell-mediated diseases.

Email: lijingguo1107@gmail.com

Background and aims: Accumulation of hydrophobic bile salts is believed to promote liver fibrosis in human cholestatic liver disease. An important difference between mice and man in regard to liver pathophysiology is their different composition of the bile salt pool with hydrophilic bile salts such as tauro-β-muricholate (TβMC)

predominating in mice, and hydrophobic bile salts such as glycochenodeoxycholate (GCDC) in man. Here, we further explored the capability of various bile salts to activate HSC in vitro and tested the role of a humanized bile salt pool in development of liver fibrosis.
Method: The human HSC line LX2 was stimulated with bile salts in standard culture medium at a slightly acidic pH (7.3) to account for the acidic microenvironment known to be present in the perisinusoidal space. Activation of cells was quantified by Western blotting for αSMA (normalized for GAPDH). C57BL/6 mice were fed a control diet or a diet enriched with GCDC (0.1% w/w) to humanize their bile salt pool and treated with bile duct ligation (BDL). Concentrations of bile acids in serum were measured by LC-MS/MS. Liver fibrosis was quantified by various histological staining and serum biochemistry.
Results: LX2 were stimulated with unconjugated bile salts, including chenodeoxycholate (CDC), cholate, deoxycholate (DC) and βMC at 20 µM, respectively. Among those, only CDC and DC, predominating hydrophobic bile salts in man, led to an increase in αSMA expression by 1.7 ± 0.5- and 1.9 ± 0.6-fold respectively, compared to control ($n = 4$, $p < 0.05$). In vivo, BDL led to development of liver fibrosis, as expected. Supplementation with GCDC increased its plasma level from 0.03% to 22.9% in BDL mice (BDL+ Control vs. BDL+ GCDC, $n = 5$, $p < 0.05$), and additionally aggravated this phenotype, as evidenced by Masson staining (BDL+ GCDC vs. BDL+ Control: 12.1 ± 1.6 vs. 9.8 ± 2.3, $n = 7$, $p < 0.05$), Sirius red staining (13.0% ± 3.3% vs. 9.0% ± 0.7%, $n = 7$, $p < 0.05$) and immunohistochemical staining for αSMA expression (7.2% ± 2.9% vs. 3.3 ± 1.2, $n = 7$, $p < 0.05$). However, GCDC diet did not change the total bile acid concentration in mice. ALT and AST serum levels were unaltered by GCDC feeding in both control and BDL-treated animals, excluding a direct co-toxic effect of GCDC. In control animals without BDL-treatment, bile salt feeding was without pro-fibrotic effects.
Conclusion: Our data add to the growing body of evidence, that human, hydrophobic bile salts can directly activate hepatic stellate cells to promote liver fibrosis. This way of 'humanization' of murine models should thus be further explored when studying liver pathophysiology or exploring novel pharmacological therapies in chronic liver disease.

THU-057
Disease-specific human ECM composition and bioactivity in MASH liver fibrosis

Lisa Longato[1], Lisa Sassi[1], Alan Holmes[1], Christopher Stevenson[1], Hiroaki Yashiro[2], Matthew Falk[2], Bernard Allan[2], Giuseppe Mazza[1].
[1]Engitix Therapeutics, London, United Kingdom; [2]Takeda Pharmaceuticals International Co, Boston, United States
Email: giuseppe.mazza@engitix.com

Background and aims: The extracellular matrix (ECM) is a complex bioactive network of macromolecules. Excessive accumulation of ECM proteins is a hallmark of fibrosis, which can occur in all organs of the body. While normal ECM-cell interactions maintain tissue homeostasis, in fibrotic conditions, the ECM promotes pathogenic responses that contribute to inflammation and fibrosis. The ECM's role in tissue damage and fibrosis progression is not fully understood, presenting an opportunity to identify and evaluate novel therapeutic targets for the treatment liver fibrosis.
Method: We describe a novel approach aimed at studying the contribution of the cirrhotic ECM on cellular functions through the development of a 3D cirrhotic ECM assay.
Results: We developed protocols to generate decellularized ECM from MASH cirrhotic livers ($n = 3$). Tissues were characterized using immunohistochemistry pre- and post-decellularization to confirm maintenance of tissue architecture and decellularization was confirmed by measuring DNA content (≤50 ng/mg of tissue). TMT proteomics was performed to study ECM composition in cirrhotic livers. Matrisome analysis identified MASH livers exhibited an enrichment of pathways related to ECM formation, remodelling, and inflammation. We demonstrated incorporating cirrhotic ECM into a disease-centric 3D assay using primary human hepatic stellate cells (HSCs) supported robust cellular viability (>95%) and led to an altered secretory profile compared with cultures established in healthy ECM. Additionally, these cells maintained their ability to respond to fibrogenic mediators.
Conclusion: The development of fibrosis results from the complex interplay of the extracellular microenvironment and the cells within the liver. This cross talk can lead to the loss of normal tissue architecture and organ function. We describe the development of a novel disease-centric assay to enhance our understanding of the pathogenic mechanisms. This assay focuses on the cross talk between cirrhotic ECM and cells and will support the development of novel anti-fibrotic therapies.

Blockage of microfibrillar-associated protein 4 (MFAP4) decreases liver fibrosis in two murine models of steatotic liver disease

Maximilian Joseph Brol, Reine Kanaan[1], Robert Schierwagen[2], Frank Erhard Uschner[2], Aleksander Krag, Jonel Trebicka, Grith Sorensen[3], Sabine Klein[2]. *[1]Department of Clinical Research, Research Unit of Urology, University of Southern Denmark, Odense, Denmark; [2]Department of Internal Medicine B, University Hospital Münster, Münster, Germany; [3]Department of Cancer and Inflammation Research Institute of Molecular Medicine, University of Southern Denmark, Odense, Denmark*
Email: maximilian.brol@ukmuenster.de

Background and aims: Liver fibrosis, a key feature of chronic liver diseases, represents the progressive accumulation of extracellular matrix proteins that can lead to cirrhosis and subsequent portal hypertension, if left untreated. Microfibrillar-associated protein 4 (MFAP4) is a key protein involved in microfibril formation during fibrillin assembly in elastin formation. MFAP4 levels in the liver increase with ongoing fibrogenesis. Circulating and hepatic MFAP4 showed good predictive ability for liver fibrosis. However, no therapeutic studies were conducted towards this protein. We aimed to investigate the efficacy of a MFAP4 blocking antibody in well-established mouse models of steatotic liver disease.
Method: Hepatic *MFAP4* was determined in human liver transcriptomes (cirrhosis ($n = 22$); non-cirrhotic individuals ($n = 8$)). For the *in vivo* study, two carbon tetrachloride (CCl_4)-based models of experimental liver fibrosis (intraperitoneal injection 2×/week for 7 weeks) were used in male C57Bl/6 mice. A metabolic dysfunction-associated steatotic liver disease (MASLD) model using CCl_4 and Western diet and an alcohol-associated liver disease (ALD) model using CCl_4 + alcohol in the drinking water (stepwise increase to 16%). Mice received either the MFAP4 antibody (20 mg/kg in week 5 and 5 mg/kg in week 6 and 7) or a vehicle intraperitoneally ($n = 8–10$ for each group). Prior to sacrifice, portal pressure (PP) was measured *in vivo*. After sacrifice, hepatic fibrosis was evaluated using Sirius Red staining, hepatic hydroxyproline content and qPCR for *Col1a1* and *Tgfb*. Hepatic elastin and MFAP4 were determined via Western Blotting.
Results: In our human transcriptomic data set, MFAP4 was identified to be highly upregulated during cirrhosis, and was well correlated with established genes involved in fibrogenesis. In the MASLD model mice developed portal hypertension (median PP = 10 mmHg), which trended to improve in the intervention group (median PP = 8 mmHg). Hepatic collagen accumulation (Sirius Red staining) improved significantly in MASLD mice treated with MFAP4-antibody ($p = 0.03$). In ALD mice, this improvement in treated mice was less strong. Hepatic hydroxyproline levels, an important component of collagen synthesis, confirmed the observations from the histological staining in both models (for MASLD: $p = 0.11$). Hepatic collagen (*Col1a1*) and *Tgfb*-expression also trended to decrease in both models, with a stronger effect in MASLD mice. Finally, Western blot deciphered a decrease of hepatic elastin levels in both models after MFAP4 blockage.

Conclusion: Our study showed that blockage of MFAP4 in murine MASLD and ALD models displays antifibrotic effects in the liver and should be therefore further evaluated as antifibrotic treatment for steatotic liver disease.

Email: thomas.oconnell@medicuseconomics.com

Background and aims: Resmetirom is the first approved treatment in the United States (US) for noncirrhotic metabolic dysfunction-associated steatohepatitis (MASH; formerly known as nonalcoholic steatohepatitis [NASH]), conditionally approved for use in adults with moderate to advanced liver fibrosis consistent with stages F2 to F3. Patient selection for treatment with resmetirom may be based on evidence of fibrosis from noninvasive tests (NITs). Liver stiffness measurement (LSM) of 8–20 kPa by vibration-controlled transient elastography (VCTE) (with exclusion of cirrhosis) is considered a potential signal of fibrosis stages F2–F3. The LiverRisk Score (LRS) is a NIT based on blood-based biomarkers and demographics, developed for prediction in the general population of liver fibrosis and future liver-related outcomes. This study evaluated in US adults the performance of the LRS for prediction of LSM ≥8 kPa and ≥20 kPa compared to the Fibrosis-4 (FIB-4) Index.
Method: An observational analysis was conducted of the National Health and Nutrition Examination Survey (NHANES) 2017–2020 cycle, including participants who had complete information to calculate the LRS (i.e., age, sex, aspartate aminotransferase, alanine aminotransferase, gamma-glutamyl transferase, fasting glucose [imputed from non-fasting when missing], total cholesterol, and platelet count). Performance of the LRS vs. FIB-4 for prediction of LSM ≥8 kPa and ≥20 kPa was evaluated as area under the curve (AUC), estimated by survey-weighted logistic regression of LSM ≥8 kPa/ ≥20 kPa vs. the LRS or FIB-4.
Results: The unweighted study population included N = 7,005 participants. The LRS demonstrated significantly ($p < 0.05$) superior discrimination of LSM ≥8 kPa vs. FIB-4 in all adults, with AUC (95% confidence interval [CI]) of 0.73 (0.71–0.75) for LRS and 0.63 (0.61–0.65) for FIB-4. Discrimination remained numerically superior for LSM ≥20 kPa, with AUC (95% CI) of 0.79 (0.74–0.84) for LRS and 0.73 (0.67–0.79) for FIB-4. Improved accuracy was driven by lower false positive rates (at fixed sensitivity) for LSM ≥8 kPa, and higher true positive rates (at fixed specificity) for LSM ≥20 kPa.
Conclusion: In US adults, the LRS demonstrated superior accuracy vs. FIB-4 for prediction of LSM ≥8 kPa and ≥20 kPa, which could facilitate screening for noncirrhotic MASH with fibrosis stages F2–F3.

Insulin-like growth factor binding protein 7 promotes the development of metabolic dysfunction-associated steotic liver disease-related hepatic fibrosis and induces decreased cardiac function

Wenjing Ni[1], Qianqian Chen[1], Yixuan Zhu[1], Fajuan Rui[1], Zhiwen Fan[1], Shengxia Yin[1], Qianwen Zhao[1], Jie Li[1]. [1]*Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, China*
Email: lijier@sina.com

Background and aims: Individuals with metabolic dysfunction-associated steotic liver disease (MASLD) are at an increasing risk of both liver-related adverse outcomes and cardiovascular diseases. However, the dynamic interplay between liver and cardiac function in the context of MASLD remains poorly understood. This study aimed to uncover the role of insulin-like growth factor binding protein 7 (IGFBP7) in the development of liver fibrosis and its associations with cardiac function.
Method: Circulating IGFBP7 levels and liver tissue expression were analyzed in patients with liver fibrosis. Male C57BL/6J mice (six weeks old) were fed either a control chow or a high-fat, high-fructose diet (HFFD) for 20 weeks to induce MASLD-associated liver fibrosis. Igfbp7-targeting shRNA was placed downstream of the Postn promoter and packaged into AAV6 (AAV-shIgfbp7) to deplete Igfbp7 in mature myofibroblasts. Left ventricle ejection fraction (LVEF) of mice was assessed by echocardiography. Liver histology was evaluated using immunohistochemistry (IHC), hematoxylin-eosin, picrosirius red and Masson's trichrome. Human immortalized hepatic stellate cells (LX-2) were activated with transforming growth factor-beta (TGF-β) for in vitro studies.
Results: Circulating IGFBP7 levels were positively correlated with liver stiffness measurements (LSM) in patients with liver fibrosis and concurrent heart failure. IHC analysis of liver samples confirmed that IGFBP7 expression was proportionally associated with the severity of liver fibrosis. Similar trends were observed in mice subjected to an HFFD. Compared to control mice, MASLD mice exhibited a significant reduction in LVEF, which was attenuated upon Igfbp7 depletion. In primary hepatic stellate cells (HSCs) isolated from wild-type mice, Igfbp7 mRNA levels increased along with myofibroblast markers (*Acta2, Postn, Col1a1*) during spontaneous activation. TGF-β-activated LX-2 cells exhibited increased Igfbp7 expression, along with enhanced migration, proliferation, and contraction abilities. Notably, these effects were mitigated by reducing Igfbp7 expression.
Conclusion: IGFBP7 is a promising biomarker for assessing liver fibrosis severity and cardiac dysfunction in individuals with MASLD. Further studies are warranted to elucidate the underlying mechanisms.

THU-061

The study of pathogenesis of the progression of liver cirrhosis

Oksana Shapoval[1], Vira Vyshyvanyuk[1]. [1]*Ivano-Frankivsk National Medical University, Ivano-Frankivsk, Ukraine*
Email: oshapoval123@gmail.com

Background and aims: In the case of liver cirrhosis (LC) the increased permeability of the intestinal mucosa and portosystemic shunting allows endotoxins and cytokines to penetrate into the system circulation and causes pathogenetic changes. The aim was to evaluate the peculiarities of the LC by studying the main pathogenetic links of the disease, namely endotoxicosis, level of cytokines and the state of the detoxification function of the liver.
Method: 105 patients with LC were examined (14 females and 91 males with age 34–64 years old. The duration of the disease in patients ranged from 2 to 9 years. According to Child-Pugh score, the patients were distributed as follows: 63.8% (67 patients) in class B and 36.2% (38 patients) in class A. The expression of endogenous intoxication was assessed by the levels of bacterial endotoxin. The levels of TIMP-1 and TGF-beta1 were determined by ELISA method (DIACLONE, France). Determination of liver detoxification function was done by the 13C-methacytin breath test (13C-MBT).
Results: The assessment of endogenous intoxication revealed an increase the level of bacterial endotoxin in patients with LC: (81.32 ± 2.1) pg/ml, which was significantly different from healthy individuals (23.6 ± 0.91) pg/ml ($p < 0,05$). Moreover, the level of bacterial endotoxin in patients with class B exceeded this it in the patients with class A by 19.5%. It was established that the levels of the studied indicators increase with progression of the LC and reliably different depending on the severity of the disease. The level of TIMP-1 in

patients with class A was (497.7 ± 5.6) pg/ml, and (538.4 ± 5.9) pg/ml with class B ($p < 0.001$). The level of TGF-beta1 was (453.2 ± 4.7) pg/ml in patients with class A and (496.3 ± 6.1) pg/ml with class B respectively ($p < 0.001$). During assesment of relationships of studied indicators, it was established the direct strong correlation between bacterial endotoxin and TGF-beta1 ($r = 0.75$, $p < 0.05$), bacterial endotoxin and TIMP-1 ($r = 0.72$, $p < 0.05$). Also, a strong inverse relationship was founded between bacterial endotoxin and the indicator of liver detoxification function ($r = –0.85$, $p < 0.05$), and medium power correlation between TGF-beta1 and liver detoxification function ($r = –0.66$, $p < 0.05$).
Conclusion: An increase in the level of indicators of endogenous intoxication leads to an increase of the production of pro-fibrogenic factor TGF-beta1, which stimulate fibrogenesis and decrease the detoxification function of the liver, which causes the progression of the LC.

Human umbilical cord mesenchymal stem cells attenuate liver fibrosis in mice and inhibit hepatic stellate cell activation via secreting soluble factors
Qi Zhou[1], Junyu Wang[2], Ke Cheng[3], Pingnan Sun[3], Han Moshage[2], Martin Harmsen[2], Klaas Nico Faber[2]. [1]*University Medical Center Groningen, Shantou University Medical College, Groningen, Netherlands;* [2]*University Medical Center Groningen, Groningen, Netherlands;* [3]*Shantou University Medical College, Shantou, China*
Email: q.zhou@umcg.nl

Background and aims: Mesenchymal stem cells (MSCs) have emerged as promising candidates to treat clinical liver fibrosis. However, the key factors and mechanisms underlying their anti-fibrotic effects remain largely unclear. Our aims were to assess the therapeutic efficacy of human umbilical cord (UC) MSCs in a murine liver fibrosis model and to dissect the influence of their secretome in vitro.
Method: Liver fibrosis model was induced in mice through 6–10 week CCl_4 administration, combined with weekly intraperitoneal injections of MSCs starting either at week 0 (prevention) or week 6 (therapeutic). Fluorescently-labeled MSCs were used to trace cell distribution post-injection. Liver fibrosis was evaluated using Hematoxylin and Eosin (H&E) staining, Masson's trichrome staining and immunohistochemical (IHC) staining for alpha smooth muscle actin (a-SMA). Human LX-2 (immortalized hepatic stellate) cells were treated with complete UC-MSC-conditioned medium ($CM^{UC\text{-}MSC}$), its soluble factor MSC-CM ($SF^{UC\text{-}MSC}$) or the UC-MSC extracellular vesicles ($EV^{UC\text{-}MSC}$) fraction of the secretome. Expression of fibrosis-related genes was assessed using semi-quantitative PCR, immunofluorescence staining and Western blot analysis.
Results: UC-MSCs preferentially accumulated in the livers of fibrotic mice. Administered UC-MSC reduced histological changes, collagen deposition and a-SMA expression in fibrotic mice which essentially blocked and reversed liver fibrosis. *In vitro*, $CM^{UC\text{-}MSC}$ suppressed LX-2 proliferation and TGF-beta-induced *ACTA2*/a-SMA expression, but not *COL1A1*/collagen I expression. These effects persisted in EV-depleted $SF^{UC\text{-}MSC}$. $EV^{UC\text{-}MSC}$ did not suppress *ACTA2*/a-SMA nor *COL1A1*/collagen I levels in LX-2 cells.
Conclusion: Administered therapeutic UC-MSCs preferentially accumulate in the liver and effectively prevent and reverse liver fibrosis *in vivo*, in rodents while inhibiting hepatic stellate cell activation *in vitro*. The antifibrotic effects *in vivo* are likely primarily mediated by excreted soluble factors rather than extracellular vesicles.

THU-066
Femoral vs hepatic vein plasma levels of collagen biomarkers confirm Pro-C3 as true marker of collagen synthesis in the fibrotic/cirrhotic liver
Rambabu Surabattula[1], Troels Busk[2,3], Sudha Rani Myneni[1], Diana Julie Leeming[4], Morten Karsdal[4], Søren Møller[2], Detlef Schuppan[1,5]. [1]*Institute of Translational Immunology, University Medical Center Mainz, Mainz, Germany;* [2]*Centre of Functional Imaging and Research, Department of Clinical Physiology and Nuclear Medicine, Copenhagen University Hospital, Hvidovre, Denmark;* [3]*Department of Gastroenterology, Copenhagen University Hospital, Herlev, Denmark;* [4]*Nordic Bioscience, Herlev, Denmark;* [5]*Division of Gastroenterology, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, United States*
Email: detlef.schuppan@unimedizin-mainz.de

Background and aims: There is a direct correlation between the degree of portal hypertension and the extent of fibrosis in advanced liver diseases. A thorough characterization of serum markers of true fibrogenesis vs cross-sectional fibrosis is urgently needed. We therefore investigated the putative collagen formation biomarkers Pro-C3, Pro-C6 and Pro-C5 in a setting that allows their assessment as markers of collagen production and/or removal by the liver or the periphery.
Method: 58 patients with established cirrhosis, mainly due to alcohol abuse, were included (Child-Pugh, CPA-C, n = 20, 20, 18, resp.). Patients with portal hypertension who were abstinent and clinically stable underwent hepatic vein catheterization. Fasting femoral arterial, peripheral (femoral) and hepatic venous plasma samples were collected from patients and healthy controls (n = 13). Biomarkers of collagen formation were determined in EDTA plasma using validated competitive ELISAs.
Results: Pro-C3 levels were increased vs normal controls in all three vessels of CPA, B and- C patients. Pre- and post-hepatic venous biomarker levels showed a significant net production of Pro-C3 in the liver in all CP classes. There was a trend for a progressive increase across CP classes for Pro-C6 pre- and post-liver passage. In CPB and CPC compared to CPA, the values for Pro-C6 were significantly higher in the femoral than in the hepatic vein, indicating prominent production in extrahepatic sites. Pro-C5 was increased in the hepatic vein in all CP classes vs controls, while femoral vein Pro-C5 significantly increased from CPA to CPC. Femoral vein Pro-C5 was significantly lower vs hepatic vein Pro-C5 in both patients and controls, indicating extraction in the extremities. Pro-C3 and Pro-C6 were significantly increased in patients with vs without ascites. Both Pro-C3 and Pro-C6 showed a significant correlation with age, hemoglobin, serum albumin and CP scores.
Conclusion: Pro-C3, Pro-C5 and Pro-C6 were confirmed to be significantly increased in the peripheral blood of patients with cirrhosis. Notably, only Pro-C3 showed an increasing net hepatic production along with the severity of cirrhosis from class CPA to- CPC. Interestingly, levels of Pro-C6 were compatible with a prominent extrahepatic (vascular) source, while (hepatic) Pro-C5 appeared to be extracted or excreted in the periphery.

THU-067
A simple lab based machine learning model (FAET) predicts advanced Liver Fibrosis more accurately in MASLD patients
Ashok Choudhury[1], Shobha Sharma[2], Venkata Gupta[3], Archana Rastogi[4], Tapan Gandhi[2], Shiv Kumar Sarin[1]. [1]*Institute of Liver and Biliary Sciences, New Delhi, India;* [2]*Indian Institute of Technology, New Delhi, India;* [3]*Velagapudi Ramakrishna Siddhartha Engineering College, Vijayawada, Andhra Pradesh, India;* [4]*Institute of Liver & Biliary Sciences, New Delhi, India*
Email: doctor.ashokchoudhury@gmail.com

Background and aims: Metabolic dysfunction-associated steatosis liver disease (MASLD) is often silent and progressive, affecting nearly one-fourth of the global population. However, liver biopsy remains the only accurate but invasive modality for diagnosis. We aimed to develop a machine learning model to assess liver fibrosis in MASLD patients.
Method: We analysed electronic medical records of biopsy-proven MASLD patients between 2022–23 retrospectively. Demographic, clinical and laboratory parameters were varible incorporated in the

model. Liver biopsy was used as the refrence for fibrosis assesement [NASH CRN score, F3–F4 is considered as advanced fibrosis and others as non-advanced fibrosis(NAF)]. Cleaned data was splitted into a train and test set (90:10). A total of 14 ML models were trained using PyCaret package to confirm the best performer. Extra Tree (ET) classifier, RF, lightgbm, gbc, xgboost,lr,lda, ridge,knn, ada, svm, nb,dt and qda were used. To enhance the usability, a web application "FAET Tool" was developed using Streamlit with the help of a GitHub repository. Fourteen ML models were developed and the best model was compared against the Fibrosis-4 (FIB-4) score, and APRI for detecting AF. The final best model with reduced features and a standard scaler was saved using the pickle library in Python, a web application was created using the Streamlit library. For further online deployment, a GitHub repository was created and this web application provided the remote access for real-time testing.

Results: Total of 452 patients (median age: 41 years; IQR 33–49; 75% male) had biopsy proven MASLD, and 222 (49.1%) had AF on biopsy. The FAET demonstrated the best performance, achieving 84% accuracy, an AUC of 0.82, an F1 score of 0.77, an NPV of 0.81, and a PPV of 0.91 using 13 variables. Compared to FIB-4, FAET improved accuracy by 33%, AUC by 34%, F1 score by 45%, NPV by 15.7%, and PPV by 71%. Similarly, compared to APRI, FAET improved accuracy by 58.4%, AUC by 49%, F1 score by 45.2%, NPV by 20.8%, and PPV by 111%. The higher F1 score reflects a better balance between precision and recall, and the improved NPV demonstrates a more reliable identification of patients who do not have AF. FAET model performed best with 13 features and the the best performance was mantained even with the top 5 features i.e. Age, platelet count, presence of Diabetes, Serum AST, and total Cholesterol. A web-based tool with equivalent accuracy was developed for deployment. The accuracy (79.61%), AUC (0.8725), and F1 score (0.7903) obtained in the FAET tool and was better than other models even in the selected 5 parametrs model.

Conclusion: FAET model offers a superiority over the current Fib-4 and APRI, as a non-invasive assessment tool for advanced fibrosis in MASLD patients. This is simple, easy, cost-effective, web based and has the potential for routine use pending further validation.

THU-068

EmTPx promotes liver fibrosis via enhancing IL-33 secretion from macrophage

Jing Wu[1], Yilizhati Azhati[1], Aliya Tulading[1], Tuerhongjiang Tuxun[1].
[1]*First Affiliated Hospital of Xinjiang Medical University, Urumqi, China*
Email: turgunbay@163.com

Background and aims: Liver fibrosis is a major characteristic of most chronic liver diseases and results in morbidity and mortality worldwide. *Echinococcus multilocularis* thioredoxin peroxidase (EmTPx) is an antioxidant protein, yet its specific role in liver fibrosis remains poorly understood. This study aims to elucidate the role of EmTPx in carbon tetrachloride (CCl_4)-induced liver fibrosis.

Method: During the CCl_4-induced model establishment, EmTPx was administered intraperitoneally over one month to evaluate its effects on fibrosis severity and macrophage polarization. Additionally, RAW264.7 macrophage cells were treated with EmTPx, and JS-1 hepatic stellate cells were co-cultured with the resultant cell supernatants.

Results: EmTPx administration exacerbated liver fibrosis, enhanced M1 polarization, and increased IL-33 expression in CCl_4-treated mice. In vitro, EmTPx promoted M1 polarization in RAW264.7 cells, and transcriptomic analysis indicated activation of the NF-κB signaling pathway. Selective inhibition of NF-κB using JSH-23 significantly reduced M1 polarization and IL-33 levels. Furthermore, fibrosis severity in JS-1 cells was heightened when co-cultured with the supernatant of RAW264.7 cells, a process mitigated by IL-33 inhibition.

Conclusion: Our findings reveal that EmTPx exacerbates liver fibrosis by enhancing IL-33 secretion through macrophage. EmTPx may represent a potential therapeutic target for managing liver fibrosis associated with *E.m.* infection.

Funding: This study was supported by grants from National Natural Science Foundation of China (82270632, 82260411).

THU-069

A composite score of PRO-C6 and platelet count is prognostic for liver-related outcomes in patients with chronic hepatitis C

Thomas Wiggers[1], Emilie Skovgaard[2], Morten Karsdal[3], Diana Julie Leeming[3], Keyur Patel[4]. [1]*Nordic Bioscience A/S, University of Copenhagen, Herlev, Denmark;* [2]*Nordic Bioscience, University of Copenhagen, Herlev, Denmark;* [3]*Nordic Bioscience, Herlev, Denmark;* [4]*University Health Network, Toronto, Canada*
Email: twm@nordicbio.com

Background and aims: There is a need for prognostic markers for patients with chronic liver-disease at increased risk of developing a liver-related outcome (LRO). Endotrophin, a potential driving fibroblast activation and promoting fibroinflammatory disease can be assessed using PRO-C6. We previously demonstrated the prognostic value of PRO-C6 in identifying patients with cirrhosis from chronic hepatitis C (CHC) at higher risk of developing a LRO. In this study, the aim was to explore the ability of a composite score of PRO-C6 divided by platelet count (PC) to predict LROs in The Hepatitis C Antiviral Long-Term Treatment Against Cirrhosis Trial (HALT-C) (ClinicalTrials.gov #NCT00006164).

Method: nordicPRO-C6™ was measured in serum from baseline, using a fully validated competitive enzyme-linked immunosorbent assay. A composite score was calculated by dividing the baseline value of PRO-C6 with baseline PC. Patients were dichotomized into above and below a PRO-C6/PC of 0.0968, (15/155; 15 ng/mL was the upper quartile value of PRO-C6; 155 was the cohort median of PC × 1000/mm^3. Kaplan-Meier estimates and Cox regression were used to evaluate the prognostic value of PRO-C6/PC to identify patients at higher risk of developing LROs related to decompensation and Hepatocellular carcinoma. The same analysis was performed on a subgroup of all included patients with cirrhosis, n = 151, as previously shown with PRO-C6. Data provided by NIDDK CR, a program of the National Institute of Diabetes and Digestive and Kidney Diseases.

Results: 339 patients with CHC infection from the HALT-C cohort, were included in this study. 68% were male, with median (Q1, Q3) age and BMI of 50 (47, 55) years and 29.4 (26.6, 32.6) kg/m^2, respectively. During the study follow-up time of 1400 days, 66 (19%) patients developed a LRO over a median (Q1, Q3) follow-up time of 841 (488, 1132) days. Dichotomizing the 339 patients above and below the PRO-C6/PC score cut-off, no patients in the low group had a LRO for more than a year, and the hazard ratio (HR) for having a LRO was 4.55 (95% CI = [2.66, 7.80], $p < 0.0001$) times higher in the high group compared to the low group. In the subgroup of 151 patients with cirrhosis, there were no LROs in the low group for more than two years, and a HR of 4.81 (95% CI = [2.23, 10.37], $p < 0.0001$) in the high group, with a median (Q1, Q3) follow-up time of 755 (371, 1098).

Conclusion: A composite score using PRO-C6, a biomarker of circulating endotrophin, and platelet count was associated with increased risk of developing a LRO, in patients with CHC. This composite score might provide prognostic value to identify patients with other pro-inflammatory advanced chronic liver disease at higher risk of developing a LRO. Comparison with other extracellular matrix biomarkers, and clinical outcome predictor models is ongoing. Validation of PRO-C6 and PC as prognostic markers following sustained virologic response in CHC, and other chronic liver diseases is still required.

Email: zhxuxuxx39@alumnes.ub.edu

Background and aims: Hepatic stellate cells (HSCs) are the main fibrogenic cell type in chronic liver diseases. Phenotypic heterogeneity and functional diversity of HSCs population have been described using single-cell RNA sequencing (scRNA-seq). We have shown that human induced pluripotent stem cells (iPSCs) derived HSCs (diHSCs) mimic the phenotype and function of primary HSCs. In this study, we characterize the differentiation and activation of diHSCs, with the goal of assessing the dynamics of differentiation and the cellular heterogeneity within the diHSCs population.
Method: diHSCs were generated following a well-established 12-day protocol. Activation was induced by plating diHSCs on plastic or by treating them with 10 ng/ml TGF-b. Bulk RNA sequencing (RNA-seq) was performed at days 0,2,4,6,8,10,12 of the differentiation and in both activation models. diHSCs were analyzed using scRNA-seq and compared to primary HSCs.
Results: Bulk RNA-seq analysis revealed that quiescent HSC markers, (i.e. NCAM1, RELN, DCN, GATA6) started to be upregulated at day 6, while markers associated with activation, such as PDGFRB, COL1A1, ACTA2, and LOX, increased at day 8. Expression of RELN, RSPO3, PCDH7 and PDGFRB was confirmed by immunostaining. Plastic and TGF-b activation induced distinct molecular pathways. Plastic enhanced pathways related to cell contractility, extracellular matrix remodeling, and stress response, whereas TGF-b mediated activation enriched pathways involved in carbohydrate metabolism and glycolysis. Next, we assessed whether iPSCs differentiation could recapitulate the heterogeneity of HSCs. Bulk RNA-seq analysis revealed that markers for HSC populations of the portal and central regions (GPC3, DPT, FBLN1, CCL2) and perisinusoidal regions (DBH, RBP1, CXCL14, HHIP) began to increase at day 6. Additionally, markers associated with regenerative HSCs (HGF), lipid-associated HSCs (ADH4), and antigen-presenting HSCs (PLG) were enriched starting from day 10 of differentiation. scRNA-Seq analysis of diHSCs identified five distinct populations, all of which expressed common HSCs markers but exhibited specific gene signatures related to fibrinolysis, proliferation, contractile-myofibroblastic functions, fibrogenesis, and protein synthesis. The comparison with publicly available human liver single cell data showed that the cellular heterogeneity observed in primary HSCs is present in the diHSCs population.
Conclusion: In this study we outline the dynamics of diHSC differentiation. We also demonstrate that diHSCs constitute a heterogeneous population, recapitulating the expression of markers that define HSCs populations in both health and disease. Overall, our findings highlight that iPSCs are a good tool for studying the acquisition of the phenotype and the cellular heterogeneity of HSCs.

Gut microbiota and liver disease – Liver-organ crosstalk

TOP-051

Veillonella dispar-mediated l-arginine depletion induces leydig cell mitochondrial apoptosis and suppresses testosterone synthesis to drive primary biliary cholangitis

Qing-Qing Xing[1], Jin-Shui Pan[1]. [1]*First Affiliated Hospital of Fujian Medical University, Fuzhou, China*
Email: 582398903@qq.com

Background and aims: Gut dysbiosis and testosterone are associated with the pathogenesis of primary biliary cholangitis (PBC). However, whether Veillonella dispar or its metabolites can modulate testosterone levels to rectify immune dysregulation in PBC remains unclear.
Method: We evaluated the in vivo effects of the gut microbiota Veillonella dispar in a mouse model of 2-octynoic acid-bovine serum albumin-induced cholangitis and pseudo germ-free mice, analyzed serum amino acid levels by metabolomics, measured serum testosterone levels by LC-MS/MS, photographed Leydig cell mitochondria by transmission electron scanning microscopy and confocal microscopy, and analyzed the infiltration and function of liver B lymphocytes by single-cell sequencing and flow cytometry. The in vivo effects of heterologous expression of the speA gene were evaluated in normal mice. Circulating testosterone, BAFF, and arginine levels in the PBC cohort were detected by LC-MS/MS and Elisa, respectively.
Results: Our results showed that Veillonella dispar increased serum ALP concentration, total bile acid content, and liver injury in pseudogerm-free mice and aggravated liver injury in the 2OA-BSA-induced PBC model. Compared with the control group of mice with cholangitis, the Veillonella dispar-treated group had lower serum testosterone and L-arginine levels, thereby relieving the feedback inhibition of BAFF secretion, promoting B cell proliferation and focusing in the liver, and damaging bile duct epithelial cells. Testosterone supplementation or BAFF blockade reduced the number and activity of liver B cells. Mechanistically, L-arginine maintained mitochondrial function in Leydig cells by promoting nitric oxide release, reducing mitochondrial permeability pore opening, and limiting ROS release. These effects reduced the release of cytochrome C and mitochondrial apoptosis and enhanced the expression of testosterone synthesis-related proteins (StAR, P450scc, and 3β-HSD). The presence of the speA gene in the genome of Veillonella dispar enables it to efficiently degrade L-arginine. Moreover, heterologous expression of the speA gene eliminated the protective effect of L-arginine. In terms of treatment, L-arginine administration alleviated immune-mediated cholangitis in mice by reducing Leydig cell apoptosis. Similarly, compared with healthy person, PBC patients had lower serum L-arginine and testosterone levels and higher BAFF.
Conclusion: Collectively, our findings identify a key role for L-arginine in regulating testosterone and B cell homeostasis and suggest a potential novel therapeutic strategy for the treatment of PBC.

Baseline oral microbiome composition in liver transplant recipients can help predict graft dysfunction

Rosmy Babu[1], Manjeet Kaur[1], Shvetank Sharma[1], Sukriti Baweja[1], Jaswinder Maras[1], Satender Pal Singh[1], Nilesh Patil[1], Archana Rastogi[1], Viniyendra Pamecha[1], Shiv Kumar Sarin[1], Chhagan Bihari[1]. [1]*Institute of Liver and Biliary Sciences, Delhi, India*
Email: drcbsharma@gmail.com

Background and aims: Shifting of oral microbiome to gut have been implicated in liver cirrhosis. Impact and profile of baseline oral

microbiota in liver transplant complications remained underexplored. We aimed to study the association between oral microbiome in liver transplant recipients and early post-transplant graft dysfunction (GD).
Method: Saliva and blood samples of cirrhosis recipients (n = 120) of 18–65 years and their donors (n = 120) were collected. V3-V4 Amplicon sequencing done, FastQC were checked for raw read quality, adaptor presence, and other impurities. Sequences were denoised using the DADA2 plugin from QIIME. Naive-Bayes classifier trained on SILVA 16S rRNA gene database was implemented through sklearn to classify representative sequences at 99% similarity. Sequences were rarefied at specific sampling depth prior to diversity calculation. Serum cytokine and metabolome of recipients were done.
Results: At baseline (pre-operative) donors had a higher relative abundance of Bacteroidota ($p < 0.01$), while cirrhotic recipients (n = 120) exhibited Firmicutes. At family level Streptococcaceae and Veillonellaceae were significantly abundant in cirrhotic recipients compared to their donors ($p < 0.05$, $p < 0.01$ respectively). Post-transplant GD was recorded in 44 cases. The principal coordinate analysis based on Bray-Curtis, Jaccard distance, weighted and unweighted unifrac distance followed by PERMANOVA analysis adjusted for age, gender, etiology, baseline MELD Score; showed at baseline; genus Prevotella, was significantly less ($p < 0.001$), and Streptococcaceae and Veillonellaceae were more abundant in those who had developed GD compared to non-GD. Bacteroidota abundance noted in non-GD recipients (n = 63). On follow-up of Firmicutes showed a decreasing trend post-transplantation till 180 days, indicating a shift towards a healthier microbiota. Those had non-anastomotic biliary complication (n = 6) had abundant phyla of Firmicutes (75%), post LT infections (n = 21) also had increased Firmicutes (60%) and Proteobacteria (30%) at baseline. At genus level Rothia (60%) and Streptococcus (50%) were differentially abundant in rejections (n = 17) and non-anastomatic biliary complications. At species level Prevotella salivae (85%) is significantly abundant in those who had infective complications. Indirect cues of dysbiosis were noted on serum cytokine profiling as sTNF-R1, IL-11 and IFN-beta levels were higher in GD (>2 folds). Elevated sTNFR1 levels indicated increase in Proteobacteria (+30%) and Firmicutes (+75%). Bacterial metabolite, DG (18:2(9Z, 12Z)/24:1(15Z)/0:0), PE (20:0/P-18:0) was also found unique to GD.
Conclusion: After adjustment for common confounders, baseline abundance of Firmicutes (75%), Proteobacteria (30%), Rothia (60%) and Streptococcus (50%) in recipients suggesting unhealthy oral microbiota and were associated with GD. Declining of these in non-GD suggesting healthier microbiome shift.

WED-043
Targeting the gut-liver crosstalk: the role of Gardenin A in alleviating alcohol-associated liver disease

Prashsti Chadha[1], Palash Mandal[1]. [1]*PD Patel Institute of Applied Sciences, CHARUSAT, Anand, India*
Email: palashmandal.bio@charusat.ac.in

Background and aims: Alcohol-associated liver disease (ALD) remains a major health concern with no FDA (food and drug administration)-approved therapies, highlighting the need for effective treatments. Gardenin A (GarA), a natural compound, has shown promise in metabolic-dysfunction related steatotic liver disease (MASLD), but its impact on the gut-liver axis in the context of ALD has not been explored. This study aims to evaluate the therapeutic potential of GarA in modulating the gut-liver axis in an ALD model using male Wistar rats.
Method: Male Wistar rats were administered a Lieber-DeCarli ethanol diet (5% daily and 31.5% twice during the study) for 28 days to induce ALD. Two treatment groups received GarA at doses of 50 and 100 mg/kg body weight for the final 21 days. Blood was collected for biochemical analysis of liver markers, total cholesterol (TC), and triglycerides (TG). Liver and colon tissues were harvested for RNA extraction and gene expression analysis of inflammatory cytokines, anti-oxidant genes, and gut barrier junction genes. Histological analysis was conducted using hematoxylin and eosin (H&E) staining to assess tissue morphology and damage. All experiments were carried out in replicates (n = 6) and data was expressed as mean with standard deviation. Comparisons between groups were performed using one-way ANOVA followed by Tukey's post hoc test, with a significance level set at $p < 0.05$.
Results: Treatment with GarA led to a consistent decrease in liver markers and biochemical markers of injury. Liver histology showed reduced neutrophil infiltration and necrosis in the 100 mg/kg GarA group. In parallel, colon tissue in this group exhibited improved barrier integrity compared to the ALD control group. Gene expression analysis revealed downregulation of pro-inflammatory cytokines such as Tumour necrosis factor alpha (TNFalpha), Toll-like receptor 4 (TLR4) and Interleukins 1beta, 2 and 6, and upregulation of antioxidant genes – Heme oxygenase 1 (HO1), Nuclear factor erythroid 2-related factor 2 (Nrf2) and Nuclear factor kappa-B (NFkappaB) in the 100 mg/kg GarA treated group. Additionally, genes associated with gut barrier function, including Zonula Occludens-1 (ZO1), Occludin and Claudin-1 (CLDN1), were more strongly expressed, supporting enhanced gut barrier integrity.
Conclusion: These findings suggest that GarA has potential as a therapeutic agent for ALD, by targeting both molecular pathways and organ-level functions critical to gut-liver crosstalk. By reducing key markers of liver damage and promoting gut barrier integrity, GarA may offer a novel approach for managing ALD. Beyond ALD, the observed anti-inflammatory and organ-protective effects of GarA suggest its broader applicability in other liver diseases or systemic inflammatory conditions, highlighting its versatility as a potential therapeutic agent.

WED-044
Microbial changes resulting from vertical sleeve gastrectomy attenuate obesity by modulating bile acid metabolism and the intestinal farnesoid X receptor–fibroblast growth factor 15/19 axis

Yi Xia[1], Jinpu Yang[2], Weixin Cheng[1], Zhening Liu[1], Ling Yang[1], Qien Shen[1], Yujie Liang[1], Hangkai Huang[1], Minjie Chen[1], Feng Ji[1], Chengfu Xu[1]. [1]*Department of Gastroenterology, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China, Hangzhou, China;* [2]*Department of Gastroenterology, Affiliated Hangzhou First People's Hospital, School of Medicine, Westlake University, Hangzhou, China, Hangzhou, China*
Email: 22118296@zju.edu.cn

Background and aims: Obesity is a global health priority, with more than one billion people suffering from obesity. Bariatric surgery (BS) is the most effective therapy for weight loss and is associated with changes in the gut microbiota; however, the mechanisms by which the gut microbiota contributes to metabolic benefits after BS remain to be further investigated.
Method: A vertical sleeve gastrectomy (VSG) model was constructed in high-fat diet (HFD)-induced obese (DIO) rats. The changes in the gut microbiota after surgery were tested via 16S sequencing analysis, and the bile acid profiles in the serum and ileum were determined by HPLC–MS/MS. The intestinal FXR-FGF15/19 pathway was tested via western blotting, quantitative real-time PCR and immunofluorescence (IF) staining. The serum FGF19 level was examined via ELISA. To evaluate the causal relationship and mechanism of the gut microbiota in the metabolic benefits of bariatric surgery, an antibiotic cocktail was used to eliminate the gut microbiota in obese rats after VSG surgery, and the VSG-shaped gut microbiota was transplanted into obese littermates. An FXR antagonist was used to confirm the roles of intestinal FXR in the metabolic benefits of the VSG microbiome.

Results: VSG significantly improved glucose metabolism and liver lipid accumulation in DIO rats. Depleting the gut microbiota abolished the metabolic benefits of VSG. Fecal microbiota transplantation from the VSG group reversed the metabolic effect of VSG. VSG markedly increased BSH activity and the abundance of BSH-enriched microbes, including Lactococcus and Enterococcus. The abundances of Lactococcus and Enterococcus were negatively correlated with hepatic total triglyceride (TG) levels. Increasing BSH activity in the VSG significantly increased the ratio of unconjugated bile acids in the serum and ileum, which, in turn, activated gut-restricted FXR–FGF19 signaling, including increased mRNA and protein levels of FXR and FGF19 and increased serum levels of FGF19. A similar phenomenon was observed in obese rats that received gut microbiota transfer from the VSG. Inhibiting intestinal FXR with an FXR antagonist eliminated the metabolic benefits of fecal microbiota transplantation derived from VSG.
Conclusion: Our results showed that BSH-enriched microbial changes resulting from vertical sleeve gastrectomy attenuate obesity by modulating bile acid metabolism and the intestinal FXR–FGF15/19 axis. This study suggests that increased intestinal BSH microbes may help consolidate the long-term efficacy of BS and may be a potential obesity therapy.

WED-045

PPAR α is a key molecule mwdiating the diurnal variation of sepsis in mice

Junzhou Zhao[1], Tianxiao Huang[1], Linlan Qiao[2], Qisheng Su[1], Rongqian Wu[1]. *[1]Xi'an Jiaotong University, Xi'an, China; [2]The University of Kansas Medical Center, Kansas City, United States*
Email: 736372467@qq.com

Background and aims: Studies have found that mice exposed to pathogens at ZT0 (the start of the light phase) survive better than those exposed at ZT12 (the end of the light phase). PPARα, a nuclear receptor activated by fatty acids and their derivatives, helps regulate metabolism and inflammation. Its expression changes rhythmically over the 24-hour cycle. This study focuses on understanding how PPARα contributes to the circadian differences in sepsis.
Method: Various techniques were used to study systemic metabolic responses in wild-type (WT) mice after cecal ligation and puncture (CLP) at ZT1 and ZT13, including survival analysis, biochemical assays, ELISA, RNA-seq, and LC/MS. PPAR-α knockout (KO) mice and siRNA-silenced PPAR-α (si-PPAR-α) AML12 cell lines were generated. The respiratory exchange ratio (RER) in PPAR-α KO mice was assessed using animal monitoring system, and rhythmic changes in circadian factors and PPAR-α target genes were evaluated in both PPAR-α KO mice and si-PPAR-α AML12 cells post-serum shock using qPCR. CLP models were created at ZT1 and ZT13 in PPAR-α KO mice and WT mice pre-treated with the ATGL inhibitor Atglistatin. In LPS pre-treated si-PPAR-α AML12 cells, rapamycin and chloroquine were used to investigate changes in autophagic flux through western blot. CLP models were established at ZT1 and ZT13 in Cry1/2 double-knockout (DKO) mice. Statistical analysis was performed using SPSS and R package. Results with p-values <0.05 were considered statistically significant.
Results: In WT mice, CLP at ZT13 had significantly lower levels of blood glucose, survival rates and higher levels of triglyceride compared to at ZT1. RNA-seq and LC/MS analysis of liver tissue after CLP at ZT1 and ZT13 identified the PPAR signaling pathway as the most enriched pathway. PPAR-α showed significant differences between the two time points. In PPAR-α KO mice, the RER was higher compared to WT mice. Although circadian genes retained rhythmic expression in PPAR-α KO mice and si-PPAR-α AML12 cells after serum shock, the rhythmic patterns of PPAR-α target genes were lost. In PPAR-α KO mice and WT mice were treated with the Atglistatin, there were no significant differences in blood glucose, glycerol, or survival rates between ZT1 and ZT13 post-CLP. In AML12 cells, silencing PPAR-α reduced autophagic flux. Adding rapamycin or chloroquine did not reverse these changes. Using the JASPAR database, Cry was identified as potential regulator of PPAR-α. In KO mice, the differences in survival between ZT1 and ZT13 after CLP were eliminated.
Conclusion: The diurnal variation of Cry modulates the diurnal differences in sepsis by regulating the circadian rhythm of PPAR α.

WED-046

The intestinal virome related clinical outcomes, systemic inflammation and immune functions in hospitalized cirrhosis patients – the foremost work in an indian patient cohort

Cyriac Philips[1,2], Arif Theruvath[3], Jitendra Keshri[4], Gunisha Pascricha[5], Jayasankar Madhusoodhanan[4], Subash Nagarajan[4], Yogeshwar Krishnan[6], Rajadurai Perumal[4], Ansu Alex[7], Philip Augustine[8]. *[1]Department of Clinical and Translational Hepatology, The Liver Institute, Rajagiri Hospital, Kochi, India; [2]Department of Clinical Research, Division of Gut Microbiome and The Liver, The Liver Institute, Rajagiri Hospital, Kochi, India; [3]Department of Clinical Research, The Liver Institute, Rajagiri Hospital, Kochi, India; [4]Department of Bioinformatics, MedGenome Labs, Bengaluru, India; [5]Department of Research Services, MedGenome Labs, Bengaluru, India; [6]Academic Research Laboratory, MedGenome Labs, Bengaluru, India; [7]Department of Advanced Flow Cytometry and Immunophenotyping, Rajagiri Hospital, Kochi, India; [8]Department of Gastroenterology and Advanced GI Endoscopy, Center of Excellence in GI Sciences, Rajagiri Hospital, Kochi, India*
Email: abbyphilips@theliverinst.in

Background and aims: Association between stool virome in cirrhosis patients and clinical events and outcomes, systemic inflammation and immune functions has only recently come to light. Unlike bacteria, fecal phages are sparsely linked with cirrhosis characteristics and 90-day outcomes while linkages between bacteriophages and cognitive function due to impact on bacteria is known from studies in the US. However, intestinal viral taxa were altered in fecal samples from patients with AH and associated with disease severity and mortality. Studies on virome in hospitalized cirrhosis patients and linked events and outcomes, severity of disease, inflammatory profile and immune functions from Indian patients remain unknown. In this foremost work from the Asian sub-continent, in samples collected at hospital admission, we analyzed stool virome associations with liver disease etiology and severity, long-term clinical events and immune functions and inflammatory profile.
Method: Whole genome sequencing, bioinformatics, and statistical analyses to study intestinal virome associations were performed on stool samples collected at admission from 78 cirrhosis patients who were grouped according to etiology, liver disease severity, quantified pro- and anti-inflammatory cytokines and immune functions (neutrophilic CD64, monocytic HLA-DR, monocytic CD14 expression) and Sepsis Index, a ratio of the expression of the CD64 molecule on neutrophils (NCD64) to the expression of human leukocyte antigen-DR on monocytes.
Results: Viral alpha-diversity was lower in sick MASLD cirrhosis compared to ALD (Shannon, Wilcoxon P = 0.02) while it was higher in those without ascites and hyponatremia (chao1, P = 0.008 and 0.04 respectively). Higher relative abundance (RA) of *Klebisella phage* related *Jiaodavirus* genera and *Siphoviridae* and *Cronobacter phage* spp. were notable in MASLD etiology. Anti-Gram-negative bacterial endolysin producing *Cronobacter phage* was expanded in ACLF patients and those with jaundice, ascites, and encephalopathy while *Klebsiella phage groups* were uniquely abundant in those with infection, variceal bleeding, MELD score ≥25, immune exhaustion (low mHLA-DR expression) at admission and death at 18 months. *Wifcevirus* (*E. coli* phage) was specifically expanded in those with acute kidney injury. Increased RA of *Escherichia virus Goslar* was associated with high Sepsis-Index, pro-inflammatory- and *Cronobacter phage* and *Podoviridae sp.* with anti-inflammatory cytokines.

Conclusion: Specific viral taxa and expansion of bacteriophages that target pathogenic bacterial species were uniquely expanded in sick hospitalized cirrhosis patients, adding to the body of evidence that bacteriophage therapy could be a pertinent tool in the armamentarium against complications in advanced chronic liver failure.

WED-047

A single center experience from India on associations of fungal microbiota (mycobiome) in cirrhosis - orally-predominant fungal dysbiosis in the gut and immune-escaping Candida species drive outcomes in hospitalized patients

Cyriac Philips[1,2], Arif Theruvath[3], Ansu Alex[4], Jitendra Keshri[5], Gunisha Pascricha[6], Jayasankar Madhusoodhanan[5], Subash Nagarajan[5], Yogeshwar Krishnan[7], Rajadurai Perumal[5], Philip Augustine[8]. *[1]Department of Clinical and Translational Hepatology, The Liver Institute, Rajagiri Hospital, Kochi, India; [2]Department of Clinical Research, Division of Gut Microbiome and the Liver, The Liver Institute, Rajagiri Hospital, Kochi, India; [3]Department of Clinical Research, The Liver Institute, Rajagiri Hospital, Kochi, India; [4]Department of Advanced Flow Cytometry and Immunophenotyping, Rajagiri Hospital, Kochi, India; [5]Department of Bioinformatics, MedGenome Labs, Bengaluru, India; [6]Department of Research Services, MedGenome Labs, Bengaluru, India, [7]Academic Research Laboratory, MedGenome Labs, Bengaluru, India; [8]Department of Gastroenterology and Advanced GI Endoscopy, Center of Excellence in GI Sciences, Rajagiri Hospital, Kochi, India*
Email: abbyphilips@theliverinst.in

Background and aims: *Candida* play an important role in pathogenesis and progression of various hepatobiliary disorders. Patients with cirrhosis requiring hospital admission have higher relative fecal abundance of *Candida* than outpatients with cirrhosis. Intestinal fungi fuel systemic inflammation in ALD. Candida-related fungal infections are linked with higher rates of ACLF, intensive care, and increased 30-day mortality. Data on fungal microbiota (mycobiome) and association with chronic liver failure and portal hypertension events, long-term survival, systemic inflammation, and immune functions in sick cirrhosis patients is lacking. In this original study on hospitalized sick cirrhosis patients, we analyzed stool mycobiome associations on clinical, inflammatory, and immune events.
Method: Whole genome sequencing and bioinformatics were performed on stool samples collected at admission from 78 cirrhosis patients who were grouped according to liver disease severity, measured pro- and anti-inflammatory cytokines and immune functions (neutrophilic CD64, monocytic HLA-DR, monocytic CD14 expression) and Sepsis Index (ratio of CD64 on neutrophils to mHLA-DR).
Results: Fungal alpha-diversity was significantly higher in patients with overt hepatic encephalopathy (OHE) at admission (chao1, Wilcoxon P = 0.04) and in those with high MCP-1 (protein activated in monocyte and macrophage response to fungal infections) levels (Shannon, P = 0.03). *Candida africana* and *C. albicans* predominated in ALD as well as ACLF, while *C. glabrata, C. tropicalis* and orally predominant *C. dubliniensis* were relatively abundant in MASLD cirrhosis; the latter both, also increased in patients with jaundice. The relative abundance (RA) of Saccharomycetaceae was higher in those with ascites, *C. dubliniensis* in patients with OHE, whereas *C. glabrata* in those without OHE, kidney injury, variceal bleeding, and with hyponatremia. *Kluyveromyces marxianus* and *C. dubliniensis* increased in patients who required intensive care at the outset. Increased RA of *C. glabrata* was consistently associated with lower levels of both pro- and anti-inflammatory cytokines, reduced immune exhaustion and functional monocytic depletion, while that of *C. tropicalis* with higher levels of IL-6 and TNF-alpha. *Candida dubliniensis* was associated with immune exhaustion (lower mHLA-DR expression). A higher RA of both *C. dubliniensis* and *C. glabrata* in stool microbiome was suggestive of probable/proven sepsis as per Sepsis Index variable.
Conclusion: Mycobiome changes at admission in sick cirrhosis patients are associated with specific clinical events and long-term survival. Various species belonging to *Candida* genus were expanded or reduced with respect to systemic inflammation and immune exhaustion demonstrating important role of gut mycobiome in driving cirrhosis-related complications and outcomes.

WED-048

Deep insights on gut bacterial associations with long-term clinical events, host immunology, and inflammatory cytokines in hospitalized Indian cohort of patients with cirrhosis

Cyriac Philips[1,2], Arif Theruvath[3], Jitendra Keshri[4], Gunisha Pascricha[5], Jayasankar Madhusoodhanan[4], Subash Nagarajan[4], Yogeshwar Krishnan[6], Rajadurai Perumal[4], Ansu Alex[7], Philip Augustine[8]. *[1]Department of Clinical and Translational Hepatology, The Liver Institute, Rajagiri Hospital, Kochi, India; [2]Department of Clinical Research, Division of Gut Microbiome and The Liver, The Liver Institute, Rajagiri Hospital, Kochi, India; [3]Department of Clinical Research, The Liver Institute, Rajagiri Hospital, Kochi, India; [4]Department of Bioinformatics, MedGenome Labs, Bengaluru, India; [5]Department of Research Services, MedGenome Labs, Bengaluru, India; [6]Academic Research Laboratory, MedGenome Labs, Bengaluru, India; [7]Department of Advanced Flow Cytometry and Immunophenotyping, Rajagiri Hospital, Kochi, India; [8]Department of Gastroenterology and Advanced GI Endoscopy, Center of Excellence in GI Sciences, Rajagiri Hospital, Kochi, India*
Email: abbyphilips@theliverinst.in

Background and aims: Detrimental changes to gut microbiota are closely linked to development of decompensation, prediction of hospitalization, increased risk of extra-hepatic organ failure (mainly hepatic encephalopathy), nosocomial infections and intensive care and death. In this foremost work from the Asian sub-continent, in stool samples from cirrhosis patients collected at hospital admission, we analyzed gut-microbial (GM) associations with disease etiology and severity, long-term clinical events, immune functions and inflammatory profile.
Method: Stool samples were collected at admission from 78 patients. Patients were grouped according to etiology, liver disease severity, immune functions (neutrophilic CD64, monocytic HLA-DR, monocytic CD14 expression and Sepsis Index), and levels of inflammatory cytokines (pro: IL-1α and β, IL-2,6,8, IFN-γ, MCP-1, TNF-α, VEGF/ anti: IL-4,10, EGF). Whole genome sequencing, bioinformatics, and statistical analyses to study microbial associations were performed as per standard protocols.
Results: Males predominated (N = 68, 87.2%) with median age 58 years. MASLD (43, 55.1%) was most common etiology. Around 20% (15) had ACLF and 38.5% (30) required ICU management at the outset. At 18 months, 43.6% (34) patients died. Patients with MELD≥25 had significantly lower alpha-diversity. Relative abundance of *E. coli* and *K. pneumoniae* were remarkably high in MASLD and ALD respectively. Severe and significant reductions in several short-chain-fatty-acid producing probiotic-species were notable in those admitted directly to ICU and ACLF patients. Statistical analysis revealed that *Clostridium spp.* was reduced in Child C class, orally-predominant bacteria *Shaalia odontolytica* expanded in gut of those with variceal bleeding, while *Lactococcus* and *Eubacterium* lessened in patients with higher MELD scores and *Blautia* and *Terrisporobacter* reduced in those dying at 18 months. *Eggerthella spp.* associated with sarcopenia expanded in patients with higher IL-4 levels, the latter, a marker of muscle regeneration. Increased anti-inflammatory responses were associated with *Bifidobacterium*, *Lactococcus* and endogenous steroid-producing *Mycolicibacterium*. Elevated pro-inflammatory cytokines and increased immune exhaustion were associated with significant expansions in *Sutterella*, *Ruminococcus*, and *Roseburia*.
Conclusion: Etiology, higher liver disease severity, decompensation and extrahepatic organ failures in hospitalized cirrhosis patients were associated with specific changes in GM communities. GM

modulation targeting expansion of beneficial bacteria using rational donor fecal transplant or personalized probiotic therapies could be a promising option for further research, in modifying adverse natural history of disease in hospitalized cirrhosis patients.

WED-049
Dietary bacterial D-lactate modulates liver steatosis and ameliorate experimental MASLD

André Santos[1], Raquel Duarte[1], Vanda Marques[1], Thomas Fließwasser[2], Cecilia Rodrigues[1]. [1]*iMed.ULisboa, Faculty of Pharmacy, University of Lisbon, Lisbon, Portugal;* [2]*Universitätsklinikum Bonn, UKB Institut für Pharmazeutische Mikrobiologie (IPM), Bonn, Germany*
Email: afasantos@ff.ulisboa.pt

Background and aims: Probiotic supplementation, particularly with *Lactobacillaceae* strains, has demonstrated notable liver health benefits, including reductions in serum liver enzyme levels, hepatic fat accumulation, and obesity-related complications. Recent studies on *Limosilactobacillus reuteri* DSM17938 highlighted the potential of its D-lactate production in liver protection, particularly through modulation of macrophage activity, which may help mitigate fibrosis. Unlike L-lactate, primarily synthesized by eukaryotic cells, D-lactate is predominantly produced by bacteria and has been shown to possess immunomodulatory properties, influencing macrophage phagocytosis, Kupffer cell function, and tumor suppression in the liver. This study aims to explore the effects of low-dose D-lactate in reducing hepatic lipid accumulation and mitigating MASLD progression, potentially positioning D-lactate-producing probiotics as a groundbreaking therapeutic strategy for managing liver diseases.
Method: We employed two experimental mice models: a methionine choline-deficient (MCD) diet model supplemented with *L. reuteri* DSM17938 and a 20-week High-Fat High-Fructose Diet (HFHFD) model supplemented with either *L. reuteri* DSM17938 *or* 1 mM D-lactate. After sacrifice liver and small intestinal histology and mRNA expression levels related to inflammation, lipid metabolism, and fatty acid transport were assessed. Additionally, D-lactate role was evaluated *in vitro* by examining its effects on palmitic acid accumulation and mRNA expression associated with hepatic lipid transport, synthesis, and storage.
Results: Mice fed an MCD diet with L. reuteri showed reduced hepatocellular vacuolization and inflammation, though serum ALT and AST levels were unchanged. Supplementation lowered liver fibrosis markers and downregulated lipid metabolism and inflammation genes. In vitro, 1 mM D-lactate reduced lipid accumulation and lipid marker expression in PA-exposed hepatocytes. In a 20-week HFHFD model, D-lactate supplementation reduced weight gain, liver-to-body weight ratio, steatosis, serum ALT levels, hepatic inflammation, and fibrosis markers. It also modulated small intestine immunity and gut microbiota, enhancing beneficial bacteria, underscoring its role in the gut-liver axis.
Conclusion: Our findings demonstrate that *L. reuteri* effectively alleviates experimental MASLD, partially through the production of intestinal D-lactate, which modulates hepatic fatty acid metabolism. This study highlights the potential of D-lactate to attenuate MASLD by regulating liver metabolism, reducing inflammation, and reshaping gut microbiota composition. These results position low-dose D-lactate as a promising therapeutic agent, offering an innovative approach for the management and prevention of MASLD.

WED-050-YI
Fecal microbiota transplant activates hepatic PPAR-alpha resulting in remission of alcohol-related liver disease in murine model

Ashi Mittal[1], Nishu Choudhary[1], Anupama Kumari[1], Kavita Yadav[1], Jaswinder Maras[1], Shiv Kumar Sarin, Shvetank Sharma[1]. [1]*Institute of Liver and Biliary Sciences, New Delhi, India*
Email: ashi08mittal@gmail.com

Background and aims: Fecal microbiota transplantation (FMT) is a promising therapeutic for alcohol-related liver disease (ALD). To combat malnutrition, patients are recommended high protein diet. This study explores how pre-educating donor microbiota with high protein could enhance FMT efficacy and investigates key signaling pathway underlying therapeutic effects of diet optimized FMT in ALD.
Method: ALD was induced in C57BL/6N mice using Lieber-DeCarli ethanol diet with thioacetamide over 8 weeks. FMT was performed from donors on standard or protein enriched diets, with recovery assessed post 7 days. Gut microbiota, stool metabolome and hepatic proteome were analyzed using 16S rRNA sequencing and LC-MS/MS. Based on proteomic findings, role of PPAR-alpha was validated using GW6471 inhibitor in a separate cohort of mice. Liver and intestinal injury was assessed using biochemical, histological and molecular parameters.
Results: Protein FMT (PF) showed superior efficacy over Standard FMT (SF), showing significant reductions in serum ALT (-1.5 fold change [FC], $p = 0.02$), AST (−1.3 FC, $p = 0.04$), hepatic steatosis (−1.8 FC, $p = 0.01$), and fibrosis (−1.4 FC, $p = 0.04$). PF reduced the gene expression of hepatic pro inflammatory markers TNFα (−1.5 FC, $p = 0.03$) and IL6 (−1.6 FC, $p = 0.02$). PF also increased intestinal tight junction protein ZO1 (1.9 FC, $p = 0.05$) with reduction in plasma endotoxin (−1.6 FC, $p = 0.06$), maintaining intestinal barrier integrity. PF significantly enhanced abundance of SCFA producer *Muribaculum* (2.4 FC, $p = 0.002$) and *Lachnospiraceae NK4A136* (2 FC, $p = 0.01$) while reducing opportunistic pathogens *Staphylococcus* (−6.7 FC, $p < 0.001$) with a concomitant increase in stool SCFA levels (butyric and propionic acid, FC > 1.5, $p < 0.05$). Hepatic proteome showed PF mediated upregulation of PPAR signaling, fatty acid degradation and oxidative phosphorylation (FC > 2, $p < 0.05$), with downregulation of necroptosis. In PF, PPAR alpha was most abundant, validated at mRNA level (2.3 FC, $p = 0.04$). A concomitant upregulation of PPAR alpha target genes involved in mitochondrial beta-oxidation (Cpt1, 1.5 FC, $p = 0.008$; Acox1, 1.3 FC, $p = 0.07$; Fabp1, 1.2 FC, $p = 0.001$) was also observed. The mechanistic role of PPAR alpha was validated using inhibitor GW6471. Western blot confirmed −2.3 FC inhibition ($p = 0.01$). PPAR alpha inhibition with FMT abolished therapeutic benefits, causing elevated serum injury markers (AST, 1.7 FC, $p = 0.003$; ALT, 2 FC, $p = 0.002$; Triglycerides, 1.4 FC, $p = 0.06$), increased hepatic lipid accumulation (1.9 FC, $p = 0.03$), and suppressed PPAR alpha target genes ($p < 0.001$; Cpt1 = −5 FC; Acox1 = −4.3 FC; Fabp1 = −4.7 FC).
Conclusion: Diet optimized FMT improves its therapeutic efficacy in ALD through hepatic PPAR alpha activation. Increased SCFA producing bacteria elevate stool SCFAs, which likely act as PPAR alpha ligands, promoting fatty acid beta-oxidation and reducing liver injury. PPAR-alpha inhibition abolished these benefits, highlighting its critical role in FMT mediated disease resolution.

WED-055
Microbiota-derived S-equol ameliolates inflammatory pathway in metabolic dysfunction-associated fatty liver disease

Kwon Goo-Hyun[1], Min Ju Kim[1], Kyeong Jin Lee[1], Jung A. Eom[1], In Gyu Park[1], Sung-Min Won[1], Ki Tae Suk[1], Dong Joon Kim[1]. [1]*Hallym University Institute for Liver and Digestive Diseases, Chuncheon, Korea, Rep. of South*
Email: d24020@hallym.ac.kr

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the most common liver disease and increasing worldwide. MASLD progression is associated with gut microbiota and its metabolites. The therapeutic effect of S-equol was highlighted via integrated network pharmacology from our most study. In this study, we aim to evaluate the liver-protective effects of S-equol and identify key microbial species responsible for its metabolism to assess its therapeutic potential in MASLD.

Method: Network pharmacology analysis and 16S rRNA analysis of human stool samples [healthy controls (n = 100) and MASLD patients (n = 100)] were conducted. 5 weeks age male C57BL/6J mice were fed a high-fat Western diet for 12 weeks. S-equol and *Lactobacillus paracasei* were fed 3 times a week orally feeding. Cecal Sample obtained from mice was centrifuged, the supernatant was treated with ACN and MeOH, and analyzed by LC-MS. The progression of MASLD was assessed based on liver histopathology and gene expression levels. Transcriptomic analysis was performed on liver tissue, and changes in microbial composition were examined using 16S-based sequencing of cecal samples.
Results: In human data, *Lactobacillus* levels were decreased (0.2%) in MASLD patients. In the network pharmacology analysis, isoflavone is metabolized to S-equol by L.paracasei JS1 species and S-equol showed inhibitory mechanism in binding to IL-6. In the S-equol-treated group, pathological analysis revealed a reduction in fat layer (steatosis; 2 vs. 1) and inflammation (Stage; 1.5 vs. 0.5) in MASLD mice, along with the regulation of fat synthesis (FAS, PPAR-gamma, SREBP1; $p < 0.01$) and inflammatory genes (MCP-1, TNF-alpha, and TGF-beta; $p < 0.05$) at the mRNA level. In addition, we performed RNA sequencing in liver tissue was confirmed to be a pathway related to inflammation and HSD3B5 the enzyme crucial for steroid hormone biosynthesis significant upregulation ($p < 0.01$) in the s-equol treatment group suggests a potential role in liver injury recovery pathways. Total of 169 substances were searched 68 in positive ion mode, 78 in negative ion mode, and 23 in neutral ion mode. Among them, S-equol obtained results in positive ion mode, and Daidzein obtained results in neutral ion mode. S-equol was higher in Nomarl Control compared to Western group, and it was confirmed that the amount of S-equol significantly increased in the group administered L.paracasei compared to the Western diet group. 16S rRNA sequencing of cecal samples revealed distinct changes in both alpha and beta diversity in the s-equol treatment group, highlighting its impact on microbial community composition.
Conclusion: This study demonstrates the significant liver-protective effects of S-equol in a MASLD model. S-equol is a representative metabolite produced by gut microbiota during the metabolism of daidzein that offering potential for microbiome-targeted therapies for MASLD and related liver disorders.

WED-056

Absence of cholesterol gallstone formation in male C57BL/6 mice by abrogation of hepatic thyroid hormone action

Denise Zwanziger[1], Elena Schmaler[1], Manuela Kowalczyk[1], Frédéric Flamant[2], Karine Gauthier[2], Christian Lange[3], Lars Moeller[1]. [1]*University Duisburg-Essen, University Hospital Essen, Department of Endocrinology, Diabetes and Metabolism, Essen, Germany;* [2]*University Lyon, Institut de Génomique Fonctionnelle de Lyon, Lyon, France;* [3]*Ludwig-Maximilian-University Munich, Medical Clinic and Polyclinic II, Munich, Germany*
Email: denise.zwanziger@uk-essen.de

Background and aims: Thyroid hormone (TH) impacts the hepatobiliary system. Epidemiological studies suggest a link between thyroid dysfunction and cholestatic liver disease. In previous studies we could confirm that a severe systemic TH deficiency promotes cholesterol gallstones. Using the lithogenic mouse model, we investigate whether changes in the systemic TH status or abrogation of hepatic TH action impact cholestatic liver disease.
Method: Male C57BL/6 wildtype (WT) mice received a six weeks lithogenic diet either under iodine sufficient or deficient condition. Male hepatocyte specific TRβ knockout (hepTRβKO) mice received a six weeks lithogenic diet to investigate the role of abrogated hepatic TH action. Biliary cholesterol gallstone and crystal prevalence, liver histology, liver and thyroid functions test, TH- and cholestasis-responsive markers were evaluated.
Results: Cholesterol gallstones were observed in lithogenic diet supplemented WT mice under iodine sufficient condition. In the iodine deficient group, a higher prevalence of cholesterol gallstone formation was observed, and the low iodine regiment reduced both systemic TH concentration and hepatic *deiodinase 1* (*Dio1)* mRNA expression. In hepTRβKO a six-week lithogenic diet treatment could not induce macroscopic visible cholesterol gallstones, whereas a reduced lipid content and elevated gene expression of the cytochrome P450 enzyme *Cyp2c39* were observed.
Conclusion: Systemic TH deficiency increases the pro-lithogenic response of male mice. Abrogation of hepatic TH action in male hepTRβKO mice shows an anti-lithogenic effect with an elevated expression of hepatic *Cyp2c39* encoding for an n-3 fatty acid producing enzyme. The results provide new insights into the regulatory principle of local TH action in the hepatobiliary system.

Microbially conjugated bile salts undergo hepatobiliary secretion in humans and mice

Frank Schaap[1], Ümran Ay[2], Hans van Eijk[1], Martin Leníček[3], Jesus M. Urman[4], Carmen Berasain[5], Jan G. Hengstler[6], Matías A. Avila[5], Steven Olde Damink[1], Ahmed Ghallab[6]. [1]*NUTRIM Institute of Nutrition and Translational Research in Metabolism, Maastricht University, Department of Surgery, Maastricht, Netherlands;* [2]*University Hospital RWTH Aachen, Department of General, Visceral and Transplant Surgery, Aachen, Germany;* [3]*Institute of Medical Biochemistry and Laboratory Diagnostics, Faculty General Hospital and 1st Faculty of Medicine, Charles University, Prague, Czech Republic;* [4]*Servicio de Digestivo, Hospital Universitario de Navarra, Pamplona, Spain;* [5]*Hepatology Laboratory, Solid Tumors Program, Center for Applied Medical Research (CIMA), University of Navarra, Pamplona, Spain;* [6]*Department of Toxicology, Leibniz Research Center for Working Environment and Human Factors, Technical University Dortmund, Dortmund, Germany*
Email: frank.schaap@maastrichtuniversity.nl

Background and aims: We recently showed that *N*-amidates of (chenodeoxy)cholic acid ([CD]CA) with leucine, phenylalanine or tyrosine, activate bile salt receptors at the cell surface (i.e. TGR5) and inside the cell (i.e. FXR), and are substrates of human bile salt transporters. Despite potential for intestinal absorption, we found levels of these microbial bile salt conjugates (MBSCs) to be negligible in mesenteric and portal blood of patients, while being readily detected in human bile. In this study, we investigated degradation in the intestinal lumen as possible cause of marginal presence of MBSCs in blood, and determined MBSC levels in ductal bile of patients with benign or malignant conditions of the biliary system.
Method: Male C57BL/6J mice were gavaged with a single dose of *D*- or *L*-TyrCA (tyrosocholic acid; 50 mg/kg BW, n = 3 per group), and blood was sampled from the jugular vein at baseline and up to 240 min after gavage. Animals were sacrificed after 4 hours, and portal and hepatic venous blood and bile were collected. TyrCA levels were quantified by LC-MS. Furthermore, MBSCs (i.e. Leu[CD]CA, Phe[CD]CA and Tyr[CD]CA) were determined in ductal bile collected via ERCP from patients with choledocholithiasis (n = 20), benign biliary strictures (n = 7), cholangiocarcinoma (n = 20) or pancreatic ductal adenocarcinoma (n = 20).
Results: In mice, neither TyrCA enantiomer was detected in blood at baseline. Gavage of *L*-TyrCA did not result in quantifiable levels in the systemic circulation (i.e. <2.5 nmol/L), contrasting with readily detection of *D*-TyrCA from the earliest time point after gavage, with median levels reaching 36 nmol/L at sacrifice. Portal TyrCA levels were >200-fold higher in mice gavaged with the *D* enantiomer. Porto-hepatic venous differences indicate that both TyrCA enantiomers underwent marked hepatic extraction. Only the *D* enantiomer was recovered in bile, approaching low millimolar concentration. In patients, MBSCs were detectable in bile with variable incidence among patient groups (from 30% to 86%), with median group levels being similar when considering MBSC-positive samples (from 6.5 to 35.2 nmol per mmol total bile salts; $p = 0.122$). Median levels were

indistinguishable between benign and malignant conditions (17.7 vs. 8.1 ppm; p = 0.146). In CCA, nutritional and immunological status was better in patients having detectable biliary MBSCs.
Conclusion: Following gavage, a plasma response was only observed for *D*-TyrCA. Resistance of the *D* enantiomer to degradation by pancreatic carboxypeptidases and/or bacterial bile salt hydrolases was observed *in vitro*, and this may contribute to the divergent plasma excursions. MBSCs undergo hepatobiliary secretion. MBSCs were detected in bile from patients with different conditions affecting the biliary system. Determinants of their presence in bile and (patho)physiological relevance of biliary MBSCs require further study.

WED-058
An integrative multi-omics and machine learning framework for diagnostic biomarker identification in patients with liver cirrhosis
In Gyu Park[1], Sang Joon Yoon[1], Sung-Min Won[1], Ki Kwang Oh[1], Un Joo Lee[2], Younglim Ham[3], Ki Tae Suk[1]. *[1]Institute for Liver and Digestive Diseases, Hallym University, Chuncheon, Korea, Rep. of South; [2]Hallym University, Department of Electronic Engineering, Chuncheon, Korea, Rep. of South; [3]Daewon University College, Department of Nursing, Jaecheon, Korea, Rep. of South*
Email: ktsuk@hallym.ac.kr

Background and aims: Cirrhosis is the final stage of chronic liver disease, presenting significant diagnostic challenges due to its multifactorial nature. Recent advances in integrated multi-omics analyses have shown potential for identifying novel biomarkers and improving diagnostic accuracy. This study aims to leverage shotgun metagenomics data from fecal samples to integrate microbial profiles, functional gene data, and metabolites. The goal is to develop machine learning (ML)-based algorithms for the diagnosis of cirrhosis and to identify potential key biomarkers.
Method: This study enrolled 34 patients with cirrhosis and 49 non-cirrhosis controls for metagenomic and metabolomic analyses. Shotgun metagenomics data were processed to extract microbial species profiles and KEGG Orthology (KO) genes, which were then integrated with metabolite data. The resulting dataset underwent feature selection using the Boruta algorithm, a ML-based feature selection method, to identify significant features for group classification. Four ML algorithms—Support Vector Machine (SVM), Random Forest (RF), 1D Convolutional Neural Network (CNN), and Multi-Layer Perceptron (MLP)—were applied to evaluate the performance of selected features for group classification. Each model's diagnostic performance was assessed using 10-fold cross-validation, with the area under the receiver operating characteristic curve (AUROC) as the evaluation metric.
Results: ML-based feature selection identified 40 microbial species, 64 KO genes, and 24 metabolites as key biomarkers. Among these, *Veillonella parvula* was identified as the most significant microbial species, *K02899* as the most important KO gene, and *deoxycholic acid* as the key metabolite with the highest feature importance. The model's diagnostic performance achieved an average AUROC of 0.91 when using the 40 microbial species, 0.88 with the 64 KO genes, and 0.86 with the 24 metabolites as key biomarkers. Notably, when integrating all 40 microbial species, 64 KO genes, and 24 metabolites, the diagnostic performance reached an AUROC of 0.96. These results demonstrate that multi-omics integration significantly enhances the accuracy of cirrhosis diagnosis and aids in identifying critical biomarkers.
Conclusion: This study highlights the contribution of multi-omics data integration in improving the accuracy of cirrhosis diagnosis and underscores the potential of machine learning-based approaches in identifying key biomarkers associated with cirrhosis. These findings suggest that multi-omics analysis may provide new directions for liver disease diagnosis and personalized treatment strategies, offering promising avenues for future research in liver disease.

WED-059
The role of the gut microbiota in high-fat diet-induced hepatic steatosis in juvenile and adult mice
Isidora Alempijević[1], Miloš Vratarić[1], Ana Teofilović[1], Danijela Vojnović-Milutinović[1], Nataša Veličković[1], Bojana Mićić[1], Sanja Kovačević[1], Ana Djordjevic[1]. *[1]Institute for Biological Research "Siniša Stanković" National Institute of the Republic of Serbia University of Belgrade, Belgrade, Serbia*
Email: isidoraalempijevic@gmail.com

Background and aims: A high-fat diet (HFD) disrupts hepatic lipid metabolism and contributes to steatosis, with the gut microbiota playing a key role through bacterial metabolites. As the composition of the gut microbiota changes with age, the timing of HFD introduction could influence hepatic lipid metabolism. Therefore, the aim of this study was to investigate the role of gut microbiota composition in hepatic lipid metabolism disturbances in juvenile and adult mice on HFD.
Method: Male C57BL/6J mice were divided into three groups: a control group on a standard diet (10 kcal% fat, D12450J, Research Diets) and two groups on a HFD (60 kcal% fat, D12492, Research Diets,) starting either in the juvenile (3rd week) or adult phase (9th week). All animals were sacrificed at 17 weeks of age. Liver sections were analyzed histologically and levels of markers of hepatic lipid metabolism were determined by Western blot or qPCR. The composition of the gut microbiota was determined by 16S rRNA sequencing. Metabolites were quantified by HPLC, while their effects on lipid metabolism were assessed by measuring the levels of G-protein-coupled receptor 43 (GPR43) and farnesoid X receptor (FXR) in the liver.
Results: HFD-induced hepatic steatosis occurred in both juvenile and adult mice, although the mechanisms underlying this pathology differed between the two groups. Adult mice showed increased de novo lipogenesis and decreased β-oxidation, whereas juvenile mice showed increased fatty acid uptake and decreased triglyceride secretion. The composition of the gut microbiota and their metabolites differed between groups, resulting in lower total SCFA, acetate, and predicted bile acid production in adults. These results were accompanied by decreased expression of GPR43 and FXR, which could contribute to altered hepatic lipid metabolism in adult mice.
Conclusion: The results show that changes in gut microbiota composition induced by HFD are more detrimental in adult mice, since it is associated with increased de novo lipogenesis and decreased β-oxidation in the liver, as well as reduced production of beneficial microbial metabolites. These results pinpoint that the effect of high-calorie diets on the gut microbiota is age-specific, with more prominent metabolite-driven effects on lipid metabolism in adult mice.

WED-060
Gut microbial antibiotic resistance genes in clinicians taking care of cirrhosis patients shows wide variation according to country income and could be a risk factor for bidirectional transmission
Amal Ahmad[1], Masoumeh Sikaroodi[1], Patrick Gillevet[1], Jasmohan Bajaj. *[1]George Mason University, Manassas, United States*
Email: jasmohan.bajaj@vcuhealth.org

Background and aims: Antimicrobial resistance (AMR) associates with poor outcomes in cirrhosis, the rates of which vary worldwide. Efforts to reduce transmission of resistant bacteria are critical. Gut microbes of clinicians could be reservoirs. During COVID-19 cirrhosis-related ICU nosocomial infections reduced likely due to lower contact. Aim: Determine presence of antibiotic resistance bacteria in gut microbiota of clinicians taking care of cirrhosis patients.
Method: Clinicians taking care of cirrhosis pts were approached to provide stool and queried regarding demographics, practice region, recent travel, no. of cirrhosis inpatients/outpatients seen & number with resistant infections. Metagenomic analysis including RGI for

AMR carriage were performed and compared between USA vs other regions, foreign travel, & those with infections.
Results: 62 clinicians (51 yrs, 58% men, 91% doctors, rest NPs) were included. 58% were from US, rest from low/middle income countries (LMICs) in Asia (20%), Eastern Europe (11%) & Latin America (11%). 71% were in practice for >10 yrs, most (80%) in public hospitals. Most had recent travel with >65% foreign travel. 53% saw >11 cirr outpts/wk, 35% >11 cirrhosis inpts/wk, & 75% saw ICU pts. Most (80%) saw >1–5 cirr pts with resistant infections/mth. None were on antibiotics. US vs others were statistically similar regarding resistant infections & no. of inpts/outpts seen. Microbiome: *USA vs others*: Short-chain fatty acid (SCFA) producers were higher in US clinicians (*Lachnospiraceae*, *Oscillispiraceae*) while Archaea, Proteobacteria, & sulfur-metabolizers (*Desulfovibrionaceae*) were higher in LMIC clinicians. Anti-tubercular (TB) resistance (Isoniazid, ethionamide & rifampin) genes, high-level fluoroquinolone (gyrB/parc) were ↑ in LMIC while fosfomycin E.coli & eatAv *E. faecium* resistance were↑ in USA. *Foreign travel*: ↑Enterobacteriaceae, Prevotellaceae & Actinomycetes and lower Archaea & SCFA producers were seen with foreign trips. Fluoroquinolone gyrB, S.aureus fusA & rifampin resistance was higher with foreign while E.coli Fosfomycin resistance was higher with domestic travel. *Pts with resistant infections*: Those taking care of resistant infection pts had ↑vancomycin ligase & isoniazid resistance genes with ↑Proteobacteria & Erysipelothricaceae taxa.
Conclusion: We found major variations in gut microbiota & AMR gene profiles among clinicians caring for cirrhosis pts globally. Higher anti-tuberculosis resistance genes in clinicians from low/middle income countries & greater E.coli/E.faecium resistance genes were found in US-based clinicians. Recent foreign travel and caring for patients with resistant infections affected AMR gene content, including anti-TB resistance genes. The higher TB resistance genes in clinicians from LMICs raises the possibility of bi-directional transmission. There is a need to evaluate AMR reserve within clinicians as a source for antibiotic resistance in cirrhosis and vice-versa.

WED-061

Gut metagenomic profiles predict 90-day hospitalizations despite controlling for diet, demographics & cirrhosis details in a multi-country cohort of patients with cirrhosis

Jasmohan Bajaj, Darja Nikitina[1], Masoumeh Sikaroodi[2], Mario Álvares-da-Silva[3], Aldo Torre[4], Ki Tae Suk[5], Ramazan Idilman, Mette Lauridsen[6], Elise Jonasson Nielsen[6], Hye Won Lee[7], Satya Priya Sharma[5], Matheus Truccolo Michalczuk[8], Jesus Alejandro Ruiz Manríquez[9], Edita Kiudeliene[1], Dilara Turan Gökçe[10], Sai Bojja[2], Juozas Kupcinskas[1], Patrick Gillevet[2]. *[1]Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]George Mason University, Manassas, United States; [3]Universidade Federal do Rio Grande do sul, Porto Alegre, Brazil; [4]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico; [5]Hallym University Medical Center, Chuncheon, Korea, Rep. of South; [6]Hospital of Southwest Jutland, Esbjerg, Denmark; [7]Yonsei University Medical Center, Seoul, Korea, Rep. of South; [8]Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil; [9]Hospital General "Dr. Manuel Gea González", Mexico City, Mexico; [10]Ankara University Medical Center, Ankara, Türkiye*
Email: jasmohan.bajaj@vcuhealth.org

Background and aims: Prediction of outcomes such as hospitalizations is critical in cirrhosis to ensure timely prevention. Microbial composition is altered in cirrhosis but can show wide variation between countries. Aim: define microbial features that associate with 90-day hospitalization in a multi-national cirrhosis cohort.
Method: Cirrhosis outpatients were recruited from 7 countries (USA, Türkiye, Korea, Denmark, Lithuania, Brazil & Mexico). Demographics, cirrhosis severity (MELD, complications, labs, medications), diet history, were recorded, stool collected & pts followed for 90 days for hospitalizations. Shotgun metagenomics for NGS was performed on stool. Regression analysis was performed using Maaslin2 for 90-day hospitalizations prediction. Covariates were chosen after PERMANOVA analysis & microbial species were added. Variables with $p < 0.05$ & $q < 0.05$ were considered significant.
Results: 679 cirrhosis pts (170 US, 90 Brazil, 53 Denmark, 93 each Lithuania & Mexico, 99 Korea & 84 Türkiye) were enrolled. 60% were men, MELD 12 ± 5, albumin3.5 ± 0.70, Na 138 ± 7. Most common etiology was alcohol (35%) then viral (31%) & MASLD (17%). 56% were decompensated (35% on lactulose, 19% on rifaximin, 44% prior ascites, 19% prior variceal bleed, 31% on NS βblockers). Diet varied esp with yogurt & coffee intake. 90-day Hospitalizations: Seen in 169 (25%), most of which 133 (79%) were liver-related. Country-wise rate differed with lowest in Brazil & Türkiye and highest in Lithuania & Korea). PERMANOVA showed that MELD, decomp status, yogurt intake, country of origin & HE-medications were significant covariates. Maaslin2: 15 species associated with hospitalizations after controlling for country, decomp status, MELD score, yogurt, HE medications & alcohol etiology.
Linked with ↓ hospitalizations: All had $p < 0.01$, *Ruthenibacterium lactatiformans* (coeff = 2.9, $q < 0.001$), *Bacteroides uniformis* (−2.3, p & $q < 0.001$), Flavonifactor plautii (−2.2, $q < 0.001$), *Faecalibacterium prausnitzii* (−1.9, $q = 0.02$), *Clostridium fessum* (−1.7, p & $q < 0.001$), Eggerthella lenta (−1.7, $q = 0.01$), *Clostridiales bacterium* (−1.7, $q = 0.01$), *Bifidobacterium pseudocatenulatum* (−1.7, $q = 0.05$), *Anaerobutyricum hallii* (−1.6, $q = 0.02$), *Eubacterium ramulus* (−1.4, $q = 0.02$), *Clostridium leptum* (−1.4, $q = 0.04$), *Intestinimonas butyriciproducens* (−1.3, $q = 0.04$), GGB9614_SGB15049 (−1.2 $q = 0.04$) & GGB2653_SGB3574 (−1.2, $q = 0.03$). These are short-chain fatty acid or lactate producers, or those involved in beneficial immune function. Linked with ↑ hospitalizations: *Enterococcus faecium* (Coeff 2.0, $p < 0.001$, $q = 0.003$), which is a pathobiont.
Conclusion: In a prospective cohort of outpatients with cirrhosis from 7 countries, microbial profiles could predict 90-day hospitalizations despite controlling for diet, cirrhosis details, country of origin, and demographics. Microbial profiling could improve risk prediction in cirrhosis beyond single center studies.

WED-063

Gut fungi in liver cirrhosis: characterizing mycobiota alterations and links to disease stages

Darja Nikitina[1], Edita Kiudelienė[1], Limas Kupčinskas[1], Jasmohan Bajaj[2], Juozas Kupcinskas[1], Jurgita Skieceviciene[1]. *[1]Institute for Digestive Research, Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Division of Gastroenterology, Hepatology and Nutrition, Virginia, United States*
Email: darja.nikitina@lsmu.lt

Background and aims: Recent studies have highlighted the significant role of gut microbiota in the pathogenesis of liver diseases. While research on bacterial changes in the gut has grown, the role of gut fungi (mycobiota) in LC has only recently begun to gain attention. However, further studies are essential to fully understand the impact of mycobiota alterations in LC. The aim of this study was to examine changes in the mycobiota profile by comparing stool samples from LC patients to those of a control group, and to explore the relationship between mycobiota alterations and clinical characteristics of the patients.
Method: The study analyzed stool samples from 83 LC patients and 48 control participants. LC group included Child-Turcotte-Pugh (CTP) A – 38%, CTP B – 38%, CTP C – 24%; MELD score ≥15–49%, MELD score <15–51%; Compensated LC – 24%, Decompensated LC – 60%, Recompensated LC – 16%. Additionally, 42% of patients were on lactulose, 29% on proton pump inhibitors, and 32% on carvedilol. Only DNA samples meeting the quality criteria were used for PCR amplification of the fungi-specific ITS2 region. Sequencing was performed using the NanoKit Illumina kit and the MiSeq Illumina platform.

Results: PERMANOVA analysis revealed significant differences in the global fungal profile between the LC group and controls, as well as across groups defined by MELD score, CTP classification, decompensation status, and lactulose prescription. Compared to controls, the LC group showed increased abundance of eight fungi and decreased abundance of twelve. Most significantly abundant fungi were found at multiple taxonomic levels. No significant differences in fungal alpha-diversity were observed. The fungi most associated with poorer health were in the *Saccharomycetales* family, including *Candida* species. Eleven taxa were linked to reduced disease severity in LC patients. Seven fungi were significantly more abundant in patients with decompensated liver function compared to those with compensated or recompensated liver function, while *Basidiomycota* was elevated in the compensated vs. recompensated comparison. Five fungi were associated with the absence of lactulose intake, and three were elevated in patients taking lactulose. Elevated levels of three fungi were also found in patients on non-selective beta-blockers. Our study showed no correlation between bacteria and fungi in terms of abundance or diversity in patient stool samples, with moderate correlations found only in the control group.
Conclusion: The mycobiota profile of LC patients differs from controls and correlates with clinical characteristics, particularly in global profile and specific fungi, but not alpha diversity. *Candida* is enriched in patients with more severe liver function. Minor fungal taxa are associated with reduced disease severity. Lactulose and carvedilol influence mycobiome composition. No strong correlation was found between fungal and bacterial communities in LC patients or controls.

Targeting gut-liver axis crosstalk with probiotic Lactobacillus rhamnosus attenuates ductular reaction in Mcpip1-deficient mice
Katarzyna Trzos[1], Tomasz Hutsch[2], Anastasiia Koval[3], Gabriela Machaj[3], Leidy Alejandra Gonzalez Molano[4], Jacqueline Rehner[4], Maximilian Olaf Förster[4], Marcin Bednarek[5], Bahtiyar Yilmaz[6], Magda Pilarczyk-Zurek[3], Szymon Surma[3], Joanna Koziel[3], Marcin Krawczyk[2], Andreas Keller[4], Soeren Becker[4], Guillem Ylla[3], Jolanta Jura[3], Jerzy Kotlinowski[3]. *[1]Doctoral School of exact and Natural Sciences, Jagiellonian University, Jagiellonian University, Cracow, Poland; [2]University of Warsaw, Warsaw, Poland; [3]Jagiellonian University, Cracow, Poland; [4]Saarland University, Saarbrucken, Germany; [5]ALAB, Warsaw, Poland; [6]Bern University, Bern, Switzerland*
Email: kat.trzos@doctoral.uj.edu.pl

Background and aims: PBC progression leads to the development of fibrosis, cholestasis, liver cirrhosis. Mcpip1fl/flAlbCre mice, with the Zc3h12a gene (encoding Mcpip1 protein) deleted in liver epithelial cells, exhibit typical PBC symptoms (increased levels of antimitochondrial and antinuclear antibodies, elevated total bile acids, and intrahepatic bile duct hyperplasia, disruption of bile duct epithelium and fibrosis). The primary objective of this project is to elucidate PBC symptoms in these mice following the administration of first- and second-line therapies commonly employed in PBC patients. The study incorporates the use of a probiotic (Lactobacillus rhamnosus) due to emerging evidence suggesting that gut microbiota via gut-liver axis can play a key role in PBC development and progression.
Method: Mcpip1fl/fl and Mcpip1fl/flAlbCre male mice at 6 weeks of age were randomly divided into five groups for drug treatment. Control group received corn oil, other groups received consecutively Lbr (L. rhamnosus, 10^9 CFU per day) suspended in water, ursodeoxycholic acid (UDCA, 15 mg/kg body mass per day) diluted in corn oil, UDCA and Lbr, UDCA and obeticholic acid (OCA, 10 mg/kg body mass per day) both diluted in corn oil. After 6 weeks of treatment, all mice were sacrificed, and the collected material analyzed by, amongst other, detailed serum liver tests, ELISA tests for the presence of anti-PDC-E2 autoantibodies, histological stainings (H&E, PSR) and qPCRs of livers and intestines, next generation sequencing (NGS) of total RNA from livers. Feces were collected for microbiome and shotgun sequencing.
Results: After 6-weeks of treatment significant proliferation of cholangiocytes and fibrosis in livers from Mcpip1 knock-out mice was detected, together with high serum level of total IgM, total bile acids and anti-PDC-E2 autoantibodies. NGS analysis revealed that processes such as humoral immune response and T cell activation are significantly enriched in control knock-out mice. Comparison of Lbr-treated and control knock-out mice revealed significant suppression of these processes. Moreover, in the gut, control knock-out mice exhibit significant increase of intraepithelial lymphocytes infiltration, mucosal and enterocyte height. Pathological phenotype in the gut were ameliorated by Lbr treatment which also provided a positive shift in microbiome composition of knock out mice. Firmicutes to bacteriodetes ratio was increased, as well as abundance of some butyrate-producing strains, such as Lachnospiraceae in mice after Lbr treatment.
Conclusion: This study points out a beneficial effect of probiotic use in complex, chronic, cholestatic liver diseases, such as PBC. The phenotype in Mcpip1fl/flAlbCre mice is significantly ameliorated by targeting gut-liver axis and host microbiome with the use of Lbr, thus the vicious circle can be broken, and the progression of PBC-like disease can be eased.

WED-065
Myricetin alleviates steatotic liver disease through gut microbiota modulation and Wnt-signaling inhibition
Ki Tae Suk[1], Min Ju Kim[1], Kyeong Jin Lee[1], Sung-Min Won[1], In Gyu Park[1], Kwon Goo-Hyun[1], Younglim Ham[2], Jung A. Eom[1]. *[1]Institute for Liver and Digestive Diseases, Hallym University, Chuncheon, Korea, Rep. of South; [2]Daewon University College, Department of Nursing, Jaecheon, Korea, Rep. of South*
Email: ktsuk@hallym.ac.kr

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a global health problem that can lead to the development of severe liver disease. Myricetin, a member of the flavonoid class contained in spinach, berries, tea and red wine, has numerous pharmacological properties such as anti-oxidative, anti-inflammatory, anti-fibrotic, anti-obesity, and anti-diabetic effects. However, it has not been revealed yet whether myricetin is associated with gut microbiota modulation and Wnt-signaling inhibition that regulates lipogenesis. We aimed to evaluate the effect of myricetin on lipid accumulation inhibition in MASLD.
Method: To investigate clinical characteristics of gut microbiota associated with liver disease, network pharmacology analysis and 16S rRNA analysis of human stool samples (30 healthy controls and 40 MASLD patients) were conducted. For animal experiment to prove the efficacy of myricetin, the mice were randomly divided into a normal control (n = 5), normal diet with myricetin treatment (150 mg/kg, n = 7), Western diet (n = 6), Western diet with myricetin treatment (150 mg/kg, n = 5). We used Western diet-induced MASLD, and myricetin was fed to the mice by oral gavage five times a week for 14 weeks. We performed oral glucose tolerance test, mice were fasted for 16 hours before the oral gavage with glucose (2 g/kg). MASLD severity was determined based on liver/body weight, pathological makers. We conducted qPCR analysis for Wnt-signaling pathway target genes.
Results: In human data, *Escherichia* (23.07%) and *Bifidobacterium* (1.34%) levels were increased in MASLD patients. On the contrary, the levels of *Bacteroides* decreased (75.74% → 62.91%). In the network pharmacology analysis, myricitrin is metabolized to myricetin by *Escherichia* species and myricetin showed inhibitory mechanism in binding to GSK3-β of Wnt-signaling pathway. In the MASLD model, myricetin treatment group significantly improved liver/body weight ratio, with lower steatosis grade (1 VS. 2) and NAS score (1 VS. 3) compared to the Western diet group. Myricetin supplementation improved glucose tolerance compared with the control group and

significantly decreased the expression of Acc1 (p = 0.0228) and Scd1 (p = 0.0069) mRNA levels associated with lipogenesis. Additionally, in Wnt-signaling target genes, Lrp5 and Gsk3-beta (p = 0.0045) were down-regulated by normalizing RNA sequencing data. Clustering showed that *Proteobacteria (phylum)* (2.34% → 5.39%), *Escherichia,* and *Bifidobacterium* were enriched in the myricetin group (more than 1%). Additionally, administration of myricetin showed an increase in compared to the control group.
Conclusion: We suggest that myricetin ameliorates lipid accumulation through inhibiting Wnt-signaling pathway and modulating gut microbiota composition. We assess the potential of myricetin to alleviate MASLD.

WED-066
Bacteroides caccae alleviates hepatic fibrosis by suppressing inflammation
Kyeong Jin Lee[1], Ki Tae Suk[1], Sung-Min Won[1], Min Ju Kim[1], In Gyu Park[1], Jung A. Eom[1], Kwon Goo-Hyun[1], Dong Joon Kim[1]. [1]*Institute for Liver and Digestive Diseases, Hallym University, Chuncheon, Republic of Korea, Chuncheon, Korea, Rep. of South*
Email: ktsuk@hallym.ac.kr

Background and aims: Hepatic fibrosis represent a key pathological change in the progression of chronic liver disease (CLD). Various forms of CLD, including metabolic-associated steatohepatitis (MASH), viral hepatitis, alcohol-related liver disease (ALD), and autoimmune liver disease, can progress to cirrhosis, which serves as a major risk factor for hepatocellular carcinoma (HCC). Recent reports suggest that certain microbiotas may help inhibit or ameliorate the progression of MASH-associated cirrhosis. This study aimed to characterize the role of *Bacteroides caccae (B. caccae)* in the gut microbiome of patients with CLD. Furthermore, using a mouse model of MASH-associated cirrhosis, we evaluated the effects of *B. caccae* on the gut microbiota and investigated the associated molecular mechanisms.
Method: To identify distinctive microbiota in liver cirrhosis, 217 stool samples were divided into healthy control (n = 100), MASH (n = 100), MASH associated cirrhosis (n = 10), and HCC (n = 7) group. To induce a MASH-associated cirrhosis model through dietary intervention, mice were fed a 3,5-Diethoxycarbonyl-1,4-Dihydrocollidine (DDC; 0.1%–0.05%) for three weeks. The diet consisted of 0.1% DDC in the first week, followed by 0.05% DDC for the subsequent two weeks. *B. caccae* was suspended in PBS at a concentration of 8×10^8 CFU/g and administered three times per week. The experimental mice were divided into three groups: a normal diet group (n = 7), a DDC diet group (n = 8), and a strain group (DDC diet supplemented with *B. caccae*, n = 8). CO_2 euthanasia was conducted, and liver tissues were fixed in 4% paraformaldehyde or frozen in liquid nitrogen. The left lobe of the liver was used for mRNA analyses. All experiments were performed in a blinded and randomized fashion.
Results: The relative abundance of *B. caccae* was significantly altered in the gut microbiota of cirrhotic patients compared to healthy individuals (healthy, 1.02%; MASH, 1.41%; MASH associated cirrhosis, 0.0067%; HCC, 1.1235%). In the mouse model, strain group (AST 350.9 ± 239.3, ALT 394.9 ± 230.7, BIL 0.3 ± 0.2) shows significantly improved in serum biochemical markers compared with DDC group (AST; 756.7 ± 103.9, ALT; 1099.6 ± 214.8, BIL; 1.1 ± 0.3). In addition, exhibiting protective pathological effects hepatic inflammation, hepatocellular damage, and fibrosis. The strain group downregulated the expression of inflammation-related markers (TNF-alpha, S100a8, S100a9, Mmp12, and other associated markers) and fibrosis-related markers (Col1a1, alpha-SMA, Acta2, and other related markers) in liver tissues compared with the DDC group, thereby improving liver function and alleviating tissue damage.
Conclusion: Our results suggest that *B. caccae* attenuate MASH-associated cirrhosis in a mouse model by suppressing inflammation and fibrosis.

WED-067
Akkermansia muciniphila inhibits serotonin-induced fibrosis progression in liver injury mouse model
Ki Tae Suk[1], Sung-Min Won[1], Min Ju Kim[1], In Gyu Park[1], Jung A. Eom[1], Kyeong Jin Lee[1], Younglim Ham[2], Kwon Goo-Hyun[1]. [1]*Institute for Liver and Digestive Diseases, Hallym University, Chuncheon, Korea, Rep. of South;* [2]*Daewon University College, Department of Nursing, Jaecheon, Korea, Rep. of South*
Email: ktsuk@hallym.ac.kr

Background and aims: Serotonin is an important transmitter that mediates various neurological and non-neurological physiological processes. However, paradoxically, while it may promote liver regeneration, it also has the potential to accelerate liver damage. *Akkermansia muciniphila* (*A. muciniphila*) has been reported to improve various metabolic diseases and liver diseases by modulating the gut-liver axis. We identified the exacerbation of liver fibrosis by serotonin treatment in liver injury mouse model and evaluated the inhibitory effect of *A. muciniphila* on serotonin-induced liver damage.
Method: Six-week-old male C57BL/6J mice were divided into 6 groups (n = 5/group; Normal control, normal control + serotonin, 3,5-Diethoxycarbonyl-1,4-Dihydrocollidine diet-fed [DDC, 0.1%], DDC diet + serotonin [100μM], 2 DDC diet-fed + serotonin [100 μM] + *A. muciniphila* [10^9 CFU/200ul for 2 times; live *A. muciniphila*, pasteurized *A. muciniphila*]). Serotonin was injected 100μM once through spleen injection. *A. muciniphila* was administered orally 24 hours and 12 hours before spleen injection. The weight, blood biochemistry, histopathology, and molecular biological analysis were performed.
Results: Directly treatment with serotonin through spleen injection method accelerated the progression of liver fibrosis. However, oral administration of *A. muciniphila* before serotonin treatment inhibited the progression of fibrosis. Supplementation of *A. muciniphila* (live and pasteurized) decreased ALT (Live, p = 0.01; Pasteurized, p = 0.008), AST (Live, p = 0.05; Pasteurized, p = 0.26), liver fibrosis area (Live, p = 0.004; Pasteurized, p = 0.004), and decreased the expression of fibrosis-related genes. In addition, *A. muciniphila* suppresses fibrosis progression by down-regulating 5-hydroxytryptamine receptor (5-HTR) 2A/2B.
Conclusion: Serotonin promote fibrosis progression in a DDC diet-induced liver injury mouse model. *A. muciniphila* is effective in inhibiting serotonin-induced fibrosis progression by down-regulating serotonin receptor 5-HTR 2A/2B.

Email: jjgmarin@usal.es

Background and aims: After being secreted to the intestine, bile acids (BAs) are actively re-covered by the ileum, mainly due to the apical sodium-dependent bile salt transport (ASBT). BAs are then released toward portal blood, which returns them to the liver.

Hepatocytes efficiently take up BAs from sinusoidal blood mainly through the Na^+-taurocholate co-transporting polypeptide (NTCP), with a minor contribution of the organic anion-transporting polypeptides (OATPs). Bacteria-mediated conjugation of BAs with non-canonical amino acids has been described to occur during their intestinal transit. Here, we have elucidated whether the most abundant microbial BA conjugates (MBACs) can also enter the enterohepatic circulation and whether they accumulate in patients with hepatobiliary dysfunction.
Method: Three MBACs were chemically synthesized by forming an amide bond between cholic acid (CA) and tyrosine (Tyr-CA), phenylalanine (Phe-CA), and leucine (Leu-CA). MBAC cholephilic behavior was evaluated in cellular and animal models. Transporter interactions were analyzed by molecular docking and dynamics simulations. In patients undergoing surgical or endoscopic bile collection, MBAC levels were determined in the bile by HPLC-MS/MS.
Results: Intravenous injection of MBACs in rats resulted in their efficient secretion into bile, with kinetics similar to glycocholic acid (GCA). Adding MBACs to the microbiota-free *in situ* isolated rat ileum lumen resulted in biliary secretion of intact MBACs. Similar results were obtained with GCA. In cells expressing human BA transporters, MBAC uptake, like that of GCA and taurocholic acid (TCA), was markedly enhanced by NTCP and ASBT. TCA inhibited this transport. In contrast, MBAC uptake was poorly mediated by OATP1B3 and scarcely by OATP1B1. These findings are consistent with results from molecular modeling studies, which provide insights into the interactions between MBACs and BA transporters, ASBT and NTCP. These interactions closely resemble those observed with liver-derived BA conjugates GCA and TCA. The analysis of human bile revealed the presence of MBACs (typically <100/10^6 molecules of total BAs) in samples collected from some (but not all) patients with liver cancer - hepatocellular carcinoma (8/12) and extrahepatic (7/33) and intrahepatic (7/10) cholangiocarcinoma- as well as other malignant - pancreatic ductal adenocarcinoma (27/55) - and non-malignant - benign stenosis (4/10), and choledocholithiasis (8/25) - conditions. An inverse relationship was found with total BA concentrations but not with age or outcomes of cancer patients.
Conclusion: MBACs behave as cholephilic compounds. BA transporters take them up with efficacy in the order of that of major primary conjugated BAs. The appearance of MBACs in the bile of some cancer patients is not related to hepatobiliary dysfunction but probably to changes in the microbiota that favor the proliferation of species able to generate MBACs.

WED-069

Gut microbiota composition of obesity resistant mice protects from high fat diet-induced steatosis

Milos Vrataric[1], Ana Teofilović[1], Danijela Vojnović-Milutinović[1], Nataša Veličković[1], Bojana Mićić[1], Sanja Kovačević[1], Ana Djordjevic[1]. *[1]Institute for Biological Research "Siniša Stanković" National Institute of the Republic of Serbia University of Belgrade, Belgrade, Serbia*
Email: milosvrataric96@gmail.com

Background and aims: Obesity, which is characterized by excessive fat accumulation, is a global health and economic burden. While most people on a high-calorie diet develop obesity and related metabolic diseases, some remain obesity resistant (OR). Obesity-induced changes in the gut microbiota increase capacity of the microbiota to harvest energy from the food, leading to fat accumulation and metabolic complications. Therefore, the aim of this study was to investigate the gut microbiota composition that contribute to obesity resistance and protect against the development of hepatic steatosis under a high-fat diet (HFD) regime.
Method: Male C57BL/6J mice were divided into two groups: a control group fed a standard diet containing 10 kcal% fat (D12450J, Research Diets) and a group fed a HFD containing 60 kcal% fat (D12492, Research Diets,). After 14 weeks, the mice on HFD were classified as obese or OR based on a 30% difference in body weight gain compared to the control group. The gut microbiota was analyzed by 16S rRNA sequencing of bacterial DNA isolated from fecal samples. Liver and small intestine sections were examined histologically, while changes in fatty acid uptake in these tissues were assessed by Western blot.
Results: Functional prediction of the gut microbiota activity revealed altered fatty acids metabolism and their biosynthesis in OR mice as compared to the obese group. In addition, a negative correlation between serum triglyceride levels and the relative abundance of Lactobacillus was found, and a positive correlation with the relative abundance of Desulfovibrio and Helicobacter. This change in the gut microbiota composition paralleled the decreased protein levels of free fatty acid transporters in the small intestine and liver of OR mice, which likely protect the liver from ectopic lipid deposition and steatosis characteristic for obese animals.
Conclusion: Increased abundance of Lactobacillus and decreased abundance of Desulfovibrio and Helicobacter is microbiota profile characteristic for obesity resistant animals, which is linked with reduced fatty acid transporters and decreased accumulation of lipids as compared to the obese animals. These results provide possible candidates for the probiotics that could potentially protect against obesity related complications.

Fecal microbiota transplantation results in increased caproic acid which alleviates steatosis and reduces ethanol-induced hepatotoxicity (in vivo and in vitro)

Nishu Choudhary[1], Ashi Mittal[1], Sandeep Kumar[1], Deepanshu Maheshwari[1], Kavita Yadav[1], Anupama Kumari[1], Jaswinder Maras[1], Shiv Kumar Sarin, Shvetank Sharma[1]. *[1]Institute of Liver and Biliary Sciences, New Delhi, India*
Email: nishuchoudhary987@gmail.com

Background and aims: Fecal microbiota transplantation (FMT) shows promise in treating alcohol-related liver disease (ALD). Dietary changes modify donor gut microbiota, which increase short chain fatty acids (SCFA), reduce gut leakiness and dysbiosis. However, how altered microbiota interacts with host remains unclear. We identified the microbial metabolites and explored their efficacy in murine model of ALD.
Method: Donor mice for FMT were fed an egg or soya protein enriched diet for two weeks before stool collection. FMT was performed in ALD mice model withsamples collected at baseline and day7 post-treatment to assess serum liver injury biomarkers, liver histopathology, and RT-PCR for inflammatory and lipid metabolism genes. Gut microbiota (16S rRNA) and metabolomes (fecal, plasma, hepatic) were analyzed using LC-MS/MS. Among the metabolites, caproic acid (CA) efficacy was tested in ethanol-administered Huh7 cells (100 mM ethanol for 3 days, 0.9 mM CA for 24 hours) and ALD mice (2.5% w/w CA). Beta-oxidation was analyzed using the Seahorse Extracellular Flux assay.
Results: Soya-FMT (S-FMT) reduced the liver injury significantly compared to egg-FMT as assessed by reduction in AST (1.2 FC, $p = 0.002$), bilirubin (1.2 FC, $p = 0.03$) and hepatic steatosis (1.7 FC, $p = 0.01$). S-FMT decreased hepatic TNFα (1.5 FC, $p = 0.02$) and IL6 (1.6 FC, $p = 0.02$) and increased the abundance of commensal (SCFA producing) taxa Coriobacteriaceae UCG-002 (1.5 FC, $p = 0.04$) and Acinetobacter (5.2 FC, $p = 2.55E-13$) and reduced abundance of opportunistic taxa Desulfovibrio (2.14 FC, $p = 0.02$) and Staphylococcus (9.6 FC, $p = 2.20E-33$). Metabolomics showed an increase in hepatic glutathione metabolism ($p = 0.04$) and, beta-oxidation of fatty acids ($p = 0.03$) and reduction in linoleic acid ($p = 0.01$) metabolism in S-FMT. It significantly increased stool bile acid and SCFA levels ($p < 0.05$), with increase in stool and plasma caproic acid (3 FC, $p = 0.0065$; 2 FC, $p = 0.01$, respectively). Stool bile acids showed increase in ursodeoxycholic acid (2 FC $p = 0.03$) and decrease in deoxycholic acid (1.8 FC, $p = 0.001$). Caproic acid supplementation reduced AST (2.6 FC, $p = 0.01$), ALT (2.3 FC, $p = 0.1$) and bilirubin (3 FC, $p = 0.06$) compared to untreated with reduction in inflammatory (IL6,

2.3 FC, p = 0.05; TNFa, 1.6 FC, p = 0.001) and lipid metabolites (5 FC, p = 0.03) and an increase in mitochondrial beta-oxidation (CPT1a, 2.5 FC, p = 0.05; Acox1, 3 FC, p = 0.04; PPARa, 4 FC, p = 0.001). After caproic acid administration, Huh7 cells also showed reduction in ethanol injury (IL6, 2.2 FC, p = 0.1; TNFa, 3.6 FC, p = 0.05; NFkb, 2.3 FC, p = 0.05), lipid accumulation (4.3 FC, p = 0.02) and concomitantly found to be dependent on beta-oxidation (3 FC, p = 0.05).
Conclusion: Soya-FMT was more effective in alleviating ALD injury. Caproic acid significantly mitigated steatosis in vitro and in vivo by enhancing beta-oxidation, thereby improving liver function. Caproic acid emerges as a promising therapeutic compound for further studies in alcoholic liver disease.

WED-075-YI
Restoration of gut microbiome-nitrogen metabolism post oral administration of black carrot extracellular vesicles in hepatic encephalopathy
P Debishree Subudhi[1], Jitendra Kumar[1], Anupama Kumari[1], Shivani Gautam[1], Shruti Sureshan[1], Ananthu Narayan[1], Ashmit Mittal[1], Chhagan Bihari[1], Shiv Kumar Sarin[1], Sukriti Baweja[1].
[1]*Institute of Liver and Biliary Sciences, New Delhi, India*
Email: sukritibiochem@gmail.com

Background and aims: Dysregulated nitrogen metabolism and gut dysbiosis contributes to hepatic encephalopathy (HE). We aimed to restore mucosal integrity and gut commensals by black carrot extracellular vesicles (BC-EV). Enriched with curative biomolecules, promote gut microbiome rebiosis, may lower ammonia and improve cognition in HE.
Method: BC-EV (52–200 nm, zeta potential-17 ± –2.4 mV)10^9 particles orally administered in thioacetamide (TAA) HE rat model. Fecal metabolomics by LC-MS, 16S rRNA metagenomics, biochemical, histopathological, and cognitive assessments were performed. Baseline CLD-HE patients (n = 10; healthy = 11;no prior treatment) also investigated. The nitrogen-metabolism associated genes profiling by qRT-PCR. The omics was performed to identify BC-EV cargoes. Stability in gastric/ intestinal conditions and effects on *Lactobacillus (LGG*) growth were evaluated.
Results: Fecal metabolomics in CLD-HE patients compared to healthy revealed 156 differentially expressed metabolites (61 upregulated and 95 downregulated). Notably, primary bile acid biosynthesis, fatty acid degradation, pyruvate metabolism, and terpenoid backbone biosynthesis found upregulated, whereas neomycin, kanamycin, and gentamicin, amino acid and amino sugar and butanoate metabolism (acetoacetic acid, p = 0.007) were downregulated. In TAA-HE rats (ammonia: 145.3 ± 43.6 μmol/L, bilirubin: 0.36 ± 0.05 mg/dL, AST: 83.05 ± 4.5 IU/mL, p < 0.001), similar alterations were observed with 53 metabolites downregulated amino acid, nitrogen, and butanoate pathways (butyric acid, p = 0.002) compared to control rats. BC-EV administration reduced ammonia (92.2 ± 23.6 μmol/L; p = 0.004), improved albumin (p = 0.007), hepatic ornithine, arginase levels (p = 0.028), cognitive functions (p = 0.004), than vehicle-HE rats. BC-EV modulated gut microbiota, reducing *Escherichia-Shigella* (p < 0.005) and promoting butyrate-producers *Lachnoclostridium* (p < 0.01), urea cycle/amino acid modulating staphylococcus and corynebacterium inversely corelated with ammonia (r = –0.94; p = 0.017). BC-EV increased occludin (p = 0.01) and anti-inflammation (IL-10, IL-22; p ≤0 .01), validated by PICRUSt analysis. Co-culture with LGG-BC-EV, growth of LGG enhanced (p = 0.004). BC-EV fecal metabolites L-lysine (p = 0.01), D-proline, and butyric acid (p < 0.05) were elevated. However, protein cargoes of BC-EV identified as isocitrate and oxoglutarate dehydrogenases, enzymes of TCA cycle support ammonia-consuming gut microbial metabolism. Gastric digestion *in vitro* reduced particle size with intact zeta potential.
Conclusion: HE patients and TAA-HE rats show impaired butanoate metabolism, restored by BC-EV. Ammonia reduction inversely correlates with Corynebacterium, which consumes ammonia to produce L-lysine, enhancing butyrate production. BC-EV offers a safe, effective therapy to improve gut-liver-brain axis.

WED-076
Association between gut fungal microbiota and subclinical coronary atherosclerosis in patients with MASLD
Nantawat Satthawiwat[1], Sunchai Payungporn[2], Pisit Tangkijvanich[1].
[1]*Center of Excellence in Hepatitis and Liver Cancer, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand;* [2]*Department of Biochemistry, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand*
Email: pisittkvn@yahoo.com

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) is an independent risk factor for cardiovascular disease (CVD). Recent evidence also indicates that gut bacterial microbiota is closely linked to CVD development. However, the role of intestinal fungi in the pathogenesis of CVD, particularly subclinical coronary atherosclerosis (SCA), is still to be determined. This study aimed to investigate the association of gut fungal microbiota with SCA in patients with MASLD.
Method: A cross-sectional study was conducted involving 103 MASLD patients without established CVD. Fibrosis and steatosis were assessed by magnetic resonance elastography (MRE) and proton density fat fraction (PDFF), respectively. SCA was detected based on coronary artery calcification (CAC). The internal transcribed spacer (ITS) sequencing was conducted to examine fecal fungal microbiota composition. Blood samples were analyzed for cytokine levels using LEGENDplex™ Human Cytokine Panel and trimethylamine-N-oxide (TMAO) concentration using liquid chromatography-mass spectrometry (LC-MS/MS).
Results: The mean age of the patients was 60.8 ± 11.2 years, and 53 (51.5%) were men. Thirty-two (31.1%) patients had advanced fibrosis (stage F3–F4). The CAC score positively correlated with MRE measurement (r = 0.459, p < 0.001) and tended to have a weak correlation with TMAO level (r = 0.223, p = 0.098) but was not correlated with PDFF value (r = –0.028, p = 0.837). Patients with F3–F4 had significantly higher CAC scores than those with F0–F2 (548.2 ± 592.7 and 244.1 ± 476.8, p = 0.039, respectively). Regarding fungal microbiota analysis, there was no significant difference in alpha- and beta-diversities between the F0-F2 and F3-F4 groups. A higher abundance of Candida albicans was significantly detected in fecal samples of patients with F3–F4 compared to patients with F0–F2 only in the subgroup with BMI ≥30 kg/m² and/or presence of T2DM (OR = 1.02, 1.01–1.04, p = 0.014). In this subgroup, the relative abundance of Candida albicans was significantly correlated with CAC score (r = 0.407, p = 0.023) and interleukin (IL)-17A level (r = 0.–442, p = 0.013) but not associated with TMAO level (r = 0.082, p = 0.562).
Conclusion: MASLD patients with advanced fibrosis had elevated CAC scores, indicating an increased risk of CVD development. The enrichment of Candida albicans was shown to be associated with subclinical atherosclerosis, particularly among obese patients with or without T2DM.

Email: q.j.augustijn@amsterdamumc.nl

Background and aims: Gut microbiome modulation is gaining attention in the unmet therapeutic need of metabolic dysfunction-associated steatohepatitis (MASH), both with probiotics and fecal microbiota transplantation (FMT). Yet, their combination has never been investigated. Here we investigated next-generation beneficial bacteria (NGBB) *Anaerobutyricum soehngenii*, pasteurized *Akkermansia muciniphila* and *Bifidobacterium animalis subsp. lactis* combined with FMT in a diet-induced MASLD mouse model.
Method: Male C57BL/6J mice received a Western-type high-fat diet and water with 15% fructose (WDF) for 20 weeks to induce MASLD. From week 10, mice received daily gavages with either 1) a combination of A. soehngenii, pasteurized A. muciniphila and B. animalis subsp. lactis (NGBB), 2) FMT of a healthy human donor, 3) NGBB combined with FMT (FMT-NGBB), or 4) placebo. FMT, NGBB and FMT_NGBB treated mice received fructo-oligosaccharides in drinking water. Chow-fed mice were included as control group.
Results: WDF resulted in steatohepatitis. Compared to placebo, only the FMT-NGBB treatment resulted in a lower relative liver weight and a 47% lower hepatic triglyceride concentration (32.4 [95%CI 21.4–43.3] vs. 60.9 [95%CI 42.4–79.5] nmol/mg liver, $p < 0.05$). In line, FMT-NGBB treatment resulted in better histopathological steatosis and lobular inflammation scores. While hepatic lipogenic and oxidative mRNA expressions were not affected by the treatments, FMT-NGBB treated mice had lower *Cd36* expression, which might be indicative for reduced hepatic fatty acid uptake. Expression of *Col1A1* was decreased more than twofold in the FMT and FMT-NGBB group when compared to placebo (p 0.0002 and p 0.0003, respectively). Moreover, a first analysis of RNA sequencing showed a reduction of mRNA expression of genes related to lipid metabolism, inflammation and fibrosis in livers of FMT-NGBB treated mice.
Conclusion: Remarkably and in contrast to the single treatment arms, FMT supplemented with next-generation beneficial bacteria reduced hepatic steatosis in mice by 47%. Histopathological steatosis and inflammation scores improved after FMT_NGBB treatment. RNA sequencing showed a reduction of hepatic mRNA expression of genes involved in inflammation and fibrosis. These findings highlight the potential of combining microbiota modulation strategies for MASH.

WED-078
Sex-specific effects of beta-blockers on the gut microbiome and metabolome in liver cirrhosis

Rosa Haller[1,2], Maximilian Nepel[1], Julia Traub[3], Tobias Madl[4,5], Hansjörg Habisch[4], Angela Horvath[1,2], Vanessa Stadlbauer[1,2,5].
[1]Division of Gastroenterology and Hepatology, Department of Internal Medicine, Medical University of Graz, Graz, Austria; [2]Center of Biomarker research in Medicine (CBmed) GmbH, Graz, Austria; [3]Department of Clinical Medical Nutrition, University Hospital Graz, Graz, Austria; [4]Otto Loewi Research Center, Medical University of Graz, Graz, Austria; [5]BioTechMed-Graz, Graz, Austria
Email: rosa.haller@medunigraz.at

Background and aims: Beta-blockers (BB) are used in liver cirrhosis to manage portal hypertension and variceal bleeding, with emerging evidence suggesting potential benefits in systemic inflammation. Their effect on the gut microbiome, crucial for cirrhosis progression, remains poorly understood. We aim to investigate the impact of BB on the gut microbiome and metabolome in liver cirrhosis patients, focusing on sex-specific differences.
Method: 121 patients with liver cirrhosis were recruited. MELD scores were available for all, stool samples of 99 patients (metabolome analysis), and 16S rRNA gene sequencing data of 84 (62 men, 65 ± 7 years; 22 women, 58 ± 13 years, $p = 0.012$) patients (microbiome analysis). To explore sex-specific differences, patients were grouped by sex and compared across non-selective beta-blockers (NSBB), selective beta-blockers (SBB), and no intake. Alpha- and beta-diversity, as well as ANCOM and LEfSe, were used to analyze microbiome differences. The metabolome was assessed using NMR and analyzed using orthoPLS-DA in MetaboAnalyst 6.0.
Results: 40 patients took NSBB (11 women) and 22 took SBB (4 women). In men, MELD scores were lower for SBB users compared to NSBB ($p = 0.031$), while no differences were observed in women. Microbiome analysis showed increased alpha diversity in male SBB users compared to NSBB ($p < 0.05$), with no changes in women. Beta diversity was not different between drug groups and sexes. ANCOM and LEfSe identified a higher abundance of short-chain fatty acid (SCFA) producers, Prevotella and Phascolarctobacterium, in both NSBB and SBB users compared to non-users. In contrast, in women, SCFA producers UCG-002 and Subdoligranulum were more abundant in non-BB users, while Ruminococcaceae Incertae Sedis higher in SBB users. In the metabolome, l-valine was associated with no BB intake in men, while the purine derivative hypoxanthine was elevated in BB users, particularly SBB. Hypoxanthine was also linked to BB intake in women, indicating shared metabolomic responses across sexes despite microbiome differences (all VIP ≥2.5).
Conclusion: BB use in liver cirrhosis patients induces distinct microbiome and metabolome changes with notable sex-specific differences. In men, SBB intake was linked to lower MELD scores, increased diversity, and beneficial bacteria, while in women, beneficial bacteria were associated with the absence of BB intake. Metabolome analysis revealed fewer sex-specific differences, with both sexes showing increased hypoxanthine, which has been associated with improved gut permeability and Prevotella abundance. Further research is needed to understand drug-microbiome interactions better.

Quantification of genes encoding bacterial sialidases and enzymes of the nan cluster in combination with cutaneous T cell-attracting chemokine (CTACK) in bile for the early detection of cholangiocellular carcinoma in patients with primary sclerosing cholangitis (PSC)

Antonia Triefenbach[1,2,3], Anika Freise[1,3], Helin Abdullah[1], Leonard Knegendorf[4], Dietmar Pieper[5], Christine Falk[6], Heiner Wedemeyer[1], Friederike Klein[1,2,3], Benjamin Heidrich[1,2,3].
[1]Department of Gastroenterology, Hepatology and Endocrinology, Hannover Medical School (MHH), Hannover, Germany; [2]German Center for Infection Research (DZIF), Hannover-Braunschweig, Germany; [3]Cluster of Excellence RESIST (EXC 2155), Hannover Medical School (MHH), Hannover, Germany; [4]Institute for Medical Microbiology and Hospital Epidemiology, Hannover Medical School (MHH), Hannover, Germany; [5]Helmholtz Centre for Infection Research, Braunschweig, Germany; [6]Institute of Transplant Immunology, Hannover Medical School (MHH), Hannover, Germany
Email: triefenbach.antonia@mh-hannover.de

Background and aims: Primary sclerosing cholangitis (PSC) is a devastating disease of the biliary tract. Affected patients suffer from recurrent bacterial cholangitis due to the destruction of the biliary tract. Many patients develop cholangiocellular carcinoma (CCA) due to recurrent and/or chronic inflammation. However, the detection of CCA in these patients is difficult and in many cases not successful. In a former study we identified the degradation of cholangiocellular glycocalyx by bacterial sialidases as a new pathomechanism in PSC. In

the present study we aimed to analyze the clinical use of detection and quantification of genes encoding bacterial sialidases, N-acetylneuraminate lyases and N-acetylmannosamine kinases in combination with cytokines in bile of patients with PSC for the detection of CCA.

Method: During routine endoscopic retrograde cholangiography (ERC) bile was collected in 112 patients with PSC with and without CCA during 2008–2020. Bile was aliquoted and stored immediately at –80°C. In order to quantify the amount of genes encoding bacterial sialidases, lyases and kinases we developed an in-house qPCR. DNA was isolated after mechanic lysis with the EurX-Kit. In a sub-cohort of 88 patients with 137 samples 29 cytokines were measured.

Results: In the overall cohort, pool 1 (sialidases), pool 4 (lyases) and pool 5 (kinases and lyases) showed significantly higher DNA concentrations in patients with PSC and CCA compared to patients without CCA (pool 1: 2.80×10^4 vs. 7.10×10^5 copies/µl; $p < 0.0001$) (pool 4: 1.31×10^4 vs. 7.22×10^5 copies/µl; $p < 0.0001$) (pool 5: 2.91×10^3 vs. 1.67×10^4 copies/µl; $p < 0.0001$). The area under the curve (AUC) for the pools were 0.831 for pool 1, 0.793 for pool 4 and 0.754 for pool 5. Based on the Youden-Index we identified for each parameter a balanced cut-off with 1.65×10^5 copies/µl for pool 1, 3.16×10^5 copies/µl for pool 4 and 9.83×10^3 copies/µl for pool 5. In the sub-cohort, we identified 4 cytokines differentiating between patients with PSC with and without CCA. Out of these CTACK showed the best performance with a specificity of 0.78, sensitivity of 0.90 and an AUC of 0.872. Based on the Youden-Index we identified a balanced cut-off with 7.6. In a next step we could increase the diagnostic value with a combination of our parameters. Patients with at least 2 out of 4 parameters being positive had a CCA with a specificity of 87.4% and a sensitivity of 84.6%.

Conclusion: Based on our new qPCR for bacterial sialidases, lyases and kinases in combination with CTACK we developed a new diagnostic tool for the early detection of CCA in patients with PSC. Early detection of CCA is crucial for the outcome of affected patients. Therefore, we see a huge diagnostic potential of our approach. However, further prospective studies in independent cohorts is needed to validate our system.

WED-080-YI

Gut multiomics links bacterial-driven increase in Lactate with the development of shock and identifies metabolite panel for prediction of adverse outcomes in ACLF patients

Gaurav Tripathi[1], Vasundhra Bindal[1], Yash Magar[2], Neha Sharma[1], Sushmita Pandey[1], Manisha Yadav[3], Babu Mathew[3], Nupur Sharma[3], Rimsha Rimsha[3], Sanju Yadav[3], Abhishak Gupta[4], Shvetank Sharma[3], Rakhi Maiwall[3], Shiv Kumar Sarin, Jaswinder Maras[1]. *[1]Institute of liver and billiary sciences, DELHI, India; [2]Amity Stem Cell Institute, Haryana, India; [3]Institute of liver and billiary sciences, New Delhi, India; [4]Artemis Hospital, Haryana, India*
Email: jassi2param@gmail.com

Background and aims: Acute on chronic liver failure (ACLF) is associated with septic shock (lactate > 2 mM/l) through liver dysfunction and immune dysregulation. Gut microbial and metabolic imbalances worsen inflammation, increasing multi-organ failure and mortality risk. This study screened gut and plasma meta-proteomes and metabolomes to identify indicators linked to adverse outcomes in ACLF patients.

Method: Baseline stool and plasma samples were collected from 50 healthy controls, 50 alcoholic cirrhosis, and 100 alcohol-associated liver failure patients (non-sepsis: 20, sepsis: 30, septic shock: 50). High-resolution mass spectrometry (HRMS) was used to analyze human and bacterial metabolomics and meta-proteomes, which were cross-correlated with clinical parameters and severity indices (MELD, SOFA, CTP, DF). Probability of detection (POD) models for septic shock and early mortality were developed based on bacterial and metabolite markers and validated in 300 patients using HRMS and machine learning (ML).

Results: Stool and plasma metabolome analysis identified over 1,200 metabolites, with more than 300 upregulated (FC > 1.5; $p < 0.05$) in septic shock patients, associated with B-oxidation, TCA cycle, bile acid biosynthesis, fatty acid, and tryptophan metabolism. Notably, septic shock patients showed elevated levels of over 26 carboxylic acid metabolites, including malate, fumarate, oxaloacetate, and lactate, linked to lactate accumulation ($p < 0.05$). Stool and plasma metaproteome analysis identified more than 100 bacterial species of them > 40 bacterial species were upregulated in septic-shock patients ($p < 0.05$). Bacterial diversity was found to be lowest in Septic shock patients ($p < 0.05$) and showed significant increase in Bifidobacterium lactis (FC > 55000, AUC > 0.98), Clostridium botulinum (FC > 20000, AUC > 0.89), Clostridium perfringens (FC > 13, AUC > 0.92) and Clostridium acetobutylicum (FC > 6, AUC > 0.87). Interestingly, septic shock showed increase in Bifidobacterium lactis and Clostridium species; which contribute in acidic metabolites (acetate, butyrate and others) and increased lactate levels. Probability for Diagnosis (POD) of non-survival calculated based on Chenodeoxyglycocholate (FC > 756), Geranyl acetate (FC > 477), Taurochenodeoxycholicacid (FC > 193), Glycocholic acid (FC > 760), Ornithine (FC > 291) correlated with clinical parameters and severity ($R^2 > 0.7$, $p < 0.05$), showing diagnostic efficiency of AUC > 0.95 and HR = 5.2 ($p < 0.05$). Increased Clostridia species and top5 metabolite panel on validation in 300 independent patients demonstrated > 95% sensitivity/specificity for predicting shock and early mortality.

Conclusion: The study identifies Bifidobacterium lactis and Clostridium species as key drivers of lactate increase and septic shock. The metabolite panel offers a reliable biomarker for diagnosing septic shock and predicting mortality in critically ill patients.

WED-081-YI

Role of alcohol-associated gut microbiota in driving liver fibrosis via tgfbr1 kinase alterations in alcohol associated liver disease

Manisha Yadav[1], Abhishak Gupta[2], Neha Sharma[1], Vasundhra Bindal[1], Sanju Yadav[1], Rimsha Rimsha[1], Gaurav Tripathi[1], Nupur Sharma[1], Sushmita Pandey[1], Babu Mathew[1], Shiv Kumar Sarin, Jaswinder Maras[1]. *[1]Institute of liver and Biliary sciences, New Delhi, India; [2]Artemis, GURUGRAM, India*
Email: jassi2param@gmail.com

Background and aims: ALD is worsened by gut dysbiosis, affecting inflammation, fibrosis, and metabolism. While gut microbiota influence fibrosis, their role in ALD is unexplored. This study investigates how alcohol-associated gut microbiota (AGM) induces liver kinome alterations, driving inflammation and fibrosis.

Method: ALD rats were developed using a 40% Lieber-DeCarli ethanol diet. AGM-linked kinome changes were studied in humanized rats colonized with stool from SAH patients (SAHs→HR) and compared to ALD rats transplanted with healthy donor stool (HD→ALDR). Stool and liver samples (n = 6/group) underwent metaproteome and phosphoproteome analyses. AGM-associated kinome changes, particularly in fibrosis induction, were identified and validated, with a focus on the roles of *Streptococcus pyogenes* and Lactobacillus in hepatic stellate cell activation (LX2 line).

Results: Stool metaproteome identified significant increase in 10 bacterial genera including *Streptococcus, Staphylococcus, Clostridium,* & others in SAHs→HR similar to ALD ($p < 0.05$). COG functional analysis showed increased post-transcriptional protein modifications (PTM) & reduced lipid transport & metabolism, indicating that AGM contributes to PTM changes & steatosis as seen in ALD ($p < 0.05$). Liver kinome analysis in SAHs→HR rats showed 85 significantly upregulated kinases, with 34 overlapping with ALD rats ($p < 0.05$) associated with inflammation (12: Mapk14, Map3k10, & others), fibrosis (4-Igf1r, Tgfbr1, Col4a1), lipid metabolism (11-Cdk14, Cdk18, Cdk13, & others), & regeneration (3-Bmpr1a, Met, Igf1r). Interestingly, HD→ALDR significantly reversed the levels of *Streptococcus* 10 folds, *Staphylococcus* 3 folds, and *Clostridium* 5 folds & 18 kinases associated

to inflammation (Btk, Camk4, Mapk, Met, Nuak1 & others) & fibrosis (Col4a1, Tgfbr1, Fgfr2 & others, $p < 0.05$). Metaproteome & kinome correlation analysis showed that *Streptococcus* genus directly correlated with inflammation & fibrosis (Btk, Mapk, Tgfbr1) linked kinases ($r2 > 0.9$, $p < 0.05$), suggesting that AGM may promote fibrosis in ALD via modulation of these kinome. A significant reduction in Tgfb (1.5 folds) was also found post FMT in SAH patients validating our observation. Further the linkage of pathogenic strain of *Streptococcus pyogenes* to fibrosis was established by treating LX2 cell line with its secreatome which showed significant induction of TGFβ (5.1 folds) and TGFBR1 (3.8 folds) expression, confirming the role of *Streptococcus pyogenes* in fibrosis induction.

Conclusion: Alcohol-associated gut microbiome alters the liver kinome, driving inflammation, fibrosis, & lipid dysregulation, with *Streptococcus pyogenes* promoting TGFβ/TGFBR1-mediated fibrosis. FMT from healthy reversed these effects, highlighting the therapeutic potential of gut microbiota modulation in ALD & identifying kinases & bacteria as targets for treatment.

WED-082-YI

Gut-oral microbial translocation promotes ammonia metabolism in liver cirrhosis

Yi Jin[1], Frederick Clasen[1], Jose G. Guevara[1], Debbie L. Shawcross[2], Jonel Trebicka[3,4], Rajiv Jalan[4,5], Vishal C. Patel[2,6,7], David Moyes[1], Saeed Shoaie[1]. [1]*Centre for Host-Microbiome Interactions, Faculty of Dentistry, Oral & Craniofacial Sciences, King's College London, SE1 9RT, London, United Kingdom;* [2]*Institute of Liver Studies, Department of Inflammation Biology, School of Immunology and Microbial Sciences, King's College London, SE5 9NU, London, United Kingdom;* [3]*Department of Internal Medicine B, University of Münster, Münster, Germany;* [4]*European Foundation for the Study of Chronic Liver Failure, EFCLIF, Barcelona, Spain;* [5]*Liver Failure Group, UCL Institute for Liver and Digestive Health, Upper third floor, Royal Free Campus, Rowland Hill Street, Hampstead, NW3 2PF, London, United Kingdom;* [6]*Roger Williams Institute of Liver Studies, Faculty of Life Sciences and Medicine, King's College London, SE5 8AF, London, United Kingdom;* [7]*Institute of Liver Studies, King's College Hospital NHS Foundation Trust, SE5 9RS, London, United Kingdom*
Email: saeed.shoaie@kcl.ac.uk

Background and aims: Alterations in gut and oral microbiota have been implicated in the pathology of liver cirrhosis (LC). Gut-oral microbial translocation and oralisation of gut microbiota are associated with the progression of LC; yet their contributions to metabolic dysregulation and disease severity remain unclear. This study aims to elucidate the mechanistic link between microbial translocation and metabolic alterations in LC.

Method: Publicly available shotgun metagenomic data of paired saliva and faecal samples from liver cirrhosis patients ($n = 85$) and healthy controls ($n = 61$) were used in this study with different severity, and presence of hepatic encephalopathy. A microbial reactobiome was constructed to profile metabolic gene functions and identify metabolic patterns within oral and gut microbiomes. Unsupervised clustering was performed to explore reactobiome clusters and the association non-parametric test was applied to investigate how the determined reactotypes stratified clinical metadata. The gut-oral reactobiome distance for each individual was determined using Bray-Curtis dissimilarity based on paired data, and their association with disease severity (as measured by MELD scores) was assessed by linear regression. For key species, genome-scale metabolic models and constraint-based modelling were applied to predict the metabolic flux turnovers, including ammonia production, at both the species and community levels. Co-abundance network analysis was integrated with simulation results to identify key microbial contributors within the microbiome.

Results: Distinct metabolic profiles of gut and oral microbiota were identified in LC patients, revealing two oral reactotypes and three gut reactotypes associated with LC severity ($p < 0.05$). The oral-gut reactobiome distance decreased linearly with increasing MELD score ($p < 0.01$). Patients with lower oral-gut reactobiome distances (low-OGD) exhibited co-abundance of sixteen microbial species in both oral and gut niches. Some of these species were predicted to produce significantly higher levels of ammonia compared to healthy gut commensals ($p < 0.05$) via amino acid metabolism pathways. Among these species, predominantly oral-origin species were identified as key contributors to high ammonia production, based on integrated network analysis. Community-level modelling further predicted an increased ammonia level in the low-OGD model when adding the key species, implicating that oral-originating species contribute to exacerbating ammonia toxicity in liver cirrhosis.

Conclusion: This study identifies the gut-oral translocation of specific microbes as a potential driver of increased ammonia production in liver cirrhosis. The convergence of the metabolic profiles of oral and gut microbiota, linked with disease severity, highlights the potential role of oral-originating microbes in exacerbating cirrhosis through enhanced ammonia production in the gut.

Disruption of mitochondrial dynamics and stasis leads to liver injury, innate immune response and tumorigenesis

Wen-Xing Ding[1], Xiaowen Ma[1], Xiaoli Wei[1], Hongmin Ni[1], Chen Zhang[1], Mengwei Niu[1]. [1]*University of Kanas Medical Center, Kansas City, United States*
Email: wxding@kumc.edu

Background and aims: Mitochondrial dysfunction has been implicated in aging and various cancer development. Mitochondria are dynamic organelles that constantly undergo fission via DRP1 (gene name *Dnm1l*) and fusion via MFN1/2 and. However, whether and how dysregulation of mitochondria dynamics would be involved in liver pathogenesis and tumorigenesis is unknown.

Method: *Dnm1l* Flox/Flox ($Dnm1l^{F/F}$), $Mfn1^{F/F}$ and $Mfn2^{F/F}$ mice were crossed with albumin-Cre mice to generate liver-specific *Dnm1l* knockout (L-*Dnm1l* KO), L-*Mfn1* KO, L-*Mfn2* KO, L-*Mfn1, Mfn2* double KO (DKO), and L-*Mfn1, Mfn2, Dnm1l* triple KO (TKO) mice. These mice were housed for various periods up to 18 months, blood and liver tissues were harvested for biochemical and histological analysis. Liver tissues were used for transcriptomic and metabolomic analysis.

Results: L-*Dnm1l* KO mice exhibited elevated serum ALT levels, increased accumulation of hepatic megamitochondria, and fibrosis as early as 2 months of age. By 12 months, a significant 63% of male mice developed spontaneous liver tumors, primarily hepatocellular adenomas, and this incidence rose to 100% by 18 months. Female L-*Dnm1l* KO mice also developed liver tumors, but at a much lower incidence. In contrast, neither L-*Mfn1* KO nor L-*Mfn2* KO mice showed significant liver injury or tumor development. However, a small percentage (29%) of DKO mice did develop tumors between 15 and 18 months of age. In L-*Dnm1l* KO mice, increased DNA damage, cellular senescence, and compensatory proliferation were observed, while these effects were less pronounced in L-*Mfn1* KO, L-*Mfn2* KO, or DKO mice. This suggests that mitochondrial fission plays a crucial role in maintaining hepatocyte homeostasis and preventing liver tumorigenesis. Interestingly, the further deletion of *Mfn1* and *Mfn2* in L-*Dnm1l* KO mice significantly reduced the formation of megamitochondria, liver injury, fibrosis, and tumorigenesis. This indicates that mitochondrial stasis is vital for maintaining hepatocyte function. RNA sequencing analysis revealed substantial activation of the cGAS-STING-interferon and tumor microenvironment pathways in the livers of L-*Dnm1l* KO mice, but these gene expression changes were notably corrected in TKO mice. Additionally, metabolomics and

transcriptomics analyses indicated increased pyrimidine synthesis and decreased expression of genes related to mitochondrial structure and metabolism in the livers of L-*Dnm1l* KO mice, effects that were mitigated in TKO mice.
Conclusion: Mitochondrial dynamics and stasis are essential for maintaining hepatic mitochondrial homeostasis and hepatocyte functions. The loss of hepatic DRP1 promotes liver injury and tumorigenesis; however, these issues can be corrected by the deletion of MFN1 and MFN2, which restores hepatic mitochondrial stasis.

SAT-042-YI
Rapid multiplex liver gene editing in mice using adeno-associated virus 8 or lipid nanoparticles
Dandan Wu[1], Isabelle Bolt[1], Dagmar Tolenaars[1], Wietse In het Panhuis[1], Coen Paulusma[1], Roy van der Meel[2], Stan F.J. van de Graaf[1]. [1]*Tytgat Institute for Liver and Intestinal Research, Amsterdam University Medical Centers, University of Amsterdam, Amsterdam Gastroenterology, Endocrinology Metabolism (AGEM), Amsterdam University Medical Centers, Amsterdam, Netherlands;* [2]*Laboratory of Chemical Biology, Department of Biomedical Engineering, Eindhoven University of Technology, Institute for Complex Molecular Systems (ICMS), Eindhoven University of Technology, Eindhoven, Netherlands*
Email: k.f.vandegraaf@amsterdamumc.nl

Background and aims: Conventional methods to generate liver-specific knockout mouse models for multiple genes are often time-consuming and inefficient. Here, we present a streamlined, CRISP-Cas9-based approach that enables rapid, efficient and multiplex liver-targeted gene editing using adeno-associated viral 8 (AAV8) or lipid nanoparticles (LNPs). This approach leverages selection pressure from tyrosine metabolism to increase gene editing efficiency: Hepatic fumarylacetoacetate hydrolase (*Fah*) deficiency is lethal in mice, but can be rescued by knocking down upstream enzyme 4-hydroxyphenylpyruvate dioxygenase (*Hpd*). In *Fah* deficient mice, *Hpd* -edited hepatocytes have a survival advantage, thus plasmids targeting *Hpd* and a separate gene of interest (GOI) can therefore be used to rapidly generate mice with multiple liver-specific knockdown and overexpression of nearly any gene product.
Method: In this study, we generated $Fah^{-/-}/spCas9^{Tg}$ mice that constitutively express the spCas9 recombinase. These mice were injected with two AAV8 vectors, each containing two gRNAs targeting an intron of *Hpd* and an exon of a gene of interest (GOI). The successfully-edited hepatocytes with *Hpd* knockdown gain a survival advantage, enabling efficient deletion of two GOIs. Each AAV8 vector also contains a CMV promotor flanked by a multiple cloning site, enabling overexpression of any desired gene as long as it can be packaged in AAV. Additionally, we tested LNP as an alternative non-viral method to deliver individual gRNAs.
Results: Complete *Hpd* knockout in the murine liver was achieved within two months using either AAV8 or LNP delivery systems, with no adverse effect on body weight and liver toxicity enzymes. Using the AAV strategy, we successfully generated humanized sodium taurocholate cotransporting polypeptide (NTCP) mice within 4 weeks by simultaneously deleting endogenous murine NTCP and expressing human NTCP.
Conclusion: This approach provides an efficient and safe strategy for rapid, multiplex gene editing via AAV8 or LNP delivery. The successful generation of humanized NTCP mice demonstrates the potential of this approach for creating advanced humanized mouse models. This system paves way for studying complex polygenetic liver disorders and supports future development of combination therapies.

SAT-043
rhTPO promotes hepatocyte proliferation in rats with acute liver failure through the MAPK and PI3K AKT signaling pathways
Jing Liang[1], Fengzheng Han[1], Fei Tang[1]. [1]*Tianjin Third Central Hospital, Tianjian, China*
Email: haolele77@sina.com

Background and aims: Liver failure is a clinical syndrome with high mortality and poor prognosis. Research showed that TPO analogue treatment could help improve platelets and promote liver function recovery. This study explored the effects and possible mechanisms of Recombinant human thrombopoietin (rhTPO) on liver regeneration in rats with acute liver failure (ALF).
Method: SD rats were randomly divided into control group (n = 24) and TPO group (n = 24). Both groups were given physiological saline or TPO at a dose of 15 ug/Kg/day subcutaneously before modeling for 5 consecutive days. The ALF rat model was induced by D-galactosamine salt (D-GalN) 1500 mg/kg. After modeling, the TPO group and the control group rats were subjected to venous blood collection at 6 hours, 24 hours, and 72 hours, respectively. Eight rats were euthanized in each group to detect peripheral blood platelet count and liver function indicators. The changes in liver function and liver weight were compared. The proliferation of liver cells was analyzed by immunofluorescence staining of liver tissue. Perform transcriptome and proteomic analysis in both TPO group and control group at 72 hours, and compare the differentially expressed genes and proteomic changes in the liver tissues of the two groups.
Results: The PLT count of ALF rats in the TPO group was significantly higher than control group, and the ALT levels in the TPO group were significantly lower than control group at 6 and 24 hours (650.8 U/L vs. 1321.2 U/L, P = 0.044 and 682.0 U/L vs. 1152.7 U/L, P = 0.048). The TBil level in the TPO group at 72 hours was significantly lower than control group (0.3 μ mol/L vs. 7.4 μ mol/L, P = 0.028), and the liver weight after TPO pretreatment was significantly higher than control group (P < 0.01). The Ki67 proliferation index and BrdU positive cell proportion in ALF rat liver tissue were significantly higher than control group (P < 0.05). The mRNA sequencing results showed that compared with the control group, the TPO pretreatment group had 262 upregulated genes and 188 downregulated genes. The proteomics results showed that the TPO pretreatment group had 24 upregulated genes and 12 downregulated proteins. After taking the intersection of differentially expressed genes from transcriptome sequencing and differentially expressed proteins from proteomics, a total of 10 genes were identified as common differentially expressed genes, including IL, Mylk3, Nras, Map2k2, Hgf, Pf4, Map2k1, Mt1, AnxiA8, and Gp1bb. The GO and KEGG showed that the differentially expressed genes were mainly related to the MAPK signaling pathway and PI3K-AKT signaling pathway.
Conclusion: Inducing platelet elevation through rhTPO could promote liver function recovery and increase liver cell proliferation in ALF rats through differentially expressed genes related to the MAPK signaling pathway and PI3K-AKT signaling pathway.

SAT-044-YI
Dynamic hepatocyte adaptations in acute biliary hypertension: role of canalicular remodeling, mechanosensors activation and alternate bile transport
Himanshi Himanshi[1], Rajni Yadav[1], Aishwarya Bhatnagar[1], Vaibhav Tiwari[1], Tahseen Khan[1], Rajkumar Tulsawani[2], Savneet Kaur[1], Shiv Kumar Sarin[1], Dinesh Mani Tripathi[1]. [1]*Institute of Liver and Biliary Sciences, New Delhi, India;* [2]*DIPAS, DRDO, New Delhi, India*
Email: dineshmanitripathi@gmail.com

Background and aims: Cholestasis can cause severe hepatotoxicity and increased biliary pressure leading to biliary hypertension. The role of bile canalicular mechanosensors in response to biliary hypertension is unexplored. We aimed to investigate the canalicular dynamics in response to bile fluid stasis and the mechanisms involved.

Method: Biliary pressure and flow index was monitored in bile obstruction model at B4H (4 hrs) and B24H (24 hrs) hours post-surgery. Primary hepatocyte was isolated, gene and protein expression analysis were done followed by flow cytometry. Biochemical, histological, immunofluorescence imaging, molecular and cellular analysis was carried out on liver tissue.
Results: The biliary pressure was raised (12.2 mmHg) immediately and was stabilized at 4 hr (16 mmHg) and 24 hr (14.2 mmHg) post bile flow obstruction. Bile flow index was increased in B4H (3.3 ul/min/g) and decreased in B24H (2.2 ul/min/g) from baseline (2.8 ul/min/g). Histology revealed increased bile canaliculi diameter, inflammation, macrophage infiltration and ductular reactions in B4H and B24H. Portal fibrosis was observed in both 4 hrs (2×) and 24 hrs (1.5×). However, increased invasive ductular reactions were observed at 24 hr. Interestingly, canalicular marker CD13 was increased at both 4 and 24 hr ($p < 0.01$). Liver enzymes AST, ALT, ALP and GGT were increased, bilirubin was unchanged at both 4 and 24 hr. Mechanistically, hepatocyte junctional proteins, Connexin32, Connexin 26, IntegrinB1 and Claudin markedly reduced at both 4 and 24 hrs ($p < 0.05$). In isolated primary hepatocytes, mechanosensors PIEZO1, YAP, TAZ and it's downstream TEAD1 were upregulated at 4 and 24 hrs ($p < 0.05$). RhoA/ROCK1 dependent cytoskeletal remodelling proteins Cofilin, profilin, calpain were increased at 4 and 24 hr ($p < 0.01$). However, protein expression of RhoA was reduced ($p < 0.05$). Expression of actin was increased in 4 hrs but reduced in 24 hrs ($p < 0.001$). Also, nucleoskeletal genes LaminA/C and Matrin 3 increased in both 4 and 24 hr leading to cell death that was supported with increased expression of HMGB1 and decreased albumin expression in both 4 and 24 hrs ($p < 0.05$). Increased FGFR4, CYP27A1 confirms activation of alternative bile acid metabolism pathway supports hepatocellular damage. Nevertheless, bile transport was increased at 4 and 24 hrs indicating alternative bile efflux mechanism.
Conclusion: This novel study reports that the bile stasis induced pressure on hepatocytes alters bile canaliculi dynamics and activate hepatocellular mechanosensors that further regulates the cytoskeletal and nuclear remodelling. Loss of cytoskeleton and junctional proteins indicates compromised hepatocyte integrity leading to cellular death. Also, in early stages, bile acid synthesis shifts to alternative pathway regulated via FXR signalling leading to decreased bile flow and increased transport of bile. Hence, biliary canaliculi mechanosensors are the key regulators of bile fluid dynamics under bile fluid stasis induced pressure.

SAT-045
10 year analysis and trends in liver biopsy; a single centre experience

Jennifer Cathcart[1], Martha Baylis[1], Isabella Falltrick[1], Shaun Walsh[2], Ruairi Lynch[1], John F. Dillon[1]. [1]*University of Dundee, Dundee, United Kingdom;* [2]*Pathology Department, Ninewells Hospital, Dundee, United Kingdom*
Email: jeni123@live.com

Background and aims: The advent of the widespread use of non-invasive assessment of liver disease has altered practice with regards to liver biopsy. However liver biopsy remains the gold standard diagnosis for certain liver conditions. We have reviewed 10 years of liver biopsy data to assess how our practice has changed over this timeframe. We aimed to assess the impact of improved diagnostic techniques on the biopsy practice in NHS Tayside (NHST).
Method: We conducted a retrospective search for liver biopsies performed in NHST from 2014 to 2023. Biopsy results were linked to demographic data. Statistical analysis was performed using a CHI squared test with a p-value of 0.05.
Results: 1035 liver biopsies were performed on 967 patients with the peak number of biopsies being performed in 2016 (n = 140). 563 (54.4%) were targeted biopsies of liver lesions with the remainder being non-targeted. Over time there has been a reduction in the number of targeted biopsies performed [n = 65 (2013) vs n = 55 (2023)] and a trend to a higher proportion of biopsies positive for malignant disease 78.4% (229/292) in 2014–2018 to 84.9% (230/271) in 2019–2023 ($p < 0.05$). Similarly, there has been a reduction in number of non-targeted biopsies over time [n = 58 (2014) vs n = 43 (2023)]. There has been no significant change in proportion of biopsies diagnostic of autoimmune liver disease over time with 23.2% (n = 71/306) in 2014–2018 and 28.3% (n = 47/166) in 2019–2023 ($p = 0.22$). There have been no recent biopsies for staging viral hepatitis and the indications are almost completely diagnostic uncertainty rather than staging disease. There has been a significant trend to a reduction in liver biopsies showing steatotic liver disease: 43.8% (134/306) in 2014–2018 vs 28.9% (48/166) 2019–2023 [$p < 0.05$]). Additionally, there has also been a trend to a reduction in non-targeted biopsies showing normal histology from 5.6% (17/306) in 2014–2018 to 3.0% (5/166) in 2019–2023 ($p = 0.21$).
Conclusion: There has been a significant increase in the proportion of targeted biopsies yielding malignant pathology, suggesting more judicious use of biopsies possibly related to improved imaging techniques. Additionally, there has is a significant reduction in biopsies demonstrating steatotic liver disease which could be related to the more widespread use of non-invasive techniques for diagnosing steatotic liver disease.

SAT-046
Effects of N-acylethanolamines in an in vitro model of metabolic stress: evidence on autophagy and related pathways in hepatic cells

Nicole Pia Navatti[1], Stefania Melini[1], Filomena Del Piano[2], Federica Comella[1], Nicola Opallo[1], Chiara Annunziata[3], Giuseppina Mattace Raso[1], Federico Pietrocola[3], Claudio Pirozzi[1], Rosaria Meli[1]. [1]*Department of Pharmacy, University of Naples Federico II, Naples, Italy;* [2]*Department of Veterinary Medicine and Animal Productions, Naples, Italy;* [3]*Department of Cellular and Molecular Biology, Karolinska Institutet, Stockholm, Sweden*
Email: stefania.melini@unina.it

Background and aims: Nutrient excess can induce the chronic activation of adaptive cellular stress mechanisms, including autophagy and oxidative stress. Autophagy is a process required for removing damaged molecules and subcellular elements, including proteins, lipids, and organelles to reestablish homeostasis in response to stress. Targeting these stress-related cellular responses can be useful to prevent or treat hepatic dysmetabolism associated with obesity. N-acylethanolamines (NAEs) are endogenous lipid-signaling molecules belonging to noncanonical endocannabinoids, involved in inflammation and energy metabolism. Here, we investigated the role of NAEs in modulating the autophagic process in presence or not of metabolic stress stimulus in hepatocarcinoma cell line (HepG2).
Method: Cells were pre-challenged or not with 100 μM palmitate (PA) for 1 hour; then, they were treated with 3 μM NAEs (palmitoylethanolamide, oleoylethanolamide, linoleylethanolamide, and stearoylethanolamide) for 24 hours, followed by 3-hour treatment with the inhibitor of autophagosome-lysosome fusion bafilomycin (1 μM), used to better evaluate the possible increase of autophagic process. Western blot and Real Time PCR were performed to analyze the expression of proteins and genes involved in autophagic process. SeaHorse XP metabolic analyzer was used to evaluate mitochondrial bioenergetics after PA challenge in presence or not of NAEs.
Results: First, we showed that all NAEs alone induced the activation of autophagy, increasing the expression of LC3-II, a standard marker for autophagosomes, and reducing the proteasomal degradation of ubiquitinated proteins, as shown by decreased p62 protein expression. The stimulation of HepG2 cells with PA mimicked the pathological context linked to lipid overload and following metabolic stress. PA challenge reduced cell viability and induced the compensatory activation of autophagic pathway. Notably, NAEs limited PA-induced cytotoxicity and further increased LC3-II expression

enhancing the degradation and recycling processes involved in the maintenance of hepatic cellular homeostasis. Consistently, NAEs increased the transcription of autophagy-related (ATG)3 and ATG7, which contribute to phagophore elongation. Finally, among all NAEs at 3 μM, solely palmitoylethanolamide improved the mitochondrial bioenergetics compromised by PA restoring basal respiration, inducing proton leak and modulating ATP-linked respiration. This latter finding suggests a different activation and/or potency of all NAEs on mitophagy and related pathways.
Conclusion: This *in vitro* evidence lays the groundwork for identifying new conceivable applications of NAEs in enhancing cellular homeostasis and improving hepatic metabolic alterations by modulating autophagy and/or mitophagy activated by nutritional metabolic stress.

SAT-047
The updated LiverSCA: a widespread and user-friendly cell atlas in human primary liver cancer and steatotic liver disease
Tina Suoangbaji[1]. [1]*The University of Hong Kong, Hong Kong, Hong Kong*
Email: u3009992@connect.hku.hk

Background and aims: Primary liver cancer (PLC) primarily consists of hepatocellular carcinoma (HCC) and intrahepatic cholangiocarcinoma (ICC), with HCC being the most common, accounting for over 90% of all PLC cases. HCC is characterized by significant cellular and molecular heterogeneity. Metabolic dysfunction-associated steatohepatitis (MASH) is a type of steatotic liver disease (SLD) defined by the presence of hepatic steatosis alongside at least one cardiometabolic risk factor, without any other identifiable cause.
Method: The current version of LiverSCA has greatly improved the comprehensiveness and functionality of the cell atlas. It now includes advanced gene expression analyses using various comparative visualization plots and a more extensive dataset collection that identifies different subtypes and etiological risk factors associated with PLC and SLD.
Results: LiverSCA cell atlas features six phenotypes of liver (normal, HBV-HCC, HCV-HCC, non-viral HCC, ICC, and MASH), encompassing data from 63 patients and over 248,000 cells. We have also integrated comparative visualization methods that enable users to examine and compare gene expression levels between two distinct phenotypes simultaneously. Additionally, the significant differences in tumor microenvironments (TMEs) across PLC subtypes and phenotypes, along with varying immune cell infiltration patterns, underscore the need for more specialized therapeutic strategies that reflect the intrinsic characteristics of PLC.
Conclusion: By utilizing LiverSCA, researchers can visualize single-cell data in an accessible way, promoting collaboration between computational and wet-lab teams and enhancing understanding of PLC. We are dedicated to the ongoing development of LiverSCA and aim to provide a valuable resource for researchers investigating the cellular and molecular landscapes of PLC. For future plan, we will continue to enhance LiverSCA by incorporating more etiologically specific PLC datasets and believe that LiverSCA will be an essential tool for researchers seeking to unravel the complexity and heterogeneity of PLC.

SAT-048
Regulation of thyroid hormone metabolism by HNF4A via modulation of deiodinase activity in hepatocytes
Xinru Zhang[1], Charlotte Ehle[2], Aishwarya Iyer-Bierhoff[2], Joëlle Wiersema[1], Anita Boelen[1], Eveline Bruinstroop[3]. [1]*Research Institute Amsterdam Gastroenterology Endocrinology & Metabolism (AGEM), Amsterdam UMC, Endocrine Laboratory, Department of Laboratory Medicine, Amsterdam Gastroenterology, Amsterdam UMC, University of Amsterdam, Amsterdam, Netherlands;* [2]*Institute of Biochemistry and Biophysics, Center for Molecular Biomedicine, Friedrich Schiller University Jena, Jena, Germany;* [3]*Research Institute Amsterdam Gastroenterology Endocrinology & Metabolism (AGEM), Amsterdam UMC, Department of Endocrinology and Metabolism, Amsterdam UMC, University of Amsterdam, Amsterdam, Netherlands*
Email: x.zhang1@amsterdamumc.nl

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) comprises a spectrum ranging from hepatosteatosis through steatohepatitis to fibrosis and irreversible cirrhosis. Hepatocyte nuclear factor 4A (HNF4A), a nuclear hormone receptor highly expressed in the liver, plays a central role in regulating hepatic lipid metabolism by modulating fat storage via lipophagy. Previously, we identified type 1 iodothyronine deiodinase (DIO1), a key enzyme in thyroid hormone metabolism, as a crucial metabolic regulator in the progression of MASLD. We hypothesized that HNF4A may regulate DIO1 activity, thereby influencing thyroid hormone regulated gene expression in hepatocytes. To test this hypothesis, we examined the effects of HNF4A on DIO1 activity and T3 responsive genes in a HepG2 cell line with an inducible overexpression of HNF4A or HNF4A knock down.
Method: For HNF4A overexpression, HepG2 cell lines were transfected with a doxycycline-inducible (DOX) myc-tagged HNF4A transgene. For HNF4A knockdown, HepG2 cells were transiently transfected with HNF4A siRNA to reduce HNF4A mRNA expression. DIO1 activity was measured using HPLC with a radioactive rT3 tracer, and *DIO1* and T3 responsive gene expression was quantified by RT-qPCR. Cell experiments were at least performed three times with each experiment having a technical triplicate.
Results: Overexpression of *HNF4A* resulted in a strong increase in *DIO1* mRNA expression and DIO1 activity compared to control cells. This was accompanied with increased expression of *KLF9*, *G6PC1*, *SPOT14*, *CPT1A* and *PCK1* mRNA. In contrast, knockdown of *HNF4A* mRNA in HepG2 cells led to a significant decrease in *DIO1* mRNA expression and DIO1 activity along with reduced expression of most T3 responsive genes, including *G6PC1*, *CPT1A*, and *PCK*1.
Conclusion: In conclusion, this study shows that HNF4A is a potent regulator of DIO1 in hepatocytes. The alterations in DIO1 are associated with contradictory changes in the expression of T3 responsive genes. Further analyses are needed to explain the HNF4A-DIO1 related changes in T3 responsive gene expression but it is clear that HNF4A plays a role in regulating thyroid hormone concentrations via DIO1 in the hepatocyte.

Immune-mediated and cholestatic disease: Experimental and pathophysiology

TOP-363
A novel orally bioavailable small-molecule inhibitor of the sodium taurocholate co-transporting polypeptide (NTCP) prevents HBV infection and ameliorates cholestasis in humanized mice models
Kalliopi Pervolaraki[1], Jean-Christophe Vanherck[1], Charlène Marcadet[1], Lieven Verhoye[2], Amse De Meyer[2], Madina Rasulova[3], Heyrhyoung Lyoo[3], Jasmine Paulissen[3], Kristof De Vos[3], Isabelle Bolt[4], Esther Vogels[4], Dagmar Tolenaars[4], Patrick Chaltin[5], Arnaud Marchand[1], Matthias Versele[1], Johan Neyts[3], Pieter Annaert[3], Hendrik Jan Thibaut[3], Philip Meuleman[2], Stan F.J. van de Graaf[4]. [1]*CISTIM Leuven vzw, Leuven, Belgium;* [2]*Ghent University, Ghent, Belgium;* [3]*KU Leuven, Leuven, Belgium;* [4]*Amsterdam UMC, Amsterdam, Netherlands;* [5]*Centre for Drug Design and Discovery, Leuven, Belgium*
Email: k.f.vandegraaf@amsterdamumc.nl

Background and aims: The sodium taurocholate co-transporting polypeptide (NTCP, *SLC10A1*) is the main transporter of conjugated bile acids at the basolateral membrane of hepatocytes and serves as the entry receptor for the hepatitis B virus (HBV) and hepatitis delta

virus (HDV). Daily injection with a synthetic peptide called bulevirtide (previously Myrcludex-B) is approved in the EU for treatment of patients co-infected with HBV and HDV. Pre-clinical studies suggest that pharmacological inhibition of hepatic bile salt uptake using bulevirtide ameliorates cholestatic liver injury. Both treatment of viral hepatitis and cholestatic liver diseases require chronic treatment, thus indicating the necessity of orally available small molecule inhibitors for this liver-specific transporter/receptor.

Method: A comprehensive drug discovery effort was conducted to identify and optimize potent and selective small-molecule inhibitors of NTCP-mediated bile acid uptake and HBV/HDV entry inhibitors with adequate *DMPK* characteristics, suitable for oral dosing. Urokinase-type plasminogen activator-severe combined immunodeficiency (uPA-SCID) mice engrafted with human hepatocytes were used to determine *in vivo* impact on bile acid kinetics and HBV infection. Finally, in vivo effects of the lead candidate were assessed in two distinct DDC-induced cholestasis mouse model transgenic for human NTCP.

Results: We identified a novel chemical series of NTCP inhibitors with multiple compounds with single-digit nM potency for NTCP and high selectivity (>100×) against ASBT and BSEP mediated bile salt transport. Consistently, these compounds dose-dependently reduced intracellular bile acid levels in sandwich-cultured human hepatocytes. *In vitro* infection studies demonstrated low nM HBV and HDV entry inhibition, similar to bulevirtide. We prioritized a lead molecule, CIM212930, with good oral bioavailability and excellent liver distribution. PK/PD experiments with CIM212930 in uPA/SCID mice with humanized livers illustrated dose-dependent and prolonged elevation of serum bile acid levels demonstrating both target engagement and indicative of a once-daily oral dosing regimen. Finally, CIM212930 completely blocked HBV infection in a humanized liver mouse model and largely reduced liver damage in DDC-induced cholestasis models.

Conclusion: We describe novel and specific small-molecule orally bioavailable NTCP inhibitors that have the potential to treat HBV/HDV and cholestatic liver disease.

Background and aims: Natural killer T (NKT) cell mediated inflammation has been shown to play a role in chronic inflammatory bile duct disorders such as primary sclerosing cholangitis (PSC). These cells are a subset of unconventional T-cells enriched in mouse liver that recognize lipid antigens presented by CD1d. We have previously demonstrated that oxazolone, a NKT cell activating agent, can induce cholangitis in mice. To determine whether biliary epithelial cells (BECs) participate as antigen presenting cells, we challenged mice with a conditional deletion of CD1d on biliary epithelial cells ($Cd1d^{\Delta BEC}$) and WT ($Cd1d^{fl/fl}$) mice with intrabiliary injection of the oxazolone.

Method: $Cd1d^{\Delta BEC}$ mice were generated by crossing *ASBT*cre$^{+/-}$ mice with $Cd1d^{fl/fl}$ mice. 1% oxazolone and 65% DMSO (vehicle) were injected into bile ducts of $Cd1d^{fl/fl}$ and $Cd1d^{\Delta BEC}$ mice. Weight and clinical symptoms were monitored daily. The mice were sacrificed 2 days or 7 days following surgery. Liver tissue was assessed for portal inflammation and inflammatory infiltrates characterized with immunohistochemistry. Serum was analysed for alanine transaminase (ALT), aspartate transaminase (AST), alkaline phosphatase (ALP) and bilirubin.

Results: Intrabiliary injection of oxazolone as compared to vehicle in WT ($Cd1d^{fl/fl}$) mice caused acute cholangitis with severe liver inflammation, significant weight loss (16% *vs.* 6%, * p = 0.03), increased amount of total pain score (1.5 *vs.* 6.5, * p = 0.02), elevated liver enzyme markers of ALT, AST, ALP and bilirubin, and increased histologic grade of cholangitis that peaked at day 2 following surgery. $Cd1d^{\Delta BEC}$ mice were protected against disease with significantly better survival (* p = 0.04), quicker recovery and improved disease parameters compared to WT ($Cd1d^{fl/fl}$) mice, *i.e.* less body weight loss (13.2% *vs.* 18.7%, * p = 0.02), less total pain (2.3 *vs.* 4.4, * p = 0.02) and lower bilirubin serum levels (145 µmol/L *vs.* 340 µmol/L, * p = 0.03). This was parallelled by a milder histopathological phenotype in the liver with decreased periportal infiltration, bile duct hyperplasia and necrosis (2.82 *vs.* 5.11, ** p = 0.007).

Conclusion: In this study we have demonstrated that NKT cells can drive inflammation that is dependent on CD1d on cholangiocytes in the bile ducts when directly exposed to intrabiliary oxazolone. These findings suggest that modulation of NKT driven immune pathways may represent a therapeutic approach in inflammatory cholangiopathies such as PSC.

Background and aims: Glucocorticoids are anti-inflammatories that have been the standard of care for patients with autoimmune hepatitis (AIH) for decades. Most patients respond well; however, up to 20% may fail treatment and require a liver transplant. There are no prediction criteria for response to glucocorticoids; as a result, non-responders are at risk of infection without benefitting from a delay in liver damage. Hepatocytes comprise up to 80% of the liver mass, and we previously showed that they delete regulatory T cells (Treg) by enclysis. Given that Treg cell enclysis was increased in AIH patients who failed treatment compared to those with metabolic dysfunction-associated steatohepatitis (MASH), we were interested in establishing the effect of glucocorticoids on enclysis in human livers.

Method: We used high-content fluorescent imaging-based assays to treat hepatocytes and hepatoma cells with glucocorticoid receptor alpha (GR-α) agonists and antagonists, quantified enclysis by scoring cell-in-cell structures. GR-α expression and cellular localisation were measured by immunofluorescence. Hepatocyte GR-α expression, cellular and spatial localisation were evaluated by immunohistochemistry and digital pathology in formalin-fixed, paraffin-embedded liver sections from non-cirrhotic donors and cirrhotic patients with AIH or MASH (n = 10 each). QuPath software quantified hepatocyte nuclear GR-α in zones 1, 2 and 3. Fresh liver segments from the same conditions were treated with glucocorticoid agonists and antagonists, and the effects on hepatocyte GR-α expression were measured by protein expression and targeted tissue transcriptomic analyses (Nanostring nCounter).
Results: Dexamethasone, prednisolone and budesonide treatment reduced enclysis in vitro, and the GR-α antagonist mifepristone increased enclysis. One hour pre-treatment with glucocorticoids was sufficient to induce hepatocyte nuclear translocation of GR-α in vitro and ex vivo, which correlated with reduced enclysis. In non-cirrhotic livers and MASH, there was no regional difference in hepatocyte nuclear GR-α expression, but AIH livers that failed treatment had reduced nuclear GR-α in peri-fibrous hepatocytes compared to periportal. Glucocorticoid treatment of liver explants ex vivo caused nuclear translocation of hepatocyte GR-α in some patients but not others.
Conclusion: Hepatocyte nuclear GR-α expression correlated with enclysis inhibition, revealing differences in inflammation-proximal hepatocytes in AIH and MASH. Further research is needed to assess any predictive value of hepatocyte nuclear GR-α for response to glucocorticoids in AIH.

Bile and plasma metabolome reveals association of TMA-TMAO pathway metabolites with gallstone disease progression
Vipin Yadav[1], Deepti Sharma[1], Ragini Kilambi[1], Nihar Mohapatra[1], Archana Rastogi[1], Vaishali Yadav[1], Sherin Thomas[1], Nirupma Trehanpati[1], Guresh Kumar[1], Viniyendra Pamecha[1], Shiv Kumar Sarin, Gayatri Ramakrishna[1]. [1]*Institute of Liver and Biliary Sciences, New Delhi, India*
Email: rgayatri@ilbs.in

Background and aims: India accounts for 10% of the global burden of gallstone disease (GSD) and gallbladder cancer (CaGB). Due to low diagnosis rates, gallbladder cancer has poor prognosis. This study aims to identify plasma and bile metabolites as potential biomarkers for GSD and CaGB and explore their role in gallstone disease progression using a diet-induced mouse model.
Method: Metabolomic profiling was done for plasma and bile samples in the discovery cohort of healthy control, HC (P = 14, B = 14), GSD (P = 30, B = 30), & CaGB (P = 56, B = 26) patients. For validation analysis, HC (P = 22, B = 3), GSD (P = 21, B = 10) & CaGB (P = 22, B = 18) samples were again subjected to untargeted metabolomics. The significantly altered metabolites identified via untargeted metabolomics were then evaluated in human plasma (n = 37) by targeted metabolomics. The key identified metabolite i.e. TMAO, was administered to C57BL/6 mice in supplementation with lithogenic diet to assess its impact on gallstone disease. qPCR was done in human (n = 40) and mice (n = 20) gallbladder tissue samples to study the expression of ATP-Binding Cassette (ABC) transporters involved in bile salts and cholesterol secretion.
Results: Bile & plasma metabolome analysis identified TMA and other metabolites associated with TMA pathway, including TMAO, carnitine, betaine & choline as significantly altered in GSD & CaGB patients. ROC analysis showed that combined TMAO & pipecolic acid yield AUC of 0.99 ($p > 0.05$), indicating strong predictive potential for GSD formation. While, TMAO along with N-acetyl neuraminic acid showed AUC of 0.91 ($p > 0.01$) in CaGB. Further, targeted metabolomics in plasma also showed increased TMAO levels in CaGB (620.82 ± 223.72 µg/ml) compared to GSD (449.12 ± 194.06 µg/ml) ($p = 0.30$) and HC (35.65 ± 19.39 µg/ml) ($p = 0.0001$). C57BL/6 mice fed with lithogenic diet+0.3% TMAO (Gr.1) exhibited an earlier onset and higher frequency of gallstones compared to mice on lithogenic diet alone (Gr.2). At 12 weeks, Gr.1 had 20% (2/10) gallstones formation, while only 10% (1/10) mice showed gallstones in Gr.2. By 20 weeks, 73.68% (14/19) of Gr.1 mice developed gallstones, compared to 62.5% (10/16) of Gr.2. Additionally, the TMAO-administered mice exhibited gallbladder metaplasia, indicating increased cellular proliferation. qPCR analysis of gallbladder tissue in mice showed significantly decreased expression of ABC transporters, ABCC3 and ABCB4 by more than 1.5-fold in Gr.1 compared to Gr.2.
Conclusion: Elevated TMAO levels may drive gallstone disease progression in humans and mice possibly by influencing ABC transporter expression in gallbladder epithelium. Combining TMAO with metabolites like pipecolic acid and N-acetylmuramic acid improves the sensitivity and specificity for predicting gallstones and cancer. The study also highlights the liver-gallbladder axis in gallstone-related diseases, as TMAO is produced in the liver.

FRI-300
Therapeutic application of circular RNA aptamers in a mouse model of primary biliary cholangitis
Kai Zhang[1], Xing Liu[1], Yongfeng Yang[1]. [1]*The Second Hospital of Nanjing, Affiliated to Nanjing University of Chinese Medicine, Nanjing, China*
Email: yangyongfeng@njucm.edu.cn

Background and aims: Primary biliary cholangitis (PBC) is an autoimmune liver disease characterized by progressive destruction of intrahepatic bile ducts leading to cholestasis, cirrhosis, and liver failure. The incidence rate of PBC is increasing year by year, but the pathogenesis of PBC has not been clarified. We aimed to evaluate the effect and mechanisms of dsRNA on PBC severity, and explore the possible of therapeutic application of circular RNA aptamers in a mouse model of PBC.
Method: Female C57BL/6J (B6) 5–6-week-old mice (n = 12 per group) were used. Essentially, a 2OA-bovine serum albumin (BSA) conjugate was injected intraperitoneally with complete Freund's adjuvant and was boosted after 2 weeks with 2OA-BSA and incomplete Freund's adjuvant after the first immunization. Poly I:C was injected intraperitoneally at a dose of 5 mg/kg once every 3 days from three days after the initial immunization with 2OA-BSA in CFA (2OA+poly I:C-treated mice). PBC severity and metabolic alterations were evaluated by histology, serum markers and bulk liver RNA sequencing. We detected the expression levels of double stranded RNA in animal models and patient samples using immunofluorescence and dot blot method and explore the mechanism that dsRNA disturbance. Finally, we assessed the therapeutic efficacy of circular RNA aptamers from 8 to 16 weeks of age.
Results: 8-week-old PBC mouse model exhibited a significant increase in CD8 T lymphocytes and pro-inflammatory cytokines such as serum IL-6, IL-12, IFN-γ, TNF-α, leading to liver fibrosis. Liver histological examination shows eosinophil infiltration and bridging like fibrosis changes, which are very similar to the histological findings of human PBC. Furthermore, we found mitochondrial dsRNA into the cytosol in mononuclear phagocyte is a general feature of PBC. Inhibition of the mitochondrial RNA polymerase, the dsRNA sensors RIGI and PKR, or the master inflammatory signaling protein MAVS, all broadly preserving other hallmarks of PBC. Moreover, cells are hypersensitized to mt-dsRNA-driven inflammation due to their reduced levels of PNPT1 and ADAR1, two proteins critical for mitigating the accumulation of mt-dsRNA and the inflammatory potency of dsRNA, Finally we found in our PBC mouse model, treatment with circular RNA aptamers which has been reported to reduce immune overactivation caused by double stranded RNA by regulating PKR activity significantly improved steatohepatitis and ameliorating fibrosis as well.

Conclusion: The level of double stranded RNA is significantly elevated in both PBC patients and mouse models, causing severe immune responses. Blocking the immune pathways related to double stranded RNA can effectively alleviate the symptoms, circular RNA aptamers are effective treatments.

FRI-301

Reactive cholangiocyte-derived orosomucoid-2 (ORM2) drives a pathogenic modulation of the injured biliary niche through macrophage reprogramming

Hanyang Liu[1,2], Guo Yin[1], Tian Lan[1], Yeni Ait Ahmed[1], Hilmar Berger[1], Marlene Kohlhepp[1], Natalja Amiridze[1], Natalia Martagón Calderón[3], Carla Frau[4], Ludovic Vallier[4,5], Milad Rezvani[3,5,6], Frank Tacke[1], Adrien Guillot[1]. *[1]Charité - Universitätsmedizin Berlin, Department of Hepatology & Gastroenterology, Berlin, Germany; [2]The Third Affiliated Hospital of Nanjing Medical University, Changzhou Medical Center, Changzhou, China; [3]Charité - Universitätsmedizin Berlin, Department of Pediatric Gastroenterology, Nephrology and Metabolic Medicine, Berlin, Germany; [4]Berlin Institute of Health Centre for Regenerative Therapies, Berlin, Germany; [5]Max Planck Institute for Molecular Genetics, Berlin, Germany; [6]Division of Gastroenterology, Hepatology and Nutrition, Cincinnati Children's Hospital Medical Center, Cincinnati, United States*
Email: adrien.guillot@charite.de

Background and aims: Injured or reactive biliary epithelial cells participate in most chronic liver injuries in a process referred to as ductular reaction, which involves multicellular interactions with marked local infiltration of macrophages and fibrogenic cell activation. The direct roles of biliary epithelial cells in shaping their cellular niche remain unknown. We aimed at investigating the effects of biliary epithelial cell-derived acute phase response protein orosomucoid 2 (ORM2) in shaping monocyte/macrophage response to liver injury.
Method: Transcriptome datasets from human and mouse livers were used, results were confirmed with multiplex immunofluorescence. A multicellular biliary-niche-on-a-chip derived from primary liver and blood cells (wild-type, Mdr2-/- mice) was established to model ductular reaction. Human blood cells collected from healthy donors and intrahepatic cholangiocyte organoids derived from normal and cirrhotic liver patients were used.
Results: Our transcriptome dataset and multiplex immunofluorescence analyses indicated a previously unrecognized involvement of the acute phase response protein ORM2 in ductular reactions in both human and mouse livers. ORM2 gene expression was increased in biliatresone-, bile acid- and acetaminophen-challenged cholangiocytes. Cholangiocyte-derived ORM2 induced unique transcriptome changes and functional adaptation of liver macrophages. ORM2-activated macrophages exacerbated cholangiocyte cell stress and Orm2 expression, but also promoted fibrogenic hepatic stellate cell activation. Mechanistically, ORM2 effects were mediated by an inositol 1,4,5-trisphosphate receptor type 2 (ITPR2)-dependent calcium pathway.
Conclusion: This study reveals a paracrine communication circuit during ductular reaction, in which reactive cholangiocyte-derived ORM2 reprograms liver macrophages, participating in a pathogenic remodeling of the immune biliary niche.

FRI-302-YI

MUCIN1 positive biliary epithelial cell heterogeneity contributes to cholestatic liver injury and promotes early liver fibrosis

Aishwarya Bhatnagar[1], Rajni Yadav[1], Himanshi Himanshi[1], Vaibhav Tiwari[1], Tahseen Khan[1], Chhagan Bihari[1], Savneet Kaur[1], Shiv Kumar Sarin[1], Dinesh Mani Tripathi[1]. *[1]Institute of Liver and Biliary Sciences, New Delhi, India*
Email: dineshmanitripathi@gmail.com

Background and aims: Biliary epithelial cells (BECs), although quiescent under homeostatic conditions, exhibit significant proliferation and remodelling during injury, termed as the ductular reaction (DR). DR plays a dual role in liver regeneration and disease progression. Specifically, persistent DR is associated with severity of fibrosis. Heterogeneity of BECs and its contribution in disease progression is not known. we aim to investigate the contribution of BEC heterogeneity and its cellular crosstalk in progression of cholestatic liver injury.
Method: Cholestatic injury was induced in mice via bile duct ligation (mBDL) at day-2 (D2), day-4 (D4), and day-7 (D7) and DDC (mDDC) diet at week-2 (W2) and week-4 (W4). In liver tissue histological, immunostaining, and gene expression analysis was done. Sham was taken as control. Primary BECs and HSCs were sorted and acquired. 3D ductal organoids were developed and indirect co-culture with HSCs was performed at D0, D2 and D7 and secretome was analysed.
Results: DDC induced cholestatic model is showing significant increased DR (>3-fold), bile stasis in all newly formed ducts, concentric ductular fibrosis (>2-fold), and necrosis in some regions. Fibrosis was increased with persistent DR as confirmed by immunostaining showing CK19+ (>2-fold, W2), (>3-fold, W4) andαSMA+ (1.5-fold, W2; 2-fold, W4). Similar patterns was observed in the well-established cholestatic BDL-model. Frequency of CK19+ primary BECs was 26% (D2), 62% (D4) and 89.7% (D7) vs. 11% (sham) showing increased population along withα-SMA+ HSCs which also peaked with 13.3% (D2), 33.8% (D4) and 52.7% (D7) vs. 3.7% (sham). 3D-Ductal organoids of D2, D4 and D7 of mBDL were developed and its secretome analysis showed increased concentration of TGF-β1 35 pg/ml (D2) 178 pg/ml (D4) and 699 pg/ml (D7) and Endothelin levels 23 pg/ml (D2), 91 pg/ml (D4), 383 pg/ml (D7) showed strong cross-talk between BECs and HSCs. Gene expression analysis of HSCs showed increased fibrotic markers (α-SMA >2-fold and GFAP 1.5-fold). Next, we checked which BECs population (small or large BECs) was increased, we further acquired epCAM+ BECs with MUC1+(large BECs) and epCAM+ with MUC1- (small BECs). MUC1+ increased with 18% along with MUC1- 67% (D2), 39% MUC1+ and 51% MUC1-(D4) and 75% MUC1+ and 46% MUC1- (D7). Similar results were seen in the IHC of MUC1 and BCL2 (markers for small cholangiocytes) for mBDL timepoints and similar was also seen gene expression of BCL2 (5-fold) and MUC1 (15-fold) indicating increased large cholangiocytes population with increased cholestasis.
Conclusion: This study revealed BEC dynamicity governed by MUC1+ phenotype and is responsible for pathological changes.3D organoid observation MUC1+ BECs promotes HSCs activation in ET1 dependent paracrine manner in cholestatic liver disease. Study also suggest MUC1- phenotype of BEC is closely associated with biliary homeostasis.

FRI-303

Immune profiling in autoimmune hepatitis identifies distinct patterns autoreactivity

Lohse[4], Joseph DeRisi[2], Michele Tana[1]. *[1]University of California, San Francisco, San Francisco, United States; [2]Chan Zuckerberg Biohub, San Francisco, San Francisco, United States; [3]University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [4]University Medical Center Hamburg-Eppendorf, Hamburg, United States*
Email: Arielle.Klepper@ucsf.edu

Background and aims: Autoimmune hepatitis (AIH) is a severe disease characterized by elevated immunoglobulin levels. However, the role of autoantibodies in the pathophysiology of AIH remains uncertain.
Method: Phage Immunoprecipitation-Sequencing (PhIP-seq) was employed to identify autoantibodies in the serum of patients with AIH ($n = 115$), compared to patients with other liver diseases

(metabolic associated steatotic liver disease (MASH) *n* = 178, primary biliary cholangitis (PBC), *n* = 26, or healthy controls, *n* = 94).
Results: Logistic regression using PhIP-seq enriched peptides as inputs yielded a classification AUC of 0.81, indicating the presence of a predictive humoral immune signature for AIH. Embedded within this signature were disease relevant targets, including SLA/LP, the target of a well-recognized autoantibody in AIH, disco interacting protein 2 homolog A (DIP2A), and the relaxin family peptide receptor 1 (RXFP1). The autoreactive fragment of DIP2A was a 9-amino acid stretch nearly identical to the U27 protein of human herpes virus 6 (HHV-6). Fine mapping of this epitope suggests the HHV-6 U27 sequence is preferentially enriched relative to the corresponding DIP2A sequence. Antibodies against RXFP1, a receptor involved in anti-fibrotic signaling, were also highly specific to AIH. The enriched peptides are within a motif adjacent to the receptor binding domain, required for signaling and serum from AIH patients positive for anti-RFXP1 antibody was able to significantly inhibit relaxin-2 singling. Depletion of IgG from anti-RXFP1 positive serum abrogated this effect.
Conclusion: These data provide evidence for a novel serological profile in AIH, including a possible functional role for anti-RXFP1, and antibodies that cross react with HHV6 U27 protein.

FRI-304
Bioinformatic analysis of the spatial transcriptomes of inflamed portal tracts in human primary biliary cholangitis
Atsumasa Komori[1], Yuki Kugiyama[1], Tomohito Kojima[1], Tomoyuki Suehiro[1], Yasuhide Motoyoshi[1], Akira Saeki[1], Shinya Nagaoka[1], Kazumi Yamasaki[1], Shiro Miura[1]. *[1]NHO Nagasaki Medical Center, Omura, Japan*
Email: atsuriko1027@yahoo.co.jp

Background and aims: Though the pathognomonic hallmark of primary biliary cholangitis (PBC) is autoreactive T cell-mediated cell injury against biliary epithelial cells, involvement of B cell and innate immune cells in inflamed portal tracts is also apparent, likely sustaining, modulating, or even establishing the microinflammatory milieu of human PBC. The aim of this study is to analyze the transcriptomes of inflamed portal tracts in PBC, using spatial transcriptome analysis in conjunction with bioinformatics tools.
Method: The liver tissue samples were obtained from four PBC patients (Case 1-3 before UDCA treatment and Case 4 with an insufficient biochemical response after 20 years of UDCA treatment) by USG-guided needle biopsy. Five-micrometer thick sections were cut from formalin-fixed paraffin-embedded (FFPE) block of biopsies and mounted on microscopy slides, followed by spatial transcriptomic analysis using Visium CytAssist Spatial Gene Expression for FFPE Human Transcriptome (10× Genomics, U.S.A.), according to manufacturer instructions (TakaraBio, Japan). Spatial transcriptomic (ST) data in each sample were analyzed by Space Ranger 2.0.0 (10× Genomics) to obtain unbiased clustering of spots. With the aid of paired HE-staining and the relative enrichment of zone 3 genes (i.e., CYP2E1) compared to entire dataset, distinct ST clusters were aligned to the inflamed portal tracts (PT) and the putative zone 3 in each sample. Firstly, in order to perform bioinformatic pathway analysis, differentially expressed genes (DEGs) in PT in comparison to that in zone 3 were uploaded into IPA software (version 12.2, Qiagen Bioinformatics, USA). Secondary, to evaluate significant similarities, PT-DEGs were compared among samples and to those in public domain dataset ($n > 215000$) by IPA Analysis Match. An absolute value Z-scores greater than 2 was considered as significant threshold for either activation/inhibition of pathway or similarities of transcriptomes.
Results: ST spots in each PBC liver sample segregated into 4 to 5 distinct clusters. While canonical pathways of PT-DEGs with the highest Z score were neutrophil degranulation (Case 1, 2, 3; 14.765, 4.583, and 6.481, respectively) and RHO GTPase cycle (Case 4; 13.304), those with the lowest were RHO GTI signaling (Case 1, 3; −6.155 and −2.673, respectively), mitochondrial dysfunction (Case 2; −3.051), and PTEN Signaling (Case 4; −5.217). Even after long-term UDCA treatment, PT-DEGs in Case 4 with insufficient biochemical response revealed the significantly most similar biological signature with that in untreated Case 1 (Z score = 89.38).
Conclusion: Transcriptomes of PT in human PBC are enriched in the activities of genes for innate immune cells, cell migration and cell adhesion, highlighting potential therapeutic targets; UDCA treatment without sufficient biochemical response might not alter transcriptomes of PT.

FRI-305
Protectin DX as a novel anti-inflammatory and anti-fibrotic therapeutic candidate for the treatment of autoimmune cholangitis
Audrey-Anne Lavoie[1,2,3], Mélanie Verreault[1,3], Jocelyn Trottier[1,3], Olivier Barbier[1,2,3]. *[1]Axe Endocrinologie-Néphrologie, Centre de recherche du CHU de Québec - Université Laval, Québec, Canada; [2]Faculté de pharmacie, Université Laval, Québec, Canada; [3]Centre de recherche Nutrition, Santé et Société (NUTRISS), INAF, Université Laval, Québec, Canada*
Email: audrey-anne.lavoie@crchudequebec.ulaval.ca

Background and aims: Primary biliary and sclerosing cholangitis (PBC; PSC) are rare liver diseases causing an accumulation of toxic bile acids (BAs) in hepatocytes. Such event promotes the development of inflammation, fibrosis, cirrhosis, and ultimately liver failure. *Reducing hepatic BA levels is an important pharmacological target for PBC and PSC treatments.* Currently, Ursodiol® (UDCA) and Ocaliva® (OCA), two BA lowering drugs, are approved for the treatment of PBC, while no drugs are available for PSC. However, since a significant proportion of PBC patients either do not respond to or are intolerant to UDCA and/or OCA, *there is an urgent need for new therapeutic options*. Our lab has shown that adding the omega-3 DHA to OCA and UDCA reduce the required doses to achieve optimal BA reduction. However, most of the effects of DHA are known to be mediated by its specialized pro-resolving mediators' derivatives, notably protectin DX (PDX), a derivative with strong anti-inflammatory properties. Thus, this study will test the hypothesis that PDX can protect liver cells against BA accumulation, BA-induced inflammation, ER stress and fibrosis.
Method: HepG2 cells and murine hepatocytes were treated with vehicle, 5 μM PDX or 50 μM DHA (positive control) for 24H. To induce ER stress and fibrosis, HepG2 cells received the same treatments, with an additional 400 μM BA mixture for 24H and 2 ng/mLTGF-β for 72H, respectively. For inflammation, THP-1 cells were treated with 100 ng/mL LPS, in addition to the previous treatments for 24H. Transcriptomic (qRT-PCR), proteomic (Western blot, ELISA), or metabolomic targeted (LC-MS/MS) approaches were then employed to assess the effects of PDX.
Results: Similarly to DHA, PDX exposure significantly reduced BA synthesis in liver cells by inhibiting *CYP27A1* gene expression ($p < 0.05$) and lowering CDCA secretion ($p < 0.05$) in HepG2 cells as well as total, primary and (un)conjugated BA ($p < 0.01$) in murine hepatocytes. PDX also promoted BA detoxification through increased mRNA expression of the transporters OSTα/β and the conjugating enzyme SULT2A1 ($p < 0.001$). Moreover, PDX displayed notable anti-inflammatory effects by significantly inhibiting the expression of the pro-inflammatory cytokines TNFα ($p < 0.001$), MCP-1 ($p < 0.001$), IL-6 ($p < 0.001$), and IL-1β ($p < 0.01$) in THP-1 macrophages, both at the transcriptomic and proteomic levels. Additionally, PDX reduced the expression of the BA-induced ER stress markers BIP ($p < 0.01$) and CHOP ($p = 0.101$), as well as of the TGF-β-induced fibrosis gene COL1A1 ($p < 0.001$) in HepG2 cells.
Conclusion: These findings suggest that PDX reduces BA hepatic levels while also mitigating inflammation, ER stress, and fibrosis in liver cells and macrophages. Given the role of BAs in the development of PBC and PSC, PDX may provide a pharmacological option for these

diseases. Further *in vivo* analyses are, however, required to validate this hypothesis.

FRI-306

Protectin DX improves the efficiency of low dose obeticholic acid to reduce hepatic bile acids and mitigate inflammation, ER stress and fibrosis in liver cells

Audrey-Anne Lavoie[1,2,3], Mélanie Verreault[1,3], Jocelyn Trottier[1,3], Olivier Barbier[1,2,3]. [1]*Axe Endocrinologie-Néphrologie, Centre de recherche du CHU de Québec - Université Laval, Québec, Canada;* [2]*Faculté de pharmacie, Université Laval, Québec, Canada;* [3]*Centre de recherche Nutrition, Santé et Société (NUTRISS), INAF, Université Laval, Québec, Canada*
Email: audrey-anne.lavoie@crchudequebec.ulaval.ca

Background and aims: Primary biliary and sclerosing cholangitis (PBC; PSC) are rare and progressive autoimmune liver diseases, characterized by an accumulation of toxic bile acids (BA) in liver cells. *The reduction of these toxins is an important pharmacological target for the treatment of these pathologies.* Currently, obeticholic acid (OCA), an inhibitor of BA synthesis, is one of the few drugs approved for the treatment of these diseases. Despite being efficient in normalizing liver enzymes, OCA is associated with dose-related side effects that led the EMA to publish novel contraindications for the treatment of decompensated PBC patients. Hence, a potential strategy involves reducing the optimal required dose of OCA to enhance its safety profile, while mitigating development-associated burdens. Thus, this study investigates whether protectin DX (PDX), an omega-3 derivative with hepatic anti-inflammatory properties, can improve the response to low OCA dose in terms of BA reduction, BA-induced inflammation, ER stress and fibrosis.
Method: HepG2 cells and murine hepatocytes were treated with vehicle and low dose OCA (0.5–1 μM), in the presence or absence of 5 μM PDX or 50 μM DHA (positive control) for 24H. To induce ER stress and fibrosis, HepG2 cells received the same treatments, with an additional 400 μM BA mixture for 24H and 2 ng/mL TGF-β for 72H, respectively. For inflammation, THP-1 cells were treated with 100 ng/mL LPS, in addition to the previous treatments for 24H. Transcriptomic (qRT-PCR), proteomic (Western blot, ELISA), or metabolomic targeted (LC-MS/MS) approaches were employed to assess the effects of PDX on low dose OCA.
Results: In the presence of PDX, liver cells exhibited a stronger response to 1 μM OCA when compared to the drug alone. Indeed, OCA 1 μM caused a 54.3% reduction of CYP7A1 levels, while in the presence of PDX, the same amount led to a stronger ($p < 0.05$) reduction of this transcript to 64.7%. The combination of OCA and PDX also led to a stronger reduction of CDCA ($p < 0.05$) secretion in human liver cells medias as well as a significant decrease in total, primary conjugated ($p < 0.001$) and unconjugated ($p < 0.01$) BA in murine cells. Moreover, the addition of PDX significantly increased the mRNA expression of essential BA export transporters such as OSTα-β and MRP2 ($p < 0.001$). Additionally, PDX improved the response of OCA on inflammation by reducing the expression of the pro-inflammatory cytokines, TNFα, MCP-1, IL-6 ($p < 0.001$), and IL-1β ($p < 0.01$) in THP-1 macrophage. The PDX + OCA combination was also found to decrease the expression of ER stress marker BIP ($p < 0.01$) as well as the fibrosis gene COL1A1 ($p < 0.001$).
Conclusion: These experiments demonstrate that PDX improves the ability of a low OCA dose to inhibit BA synthesis and export as well as to mitigate inflammation, ER stress and fibrosis development in liver cells. Further analyses are, however, required to validate this hypothesis.

FRI-307-YI

IL-27 drives activation of tissue-destructive CD8+ T cells and is functionally indispensable in immune checkpoint inhibitor-induced hepatitis

Cathrin Gudd[1], Eoin Mitchell[1], Lucia A. Possamai[1], Evangelos Triantafyllou[1], Nicholas Powell[1]. [1]*Department of Metabolism, Digestion and Reproduction, Imperial College London, London, United Kingdom*
Email: c.gudd@imperial.ac.uk

Background and aims: Checkpoint inhibitor-induced hepatitis (CPI-hepatitis) is a key immune-related adverse event of cancer immunotherapy, likely mediated by monocyte-mediated $CD8^+$ T cell recruitment and activation. Here, we assess the role of IL-27 in mediating this pathogenic immune crosstalk.
Method: Serum levels of IL-27 in healthy controls (HC, n = 35) and patients with CPI-hepatitis (n = 22) were measured using U-PLEX assays. $CD8^+$ T cell activation was assessed in HC peripheral blood mononuclear cells (PBMCs) conditioned in HC (n = 3), CPI-hepatitis (n = 6) or IL-27-neutralised CPI-hepatitis (n = 6) serum for 48 hours. Experimental CPI-hepatitis was established in wild-type (C57BL/6J) 8–12 weeks old male mice through dosing with toll-like receptor 9 agonist (TLR9-L) for priming of hepatic inflammation, in combination with anti-CTLA-4/PD-1 (200 ug each; CPI) or PBS (vehicle) for up to 7 days (n = 4–8/group). To assess the role of IL-27, mice were treated with neutralizing anti-IL-27 on day 5, two days before peak liver injury. Multi-colour flow cytometry, histology/immunofluorescence and mRNA sequencing were used to characterise liver myeloid/lymphoid subsets and inflammation. Hepatocyte damage was assessed by plasma cytokeratin 18 measurement.
Results: Patients with CPI-hepatitis showed increased IL-27 serum levels, compared to HC (median concentration: CPI-hepatitis = 288.4 pg/ml, HC = 123.3 pg/ml; $p = 0.0003$). Serum IL-27 concentrations correlated positively with CD8 cytotoxicity (granzyme B: $r = 0.493$, $p = 0.03$) and activation (ICOS: $r = 0.539$, $p = 0.02$). The frequency of activated $ICOS^+CD8^+$ T cells, induced by CPI-hepatitis serum conditioned medium, was significantly reduced by antibody-mediated IL-27 neutralization ($p = 0.03$). In mice, the frequency of IL-27 producing cells was increased within the $CD11b^+$ myeloid cell compartment of CPI-treated animals, specifically liver infiltrating monocytes, compared to vehicle group ($p = 0.02$). In vivo neutralisation of IL-27 using anti-IL-27 mAb, significantly reduced $CD8^+$ T cell liver infiltration, clustering, and activation (granzyme B, perforin, IFNg), and prevented disease (normalisation of liver histology and plasma cytokeratin 18 levels).
Conclusion: Our data indicate that IL-27 is important for the recruitment and activation of tissue damaging $CD8^+$ T cells, and is functionally indispensable for liver injury in CPI-hepatitis, identifying IL-27 as a key therapeutic target in CPI-hepatitis. Future work will further characterise the mechanisms of IL-27-mediated immune regulation in tissue, including in cancer settings, to fully assess the applicability of IL-27 blockade as a viable therapeutic strategy in CPI-hepatitis.

FRI-308

Active transport via bile salt export pump (Bsep/Abcb11) is not required for cholehepatic shunting and choleretic actions of Norucholic acid (NCA/norUDCA) in mice

Claudia Fuchs[1], Oleksandr Petrenko[2], Veronika Mlitz[1], Hubert Scharnagl[3], Marcus Henricsson[4], Antonio Molinaro[4], Thomas Reiberger, Michael Trauner. Email: claudia.fuchs@meduniwien.ac.at

Background and aims: Choleretic properties of conjugation-resistant Norucholic acid (NCA, previously known as norUDCA) are associated with it's capability to undergo cholehepatic shunting inducing a bicarbonate (HCO_3^-)-rich choleresis. Previously it has been demonstrated that the apical sodium-dependent bile acid (BA) transporter (Asbt), organic solute transporter-α (Ostα), and organic anion transporting polypeptide 1a/1b (OATP1a/1b) transporters are not required for NCA-induced bile flow and biliary HCO_3^- secretion. However, the role of the canalicular bile salt export pump (Bsep) as key and rate-limiting step in biliary BA excretion was not investigated. Therefore, the goal of this study was to identify the role of Bsep for the choleretic actions of NCA.
Method: Eight weeks old male FVB/N wild type (*wt*) and *Bsep*$^{-/-}$ mice were fed with a 0,5%NCA containing diet over 4 weeks. Bile flow, BA profiling from bile, liver biochemistry and (immuno)histology, as well as RNA sequencing from bulk liver tissue and mRNA profiling by RT-PCR were performed.
Results: NCA feeding in *wt* mice increased bile flow from 1 µL/min/gLiver to 3 µL/min/gLiver. Accordingly, HCO_3^- ouput was increased 3-fold (45 nmol/min/gL in *wt* mice vs 150 nmol/min/gL in NCA-fed *wt* mice). While *Bsep*$^{-/-}$ mice had no measureable bile flow at baseline, in NCA-fed *Bsep*$^{-/-}$ mice bile flow reached 0.5 µL/min/gLiver with a HCO_3^- ouput of 14 nmol/min/gL. After NCA feeding biliary concentrations of unconjugated NCA were10-fold higher in *wt* compared to *Bsep*$^{-/-}$ mice (760 µM in *wt* versus 70 µM in *Bsep*$^{-/-}$), while the amount of taurine-conjugated NCA was100-fold higher in *wt* compared to *Bsep*$^{-/-}$ mice (5220 µM in *wt* versus 50 µM in *Bsep*$^{-/-}$). RNAseq revealed *Sult2a1, Sult2a2, Sult2a4, Sult2a5* as well as *Abcc3* and *Abcc4* among the most up-regulated genes in *Bsep*$^{-/-}$ mice fed with NCA, indicating increased BA sulfation/hydroxylation and alternative BA efflux into the blood. Of note, although serum ALT and AST levels were increased in *Bsep*$^{-/-}$ mice after NCA feeding, (immuno)histological stainings and genexpression profiling did not reveal any signs of liver inflammation and/or fibrosis.
Conclusion: Our data indicate that transport via Bsep/Abcb11 is not essential for choleretic effects of unconjugated NCA. In contrast, transport of taurine-conjugated NCA into bile requires Bsep/Abcb11.

FRI-309

Single-cell profiles of intrahepatic and peripheral immune cells reveal AIH-specific CD8+ T cells promote disease progression through cytotoxicity and macrophage interactions

Xinghuan Fu[1], Yuan Hong[1], Chi Zhang[1], Jiandan Qian[1], Long Xu[1], Yanjie Lin[1], Xueying Li[1], Wanwan Shi[1], Gui-Qiang Wang[1]. *[1]Department of Infectious Disease, Center for Liver Disease, Peking University First Hospital, Beijing, 100034, China, Beijing, China*
Email: donutmededu@163.com

Background and aims: The pathogenesis of autoimmune hepatitis (AIH) remains poorly understood, hindering accurate diagnosis and novel therapeutic target identification. In this study, we used single-cell RNA sequencing (scRNA-seq) and immune repertoire analysis to explore the immune characteristics and mechanisms in both blood and liver tissues of AIH patients.
Method: Single cells were isolated from liver biopsy and paired peripheral blood samples of 9 AIH and 3 primary biliary cholangitis (PBC) patients for 10× Genomics scRNA-seq and immune repertoire profiling. Public data from healthy individuals served as controls. Clinical analyses, scRNA-seq data from external animal models, and multiplex immunohistochemistry (mIHC) of liver biopsy sections were used for validation. Serum cytokines and chemokines were measured using liquid phase chip technology.
Results: A total of 159,411 high-quality cells were identified, categorized into CD8+ T, CD4+ T, γδT, NK/NKT-like, myeloid, B, plasma B, parenchymal, and proliferating cells. Cell distribution analysis revealed significant changes in the proportion and transcriptomic profiles of CD8+ T cells within the liver microenvironment of AIH patients. Further subcluster analysis identified a CD8+ T cell cluster in AIH patients that was positive for GZMB and VCAM1, showing high expression of TNFRSF9 and IFNG, indicating cytotoxic activity. Single-cell immune repertoire analysis confirmed active proliferation and transcriptional transition of these cells. Similar findings were validated in liver tissue from dnTgfbr2 Aire -/- mice. Co-occurrence analysis revealed six multi-cellular modules (CMs), with CM3 containing CD8+ T cells, TREM2+ macrophages (Mph), and CD5L+ Mph. The proportion of these macrophage populations was significantly elevated in AIH livers. CellphoneDB analysis showed significant interactions between CD8+ T cells and macrophages in CM3, leading to CD8+ T cell recruitment and sustained liver injury in AIH patients, compared to HC and PBC groups. Cytokine-chemokine analysis confirmed elevated serum chemokine levels in the AIH group. Preliminary validation via mIHC confirmed these findings.
Conclusion: In conclusion, we present a comprehensive single-cell immune atlas of AIH, identifying an AIH-specific cytotoxic CD8+ T cell cluster. Our findings suggest that macrophage-derived chemokines drive liver damage through interactions with CD8+ T cells, offering new insights into AIH pathogenesis and potential therapeutic targets.

FRI-310

Quantitative MRI metrics in the liver and pancreas for disease assessment in IgG4-related sclerosing cholangitis with autoimmune pancreatitis

Edward Jackson[1], Michele Pansini[2,3], George Ralli[1], Yameng Deng[4], Alexandre Triay Bagur[4], Seliat Olodo-Atitebi[2], Adam Bailey[2], Emmanuel Selvaraj[5], Michael Pavlides[2], Emma Culver[2]. *[1]Perspectum Ltd, Oxford, United Kingdom; [2]Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom; [3]Clinica Di Radiologia EOC, Lugano, Switzerland; [4]Perspectum Ltd., Oxford, United Kingdom; [5]South Warwickshire University Foundation Trust, Warwick, United Kingdom*
Email: edward.jackson@perspectum.com

Background and aims: This study used standardised parenchymal and ductal MRI metrics in the liver and pancreas to develop a novel quantitative description of IgG4-related sclerosing cholangitis and autoimmune pancreatitis (IgG4-SC and IgG4-AIP). The metrics were evaluated for their potential to monitor disease activity and distinguish between IgG4-SC and primary sclerosing cholangitis (PSC).
Method: Ten participants with IgG4-SC/AIP underwent multiparametric MRI including iron-corrected T1 (cT1) and scanner-referenced T1 mapping (srT1) to measure inflammation in liver and pancreas parenchyma respectively. Quantitative MRCP analysis of the biliary tree, common bile duct (CBD) and pancreatic duct (PD) was performed using MRCP+.
Results: cT1 and srT1 values were compared with age, sex, and BMI-matched healthy controls (n = 100) and controls with type 2 diabetes (n = 100) from UK Biobank. Metrics of the biliary tree (tree volume, number of ducts, number of strictures), PD (duct diameter, visible duct length) and CBD (duct diameter) were compared with age-matched healthy volunteers (n = 10) and participants with PSC (n = 10). Of the ten IgG4-SC/AIP participants, 7 had active pancreatic involvement ('active IgG4-SC/AIP') determined by PET-CT imaging. In the liver parenchyma, cT1 was elevated in IgG4-SC/AIP compared to matched controls (median 747 ms vs 696 ms healthy, 718 ms with type 2 diabetes; $p = 0.001$). In the pancreas, srT1 was significantly elevated in active IgG4-SC/AIP compared to matched controls (1371 ms in active disease, 744 ms healthy, 757 ms with type 2 diabetes; $p < 0.001$) but was not elevated compared to controls in

inactive disease (795 ms inactive, n.s.).Whole biliary tree volume, number of ducts and number of ducts with strictures were all significantly elevated in IgG4-SC/AIP compared to healthy controls but not PSC. Median CBD diameter was elevated in IgG4-SC/AIP compared to healthy controls and PSC (6.1 mm, vs 5.0 mm healthy 4.7 mm PSC; $p < 0.05$), regardless of IgG4 disease activity. Alongside elevated srT1, active IgG4-SC/PSC showed characteristic PD changes with either compression (reduced diameter and visible length) or focal dilation, but PD diameter did not distinguish between healthy control or PSC groups.

Conclusion: Standardised T1 mapping of increased inflammation in pancreas parenchyma distinguishes active IgG4-SC/AIP from healthy controls and should be investigated for its potential to distinguish IgG4-SC/AIP from PSC. Quantitative MRI metrics of the whole biliary tree distinguish IgG4-SC/AIP from healthy controls, while extrahepatic metrics such as CBD diameter may aid differentiation between IgG4-SC/AIP and PSC.

FRI-311

Restoring gene function in cholangiocyte organoids through lentiviral transduction

Enya Amundsen-Isaksen[1,2,3,4], Anna Katharina Frank[1,2,3,4,5], Kathrine Sivertsen Nordhus[1,2,3], Xiaojun Jiang[1,2], Fotios Sampaziotis[6,7,8,9], Espen Melum[1,2,3,4,10]. *[1]Norwegian PSC Research Center, Division of Surgery and Specialized Medicine, Oslo University Hospital Rikshospitalet, Oslo, Norway; [2]Research Institute of Internal Medicine, Division of Surgery and Specialized Medicine, Oslo University Hospital Rikshospitalet, Oslo, Norway; [3]Institute of Clinical Medicine, Faculty of Medicine, University of Oslo, Oslo, Norway; [4]Hybrid Technology Hub-Centre of Excellence, Institute of Basic Medical Sciences, Faculty of Medicine, University of Oslo, Oslo, Norway; [5]Scientia Fellowship, European Union's Horizon 2020 research and innovation program under the Marie Sklodowska-Curie grant agreement No 801133, Oslo, Norway; [6]Wellcome Trust-Medical Research Council Cambridge Stem Cell Institute, Jeffrey Cheah Biomedical Centre, University of Cambridge, Cambridge, United Kingdom; [7]Department of Surgery, University of Cambridge, Cambridge, United Kingdom; [8]Department of Medicine, University of Cambridge, Cambridge, United Kingdom; [9]Cambridge Liver Unit, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom; [10]Section of Gastroenterology, Division of Surgery and Specialized Medicine, Oslo University Hospital Rikshospitalet, Oslo, Norway*
Email: enya.amundsen-isaksen@medisin.uio.no

Background and aims: Cholangiocyte organoids derived from primary tissue are useful tools for studying biliary diseases and could potentially be used for cell-based therapy in bile duct disorders. Such approaches would also allow correction of genetic mutations affecting the bile ducts for instance as seen in cystic fibrosis. This study aimed to establish a system for functional gene restoration in cholangiocyte organoids using lentiviral transduction. We sought to demonstrate that this approach could restore function of a knocked-out gene, validate the recovery through GFP tagging and utilize co-culture experiments to demonstrate a functional effect. We used a mouse model lacking an antigen-presenting molecule (CD1d) that is functional on cholangiocytes, allowing functionally relevant co-culture assay to be used.

Method: Cholangiocyte organoids were derived from *Cd1d*$^{-/-}$ knock-out mice. Organoids were transduced with a lentiviral vector (VB220423-1199tqn) encoding the knocked-out *Cd1d* gene and a GFP reporter tag. Transduction efficiency was visualized via fluorescence microscopy and confirmed by flow cytometry with a anti-CD1d antibody. Functional restoration was evaluated using a co-culture system with natural killer T (NKT) cells and the glycolipid antigen alpha-galactosylceramide (alpha-GalCer). Cytokine production of interleukin-2 (IL-2) by alpha-GalCer activated NKT cells was measured using ELISA.

Results: Cholangiocyte organoids (n = 3 lines) were successfully transduced as evidenced by fluorescence microscopy showing clear GFP expression. The transduction efficacy was evaluated by flow-cytometry demonstrating that the transduced organoids were positive with CD1d expression. In co-culture experiments, *Cd1d* transduced organoids bound and presented alpha-GalCer to NKT cells, eliciting IL-2 release as an indication of activation. These responses were comparable to those observed with wild-type organoids and absent in KO organoids, confirming successful restoration of gene functionality after lentiviral transduction.

Conclusion: This study demonstrates that it is feasible to restore gene function in cholangiocyte organoids using lentiviral transduction. The ability to achieve both efficient transduction and functional restoration enables studies using this as a platform for studying gene-specific roles, their impact on immune interactions as shown herein, and ultimately translation into clinical medicine. These findings also lay the groundwork for refining and extending the approach to more complex systems, such as organ-on-a-chip platforms or *in vivo* studies.

Email: amib@szmc.org.il

Background and aims: Autoimmune hepatitis (AIH) is a chronic inflammatory liver disease associated with morbidity and mortality. Diagnosis often requires a liver biopsy to confirm the condition and affirm subsequent remission. While advances in liquid biopsy techniques have shown promise in cancer diagnosis, their application in liver diseases has yet to be extensively investigated. Cell-free DNA (cfDNA) in human plasma, a noninvasive liquid biopsy, offers molecular insights into the pathological processes of the organs of origin. These fragments reflect transcriptional activity within the dying cells. This study aims to evaluate the ability of chromatin immunoprecipitation and sequencing (cfChIP-seq), which informs on gene transcription in dying cells, to differentiate AIH from other chronic liver diseases.

Method: We applied cfChIP-seq to analyze plasma samples from 95 patients with AIH, either at diagnosis or during biochemical remission, and a control group comprising 18 healthy individuals and 79 patients with various liver diseases including fatty liver, primary sclerosing cholangitis, viral hepatitis and metabolic disease.

Results: Comparative analysis of plasma samples identified immune-related transcriptional processes uniquely active in the hepatocytes of AIH patients. Several significantly elevated genes were identified, including those linked to hepatic inflammation (CXCL9/10/11, GBP1, GBP5, UBD, TRIM31, HLA-DOB, and HULC) and immune mediated liver pathology (FOXP3, IL32). These genes constituted an 'AIH score' that achieved an area under the curve (AUC) of 0.9 in a validation set,

effectively distinguishing AIH from all other chronic liver diseases. RNA-seq analysis of liver biopsies from the same patient cohort further confirmed, the AIH cfChip-seq signature, of the differential expression of these genes.
Conclusion: Plasma cfChIP-seq demonstrates potential as a non-invasive diagnostic tool for AIH, offering an alternative to liver biopsy. This approach not only enhances diagnostic accuracy but also provides deeper insights into AIH pathogenesis, potentially transforming clinical management of the disease.

Email: h.elabd@ikmb.uni-kiel.de

Background and aims: Primary sclerosing cholangitis (PSC) is an autoimmune liver disease characterized by progressive inflammation and fibrosis of the bile ducts. The cause of PSC is unknown, yet multiple studies have implicated different human leukocyte antigen (HLA) genetic variants in disease development, e.g. HLA-B*08:01 and HLA-DRB1*13:01. Other studies have shown alterations in T cell responses of people with PSC. Nonetheless, the antigens driving these adaptive immune responses have not yet been identified.
Method: We aimed for an integrated analyses of adaptive immune responses in PSC; by the comprehensive profiling of the blood T cell repertoire of 504 individuals with PSC and 904 healthy controls using T cell repertoire sequencing, along with profiling of the functional antibody repertoire of 120 individuals with PSC and 202 matching healthy controls using phage-immunoprecipitation sequencing (PhIP-Seq). In follow up to the molecular data, we queried the health care records of 116 individuals in the TriNetX database for relevant disease associations.
Results: Using a hypothesis-free statistical analysis framework, we identified 1,008 T cell clonotypes that were associated with PSC. These clonotypes were mostly restricted to PSC-risk HLA variants such as the HLA-B*08:01-HLA-DRB1*03:01 haplotype as well as HLA-DRB1*13:01 and were shown to target different Epstein-Barr virus (EBV) epitopes, particularly, lytic-phase antigens such as BZLF1. Furthermore, for the PhIP-Seq data we detected elevated antibody responses toward different EBV lytic-phase antigens, predominantly the BMRF1 protein. In the TriNetX database, we detected a robust association between infectious mononucleosis, which is mainly caused by EBV, and PSC (odds ratio [OR] = 8.46; 95% CI: 4.53–15.80).
Conclusion: We report for the first time that in PSC there are expanded T and B cell responses against EBV. Furthermore, these responses were predominantly detected for lytic-phase antigens which may indicate that EBV-reactivation is a central theme in the pathogenesis of PSC. Whilst similar findings have been reported for multiple sclerosis, the OR for the association between PSC and infectious mononucleosis was more than 4-fold higher than that found for multiple sclerosis in the TriNetX database.

FRI-314-YI

Mitochondrial dynamics and auto(mito)phagy are altered in experimental models of primary biliary cholangitis, contributing to disease pathogenesis

Email: jesus.banales@biodonostia.org

Background and aims: Primary biliary cholangitis (PBC) is a chronic immune-mediated cholestatic liver disease of unknown origin. We have previously reported that the expression of microRNA-506 (miR-506) is increased in PBC cholangiocytes, targeting the $Cl^-/HCO3^-$ exchanger AE2 and leading to intracellular pH (pHi) disturbances and PBC-like features, such as PDC-E2 overexpression and immune activation. Mitophagy, an essential anti-inflammatory and quality-control mechanism that eliminates dysfunctional mitochondria, is highly dependent on pHi for its activation, though its role in PBC has not been explored. Our aim was to characterize the mitochondrial dynamics and auto(mito)phagy processes in PBC and evaluate their contribution to disease pathogenesis.
Method: miR-506-overexpressing cholangiocytes (H69 miR-506), an experimental in vitro PBC model [Banales JM, et al. Hepatology 2012; Erice O, et al. Hepatology 2018], and control cells (H69 miR- and H69)], were characterized by mass spectrometry proteomics. Mitochondrial dynamics, integrity and activity, autophagy/mitophagy, and cell viability were assessed in baseline conditions and in

the presence of different anti-cholestatic drugs or autophagy activators.
Results: High-throughput proteomics revealed that several proteins involved in mitochondrial dynamics and auto(mito)phagy are altered in H69 miR-506 cholangiocytes, compared to controls. Importantly, gene-set enrichment analysis (GSEA) revealed that processes related to antigen presentation, inflammation and mitochondrial organization/translation are increased in H69 miR-506 cells. Flow cytometry indicated a decrease in mitochondrial functionality (Mitotracker Red) in H69 miR-506 cholangiocytes compared to controls, suggesting the accumulation of dysfunctional mitochondria and impaired mitophagy. In line, the exposure of cholangiocytes to auto(mito)phagy inhibitors (3-MA and bafilomycin) induced cell death, particularly in miR-506 cells, while the activation of autophagy with Dactolisib (BEZ235) significantly reduced the toxic bile acid-induced apoptosis. Importantly, the treatment of H69 miR-506 cholangiocytes with the anti-cholestatic drugs ursodeoxycholic acid (UDCA), bezafibrate (BZF) or obeticholic acid (OCA), improved mitochondrial functionality and energy metabolism, reducing PDC-E2 overexpression.
Conclusion: Our data suggest that PBC cholangiocytes are characterized by disturbances in mitochondrial integrity and auto(mito)phagy, leading to the accumulation of dysfunctional mitochondria and aberrant presentation of mitochondrial antigens. Of note, different anti-cholestatic drugs modulate these mitochondrial disturbances, providing insights into their mechanism of therapeutic action. Besides, targeting mitochondrial dynamics and mitophagy presents a promising novel approach for PBC treatment.

FRI-315
ATP8B1 deficiency causes steatosis and PDE4-mediated glucagon resistance in liver

Email: c.c.paulusma@amsterdamumc.nl

Background and aims: Deficiency of the phospholipid flippase ATP8B1 causes infantile-onset progressive familial intrahepatic cholestasis type I (PFIC1). The *Atp8b1*$^{G308V/G308V}$ mouse, an established model for human PFIC1, carries the orthologous mutation of the Amish index kindred. Upon cholate challenge, the *Atp8b1*$^{G308V/G308V}$ mice develop cholestatic liver injury. Unexpectedly, *Atp8b1*$^{G308V/G308V}$ mice developed hepatic steatosis on normal chow, which was not present when challenged with cholate to model cholestatic injury. In the present study, we investigate how ATP8B1 deficiency affects lipid and glucose metabolism in the liver.
Method: Age-matched male *Atp8b1*$^{G308V/G308V}$ and wild-type C57BL6/J littermates on normal chow were examined. Hepatic lipid and glycogen was evaluated by histology and enzymatic quantification. Metabolic syndrome was evaluated by body weight (BW), oral glucose tolerance test (OGTT), fasting plasma glucose and lipid levels. Expression of glucagon target genes and cAMP-degrading phosphodiesterases (PDEs) were measured by real-time quantitative PCR (RT-qPCR) in primary mouse hepatocytes (PMH), human hepatoma cells HepG2 overexpressing glucagon receptor (HepG2-GCCR), and liver biopsies from control and PFIC1 patients. cAMP levels were measured by ELISA. Lentivirus-mediated shRNA expression was used to knockdown ATP8B1 in HepG2-GCCR cells.
Results: Compared to wild-type mice, *Atp8b1*$^{G308V/G308V}$ mice had increased liver/BW ratio and liver triglyceride content. Liver histology showed microvesicular steatosis; OGTT showed no evidence of insulin resistance. Remarkably, fasting levels of plasma glucose, triglyceride, and cholesterol were significantly reduced in *Atp8b1*$^{G308V/G308V}$ mice, indicating reduced hepatic glucose production and lipid secretion. Consistently, *Atp8b1*$^{G308V/G308V}$ PMH had dramatically reduced glucagon-dependent *G6pc1* expression. The cAMP levels both at the basal state and after glucagon stimulation were significantly lower in *Atp8b1*$^{G308V/G308V}$ PMH, indicating increased cAMP degradation by PDEs. RT-qPCR confirmed increased *Pde4b* and *Pde4d* expression in *Atp8b1*$^{G308V/G308V}$ PMH. Treating *Atp8b1*$^{G308V/G308V}$ PMH with glucagon and the PDE4-selective inhibitor rolipram rescued *G6pc1* expression. Similarly, ATP8B1 knockdown in HepG2-GCGR cells resulted in increased *PDE4D* expression and impaired *G6PC1* induction by glucagon. Native livers of PFIC1 patients also have increased PDE4D at mRNA and protein levels and showed extremely low glycogen content.
Conclusion: ATP8B1 deficiency leads to upregulation of cAMP-degrading PDE4D, which causes glucagon resistance, impaired gluconeogenesis, and compensatory glycogenolysis. As glucagon signaling promotes lipolysis and fatty acid oxidation, PDE4-mediated glucagon resistance likely also contributes to hepatic steatosis in *Atp8b1*$^{G308V/G308V}$ mice.

Urinary proteomics: a new diagnostic approach for primary biliary cholangitis
Wei Jiang[1], Ting Lei[1], Xiong Pei[1], Hong Tang[1], Taoyou Zhou[1], Dongbo Wu[1]. *[1]Center of Infectious Diseases, West China Hospital, Sichuan University, Chengdu, China*
Email: dongbohuaxi@scu.edu.cn

Background and aims: Early manifestations of primary biliary cholangitis (PBC) are often atypical. Urinary proteomics offers a non-invasive, accessible approach to identify potential biomarkers. This study aimed to use urinary proteomics to identify non-invasive biomarkers for PBC diagnosis.
Method: Clinical data and urine samples from 30 PBC patients and 20 healthy controls were collected. High-performance liquid chromatography (HPLC) was used to separate the peptide segments, which were then analyzed by Electrospray Ionization Ion Trap Mass Spectrometry (ESI-IT/MS) for peptide identification. Protein identification and quantification were performed using the Spectronaut 14.8 database. Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway analysis were conducted to identify immune-related differential proteins. The correlation between differential proteins and clinical indicators was assessed using Pearson's correlation test. Finally, Enzyme-Linked Immunosorbent Assay (ELISA) was used to validate the expression of selected proteins in PBC patients and healthy controls.
Results: No significant differences between the two groups were observed in terms of gender, age, bile acids, albumin, and serum creatinine ($p > 0.05$). However, there were significant differences in ALP, GGT, bilirubin, and immunoglobulin IgM ($p < 0.001$). Further, the urinary proteomics analysis revealed that a total of 109 proteins were upregulated, and 85 proteins were downregulated in PBC patients. GO analysis and KEGG pathway enrichment of the top 50 upregulated proteins were performed. And then, 10 differential proteins were found to be associated with immune regulation and inflammatory

responses (OPN, RAMP3, CD44, ACVRIB, CXCL12, CD74, CCN4, S100A8, LAMP3, PIK3Cd). Correlation analysis of the 10 differential proteins with clinical biochemical markers revealed that OPN, RAMP3, and S100A8 were significantly correlated with AST, ALT, ALP, and GGT. ELISA validation further confirmed that the expression trends of these proteins in the urine of PBC patients and healthy controls were consistent with the mass spectrometry results.
Conclusion: The urinary levels of OPN, RAMP3, and S100A8 were significantly elevated in PBC patients compared to healthy controls, highlighting their potential as diagnostic biomarkers for PBC.

FRI-317
Pharmacokinetics, safety, and tolerability of seladelpar in people with renal impairment
Jin Zhou[1], Xin Qi[1], John McFarlane[1], Raj Bhardwaj[2], Daria Crittenden[1]. [1]*Gilead Sciences, Inc., Foster City, United States;* [2]*Certara USA, Radnor, United States*
Email: jin.zhou1@gilead.com

Background and aims: Seladelpar is a first-in-class delpar (selective PPAR-delta agonist) indicated for the treatment of primary biliary cholangitis in combination with ursodeoxycholic acid (UDCA) in adults who have an inadequate response to UDCA, or as monotherapy in people unable to tolerate UDCA. Seladelpar is primarily eliminated in urine as metabolites, which are not expected to have clinically relevant pharmacological activities. In a mass balance study in humans, a single 10 mg oral dose of radiolabelled seladelpar was recovered in urine (73.4%) and faeces (19.5%). Here, we report on the effect of different degrees of renal impairment (RI) on the pharmacokinetics (PK), safety, and tolerability of a single 10 mg dose of seladelpar.
Method: In a Phase 1, open-label, parallel-group study (CB8025-11942), participants with normal (≥90 mL/min/1.73 m^2), mild (≥60 to <90 mL/min/1.73 m^2), moderate (≥30 to <60 mL/min/1.73 m^2), or severe (<30 mL/min/1.73 m^2) RI, defined by estimated glomerular filtration rate (eGFR) using the modification of diet in renal disease equation, were evaluated. Participants receiving haemodialysis were excluded. Participants with normal renal function were demographically matched by age, sex, and body mass index to participants with mild, moderate, or severe RI. A regression analysis was used to evaluate the relationship between eGFR and seladelpar PK in plasma and urine. Safety and tolerability were reported.
Results: Of 36 participants who completed the study, 12 had normal renal function and 8 each had mild, moderate, or severe RI. Seladelpar maximum plasma concentration (C_{max}) and area under the plasma concentration curve extrapolated to infinity (AUC_{0-inf}) were not meaningfully changed in participants with different degrees of RI when matched to participants with normal renal function. The geometric least-squares mean (GLSM) ratios for seladelpar C_{max} were 1.17 for mild, 0.99 for moderate, and 1.01 for severe RI. The GLSM ratios for seladelpar AUC_{0-inf} were 1.10 for mild, 1.52 for moderate, and 1.01 for severe RI. GLSM ratios for seladelpar C_{max} and AUC_{0-inf} were calculated after regrouping participants based on absolute eGFR in mL/min and were consistent with those based on body surface area–indexed eGFR in mL/min/1.73 m^2. Regressions of eGFR and seladelpar plasma or urine PK parameters had R^2 <0.04, indicating a lack of correlation between RI and seladelpar plasma exposure or urine excretion. In this study, seladelpar treatment was well tolerated, with only mild adverse events reported (Grade 1, unrelated to seladelpar).
Conclusion: Exposure to seladelpar was not meaningfully increased with different degrees of RI and appeared safe and well tolerated regardless of RI status following a single 10 mg dose. The data support that dose adjustment is not necessary for people with mild, moderate, or severe RI receiving seladelpar treatment.

FRI-318
Evaluation of the potential impact of seladelpar on the pharmacokinetics of midazolam, tolbutamide, simvastatin, rosuvastatin, and atorvastatin
Jin Zhou[1], Raj Bhardwaj[2], John McFarlane[1], Xiangyu Liu[1], Daria Crittenden[1]. [1]*Gilead Sciences, Inc., Foster City, United States;* [2]*Certara USA, Radnor, United States*
Email: jin.zhou1@gilead.com

Background and aims: Seladelpar is a first-in-class oral delpar (selective PPAR-delta agonist) indicated for the treatment of primary biliary cholangitis in combination with ursodeoxycholic acid (UDCA) in adults who have an inadequate response to UDCA, or as monotherapy in patients unable to tolerate UDCA. Seladelpar is mainly metabolised by cytochrome P450 (CYP) CYP2C9, and to a lesser extent by CYP2C8 and CYP3A4. Here, we summarise the perpetrator effects of seladelpar on CYP3A4, CYP2C9, organic anion-transporting polypeptide (OATP), and breast cancer resistance protein (BCRP), using midazolam (CYP3A4), tolbutamide (CYP2C9), simvastatin (CYP3A4 and OATP), rosuvastatin (OATP and BCRP), and atorvastatin (CYP3A4 and OATP) as probe substrates across clinical drug-drug interaction studies.
Method: To test the effect of seladelpar on CYP3A4, CYP2C9, OATP, and BCRP, healthy participants received a single dose of midazolam (15 mg), tolbutamide (500 mg), simvastatin (80 mg), or rosuvastatin (20 mg) with or without seladelpar coadministration (single or multiple doses) in crossover studies. The effect of seladelpar on CYP3A4 and OATP was also assessed in moderately obese hyperlipidemia patients in a parallel group design comparing atorvastatin (20 mg) with or without seladelpar. Pharmacokinetic (PK) parameters included maximum plasma concentration (C_{max}) and area under the plasma concentration curve (AUC).
Results: Midazolam levels were not affected by seladelpar; geometric mean ratio (GMR) (90% CI) of midazolam C_{max}, and AUC_{0-inf} with vs without seladelpar (200 mg once daily [QD]) were 0.94 (0.84, 1.06) and 0.98 (0.91, 1.06), respectively. Tolbutamide levels were not affected by seladelpar; GMR (90% CI) of tolbutamide C_{max} and AUC_{0-inf} with or without seladelpar (200 mg, 2 doses, at least 7 days apart with washout) were 1.03 (0.97, 1.09) and 1.00 (0.98, 1.03), respectively. Simvastatin levels were not altered with seladelpar (200 mg single dose); GMR (90% CI) for simvastatin C_{max} and AUC_{0-inf} were 0.95 (0.78, 1.14) and 1.17 (0.97, 1.41), respectively. Seladelpar did not significantly increase rosuvastatin levels; GMR (90% CI) for rosuvastatin C_{max} and AUC_{0-inf} with or without seladelpar (10 mg single dose) were 1.17 (0.93, 1.45) and 1.15 (0.93, 1.43), respectively. Atorvastatin levels were similar with or without seladelpar (50 mg QD); GMR (90% CI) for atorvastatin C_{max}, and AUC_{all} with or without seladelpar were 0.88 (0.54, 1.43), and 0.85 (0.57, 1.27), respectively.
Conclusion: Seladelpar did not significantly impact the PK of sensitive probe substrates including midazolam (CYP3A4), tolbutamide (CYP2C9), simvastatin (CYP3A4 and OATP), rosuvastatin (OATP and BCRP), and atorvastatin (CYP3A4 and OATP). Based on these data, it is unlikely that seladelpar would have a clinically significant impact on drugs that are substrates of CYP3A4, CYP2C9, OATP, or BCRP.

Email: juliana.jmaff@gmail.com

Background and aims: Epigenetic mechanisms, particularly DNA methylation, play an essential role in regulating gene expression during development and maintaining tissue as well as stem cell homeostasis in response to acute and chronic damage. Central to this regulation is DNA methyltransferase 1 (DNMT1), which is essential for maintaining postmitotic DNA methylation patterns. While its role during development is well explored, its relevance for activation of stem/progenitor cells during regeneration is less well explored. This project aims to explore the impact of hepatocyte-specific DNMT1 loss on liver progenitor cell-induced regeneration.
Method: We used the 3,5-diethoxycarbonyl-1,4-dihydrocollidine (DDC) injury model, in which mice were fed a diet containing this porphyrinogenic hepatotoxin that induces cholestatic liver damage. Liver-specific Dnmt1 knockout mice (Dnmt1-KO) and control animals (WT), aged 8 weeks, were fed a diet with 0.1% DDC for up to 4 weeks. At 1, 2, and 4 weeks post-treatment, 5 animals from each group were sacrificed and the organs harvested for further analysis. Liver injury was assessed by histopathology and the spatial distribution of CK19, a marker of biliary/progenitor cell, was evaluated. Global transcriptomic changes were examined by RNA sequencing.
Results: Macroscopically, livers from both groups exhibited a pronounced dark discoloration due to cholestatic liver damage. No significant differences in macroscopic number of nodules were observed. Histological examination of liver sections demonstrated significantly more pronounced liver injury, progressive structural abnormalities, and a higher degree of infiltrating immune cells in Dnmt1-KO animals in comparison to WT. Additionally, Dnmt1-KO animals exhibited a reduced liver/body weight ratio compared to WT animals, reflective of the impaired regenerative capacity in Dnmt1-KO animals. Supporting this, expansion of CK19-positive cells was significantly reduced in Dnmt1-KO animals indicating impaired stem/progenitor activation and expansion compared to WT animals. The distinct clustering of genes, combined with enrichment analysis, highlights that Dnmt1 deletion significantly impacts gene expression in pathways associated with liver homeostasis and regeneration. Specifically, pathways such as cell cycle progression, DNA replication and repair, cell cycle checkpoint regulation, and apoptosis were significantly enriched.
Conclusion: Our findings establish a critical role of DNMT1 in maintaining liver homeostasis and stem/progenitor cell activation during excessive liver damage. Loss of postmitotic methylation patterns by inhibition of DNMT1, thus, interferes with key processes involved in liver repair and cellular organization during cholestatic liver disease.

FRI-320-YI

Single-cell profiling reveals increased IGHG2+ memory and activated IGHA1+ intrahepatic B cells in primary sclerosing cholangitis

Lisa R. V. Brynjulfsen[1,2,3], Markus S. Jördens[1,2,3,4], Jonas Øgaard[1,2], Amber Bozward[5,6,7], Tom Hemming Karlsen[1,2,3,8], Ye Htun Oo[5,6,7], Espen Melum[1,2,3,8,9], Brian K. Chung[1,2,3]. *[1]Norwegian PSC Research Center, Department of Transplantation Medicine, Division of Surgery and Specialized Medicine, Oslo University Hospital Rikshospitalet, Oslo, Norway; [2]Research Institute of Internal Medicine, Division of Surgery and Specialized Medicine, Oslo University Hospital Rikshospitalet, Oslo, Norway; [3]Institute of Clinical Medicine, Faculty of Medicine, University of Oslo, Oslo, Norway; [4]Department of Gastroenterology, Hepatology and Infectious Diseases, Medical Faculty, Heinrich Heine University Düsseldorf, University Hospital Düsseldorf, Düsseldorf, Germany; [5]University Hospitals Birmingham National Health Service Foundation Trust, Birmingham, United Kingdom; [6]Center for Liver and Gastro Research, Institute of Immunology and Immunotherapy, University of Birmingham, Birmingham, United Kingdom; [7]National Institute for Health Research Birmingham Biomedical Research Center, European Reference Network Rare-Liver Center, University Hospitals Birmingham National Health Service Foundation Trust and University of Birmingham, Birmingham, United Kingdom; [8]Section of Gastroenterology, Department of Transplantation Medicine, Division of Surgery and Specialized Medicine, Oslo University Hospital Rikshospitalet, Oslo, Norway; [9]Hybrid Technology Hub, Institute of Basic Medical Sciences, University of Oslo, Oslo, Norway*
Email: l.r.v.brynjulfsen@medisin.uio.no

Background and aims: Primary sclerosing cholangitis (PSC) is an immune-mediated liver disease featuring a high prevalence of undetermined antibody reactivities and strong association with the gut-liver axis. We previously showed that clonal B cells overlap the gut and liver in PSC patients but little is known about the complete repertoire of intrahepatic B cells. To deeply characterize B cells in PSC livers, we performed single-cell RNA sequencing (scRNA-seq) and compared the phenotype and clonal overlap of B cells infiltrating PSC and disease control explants.
Method: B cells from 12 PSC and 12 disease control explants (9 PBC, primary biliary cholangitis; 3 ALD, alcohol-related liver disease) were enriched by negative selection from liver mononuclear cells, sorted for viability and analyzed by scRNA-seq for total gene and B cell receptor (BCR) expression (10× Genomics). B cell clustering was computed using Seurat v.5 and B cell clonotypes were defined by BCR expression using Loupe VDJ. Mean abundance of B cell isotypes represent the number of isotype+ B cells divided by total B cells per cluster for each disease indication. Clonal overlap among B cell clusters was calculated by Immunarch. P-values between PSC and disease controls were determined using Mann-Whitney and between PSC, PBC and ALD using Kruskal-Wallis followed by Dunn's multiple comparison testing.
Results: ScRNA-seq of 44,954 B cells from PSC, PBC and ALD explants revealed 13 distinct clusters and assigned as naïve (*IGHD*, *TCL1A*), activated (*CD80*, *CD86*), plasma (*CD38*, *SDC1*) and memory (*CD27*) B cells by differential gene expression. *IGHG2*+ B cells that largely recognize bacterial polysaccharides were enriched in memory B cells of PSC livers compared to disease controls (PSC: 8.6%, disease controls: 2.4%; $P = 0.003$) and mucosal-associated *IGHA1*+ B cells constituted a greater proportion of activated B cells in PSC compared to PBC (PSC: 17.2%, PBC: 2.9%; $P = 0.004$) but not ALD (17.4%; $P > 0.05$). Conversely, PBC livers were enriched for proinflammatory *IGHG3*+ plasma cells versus PSC and ALD (PBC: 29.4%, PSC: 4.2%, ALD: 0.0%; $P < 0.05$) and ALD explants were increased for *IGHA2*+ activated B cells compared to PSC and PBC (ALD: 17.9%, PSC: 2.3%, PBC: 1.9%; $P < 0.05$). Overlap of B cell clonotypes in PSC was strongest between activated and unswitched memory B cells, and atypical *FCRL5*+ B cells and activated B cells, whereas the greatest clonal overlap in PBC was among activated B cells and plasma cells.
Conclusion: We detected an enrichment of *IGHG2*+ memory B cells in PSC livers versus non-PSC disease controls and greater proportions of *IGHA1*+ activated B cells in PSC compared to PBC. Collectively these findings imply that intrahepatic B cells in PSC may recognize unique antigens compared to disease controls, which may originate from the inflamed gut-liver axis.

FRI-321

Identifying transporters of the solute carrier (SLC) group involved in cholangiocyte defense against toxic bile acids

Qinghong Li[1], David Trampert[1], Remco Kersten[1], Stan F.J. van de Graaf[1], Ulrich Beuers[1]. *[1]Amsterdam University Medical Center, Tytgat Institute for Liver and Intestinal Research, Department of Gastroenterology & Hepatology, Amsterdam, Netherlands*
Email: u.h.beuers@amsterdamumc.nl

Background and aims: Human cholangiocytes, consistently exposed to high millimolar levels of hydrophobic bile salts, form 5% of the liver cell population and are responsible for ~30% of bile fluid production, primarily composed of bicarbonate and water. The 'biliary bicarbonate umbrella' hypothesis proposed a protective role of bicarbonate maintaining an alkaline pH above the apical membrane and thereby preventing membrane permeation of protonated apolar glycine-conjugated bile acids, which may trigger apoptosis and subsequently

immune attack. Defects of the 'biliary bicarbonate umbrella' have been described in primary biliary cholangitis (PBC), primary sclerosing cholangitis (PSC) and IgG4-related cholangitis (IRC) more recently. In PBC, SLC4A2, the main apical biliary chloride-bicarbonate exchanger, is downregulated. The present study aims to identify additional 'umbrella genes' (SLC transporters) that may be involved in maintaining pH homeostasis and protecting against damage by hydrophobic bile acids, potentially affected in fibrosing cholangiopathies.

Method: This study utilized immortalized human H69 cholangiocytes with short hairpin RNA (shRNA) knockdown of 8 SLC genes involved in pH regulation (SLC4A4, SLC4A7, SLC9A1, SLC26A2, SLC26A4, SLC26A6, SLC26A9, SLC26A11). Fluorometric measurement of intracellular pH, radiochemical determination of 3H-glycochenodeoxycholic acid uptake, and quantification of apoptosis by caspase-3/7 assays were performed. Publicly available RNA sequencing data were analyzed using R2 Platform (https://r2.amc.nl, (GSE206364, GSE159676)).

Results: Knockdown of the SLC transporters SLC9A1 and SLC26A2 resulted in decreased cholangiocellular intracellular pH; knockdown of SLC9A1, SLC26A2 and SLC26A6 enhanced uptake of GCDC, and increased GCDC-induced apoptosis in H69 cells. Analysis of published data revealed that mRNA of SLC9A1, SLC26A2, and SLC26A6 were differentially expressed in the blood transcriptome of PBC or PSC patients compared to healthy individuals. Additionally, mRNA of SLC9A1 was upregulated in liver tissue of PBC and PSC patients relative to healthy individuals.

Conclusion: The SLC transporters SLC9A1, SLC26A2, and SLC26A6 may be involved in human cholangiocyte defense against toxic bile acids and deserve further studies as potential therapeutic targets in fibrosing cholangiopathies.

FRI-322-YI

A combined immunotherapy that maintains the balance and stability of intrahepatic regulatory T cells to enhance biliary regeneration

Man Chun Wong[1], Naruhiro Kimura[2], Gareth Hardisty[1], Ben Higgins[3], Pei-Chi Huang[3], Maxym Besh[3], Tim Kendall[3], Adriano Rossi[3], Prakash Ramachandran[3], Daniel Patten[4], Graham Anderson[4], Shishir Shetty[4], David Withers[4], Atsunori Tsuchiya[2], Shuji Terai[2], Wei-Yu Lu[3]. *[1]Institute for Regeneration and Repair, University of Edinburgh, Edinburgh, United Kingdom; [2]Division of Gastroenterology and Hepatology, Niigata University, Niigata, Japan; [3]Institute for Regeneration and Repair, University of Edinburgh, Edinburgh, United Kingdom; [4]Institute of Immunology and Immunotherapy, University of Birmingham, Birmingham, United Kingdom*
Email: s2425254@ed.ac.uk

Background and aims: Dysfunction of Tregs and the imbalance of Tregs to T effector ratios have been reported in cholangiopathies. Tregs-expansion immunotherapies are introduced clinically to increase Tregs numbers. However, how the injured microenvironment affects the balance between Tregs and effector T cells that regulate liver inflammation and repair remains unclear. This study investigates the dynamic of Tregs during liver injury and the impact of Treg numbers and stability on bile duct repair.

Method: Intrahepatic Tregs of the Foxp3GFPDTR transgenic mice were reduced during DDC diet-induced biliary injury through Diphtheria Toxin injection. For intrahepatic Tregs fate mapping and dynamic studies, the Foxp3CreERTAi14 mice were used. The Tregs will express red fluorescence protein (RFP) after tamoxifen to trace Tregs fate. Interleukin-2 complex (IL-2c) and Ox40L blocking antibodies were used to expand and stabilise Tregs. The extent of liver injury, liver fibrosis and ductular reaction were investigated with transcriptomics, immunohistochemistry and biochemical analysis.

Results: The number of intrahepatic Tregs in PSC livers did not increase compared to healthy livers, showing limited Treg infiltration. Limiting Tregs infiltration in the Foxp3GFPDTR mice suppressed ductular reaction and enhanced liver fibrosis in mice. Transcriptome analysis of bile ducts also showed downregulation in genesets involved in ductular reaction. We previously demonstrated that IL-2c injection suppressed the ductular reaction, increased liver fibrosis, and raised the serum bilirubin level. IL-2c also expanded an "ExTreg" population, characterised by the Tregs losing Foxp3 expression and acquiring a pro-inflammatory phenotype. We found the expression Ox40L co-stimulatory molecule positively correlates with the extent of liver fibrosis in PSC patients. Blocking Ox40L after IL2-c injection promoted Tregs expansion and significantly reduced the proinflammatory ExTreg population by half compared to IL-2c treatment alone. The increase in intrahepatic Tregs and stability promotes ductular reaction and reduces scarring and cholangiocyte senescence in murine cholangitis model.

Conclusion: This study shows the importance of maintaining Treg stability and sustaining a pro-regenerative intrahepatic Treg to Teff ratio during biliary injury. When Tregs are reduced or dysfunctional, biliary regeneration is impaired, and liver injury worsens. Although the IL-2c treatment successfully doubled the intrahepatic Tregs during biliary injury, it is insufficient to promote biliary regeneration due to the instability of Tregs during biliary injury. We overcame the limitation by blocking the OX40 signalling pathway to stabilise and restore Treg functions. This increased intrahepatic Tregs versus Teff ratio, restored biliary regeneration and reduced liver fibrosis. Overall, we propose a combinational approach to improve the efficiency of Treg-mediated immunotherapies for enhancing bile-duct repair.

FRI-326

Spatial transcriptomic analysis of archived primary sclerosing cholangitis livers reveals distinct molecular signatures

Sayed Aseem[1], Grayson Way[2], Stephen Hoang[1], Derrick Zhao[2], Phillip B. Hylemon[2], Michael Idowu[2], Arun J. Sanyal[2], Huiping Zhou[2]. *[1]Virginia Commonwealth University, Stravitz-Sanyal Institute for Liver Disease & Metabolic Health, Richmond, United States; [2]Virginia Commonwealth University, Richmond, United States*
Email: sayed.aseem@vcuhealth.org

Background and aims: Primary sclerosing cholangitis (PSC) is characterized by progressive fibrosis and inflammation of medium and large bile ducts. There is no effective treatment for PSC due to poorly understood pathogenesis. Detailed spatial transcriptomics of PSC bile ducts remains unexplored. This study aimed to assess the feasibility of spatial transcriptomics using archived formalin-fixed paraffin-embedded (FPE) liver tissue and to compare the transcriptomic profiles of PSC and control bile ducts.

Method: FPE liver slides from 6 PSC patients (3 males, 3 females; Caucasian and African American) and 6 control patients (3 with cirrhosis of other etiologies, 3 with histologically normal liver adjacent to metastatic cancer) were analyzed. Samples were collected 2–12 years ago after liver transplant or resection. NanoString GeoMx® Digital Spatial Profiler with the Human Whole Transcriptome Atlas probe set was employed, targeting bile ducts (EpCAM), immune cells (CD45), and myofibroblasts (αSMA). EpCAM-positive bile ducts <100 μM were classified as small ducts, while those 100–300 μM were defined as septal ducts. After normalization and batch correction, regions of interest (ROI) with disproportionate library size relative to surface area were excluded, resulting in comparable exclusions in EpCAM-positive regions. CD45-positive regions had insufficient samples for analysis. Differentially expressed genes (DEGs) were analyzed using Ingenuity Pathway Analysis (IPA) to uncover disrupted biological pathways and upstream regulators.

Results: The highest DEG count was observed in PSC regions of small bile ducts compared to fibrotic controls (EpCAM: 261, αSMA: 585; FDR <0.05). Small PSC ducts exhibited reduced expression of hepatic fibrosis and ribosomal translation pathways compared to control fibrotic small ducts. IPA revealed deactivation of fibrosis-related upstream regulators, including TGFB1. When compared to non-fibrotic counterparts, PSC small ducts showed similar

downregulation of hepatic fibrosis pathways but not ribosomal genes. Conversely, PSC septal bile ducts showed upregulated ribosomal gene expression compared to both control septal ducts and PSC small ducts. PSC septal ducts also showed suppressed hepatic fibrosis pathways compared to fibrotic counterparts, with IPA highlighting MYC oncogene activation and upregulation of cancer-associated processes. In αSMA-positive regions, PSC samples showed reduced expression of hepatic fibrosis pathways, including genes encoding matrix proteases critical for collagen degradation.
Conclusion: This proof-of-concept study demonstrates the feasibility of spatial transcriptomics in FPE liver tissue and reveals transcriptomic alterations unique to PSC. Findings include "exhausted" fibrogenesis and fibrosis remodeling, divergent ribosomal gene expression—decreased in small bile ducts but increased in septal ducts—and MYC activation in PSC septal ducts, suggesting links to cholangiocarcinogenesis.

FRI-327-YI
Genetic ablation of interleukin 17A augments fibrosis in a mouse model of cholestatic liver injury

Background and aims: Interleukin-17A (IL-17A) has been implicated in cholestatic liver diseases like primary sclerosing cholangitis, but its precise role remains unclear. This study aimed to examine the effect of IL-17A genetic ablation in a mouse model of cholestatic liver injury.
Method: Wild type (WT) and *Il-17a*$^{-/-}$ C57BL/6 mice were fed an intermittent 0.1% 3,5-diethoxycarbonyl-1,4-dihydrocollidine (DDC) diet for 21 days to induce cholestatic liver injury. Liver injury and fibrosis were assessed by serum biochemistry, histology, and immunostaining. Intrahepatic leukocyte (IHL) populations were analyzed by mass cytometry. Gene expression in IHLs was profiled using NanoString analysis. Flow cytometry identified immune cell subsets expressing the profibrogenic cytokine LIGHT.
Results: *Il-17a*$^{-/-}$ mice displayed more abundant Desmin-positive myofibroblasts and increased fibrosis following the DDC diet despite similar levels of liver injury and ductular reaction compared to WT littermates. Serum biochemical parameters of cholestasis were comparable between genotypes. Mass cytometry revealed similar increases in myeloid cells in both genotypes after the DDC diet, with a shift from lymphocyte-dominant to myeloid-dominant immune landscape in cholestatic livers. NanoString analysis of IHLs identified upregulation of seven genes in DDC-fed *Il-17a*$^{-/-}$ mice, including *Tnfsf14* (encoding LIGHT). Flow cytometry showed LIGHT expression was restricted to CD4+ T cells, particularly Th1-polarized cells, which were more abundant in *Il-17a*$^{-/-}$ mice. Hepatic stellate cells expressed LIGHT receptors, but direct stimulation with recombinant LIGHT did not increase profibrotic gene expression in vitro.
Conclusion: Genetic deletion of *Il-17a* augments hepatic fibrosis in cholestatic liver injury, likely through increased expression of LIGHT by Th1-polarized CD4+ T cells. These findings provide new insights into the role of IL-17A and CD4+ T cell subsets in cholestatic liver fibrosis, with implications for therapeutic strategies in human cholestatic liver diseases.

CCL24 blockade alters the proteomic profile of patients with primary sclerosing cholangitis and down-regulates central disease processes
Tom Snir[1], Raanan Greenman[1], Ilan Vaknin, Revital Aricha[1], Matthew Frankel[1], John Lawler[1], Adi Mor[1]. [1]*Chemomab Therapeutics Ltd., Tel Aviv, Israel*
Email: tom.snir@chemomab.com

Background and aims: Primary sclerosing cholangitis (PSC) is a chronic progressive disease, characterized by inflammation and strictures of the biliary tree within and around the liver. In the phase 2 SPRING Study evaluating the safety and tolerability of CM-101 (a CCL24 blocking monoclonal antibody) in patients with PSC, there was clinical evidence of anti-inflammatory, anti-fibrotic and anti-cholestatic activities over 15 weeks of treatment. We present the findings of a proteomic analysis exploring alterations in the circulating proteins of CM-101-treated patients compared to placebo, to further highlight the drug's mechanism of action.
Method: The Olink proximity extension assay (PEA) quantified approximately 3,000 proteins in the sera of patients with PSC treated with CM-101 at doses of 10 mg/kg (n = 21), 20 mg/kg (n = 27), and placebo treatment (n = 18). A linear mixed model was used to find differentially expressed proteins (FDR < 0.05, LogFC > 0.5) between CM-101 treated patients and those receiving placebo. Protein levels affected by treatment were used for gene set enrichment analysis (GSEA). Protein-protein interaction (PPI) networks were built to further define functional relationships between proteins.
Results: CM-101 treated patients exhibited significant changes in multiple proteins, including ones that play a role in chemotaxis, immune cell recruitment and inflammation. GSEA showed that CM-101 treatment led to down-regulation of biological processes such as cell-cell adhesion and extracellular matrix (ECM) organization, and molecular functions including binding of growth factors and integrins. PPI analysis linked treatment with CM-101 to down-regulation of gene onthology (GO) terms and pathways for leukocyte migration, cytokine and chemokine activity, and collagen binding.
Conclusion: A comprehensive proteomics analysis provided new insights into PSC disease-related pathways and additional biological evidence of the clinical activity of CM-101, specifically its impact on chemotaxis, immune cell recruitment, and fibrosis in patients with PSC. These results highlight the therapeutic potential of CM-101 and the pivotal role CCL24 plays in PSC pathology.

Immune-mediated and cholestatic disease – Clinical aspects

Statins are associated with decreased risk of disease progression and death in non-cirrhotic patients with primary biliary cholangitis
Eirini Rigopoulou[1], Vasiliki Lygoura[1], Konstantinos Papantoniou[2], George Perifanos[1], George Giannoulis[1], Nikolaos Gatselis[1], Kalliopi Zachou[1], Christos Triantos[2], George Dalekos[1]. [1]*Department of Medicine and Research Laboratory of Internal Medicine, National Expertise Center of Greece in Autoimmune Liver Diseases, European Reference Network on Hepatological Diseases (ERN RARE-LIVER), General University Hospital of Larissa, Larissa, Greece;* [2]*Division of Gastroenterology, Department of Internal Medicine, Patras General University Hospital, Greece, Patras, Greece*
Email: eirigopoulou@med.uth.gr

Background and aims: Statins seem to have pleotropic actions in patients with chronic liver diseases, including the improvement in

events related to portal hypertension. Our aim was to evaluate whether statins in non-cirrhotic patients with primary biliary cholangitis (PBC) might have an effect on disease progression, as attested by development of cirrhosis, all-cause mortality, including liver-related death (LRD) and non-liver-related death (NLRD), as such data is missing.

Method: We retrospectively analyzed prospectively collected data in 466 non-cirrhotic PBC patients (411 females, age: 54.6 ± 13 years, follow-up: 71.5 (88) months) from 2 tertiary referral centers that were either treated with statins for > 12 months due to increased cardiovascular risk (n = 227) or had a follow-up >12 months without statin treatment (n = 239).

Results: These were no significant differences between the two groups in baseline demographic, clinical and laboratory characteristics except for higher LDL levels in statin users. No differences in treatment response to UDCA (GLOBE score, Paris II) were noted between the groups. Statin users had lower rate of cirrhosis development (3.5% vs 9%, p = 0.037), lower all-cause mortality (4% vs 16.7%, p < 0.001), lower LRD (0.5% vs 6.3%, p < 0.001) and NLRD rates (3.5% vs 10.4%, p = 0.004) compared to non-statin users. Cox regression analysis revealed lower risk of progression to cirrhosis (HR = 0.486; 95% CI 0.226–1.044), significantly lower risk of all-cause mortality (HR = 0.282; 95% CI 0.137–0.583), LRDs (HR = 0.091; 95% CI 0.12–0.692) and NLDRs (HR = 0.345; 95% CI 0.155–0.766) in statin users compared to non-users.

Conclusion: Statins are associated with lower risk of cirrhosis development, of all-cause mortality, including LRDs and NLRDs in non-cirrhotic PBC patients.

Low vitamin B6 status associates with cholangiocarcinoma in primary sclerosing cholangitis

Isma Sohail[1], Peder Rustøen Braadland[1], Martin Cornillet[2], Per Ueland[3], Arve Ulvik[3], Tom Hemming Karlsen[1,4], Mette Vesterhus[5], Annika Bergquist[6], Trine Folseraas[1,4], Johannes R. Hov[1,4]. *[1]Norwegian PSC research centre, Division of surgery and specialised medicine, Oslo University Hospital, Oslo, Norway; [2]Center for infectious medicine, Department of Medicine Huddinge, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden; [3]BEVITAL, Bergen, Norway; [4]Institute of clinical medicine, University of Oslo, Oslo, Norway; [5]Department of Medicine, Haraldsplass Deaconess Hospital and Department of clinical science, University of Bergen, Bergen, Norway; [6]Unit of Gastroenterology and Rheumatology, Department of Medicine Huddinge, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden*
Email: ismas84@gmail.com

Background and aims: Cholangiocarcinoma (CCA) in primary sclerosing cholangitis (PSC) is difficult to diagnose and treat. There is a large unmet need for biomarkers for risk prediction and early diagnosis. We recently showed that low levels of pyridoxal 5′-phosphate (PLP, the active form of vitamin B6) in blood are associated with an increased risk for liver transplantation or death in PSC. Since mortality in these analyses were driven by CCAs, we aimed to determine the role of PLP as a biomarker for CCA in PSC.

Method: We included a Norwegian PSC cohort (n = 317; 77% male; median age 43; 79% with IBD) and a Swedish PSC cohort (Swehep, n = 98). Serum PLP was quantified using liquid chromatography-tandem mass spectrometry. We categorized patients as either (i) PSC with CCA at time of sampling (PSC-CCA), (ii) PSC with CCA within two years after sampling (PSC-to-CCA), or (iii) PSC with no development of CCA within two years after sampling (PSC-no-CCA). Differences in PLP levels were compared by Wilcoxon tests, and logistic regression was used to estimate the probability of CCA. Statistical analyses were performed in Stata (18.0).

Results: The Norwegian cohort included 25 PSC-CCA, 21 PSC-to-CCA and 271 PSC-no-CCA. Circulating PLP concentrations were lowest in the PSC-CCA (median 11 nmol/L, IQR 8–14) and PSC-to-CCA (median 11 nmol/L, IQR 10–27) groups, compared with PSC-no-CCA (median 22 nmol/L, IQR 15–32). Despite similar median levels, there was a trend towards lower PLP in PSC-CCA compared to PSC-to-CCA (p = 0.09), while there was strong association of lowered PLP in PSC-CCA and PLP-to-CCA compared to PSC-no-CCA (p < 0.001 and p < 0.05, respectively). In the Swedish cohort, PLP concentrations were generally higher than in the Norwegian PSC cohort, but again, the PLP concentration in combined PSC-CCA and PSC-to-CCA (n = 18) was lower compared to the PSC-no-CCA group (n = 80; median 25 nmol/L (IQR 16–37) vs median 34 nmol/L (IQR 24–52), p = 0.03). Since it would be of importance to differentiate the known association between PLP and advanced PSC from the presence or future risk of CCA in the Norwegian PSC cohort we further separated PSC-no-CCA into “early disease” (as defined by and Amsterdam-Oxford score <2; n = 153), who had median PLP 26 nmol/L (IQR 19–38), and “advanced disease” (Amsterdam-Oxford score≥2; n = 118), who had median PLP 17 nmol/L (IQR 12–25). Notably, in early disease PSC, PLP was lower in both PSC-CCA and PSC-to-CCA compared to PSC-no-CCA (p < 0.001), while the PLP distribution in the PSC-to-CCA subgroup was not statistically significantly different from that of PSC-no-CCA with advanced disease. In a logistic regression analysis, a doubling of PLP was associated with a reduced risk of developing CCA within two years (OR = 0.51, 95% CI [0.31, 0.86]). In a multivariable analysis, the Amsterdam-Oxford score did not explain additional variation in this outcome compared to PLP alone (LR χ^2 p = 0.99).

Conclusion: Vitamin B6 in blood may identify a PSC subgroup with increased risk of CCA, particularly in the early stages of PSC.

Email: e.werner@erasmusmc.nl

Background and aims: Metabolic comorbidities are increasingly present in patients with primary biliary cholangitis (PBC). While Diabetes Mellitus (DM) has been associated with unfavorable outcomes, this is not known for other metabolic comorbidities. The aim of this analysis was to assess the association between these comorbidities and the liver transplantation (LT)-free survival in a nationwide PBC population.
Method: The Dutch PBC Cohort Study (DPCS) is a retrospective study which includes every identifiable patient with PBC in the Netherlands from 1990 up to last data collection (2019-2023) in all 71 Dutch hospitals. Clinical data were obtained through medical chart review. Survival analyses were used in all patients on ursodeoxycholic acid (UDCA) for whom baseline data were available on DM, arterial hypertension, dyslipidemia and Body Mass Index (BMI). Laboratory values at 1 year were imputed using joint model multiple imputation.
Results: In total 2365 patients were included; 2094 (88.5%) were female, median age was 56.2 (IQR 47.8-66.0) years and 177 (7.5%) patients had cirrhosis. At baseline, 238 (10.1%) had DM, 441(18.6%) had arterial hypertension, 404 (17.1%) had dyslipidemia, and 1317 (55.7%) had a BMI >25 kg/m2. The median follow-up duration was 6.9 (IQR 3.1-12.3) years. In a multivariate analysis adjusted for calendar year, age, sex, cirrhosis, and liver enzymes after 1 year of UDCA, only DM was associated with the risk of LT or all-cause mortality (aHR 1.52, 95%CI 1.02-2.29, p = 0.04), while dyslipidemia (aHR 1.15, 95%CI 0.82-1.63, p = 0.41), arterial hypertension (aHR 1.17, 95%CI 0.83-1.66, p = 0.36) and a BMI>25 kg/m2 (aHR 0.83, 95%CI 0.63-1.10, p = 0.20) were not. Findings were consistent among patients without DM; neither having 1 (aHR 0.91, 95%CI 0.65-1.26, p = 0.57) or ≥2 (aHR 1.06, 95%CI 0.71-1.58, p = 0.79) metabolic comorbidities were associated with the LT-survival. In patients with DM, no statistically significantly differences in 10-years cumulative LT-free survival between patients with or without additional metabolic comorbidities were observed (63.9% vs. 68.3%, p = 0.42).
Conclusion: Presence of DM was independently associated with an unfavorable survival free of LT among patients with PBC. In contrast, arterial hypertension, dyslipidemia or being overweight were not related to the risk of LT or all-cause mortality.

Safety and efficacy of Upadacitinib in patients with primary sclerosing cholangitis and associated colitis
Ida Schregel[1], Emma Culver[2], Senamjit Kaur[2], Palak J. Trivedi[3], Sarah Al-Shakhshir[3], Jeremy Nayagam[4], Deepak Joshi[4], Alexandra Kent[4], Haim Leibovitzh[5], Oren Shibolet[5], Cynthia Levy[6], Adrielly Martins[6], Laura Cristoferi[7], Chiara Vigano[7], Pietro Invernizzi[7], Xavier Verhelst[8], Triana Lobaton[8], Gareth Parkes[9], Christoph Schramm[1]. *[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]Oxford University, Oxford, United Kingdom; [3]Birmingham University, Birmingham, United Kingdom; [4]King's College London, London, United Kingdom; [5]Tel Aviv Sourasky Medical Center, Tel Aviv, Israel; [6]University of Miami, Miami, United States; [7]IRCCS Fondazione San Gerardo dei Tintori, Monza, Italy; [8]Ghent University Hospital, Ghent, Belgium; [9]Barts Health NHS Trust, London, United Kingdom*
Email: i.schregel@uke.de

Background and aims: PSC is closely associated with the occurrence of inflammatory bowel disease (IBD). Tofacitinib (selective Janus Kinase [JAK] 1/3 inhibitor [i]), approved for the treatment of ulcerative colitis (UC), led to an improvement in colitis activity in the majority of PSC-IBD patients. There were no safety concerns in relation to PSC. In addition, there was a decrease in alkaline phosphatase in the subgroup that responded to tofacitinib with regard to their bowel disease (Schregel et al., 2023). Upadacitinib (Upa), a novel and potent orally administered selective JAK1 inhibitor, has been approved for the treatment of IBD in 2022/23 (Sandborn et al., 2020; Danese et al. 2022). Our aim was to assess safety and efficacy of Upadacitinib on liver and bowel disease in patients with PSC-IBD.
Method: Multicenter clinical data collection was conducted retrospectively at baseline, after 3, 6, 12 months follow-up (m-FU) and annually thereafter. Patients post liver transplantation were excluded.
Results: Forty (70% male) patients with a median age of 21 years from 9 centers were included of whom 31 had a complete 3-months follow-up. Of all patients, 87.5% presented with UC and 12.5% with Crohn's disease phenotype. 77.5% received at least two biologicals prior to Upa, 15% another JAKi. Adverse events occurred in 10 cases (3× elevated Transaminases, 3× (peri-)anal fissure/abscess, 3× respiratory infections, 1× low WBC). Upa was discontinued in 20%, mostly due to lack of efficacy. In those still on Upa, ALP levels non-significantly dropped from a mean of 348 at baseline to 270 U/l at 3m-FU (p = 0.068) while mucosal appearance as assessed by Mayo Endoscopic subscore significantly improved by a median difference of −1 (p = 0.015) between baseline and 6m-FU (median 2 vs 1). Transient elastography (TE) (p = 0.237; mean of 6.6 to 7.4 kPa at 6m-FU), and AST-levels remained stable between baseline and 3m-FU (144 vs 118 U/l, p = 0.597).
Conclusion: Updacitinib led to a decreased activity of PSC-associated IBD and a non-significant decrease in serum ALP levels. Additional studies are warranted to monitor safety of JAK inhibition in PSC.

Evolution of the United Kingdom's national immunoglobulin G4-related disease multidisciplinary meeting in guiding diagnosis and management of complex cases
Roshni Patel[1], Rodrigo Motta[1], Helen Bungay[1], Eve Fryer[1], Raashid Luqmani[1], David D'Cruz[2], Adrian Bateman[3], George Webster[4], Emma Culver[1]. *[1]Oxford University Hospitals NHS Foundation Trust, Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom; [2]Guys and St Thomas' NHS Foundation Trust, London, United Kingdom; [3]University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom; [4]University College London Hospitals NHS Foundation Trust, London, United Kingdom*
Email: emma.culver@nhs.net

Background and aims: Immunoglobulin G4-related disease (IgG4-RD) is an immune-mediated fibro-inflammatory disorder, with frequent pancreatic and hepatobiliary involvement. A UK National IgG4-RD multidisciplinary meeting (MDM) was introduced to improve diagnostic pathways and streamline management of patients with suspected IgG4-RD. We sought to appraise the evolution of this MDM and its value in management.
Method: Data were retrospectively collected from all patients discussed in the IgG4-RD MDM, from November 2016 to October 2024. Core specialists included Gastro-Hepatology, Rheumatology, Radiology and Histopathology with various visiting specialists (n = 14). Baseline characteristics, reason for referral, referring specialty, affected organs, medications and outcome were among the data fields collected. Patients were classed as definite, probable or not IgG4-RD based on consensus diagnostic criteria and MDM opinion.
Results: 1165 cases were discussed over eight years. Referrals came from 125 centres nationwide and 33 medical and surgical specialties, predominantly Gastroenterology (21.3%), Hepatology (18%) and Rheumatology (11.7%). The caseload rose annually (except one-year of the COVID pandemic), summating 233 discussions in the last year. Over half (58%) of all referrals sought diagnostic confirmation, 14% required review of active disease and 22.9% requested management advice, including 5.1% on relapse. Notably, the complexity of questions increased over time. 801 patients had full datasets; 543 (67.8%) referrals were new, 258 (32.2%) were follow-up. Overall, 645 (80.5%) were considered to have definite or probable IgG4-RD. 59.3% had two or more organs involved. Median organ involvement was

two (range 1–8); most frequent were pancreatic (45.8%), biliary (28.1%) and lymph nodes (22.6%). In the 645 patients with definite or probable IgG4-RD and full datasets, 18 combinations of IgG4-RD medications were prescribed at referral. 260 (40.3%) were on steroids; 169 (26.2%) on any immunosuppressant, 60 (9.3%) had used rituximab (third-line as per NHS England). MDT outcomes - further investigations requested in 433 (67.1%), change of drug recommended in 278 (43.1%), escalation of current drug dose in 20 (3.1%) cases. 101 referrals specifically requested escalation to rituximab; the MDM agreed in 91 (90.1%) cases. Concurrent malignancy was confirmed in 33 of the 645 cases: lymphoma in 25 and pancreatic cancer in four.

Conclusion: The UK National IgG4-RD MDM is an integral pathway for clinicians to facilitate advanced case discussion surrounding complex IgG4-RD, with its value demonstrated by a growing volume and complexity of referrals. Diagnostic uncertainty remains the principal reason for referral, with 80% receiving a diagnosis of probable or definite IgG4-RD, supporting the need for ongoing education in this rare disease.

THU-272

Appraising improvement in prediction of clinical outcomes based on different response criteria and liver stiffness measurements in patients with primary biliary cholangitis treated with second-line therapies

Background and aims: The confirmation of clinical benefit for second-line therapies that showed efficacy on surrogate biomarkers may be difficult in the context of primary biliary cholangitis (PBC). For this reason, EMA suggested to adopt more stringent cut-offs of biochemical parameter used to define response criteria in forthcoming clinical trials, and also to consider the variation of liver stiffness measurements (LSM). The aim of the present study was to appraise the improvement in prediction of liver-related events (LRE) based on the adoption of different response criteria and LSMs in patients with PBC treated with second-line therapies.
Method: Data were from the Italian RECAPITULATE cohort, including PBC patients treated with Obeticholic acid (OCA) in centres belonging to the Italian PBC Registry and to the CLEO PBC Study group. After excluding patients with <6 months' observation or with Child-Pugh B/C cirrhosis or previous hepatic decompensation, response to therapy was evaluated by liver enzymes and/or follow-up LSM, or by the following dichotomous criteria: ALP/ULN<1.5 with at least 40% reduction (ALP40); normal total bilirubin (TB) and ALP/ULN<1.67 with at least 15% drop (POISE); normalization of ALT, ALP and TB (normal range, NR); normalization of ALP and ALT and TB<0.7 (DEEP). LRE were defined as the occurrence of hepatic decompensation, liver transplantation or liver-related death. Cause-specific Cox regressions were fitted including the abovementioned response parameters as time-dependent covariates. Associations were evaluated through hazard ratios (HR), while predictive abilities through the c-statistics and log-partial-likelihood.
Results: 677 PBC subjects (mean age 58, women 88%, cirrhotics 29%) were followed for a median of 30 months, and 31 LRE were registered. A sub-sample of 519 individuals with available LSM (total 946 LSMs) was also analysed. TB was the most strongly associated factor with LRE (HR 2.42, 95%CI 1.94–3.02, p < 0.001) along with LSM (HR 1.06, 95%CI 1.04–1.08, p < 0.001). ALP/ULN was associated with LRE only in subjects with TB < 0.7 (HR 1.80, 95%CI 1.17–2.79, p 0.008). ALP40, POISE, NR and DEEP response criteria showed progressively larger effect size (HR ranging from 0.67 to 0.25, respectively). TB and LSM were the most predictive markers of LRE (c-statistics 0.73 and 0.83 respectively; log-likelihood test < 0.001). A multivariable model including ALP+TB+LSM reached a c-statistics of 0.85. LSM significantly improved predictivity of all the dichotomous response criteria (log-likelihood test <0.001 for all).
Conclusion: In this large cohort of PBC patients treated with second-line therapies, the adoption of more stringent response criteria was not mirrored by an improved prediction of LRE. LSM was strongly associated and predictive of LRE, both when used alone and when added to other response criteria. These findings emphasize the importance of integrating LSM to current response criteria for conducting clinical trials to inform on clinical outcomes.

THU-273

Evaluation of the association between biomarkers and patient-reported outcomes in patients with primary biliary cholangitis

Alan Bonder[1], Joanna P. MacEwan[2], Jocelyn Sun[2], Jing Li[3], Darren Wheeler[3], Radhika Nair[3], Vilas Patwardhan[4]. *[1]Division of Gastroenterology and Hepatology, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, United States; [2]Genesis Research Group, Hoboken, United States; [3]Intercept Pharmaceuticals, Morristown, United States; [4]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, United States*
Email: radhika.nair@interceptpharma.com

Background and aims: This analysis evaluated associations between liver stiffness, patient-reported outcomes (PROs), and liver biochemistries in patients (pts) with primary biliary cholangitis (PBC).
Method: This retrospective, observational study reflects the experience of pts with physician-confirmed PBC receiving care at Beth Israel Deaconess Medical Center with available PRO and laboratory data through October 2022. Laboratory data (2018–2022) included alkaline phosphatase (ALP), aspartate aminotransferase, alanine aminotransferase, total bilirubin, and gamma-glutamyl transferase (GGT). Transient elastography (TE) was used as a noninvasive measure of liver stiffness. PRO instruments included the EQ-5D-3L, PBC questionnaire (PBC-40), Chronic Liver Disease Questionnaire (CLDQ), and pruritus visual analog scale (VAS). Correlations between biomarkers, TE, and PROs from the first date available were analyzed using Spearman's rank correlation. The median time between lab tests, TE, and PRO assessments was 0 months.
Results: Of the 113 pts with available data, the mean (SD) age at diagnosis was 53.2 (12.2) years; most were White (85.8%), female (92.0%), and had private/commercial insurance (54.0%), followed by Medicare (36.3%) and Medicaid (7.1%). Most pts (96.5%) were current users of ursodeoxycholic acid. Mean (SD) test results were 9.3 (13.2) kPa for TE, 91.0 (140.1) IU/L for GGT, and 169.5 (213.7) IU/L for ALP. Among pts with ≥1 PRO assessment, the mean (SD) total scores were 6.4 (1.5) for the EQ-5D-3L (n = 92), 84.6 (30.7) for PBC-40 (n = 97), 31.5 (6.8) for CLDQ (n = 99), and 1.5 (2.3) for VAS (n = 104). Some biochemistries had low correlations (0.24–0.44) with certain domains of the PRO instruments. ALP had low correlations (0.26–0.38) with 4 of the 6 domains of the PBC-40, including the emotional, social, and itch domains. Similarly, ALP had low but negative correlations with the CLDQ emotional function (–0.25) and worry (–0.34) domains. TE measurements showed low correlations with the EQ-5D-3L mobility (0.37) and usual activities (0.32) domains and a low negative correlation with the CLDQ worry domain (–0.26). GGT had a slightly higher correlation with the EQ-5D-3L self-care domain (0.44) and low correlations with the EQ-5D-3L usual activities (0.25), PBC-40 emotional (0.25), and CLDQ worry (-0.25) domains. Similar domains from different PRO instruments showed moderate to high correlations: PBC-40 fatigue and CLDQ fatigue (-0.84), CLDQ

emotional and PBC-40 emotional (-0.58), and VAS and PBC-40 itch (0.56).
Conclusion: Consistent with published literature, liver biomarkers of disease severity were not strongly correlated with the different domains of PRO instruments. However, similar domains from different PROs show moderate to high correlations and can be used as complementary tools to assess pts' emotional and physical well-being.

THU-274
Efficacy and safety of seladelpar in patients previously treated with fibrates or OCA
Alejandra Villamil[1], Daniel Pratt[2], Andreas E. Kremer[3], Vincenza Calvaruso[4], Elena Gómez-Domínguez[5], Xin Qi[6], Sarah Proehl[6], William Barchuk[6], Timothy Watkins[6], Stuart C. Gordon[7]. *[1]The Liver Autoimmunity Unit, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina; [2]Autoimmune and Cholestatic Liver Center, Massachusetts General Hospital, Boston, United States; [3]Department of Gastroenterology and Hepatology, University Hospital Zürich, University of Zürich, Zürich, Switzerland; [4]Gastroenterology and Hepatology Unit, University of Palermo, Palermo, Italy; [5]Hepatology Unit, University Hospital 12 de Octubre, Madrid, Spain; [6]Gilead Sciences, Inc., Foster City, United States; [7]Division of Hepatology, Henry Ford Hospital, Wayne State University School of Medicine, Detroit, United States*
Email: alejandra.villamil@hospitalitaliano.org.ar

Background and aims: Seladelpar is a first-in-class delpar (selective PPAR-delta agonist) indicated for the treatment of primary biliary cholangitis in combination with ursodeoxycholic acid (UDCA) in patients (pts) with an inadequate response to UDCA or as monotherapy in pts unable to tolerate UDCA. RESPONSE was a Phase 3, randomised, placebo-controlled clinical trial of seladelpar in pts with inadequate response/intolerance to UDCA. Pts completing RESPONSE were eligible to roll over into ASSURE (NCT03301506), an ongoing, open-label, long-term, Phase 3 safety trial. Here we describe data from month 18 (month 6 of ASSURE) in pts with or without prior use of fibrates or obeticholic acid (OCA) who rolled over from RESPONSE into ASSURE.
Method: Pts received 10 mg seladelpar orally daily or placebo in RESPONSE; pts received open-label 10 mg seladelpar in ASSURE. Fibrates and OCA were prohibited during the study period and a 6-week washout was required prior to entry in RESPONSE. Data are described for pts in ASSURE with or without prior use of fibrates/OCA and based on whether they received seladelpar (continuous seladelpar pts) or placebo (crossover pts) in RESPONSE. Efficacy included the percentage of pts achieving a composite biochemical response (CBR; alkaline phosphatase [ALP] <1.67 × upper limit of normal [ULN], ALP decrease ≥15%, and total bilirubin ≤ULN). Safety assessments included adverse events (AEs) and laboratory parameters.
Results: Among pts who continued into ASSURE from RESPONSE (158), 16 continuous seladelpar and 11 crossover pts reported prior use of fibrates/OCA (total, n = 27; 17%); 88 continuous seladelpar and 43 crossover pts reported no prior use of fibrates/OCA (total, n = 131; 83%). At month 18, among continuous seladelpar pts, 9/15 (60%) pts with prior fibrate/OCA use achieved a CBR vs 54/87 (62%) pts without prior fibrate/OCA use. Among crossover pts, 7/11 (64%) pts with prior fibrate/OCA use vs 32/41 (78%) pts without prior fibrate/OCA use achieved a CBR at month 6 of ASSURE. From ASSURE initiation to month 6, incidence of AEs was similar across continuous seladelpar and crossover pts, regardless of prior OCA/fibrate use; no treatment-related serious AEs were reported.
Conclusion: In this interim analysis of continuous seladelpar and crossover pts from ASSURE, pts who reported prior use of fibrates/OCA achieved a similar sustained biochemical response with seladelpar compared with pts who reported no prior use. Seladelpar appeared safe and well tolerated in this subgroup.

THU-275
Terminology, diagnosis and management of primary biliary cholangitis-autoimmune hepatitis variant syndrome (PBC-AIH): results from an international Delphi consensus process
Alessio Gerussi[1,2], Marcial Sebode[3,4], Eugenia Nofit[2], Anna Stoelinga[5], Davide Bernasconi[6], Angela Leburgue[7], Pietro Invernizzi[2,8], Christoph Schramm[3,4], Bart van Hoek[5], Dina Tiniakos[9,10], luigi terracciano[11,12], Marco Carbone[8,13], Ansgar W. Lohse[3,4]. *[1]Department of Medicine and Surgery, Monza, Italy; [2]Division of Gastroenterology, Center for Autoimmune Liver Diseases, European Reference Network on Hepatological Diseases (ERN RARE-LIVER), Fondazione IRCCS San Gerardo dei Tintori, Monza, Italy; [3]I. Email: alessio.gerussi@unimib.it

Background and aims: Heterogeneity in definition, diagnosis and treatment of primary biliary cholangitis-autoimmune hepatitis variant syndrome (PBC-AIH) is present in guidelines and daily practice. This initiative aimed to bring together global experts to achieve consensus on the terminology, diagnosis and management of PBC-AIH.
Method: The initiative was endorsed by the ERN RARE-LIVER, the Global PBC Study Group and the IAIHG. The Delphi process included two rounds of voting, and followed a modified approach according to the "RAND/UCLA Appropriateness Method." A core group of experts identified the unmet needs and areas of uncertainty, identified panelists worldwide, drafted the first set of statements, analyzed and discussed the results of the first round, organized a physical meeting at EASL 2024 in Milan, and drafted a second round of statements restricted to those areas that did not reach consensus after the first round.
Results: The first round included 92 participants, while 82 took part in the second one, representing a geographically diverse panel of 78 hepatologists and 14 liver pathologists. Consensus was reached on definition (variants), suspicion criteria (incomplete response to UDCA with disproportionate elevation of transaminases compared to cholestasis), liver biopsy indications to diagnose PBC-AIH (mandatory in PBC patients, need for revision of the index biopsy in AIH patients first). The panel agreed that diagnosis should be periodically re-evaluated, since features can occur sequentially, and that PBC-AIH is associated with worse prognosis as compared to PBC alone. Severe interface hepatitis in patients with PBC would require immunosuppression, but age, comorbidities, stage and patient preferences should be considered.
Conclusion: This Delphi initiative successfully convened PBC and AIH experts to establish consensus in a complex, understudied area lacking evidence-based guidelines. The resulting statements offer a basis for prospective studies and standardized clinical protocols, aiming to enhance consistent management of PBC-AIH.

THU-276

Introduction of an advanced pharmacist clinic leads to improved assessment and treatment of patients with PBC

Alison Boyle[1,2], Fiona Marra[1,2], Alban Clareburt[1], Jude Morris[1], Michael Johnston[1], Caitlin Brown[1], Andrew Robertson[1], Stephen Barclay[1]. [1]*NHS Greater Glasgow and Clyde, Glasgow, United Kingdom;* [2]*University of Liverpool, Liverpool, United Kingdom*
Email: alison.boyle@ggc.scot.nhs.uk

Background and aims: The UK-PBC Audit identified multiple shortcomings in assessment and management of PBC nationally and within our clinics. To improve care, we introduced an Advanced Pharmacist PBC clinic (APC) in May 2023, and from June 2024 combined this with an electronic PBC template. We sought to examine the impact of this by performing an audit of APC clinic attendances using our local UK-PBC audit data as the baseline comparator.
Method: Data prospectively collated electronically from the APC, between 27/06/2024 and 01/12/2024 was compared to our 2021 UKPCA audit of patients attending standard care clinics (SCC). Continuous variables were compared using Mann-Whitney U test. Categorical variables were compared using chi-square.
Results: 438 patients (129 APC, 309 SCC) were included for analysis. Patients attending APC were representative of the SCC in terms of age (Median 65.5 v 66 years, $p = 0.823$), sex (Female 113 (87.6%) vs 276 (89.3%), $p = 0.729$), presence of cirrhosis (14 (10.9%) vs 56 (18.1%), $p = 0.058$) and prescription of ursodeoxycholic acid (urso) (119 (92.2%) vs 285 (92.2%), $p = 0.996$). Urso treated patients attending the APC clinic were more likely to be on 13–15 mg/kg of urso (112 (94.1%) vs 124 (43.8%), $p < 0.001$), and rates of second line therapy use were also numerically higher (34 (26.4%) vs 58 (18.7%), $p = 0.076$). Paris response criteria were more likely to be met in the APC cohort (117 (90.7%) vs 241 (78.0%), $p = 0.002$), though ALP normalisation rates were similar (48 (37.2%) vs 126 (40.8%), $p = .486$). Assessments of pruritis (122 (94.6%) vs 217 (70.2%), $p < 0.001$), fatigue (122 (94.6%) vs 213 (68.9%), $p < 0.001$) and bone health (112 (86.8%) vs 240 (72.9%), $p = 0.028$) were all more likely to have been documented as taking place in the APC. Additionally, patients in the APC were more likely to be on treatment for pruritis (36 (27.9%) vs 55 (17.8%), $p = 0.017$). Prospective data continue to accrue, and a further 4 months of data will be presented at conference.
Conclusion: The introduction of an Advanced Pharmacist PBC clinic, incorporating an electronic clinic template, has led to substantial improvements in the care of patients with PBC. Benefits include increased assessment of PBC-related symptoms and bone health, improved optimisation of urso dose, and higher rates of therapy for pruritus. APC attendees were significantly more likely to meet Paris response criteria.

THU-277

Psychometric evaluation of the pruritus numeric rating scale in patients with primary biliary cholangitis with moderate-to-severe pruritus

Andreas E. Kremer[1], David Jones[2], Anne Skalicky[3], Ariane Kawata[4], Milena Anatchkova[4], Adam Smith[5], Caroline Burk[6], Marvin Rock[6], Chong Kim[6], Cynthia Levy[7]. [1]*University of Zürich, University Hospital Zürich, Department of Gastroenterology and Hepatology, Zurich, Switzerland;* [2]*Newcastle University, Newcastle, United Kingdom;* [3]*Evidera, Inc, Wilmington, DE, United States;* [4]*Evidera, Inc., Wilmington, NC, United States;* [5]*Evidera, Inc., Hammersmith, London, United Kingdom;* [6]*Gilead Sciences, Foster City, CA, United States;* [7]*Schiff Center for Liver Diseases, Division of Digestive Health and Liver Diseases, University of Miami Miller School of Medicine, Miami, United States*
Email: andreas.kremer@usz.ch

Background and aims: Pruritus Numeric Rating Scale (NRS) is a patient-reported outcome (PRO) previously validated and used to assess severity of itch in various diseases. However, the Pruritus NRS measurement properties have not been assessed in Primary Biliary Cholangitis (PBC) patients who experience cholestatic pruritus in a clinical trial setting. The psychometric properties of the NRS following US FDA PRO and PFDD Draft Guidance (2009, 2023) were evaluated using the RESPONSE (NCT03602560) study, a placebo-controlled Phase 3 trial of seladelpar in patients with PBC.
Method: The 11-point Pruritus NRS (range: 0–10; no itching–worst imaginable itching) was completed daily for 6 months. Patient-reported outcomes used to support the Pruritus NRS validation included the Patient Global Impression of Severity of pruritus (PGI-S, 7-day recall), Patient Global Impression of Change of pruritus (PGI-C, start-of-study recall), 5-D Itch (2-week recall), and PBC-40 (4-week recall) and were administered at study visits. Reliability, validity, and ability to detect change analyses for the Pruritus NRS were conducted in trial participants with moderate-to-severe pruritus NRS (MSPN) (≥4 on NRS) at baseline, the target population of interest.
Results: Of the 193 RESPONSE trial participants enrolled, 72 were included in the MSPN psychometric analysis (mean [range] age: 47.1 [27–68] years; 97.2% female). Test-retest reliability of the Pruritus NRS was acceptable for itch (ICC = 0.48) in subjects with stable 5-D Itch Degree scores between Day 1 and Week 4. Convergent validity of the Pruritus NRS was supported based on moderate-to-strong correlations with 5-D Itch Degree score at Day 1, Week 4, Week 12, and Week 26 ($r = 0.60, 0.50, 0.64$ and 0.68, respectively) and the PBC-40 Itch domain score at Day 1, Week 4, Week 12, and Week 26 ($r = 0.59, 0.40, 0.49$ and 0.62, respectively). Known-groups validity was confirmed and differed significantly for comparisons between none, mild, moderate, severe levels of itch when evaluated based on 5-D Itch Degree ($p < 0.0001$) and PGI-S severity ($p < 0.0001$). Responsiveness was demonstrated by incrementally larger decreases in Pruritus NRS scores (improvement) across PGI-S ($p < 0.0001$) and PGI-C ($p < 0.0001$) levels over time.
Conclusion: Findings confirm that the Pruritus NRS utilized in RESPONSE to assess itch is a valid and reliable measure for use in detecting anti-pruritic treatment efficacy in patients with PBC-related pruritus.

Background and aims: Autoimmune hepatitis (AIH) is a rare, chronic liver disease sometimes difficult to diagnose and distinguish from other chronic liver diseases like metabolic dysfunction-associated steatotic liver disease (MASLD). We performed mass spectrometry (MS)-based proteomics of paired liver-plasma samples from AIH

patients to improve our understanding of the pathophysiology and uncover potential new biomarkers.
Method: We recruited 19 newly diagnosed AIH patients, 17 MASLD patients, and 19 healthy controls. Snap-frozen liver tissue and plasma were collected. MS-based tissue and plasma proteomics were performed using PASEF-DIA on Bruker timsTOF instrument. Differential abundance analysis was conducted using a linear model. A protein was considered differentially abundant if a false discovery rate adjusted p-value by Benjamini-Hochberg was < 0.05. For the classification of AIH versus MASLD and healthy, machine learning analyses were performed employing logistic regression models on liver and plasma proteome data. Data were validated by the Olink proteomics platform in United Kingdom Biobank (UKB).
Results: There were 2,589 and 227 differentially abundant proteins in liver and plasma, respectively, when comparing AIH with healthy, 58 of these were significant in both liver and plasma. Metabolic dysregulation and systemic immune activation were characteristics of the AIH liver and plasma proteome, respectively. When combining both the liver and plasma proteome to classify AIH versus MASLD and healthy, we achieved an average ROC-AUC of 0.95 (standard deviation 0.06). Validation in the UKB was possible for 8 of 20 predictive plasma proteins and showed consistent directional changes, with three proteins (C7, ICAM1, cAST) significantly different between AIH and MASLD/healthy, and 6 of 8 proteins (C7, ICAM1, cAST, IGFBP3, TIMP1, TTR) being significantly different between AIH and MASLD/healthy when adjusting for age and sex.
Conclusion: MS-based proteomic analyses of paired liver-plasma samples from AIH patients enabled discovery of numerous proteins with high diagnostic potential. Validation in UKB confirmed consistent directional changes for key predictive proteins. However, further validation in larger cohorts is needed to confirm these results and enhance diagnostic accuracy. Overall, proteomics holds promise as a novel non-invasive diagnostic tool for AIH.

One-year efficacy and safety of tacrolimus in chronic autoimmune hepatitis

Alessio Gerussi[1,2], Armando Curto[2,3], Eugenia Nofit[4], Davide Bernasconi[5], Alessandra Bonfichi[2,6], Daphne D'Amato[2,7], Olga Falco[2,8], Miki Scaravaglio[1,2], Federica Malinverno[2], Laura Cristoferi[2], Marco Carbone[1,9], Pietro Invernizzi[1,2]. *[1]Department of Medicine and Surgery, University of Milano-Bicocca, Monza, Italy; [2]Centre for Autoimmune Liver Diseases & Division of Gastroenterology, Fondazione IRCCS San Gerardo dei Tintori, ERN-RARE LIVER, Monza, Italy; [3]Gastroenterology Research Unit, Department of Experimental and Clinical Biomedical Sciences "Mario Serio," University of Florence, Firenze, Italy; [4]Centre for Autoimmune Liver Diseases & Division of Gastroenterology, Fondazione IRCCS San Gerardo dei Tintori, ERN-RARE LIVER, Monza, Italy; [5]Bicocca Bioinformatics Biostatistics and Bioimaging Centre - B4 School of Medicine and Surgery, University of Milano-Bicocca, Monza, Italy; [6]Department of Internal Medicine, IRCCS Fondazione Policlinico San Matteo, Pavia, Italy; [7]Gastroenterology Unit, Citta della salute e della scienza, Torino, Italy; [8]Dipartimento di Medicina, Chirurgia e Farmacia, University of Sassari, Sassari, Italy; [9]Liver Unit, ASST Grande Ospedale Metropolitano (GOM) Niguarda, Milano, Italy*
Email: alessio.gerussi@unimib.it

Background and aims: Treatment of Autoimmune hepatitis (AIH) in patients difficult-to-treat or intolerant to standard of care (SOC) can include Tacrolimus (TAC) but evidence on its efficacy and safety is still limited. We aimed to evaluate the efficacy and safety of TAC in difficult-to-treat (DTT) and SOC-intolerant AIH patients.
Method: Patients with AIH followed at Fondazione IRCCS San Gerardo dei Tintori, Monza, for 12 months of follow-up since initiating TAC were included in the study. Biochemical parameters (AST, ALT, GGT, bilirubin, albumin, IgG) were monitored at treatment initiation and during follow-up at 1, 3, 6, and 12 months.
Results: Twenty-seven AIH patients, 22 refractory and five intolerant to SOC, were included. Median age was 46 years (IQR 37, 57), with 63% female. Regarding ethnicity, 23 were Caucasian, three patients were Hispanic and one was Asian. The median bilirubin at enrollment was 0.73 (0.60, 1.39) times the upper limit of normal (ULN), median albumin was 3.71 mg/dl and median gamma globulins were 1.02 (0.72, 1.62). After 12 months of TAC therapy, a significant reduction in AST levels (from 1.8 to 0.8 times ULN) and ALT levels (from 2.5 to 0.7 times ULN) was observed, with the greatest improvements occurring within the first three months. In the 22 DTT cases, AST levels declined from 2.4 times ULN to 0.9 times ULN, and ALT levels declined from 2.7 × ULN to 0.8 times ULN. Adverse events were observed in 67% of patients. Nine patients experienced an infection, of whom one died due to pneumonia. Four patients experienced arthralgias and three experienced headache. Tacrolimus was never discontinued due to adverse events.
Conclusion: TAC can be a viable therapy for DTT or SOC-intolerant AIH patients in the chronic setting, significantly improving biochemical markers within 12 months. Side effects are frequent and require monitoring. Multicenter, randomised controlled studies are needed to better assess efficacy and safety of TAC in this sub-cohort of patients.

THU-280-YI
Efficacy, safety and long-term clinical outcomes of a low-dose versus high-dose prednisolone induction in autoimmune hepatitis: a propensity score matched analysis

Arnav Aggarwal[1], Shekhar Swaroop[1], Sagnik Biswas[1], Shubham Mehta[1], Sarthak Saxena[1], Rajkumar Bayye[1], Umang Arora[1], Ayush Agarwal[1], Samagra Agarwal[1], Deepak Gunjan[1], Baibaswata Nayak[1], Shalimar Shalimar[1]. *[1]All India Institute of Medical Sciences, New Delhi, India*
Email: arnav272@gmail.com

Background and aims: Different corticosteroid dosing regimens are used in the management of autoimmune hepatitis (AIH). We aimed to compare the efficacy of a low versus high-dose prednisolone induction regimen in achieving biochemical response in AIH.
Method: In this retrospective review of a prospectively maintained database, treatment-naive AIH patients treated with prednisolone were categorised into two groups: low-dose (≤20 mg/day) and high-dose (>20 mg/day). The primary outcome was the biochemical response, defined by the normalisation of serum transaminases within six months of treatment initiation. Secondary outcomes were index or further decompensation in compensated and decompensated patients respectively, mortality, complete biochemical response (CBR) within six months and steroid-related adverse effects. Propensity score matching (PSM) was done in a 1:1 ratio. Kaplan-Meir survival analysis was used to compare index or further decompensation, and mortality.
Results: A total of 128 patients were included, with 48 and 80 patients in the low- and high-dose groups, respectively. Median follow up duration was 34 (21–65) months. Azathioprine was used in 83.3% and 82.5% of patients, while Mycophenolate Mofetil was used in 6.3% and 8.8% of patients in the low-dose and high-dose groups, respectively. After PSM, each group consisted of 46 patients. The median starting dose was 20 (12.5–20) mg in low-dose group and 40 (40–40) mg in high-dose group. Biochemical response rates were similar between the two groups (60.9% vs. 63.0%; p = 0.830). Patients with cirrhosis had lower response than those without cirrhosis (51.2% vs. 79.1%; p = 0.002). However, within each subgroup (cirrhosis and no cirrhosis), response rates did not vary with low-dose or high-dose

prednisolone. CBR was evaluated in 75 patients, rates of which were similar between low-dose and high-dose groups (22.5% vs 20.0%, p = 0.792). Index decompensation among compensated (HR 1.07; 95% CI 0.33–3.50; p = 0.910) and further decompensation among previously decompensated patients (HR 1.65; 95% CI 0.68–4.05; p = 0.270) was similar in low-dose compared to high-dose group. No difference in mortality was present between the low-dose and high-dose groups for both compensated patients (HR 0.62; 95% CI 0.07–5.25; p = 0.665) and decompensated patients (HR 1.12; 95% CI 0.32–3.88; p = 0.857). There was a trend towards fewer steroid-related adverse effects in the low-dose group (27.1% vs. 42.5%; p = 0.080). Most common side effects were cosmetic (25%) followed by dysglycemia or diabetes mellitus (7.0%) and infection (4.7%).
Conclusion: Low-dose prednisolone induction results in similar biochemical response and clinical outcomes with possibly lower steroid-related adverse effects compared to a high-dose regimen in AIH. Thus, low-dose prednisolone induction may be appropriate where minimization of adverse effects is a high priority.

THU-285
Prognostic factors in autoimmune hepatitis: a french multicenter study
Anna Sessa[1], Edouard Bardou-Jacquet[2], Antonio Saviano[3], Lorraine Blaise[4], Marianne Ziol[4], Nathalie Ganne-Carrié[4], Stefano Caruso[5], Pierre Allaume[2], Julien Calderaro[6], Vincent Leroy[7].

Email: asessa1990@gmail.com

Background and aims: Autoimmune hepatitis (AIH) is a chronic inflammatory liver disease characterized by liver inflammation that can progress to fibrosis and cirrhosis. Few studies have assessed factors associated with major hepatic events such as death, liver transplantation, or hospitalizations. However, these data are critical for risk stratification and personalized patient management.
Method: This multicenter French retrospective study included 239 AIH patients who underwent liver biopsy between 2010 and 2023. Patients on corticosteroids for >5 days at biopsy or with >50% missing data were excluded. Logistic regression identified factors associated with treatment response at 6 and 12 months, excluding variables with >30% missing data. Cox regression assessed factors linked to hepatic events (death, transplantation, or hospitalization), excluding variables with >20% missing data.
Results: A total of 239 patients were included (median follow-up: 52.2 months (IQR 26–87)). At diagnosis, 72% of patients were presented with acute disease, 13% with acute-on-chronic disease, and 16% with chronic disease. Women represented 67% of the cohort (mean age of 50.9 years (SD 18.23)). Cirrhosis was present in 31%, 35% had a non-hepatic autoimmune disease. Median serum ALT activity was 550 IU/L [IQR 237–1097], and IgG concentration was 19.4 g/L [IQR 16–28]. ANA antibodies were positive in 83%, smooth muscle antibodies in 46%, and anti-actin antibodies in 52 patients. Induction therapy consisted of budesonide in 31 patients and prednisone/prednisolone (mean dose 0.7 mg/kg/day [SD 0.4]) in 202. Azathioprine was the first-line treatment (mean dose 1.2 mg/kg/day, SD 0.6) in 208 patients (87%). Second-line therapy was initiated in 58 patients (47 received MMF), and 23 required third-line therapy. Complete response at 6–12 months was achieved in 71% of patients. Corticosteroid dependence occurred in 15%, and 35% of initial responders experienced relapse after 6 months of treatment. Immunosuppression was stopped without relapse in 29 patients (median time from initiation to discontinuation: 38 months [IQR 23–52]). Refractory AIH was observed in 13%. A total of 39 patients experienced hepatic events (HCC: 2, death: 12, liver transplantation: 9, liver disease-related hospitalizations: 16). Variables independently associated with complete response included baseline IgG levels (OR 0.9, 95% CI 0.86–0.94, p = 0.001) and ALT levels (OR 1.6, 95% CI 1.1–2.4, p = 0.018). Significant predictors of hepatic events included refractory hepatitis (HR 6.7, 95% CI 2.5–18.0), and cirrhosis at biopsy (HR 1.6, 95% CI 1.2–2.2).
Conclusion: Achieving treatment response is critical to improving outcomes in AIH patients, particularly those with cirrhosis. New therapeutic strategies are urgently needed for patients who fail standard treatments.

THU-286
Seladelpar treatment of patients with primary biliary cholangitis improves the GLOBE score and predicts improved transplant-free survival
Bettina Hansen[1,2,3], Susheela Carroll[4], Yan Zhou[4], C. Fiorella Murillo Perez[4], Gideon M. Hirschfield[1]. *[1]Division of Gastroenterology and Hepatology, Toronto Centre for Liver Disease, University of Toronto, Toronto, Canada; [2]Department of Epidemiology, Erasmus MC, Rotterdam, Netherlands; [3]Institute of Health Policy, Management and Evaluation, University of Toronto, Toronto, Canada; [4]Gilead Sciences, Inc., Foster City, United States*
Email: bettina.hansen@utoronto.ca

Background and aims: The GLOBE score is a validated risk assessment tool that provides an estimate of transplant-free survival for patients (pts) with primary biliary cholangitis (PBC). Seladelpar is a first-in-class delpar (selective PPAR-delta agonist) with anticholestatic, anti-inflammatory, and antipruritic activity indicated for the treatment of PBC in combination with ursodeoxycholic acid (UDCA) in adults who have an inadequate response to UDCA, or as a monotherapy in pts intolerant to UDCA. This analysis evaluated the change in GLOBE score in pts with PBC on seladelpar from the pivotal, placebo-controlled Phase 3 RESPONSE (NCT04620733) trial and the subsequent open-label extension (ASSURE; NCT03301506).
Method: Pts with PBC who received UDCA for ≥12 months (M) or were intolerant to UDCA and had alkaline phosphatase (ALP) ≥1.67× the upper limit of normal (ULN) and total bilirubin (TB) ≤2× ULN were enrolled into RESPONSE and randomised 2:1 to receive daily seladelpar 10 mg or placebo. After 1 year (Y), pts were eligible for ASSURE. At this time, pts on placebo could cross over to seladelpar (crossover) and pts on seladelpar continued treatment (continuous). The change in GLOBE score was assessed for pts who received continuous or crossover seladelpar after placebo. The predicted transplant-free survival was assessed for pts who received continuous seladelpar up to 2Y or placebo up to 1Y. The contributions of ALP, TB, albumin, and platelets to changes in GLOBE score were evaluated.
Results: A total of 193 pts were enrolled. Baseline (BL) characteristics were balanced between treatment groups; 95% were female; mean (SD) age and duration of PBC were 57 (9.7) and 8 (6.6) years. Mean (SD) BL values were 314 (120.9) U/L for ALP, 0.76 (0.31) mg/dL for TB, 4.1 (0.26) g/dL for albumin, 242 (80.6) × 10^3/uL for platelets, and 0.32 (0.68) for GLOBE score. Mean (SD) changes in GLOBE score from BL at 3M and 1Y for pts on seladelpar were −0.38 (0.21) and −0.34 (0.39), respectively, vs −0.07 (0.28) and −0.01 (0.32) for pts on placebo. At 2Y, GLOBE score changes were −0.39 (0.33) and −0.42 (0.50) for pts on continuous or crossover seladelpar, respectively. For pts on seladelpar, the greatest changes in GLOBE score were attributable to the ALP component (3M, −0.20; 1Y, −0.21; 2Y, −0.19), followed by the TB component (3M, −0.11; 1Y, −0.09; 2Y, −0.13). Seladelpar treatment for 3M, 1Y, and 2Y led to predicted changes in transplant-free survival with hazard ratios (95% CIs) of 0.7 (0.7–0.7), 0.8 (0.7–0.9), and 0.7 (0.6–0.8) compared to BL, respectively. The hazard ratios (95% CIs) for pts on placebo at 3M and 1Y were 1.0 (0.9–1.0) and 1.0 (1.0–1.1). At 2Y, pts on crossover seladelpar had similar results to those on continuous seladelpar.

Conclusion: Seladelpar treatment resulted in an early decrease in GLOBE score for pts with PBC, which was maintained over 2Y and was associated with improved predicted transplant-free survival.

THU-287
Alberta has the highest prevalence of primary biliary cholangitis in North America

Bryce Tkachuk[1], Aldo J. Montano-Loza[2], Jason Jiang[3], Abdel-Aziz Shaheen[1]. [1]*University of Calgary, Calgary, Canada;* [2]*University of Alberta, Edmonton, Canada;* [3]*Alberta Health Services, Calgary, Canada*
Email: az.shaheen@ucalgary.ca

Background and aims: Reported incidence and prevalence of primary biliary cholangitis (PBC) in Calgary, Alberta, Canada was among the highest worldwide. In this study, we assessed changes in the incidence and prevalence of PBC in the whole province of Alberta, Canada (4.8 million, 2023) and examined age and sex epidemiological trends.
Method: All adult (≥18 years) individuals in Alberta who fulfilled a validated administrative databases-driven case-definition of PBC (positive predictive value 78%) between 2002 and 2022 were included in the study. We used multiple population-based administrative databases (inpatient, ambulatory care, physician claims, and Alberta registry) to identify patients with PBC. A washout period between 2002 and 2005 was considered to calculate incidence. Temporal trends of annual incidence and prevalence rates per 1 million at-risk population were assessed using Joinpoint regression analysis software. Average annual percent change (AAPC) was reported according to sex. Inflection points were evaluated during the study time. Rates were adjusted and standardized according to the Canadian population (2021).
Results: Between 2002 and 2022, we identified 3,250 patients with PBC in Alberta (71.6% female; median age 58 years). Median age at diagnosis was similar between females and males (58 vs. 59 years, $p = 0.10$). Age-adjusted incidence rate among males significantly increased during the study period and peaked in 2010 which was an inflection point (65.9 per million before trending down to 23.3 per million in 2020). Age-adjusted incidence rate among females significantly increased and peaked in 2010 [inflection point] at 88.8 per million and remained stable (82.2 per million in 2020). In 2021, age-adjusted point prevalence of PBC was 1,024 per million for females and 286 per million for males. AAPC for female PBC prevalence rate was 55.3% (95% CI: 53.0–57.4) between 2002 and 2012; and 40.5% (95%CI: 38.6–42.5) between 2012 and 2020. However, AAPC for male PBC prevalence rate was 14.2% (95%CI: 12.8–15.6%) between 2002 and 2008; 49.9% (95%: 32.1–66.1%) between 2008 and 2011; and 5.5% (95%CI: 3.3–7.6%) between 2011 and 2019 before remaining steady in the last two years of the study. There were multiple inflection points of PBC prevalence rates for both sexes in our study duration.
Conclusion: The province of Alberta has the highest reported adjusted prevalence rate in North America. While PBC prevalence rates remained stable over the last decade for males, there has been a significant increase among females. The high prevalence rates of PBC in Alberta are likely the result of early diagnosis and improved survival.

THU-288
Prognostic value of liver stiffness dynamics in patients with autoimmune hepatitis

Lukas Burghart[1], Sonja Treiber[2], David Bauer[1], Georg Semmler[2], Emina Halilbasic[2], Benedikt Hofer[2], Mattias Mandorfer[2], Michael Gschwantler[1], Michael Trauner[2], Thomas Reiberger[2], Albert Friedrich Stättermayer[2]. [1]*Klinik Ottakring, Vienna, Austria;* [2]*Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria*
Email: burghartlukas@gmail.com

Background and aims: Liver stiffness measurement (LSM) is a well-established non-invasive test to estimate the risk of fibrosis and clinically significant portal hypertension (CSPH). However, most evidence for the prognostic value of LSM is derived from viral and metabolic liver disease, while data from autoimmune hepatitis (AIH) patients are limited. In this study we investigated the prognostic value of repeated LSMs for (i) progression to hepatic decompensation, as defined by the occurrence of ascites, hepatic encephalopathy and/or variceal bleeding, and (ii) transplant-free survival (TFS).
Method: Patients presenting with AIH between Q1/2005 and Q4/2023 at the Medical University of Vienna were identified through a systematic database query. Patients with a confirmed diagnosis of AIH, based on an IAIHG Score of ≥6 were included. Clinical information was extracted from individual medical records.
Results: 236 AIH patients (mean age: 43.2 ± 18.9 years, 76.8% female) were retrospectively studied for a median follow-up of 8.1 (IQR 3.6–13.1) years. Median LSM at diagnosis was 8.7 (IQR: 5.9–14.9) kPa, 102 (43%) had advanced disease (ACLD), suggested by LSM ≥10 kPa, and in 38 (16%) CSPH was assumed by LSM ≥20 kPa. At 6 months (n = 203) and 1.5 years (n = 152) after/on AIH treatment, median LSM declined to 7.4 (IQR 5.3–11.6) kPa and 7.6 (IQR 5.3–11.8) kPa, respectively. In a ROC analysis, LSM at 6 months (M6-LSM) performed best to predict decompensation (AUC: 0.806 CI-95% [0.713–0.899]) and TFS (AUC: 0.719 [CI-95%: 0.543–0.869]). We further observed that a M6-LSM ≥10 kPa cut-off identified patients at high risk for decompensation (sensitivity: 75.0%, specificity 73.1%) and transplantation/death (sensitivity 66.7%, specificity 69.1%). Based on M6-LSM, patients with <10 kPa had a 0.8% 10Y-cumulative incidence of decompensation and a 97.8% 10Y- TFS, while 10Y-cumulative incidence of decompensation was 23.3% in patients with 10–19.9 kPa and 30.8% in patients with ≥20 kPa. 10Y-TFS was 100.0% in patients with 10–19.9 kPa but declined to 92.3% in patients with ≥20 kPa. Interestingly, the absolute and relative change between baseline and M6-LSM was neither a good predictor of decompensation (AUC: 0.425) nor of TFS (AUC: 0.429).
Conclusion: In AIH patients, LSM and particularly LSM at 6 months after immunosuppressive treatment initiation provide important prognostic information regarding decompensation and transplant-free survival. On-treatment M6-LSM ≥10 kPa identifies AIH patients at risk for progressing to decompensated liver disease, while M6-LSM ≥20 kPa indicates an increased risk of death or need for LTX.

THU-289
Efficacy of tioguanine and mycophenolate mofetil as second-line immunosuppressive treatment in autoimmune hepatitis management

Catherine Tian[1], Catherine Stedman[1,2], Michael Burt[1], Murray Barclay[1,2], Jeffrey Ngu[1,2]. [1]*Department of Gastroenterology, Christchurch Hospital, Te Whatu Ora Waitaha Canterbury New Zealand, Christchurch, New Zealand;* [2]*Department of Medicine, University of Otago, Christchurch New Zealand, Christchurch, New Zealand*
Email: cattian123@gmail.com

Background and aims: Azathioprine or 6-mercaptopurine is commonly used as a first-line maintenance treatment in the management of autoimmune hepatitis (AIH). When either intolerance or inadequate response to first-line therapy occurs, a second-line agent such as mycophenolate mofetil (MMF) is used. Tioguanine is commonly used in New Zealand to treat inflammatory bowel disease, and its use for autoimmune hepatitis has recently increased. This study aims to compare the effectiveness of tioguanine and MMF as second-line treatments for achieving biochemical remission in autoimmune hepatitis (AIH).
Method: Patients in Canterbury who fulfilled the Simplified AIH Diagnostic Criteria and were treated with tioguanine or MMF were identified. Cases were included if tioguanine or MMF were commenced as a second-line but excluded if commenced as a first- or third-line agent. Biochemical remission is defined as ALT<30 U/L. Flare is defined as elevation of ALT after achieving biochemical

remission. Statistical comparisons were conducted using Chi-square or Fisher's exact test for sample sizes <5.
Results: A total of 356 AIH patients were identified. MMF and tioguanine were commenced as a second-line agent in 42 and 10 patients, respectively. Their first-line treatments ceased because of intolerance in 67% and inadequate response in 33%. Comparing tioguanine with MMF, biochemical remission was achieved in 40% versus 57% at 6 months and 78% versus 68% at 12 months. MMF had significantly more flares than the tioguanine group (38% vs 0%; p = 0.016). Subgroup analysis showed that in patients with inadequate response to first-line treatment, the tioguanine group had significantly higher biochemical remission in 12 months (100% vs 45.5%; p = 0.037). Adverse effects were rare for both groups, only resulting in one MMF patient withdrawing treatment.
Conclusion: This is the first study comparing tioguanine against MMF in AIH management. Both tioguanine and MMF had high and comparable efficacy in achieving biochemical remission in AIH patients as a second-line agent. Tioguanine was well tolerated even in patients intolerant to azathioprine and may perform better than MMF in patients with inadequate response to first-line treatment.

THU-290
Addressing primary biliary cholangitis symptoms during consultations: an international survey of those who see patients

Caz Canavan[1], Jonathan Hailwood[2], Clare Jones[2], Jan McKendrick[2].
[1]GSK, London, United Kingdom; [2]Avalere Health, London, United Kingdom
Email: caz.x.canavan@gsk.com

Background and aims: Symptom assessment is not prioritised in current international clinical guidelines for primary biliary cholangitis (PBC), with recommendations being inconsistent or absent. This survey aims to understand healthcare professionals' (HCPs) perceptions of the discussions they have with their patients with PBC regarding symptoms.
Method: A survey of HCPs (physicians and nurses) who treat patients with PBC was conducted to capture the content of discussions throughout the patient's journey. Questions focused on symptom assessment, monitoring and access to a broader team of allied HCPs and support groups. Gastroenterologists, hepatologists, registered nurses and hepatology nurse specialists with a range of clinical experience were targeted from a database of HCPs covering North America, Europe and Asia.
Results: A total of 151 HCPs (physicians N = 121; nurses N = 30) with experience in managing PBC participated in the survey in August 2024. Overall, 95% of HCPs reported proactively asking patients about symptoms at the first consultation, when the diagnosis of PBC is established. Itch and fatigue were the symptoms most commonly discussed with all patients at this consultation (80% and 75%, respectively). Although HCPs did not commonly ask patients about symptoms in advance of a routine appointment, 97% reported proactively discussing symptoms during these consultations. The proactive discussion of itch and fatigue was less commonly reported at these interactions (72% and 67%, respectively). Over 90% of HCPs reported discussing with patients that symptoms may change over the disease course; however, only 46% always highlighted to patients that control of PBC may not correlate with an improvement in symptoms. Symptom severity was reported to be assessed using both quantitative and qualitative measures by 42% of HCPs, while 13% used only quantitative measures and 45% used only qualitative measures. To assess changes in symptoms over time, 50% of HCPs reported using both quantitative and qualitative measures, 10% used only quantitative measures and 36% used only qualitative measures. Only 54% of HCPs reported familiarity with any formal tools or scales to measure symptoms and/or the impact of PBC on patients. Regarding symptom management, 81% of HCPs prioritised specific symptoms for management (as opposed to all that are identified) and 64% reported changing their approach to symptom management depending on the stage of PBC.
Conclusion: Despite the majority of HCPs reporting that they routinely evaluate symptoms in patients with PBC, there is inconsistency in which specific PBC symptoms are proactively or routinely discussed with patients, how they are assessed (quantitatively and/or qualitatively) and how this relates to the control of their PBC. Additional guidance on symptom assessment would be beneficial to improve patients' experience.
Funding: GSK (223362).

Clinical meaningful change of pruritus numeric rating scale in adults with primary biliary cholangitis with moderate-to-severe pruritus

Cynthia Levy[1], Andreas E. Kremer[2], Anne Skalicky[3], Milena Anatchkova[3], Adam Smith[4], Caroline Burk[5], Marvin Rock[5], Chong Kim[5], Susheela Carroll[5], Daria Crittenden[5], Ariane Kawata[6], David Jones[7]. *[1]University of Miami, Schiff Center for Liver Diseases, Miami, Florida, United States; [2]University of Zurich, University Hospital Zurich, Department of Gastroenterology and Hepatology, Zurich, Switzerland; [3]Evidera, Inc., Wilmington, NC, United States; [4]Evidera, Inc., Hammersmith, London, United Kingdom; [5]Gilead Sciences, Foster City, CA, United States; [6]Evidera Inc., Wilmington, NC, United States; [7]Newcastle University, Newcastle, United Kingdom*
Email: clevy@med.miami.edu

Background and aims: Cholestatic pruritus affects people with primary biliary cholangitis (PBC) and can be extremely debilitating. The Pruritus Numeric Rating Scale (NRS) can evaluate treatment effects. This analysis followed US FDA PRO and PFDD Draft Guidance (2009, 2023) and examined the meaningful within-person change (MWPC) in the Pruritus NRS that PBC patients with pruritus perceive as a beneficial treatment effect.
Method: Data from the phase 3 RESPONSE (NCT04620733) trial of seladelpar were analyzed for participants with moderate-to-severe pruritus NRS (MSPN) (NRS ≥4) at baseline (key secondary endpoint). The NRS (range: 0–10; no itching–worst imaginable itching) was administered daily for 6 months. Two anchor measures, the 7-day recall Patient Global Impression of Severity of pruritus (PGI-S) and the Patient Global Impression of Change of pruritus (PGI-C) were administered at study visits. MWPC threshold estimates using anchor-based methods were supported by distribution-based methods and empirical cumulative distribution function (eCDF) curves. Qualitative interviews evaluated meaningful change on the Pruritus NRS in PBC adults with pruritus (NRS ≥4) outside of the trial.
Results: Of the 193 participants enrolled in the RESPONSE trial, 72 were included in the MSPN analysis (mean [range] age: 47 [27–68] years; 97% female). There was a strong relationship between change in the Pruritus NRS and PGI-S ($r = 0.50$, $p < 0.0001$) and PGI-C ($r = -0.52$, $p < 0.0001$) scores at month 6 supporting their use as anchor measures in evaluating clinically meaningful change in the MSPN population. Anchor-based analyses demonstrated MWPC estimates of ≥3-points on the Pruritus NRS corresponding to "moderate improvement" for PGI-C and 1-category improvement for PGI-S. eCDF curves had good separation between Pruritus NRS change scores and anchor categories between baseline and month 6. Distribution based analyses (comparison of NRS change score to measures of variability, like the standard error of measurement) suggested a lower threshold for score change in Pruritus NRS (0.72). Half (n = 6/12, 50%) of the interview participants supported a 3-point improvement as minimum meaningful change on the NRS.
Conclusion: Triangulation of anchor, eCDF, distribution-based analyses, and qualitative interviews of patient perception of benefit suggest a 3-point improvement in Pruritus NRS as seen with seladelpar in RESPONSE is meaningful to PBC patients with moderate-to-severe itch.

THU-292

Serum levels of IL-31 and autotaxin are independently associated with pruritus severity in patients with primary sclerosing cholangitis

Cynthia Levy[1], Daniel Pratt[2], Craig Lammert[3], Stuart C. Gordon[4], Michael Li[5], Lisa Forman[6], Richard Dean[7], Maryam Yazdanfar[7], Isha Patel[1], Raghav Bordia[2], Duru Cosar[2], Katherine Specht[2], Fawzy Barry[5], Megan McLaughlin[8], Sumanta Mukherjee[8], Usha Gungabissoon[9], Christopher L. Bowlus[7]. Email: clevy@med.miami.edu

Background and aims: Primary Sclerosing Cholangitis (PSC) is a chronic cholestatic liver disease with no approved treatment and few effective off-label therapies to reduce the symptom burden. We previously reported that over 1/3 of patients with PSC experience moderate-to-severe pruritus. However, little is known about biomarkers of pruritus in patients with PSC. The aim of this analysis was to prospectively identify biomarkers of pruritus in PSC.
Method: Patients aged 18 and older, diagnosed with PSC and without a liver transplant were enrolled at 7 academic medical centers from July 2021 to March 2024. Itch numeric rating scale (NRS), 5-D Itch, PSC-PRO, and SF-36 were completed and serum collected at the time of enrollment. For the NRS, patients reported their average and worst itch (WI) in the past 24 hours, 7 days, and 6 months. Colitis activity was assessed in patients with inflammatory bowel disease (IBD) by the Simple Clinical Colitis Activity Index (P-SCCA). Total serum bile acids (TSBA), liver biochemistries, IL-31, and autotaxin were measured. Spearman rank correlation, general linear models, and area under the receiver operator curve were used to examine the relationships between the WI in the past 7 days (WI-NRS) and serum biomarkers.
Results: A total of 200 patients were enrolled (51% male; mean (SD) age of 44.6 (16.1) years; 71% White, 11% Black/African American; 15% cirrhosis). Most patients (77%) had large duct PSC while 4% had small duct PSC and 2% had PSC-AIH. IBD was present in 70% (50% ulcerative colitis/17% Crohn's disease/3% indeterminate). WI-NRS was reported as moderate or severe (WI-NRS 4–7 or 8–10, respectively) by 48 (24%). Alkaline phosphatase (ALP) ($r = 0.26$), GGT ($r = 0.18$), ALT ($r = 0.15$), AST ($r = 0.20$), total ($r = 0.25$) and direct bilirubin ($r = 0.26$), albumin ($r = -0.18$), total serum bile acids ($r = 0.21$), autotaxin ($r = 0.28$), and IL-31 ($r = 0.40$) all correlated with WI-NRS (all p-values <0.05). Among patients with IBD, P-SCCA also correlated with WI-NRS ($r = 0.41$, $p < 0.0001$). General linear modeling demonstrated that log AST (b = –3.2), log direct bilirubin (b = 1.4), log autotaxin (b = 1.9), and IL-31 (b = 0.6) independently associated with WI-NRS (all p-values <0.05). Among patients with IBD, log autotaxin (b = 4.0, p = 0.0006) and P-SCCA (b = 1.5, P = 0.002), but not IL-31 (b = 0.5, p = 0.15) remained independently associated with WI-NRS. The area under the receiver-operator curve (AUROC) for WI-NRS <4 vs ≥4 was 0.68 (0.57–0.78) for autotaxin and 0.67 (0.56–0.79) for IL-31. Combining autotaxin and IL-31 did not improve the AUROC [0.70 (0.60–0.80)].
Conclusion: Both autotaxin and IL-31 independently associated with pruritus severity in patients with PSC. However, only autotaxin remained an independent predictor of pruritus severity after adjusting for colitis activity in patients with concomitant IBD.
This study was supported by GSK (214524).

Disparities in treatment response and liver decompensation by race and ethnicity in primary biliary cholangitis: results from the ELLA-PBC cohort

Paul Yoon[1], Adriana Shen[1], Matthew Chen[1], Tara Foroohar[1], Isai Martinez Rios[1], Sade Brown[1], Kali Zhou[1], Jeffrey Kahn[1], Brian Lee[2], Jennifer Dodge[1], Lily Dara[1]. [1]*USC Keck School of Medicine, Los Angeles, United States;* [2]*Hoag Memorial Hospital Presbyterian, Newport, United States*
Email: psyoon@usc.edu

Background and aims: Alkaline phosphatase (ALP) normalization predicts outcomes in primary biliary cholangitis (PBC). However, the impact of race, ethnicity, and insurance access on treatment response remains poorly understood. This study aims to evaluate disparities in treatment response, decompensation rates, and transplant-free survival (TFS) among racial/ethnic groups with PBC.
Method: The East Los Angeles Latinx PBC (ELLA-PBC) cohort includes predominantly Hispanic PBC patients presenting to Keck Medical Center of USC and Los Angeles General Medical Center (2006–2022). PBC was confirmed by Paris criteria. Patients with prior transplant were excluded. Kaplan-Meier 5-year TFS and cumulative incidence of progression to cirrhosis or decompensation were estimated. Complete biochemical remission (CBR; ≤1 × ULN) at 1-year post-ursodeoxycholic acid (UDCA) initiation was analyzed using logistic regression.
Results: Of 427 patients, 96 (22.5%) were White and 331 (77.5%) were non-White, including 282 Hispanic patients. Non-White patients were more often foreign-born (51.1% vs. 10.4%; $p < 0.001$) and underinsured (68.9% vs. 17.7%; $p < 0.001$). Over a median follow-up of 3.3 years, 88 patients underwent transplant or died. The 5-year TFS rates were similar for White (74.9%, 95% CI 61.7–84.1) versus non-White patients (77.1%, 95% CI 71.1–82.0; $p = 0.45$) and the Hispanic subgroup (76.1%, 95% CI 69.6–81.5; $p = 0.35$). Among patients compensated at baseline (N = 275), 51 experienced decompensation. The 5-year cumulative incidence of decompensation was higher in non-White (23.5%, 95% CI 17.4–31.3; $p = 0.20$) and Hispanic patients (25.5%, 95% CI 18.6–34.2; $p = 0.14$) versus White patients (16.4%, 95% CI 7.7–32.9). In UDCA-naïve patients (N = 158), baseline ALP levels were 231 U/L (IQR 128–565) in White, 275 (IQR 180–443; $p = 0.25$) in non-White, and 285 (IQR 193–464; $p = 0.21$) in Hispanic patients. At 1-year, CBR rates were 20.7% in White, 4.7% in non-White, and 4.3% in Hispanic patients, corresponding to a 78% and 77% lower response for non-White ($p < 0.001$) and Hispanic patients ($p = 0.001$) versus White patients. After adjusting for PBC-AIH variant and insurance status, CBR remained 65% lower in non-White ($p = 0.04$) and 55% lower in Hispanic patients ($p = 0.13$) compared to White patients.
Conclusion: Non-White and Hispanic UDCA-naïve patients with PBC had near 80% lower CBR rates at 1-year compared to White patients, with non-White differences persisting after adjusting for insurance status. Hispanic patients demonstrated a 10% higher decompensation rate compared to White patients, though not statistically significant potentially due to the smaller sample size of White patients. Given insurance status attenuated the effect of Hispanic ethnicity on CBR rates, more studies are needed to separate the effect of socioeconomic and healthcare-related disparities from race and ethnicity to improve equity in PBC outcomes.

Background and aims: Primary biliary cholangitis (PBC) is a chronic, progressive, autoimmune, cholestatic liver disease. Pruritus may occur in up to 70% of patients (pts) with PBC during the course of disease and can greatly reduce quality of life. Seladelpar (SEL) is a first-in-class delpar (selective PPAR-delta agonist) indicated for the treatment of PBC in combination with ursodeoxycholic acid (UDCA) in adults who have an inadequate response to UDCA, or as a monotherapy in pts unable to tolerate UDCA. In two Phase 3, placebo (PBO)-controlled trials (ENHANCE [NCT03602560] and RESPONSE [NCT04620733]), SEL significantly reduced pruritus among pts who had moderate to severe pruritus at baseline (defined as numerical rating scale [NRS] ≥4). Here, we present pooled pruritus outcomes across different measures of itch in pts with PBC from RESPONSE and ENHANCE with NRS ≥4 at baseline.
Method: Pts with PBC with an inadequate response/intolerance to UDCA were randomised 1:1:1 to daily SEL 5 mg, SEL 10 mg, or PBO for 52 weeks in ENHANCE and 2:1 to daily SEL 10 mg or PBO for 52 weeks in RESPONSE (ENHANCE terminated early with key endpoints amended to month [M] 3). Pooled data from pts with NRS ≥4 at baseline who received SEL 10 mg or PBO in RESPONSE and at least 6 months in ENHANCE were analysed. In a post-hoc analysis, changes across several measures of itch up to M6 (NRS, PBC-40 itch domain, and the 5-D itch scale) were assessed.
Results: Of the 126 pts with moderate to severe pruritus, 76 and 50 received SEL 10 mg and PBO, respectively, in RESPONSE or ENHANCE. Most pts at baseline were <50 years old at age of PBC diagnosis (73/126) and had a history of pruritus (122/126) and fatigue (77/126). NRS, PBC-40 itch domain, and 5-D itch scale scores were similar between the SEL and PBO groups at baseline. At M6, pts who received SEL experienced greater improvements in NRS scores (mean change from baseline of −3.12 vs −2.09 for SEL and PBO, respectively, p = 0.0004), PBC-40 itch domain scores (mean change from baseline of −2.26 vs −1.37 for SEL and PBO, respectively, p = 0.0227), 5-D itch total scores (mean change from baseline of −4.85 vs −2.30 for SEL and PBO, respectively, p < 0.0001), and 5-D itch degree domain scores (mean change from baseline of −0.96 vs −0.54 for SEL and PBO, respectively, p = 0.0005). The overall safety profiles in pts with pruritus in the SEL and PBO groups were similar in this pooled analysis. Adverse events occurred in 58/76 (76.3%) SEL and PBO 40/50 (80%) PBO patients.
Conclusion: In agreement with previous studies, this pooled analysis indicates that up to 6 months of SEL treatment reduced pruritus to a greater extent vs PBO in pts with PBC who had moderate to severe pruritus when assessed across 3 different measures of itch. SEL was well tolerated in this pt population.

Email: e.werner@erasmusmc.nl

Background and aims: Alkaline phosphatase (ALP) and total bilirubin (TB) are usually evaluated after 1 year of ursodeoxycholic acid (UDCA) when add-on second-line therapy for patients with primary biliary cholangitis (PBC) is considered. Both biochemical parameters are also included in various biochemical response criteria, which have been associated with clinical outcome in predominantly tertiary cohorts. We aimed to assess ALP and TB after one year of UDCA and their relation to long-term clinical outcome in a large nationwide cohort.
Method: The retrospective Dutch PBC Cohort Study (DPCS) includes every identifiable patient with PBC in the Netherlands from 1990 up to last data collection (2019–2023) in all 71 Dutch hospitals. Clinical data were obtained through medical chart review. Patients were included in case of available biochemistry after one year of UDCA monotherapy. Where needed and feasible, imputation was performed using joint model multiple imputation. Laboratory values are presented in upper limits of normal (ULN). Response rates at one year of UDCA and liver transplant (LT)-free survival (LTFS) were assessed according to ALP and TB cut-offs.
Results: In total, 3089 patients were included. At baseline, the median age was 57.7 (IQR 49.6–66.9) years, 2705 (87.6%) were female, 201 (6.5%) had cirrhosis, median ALP was 1.9 (IQR 1.3–3.2) and median TB was 0.5 (IQR 0.4–0.8). After one year of UDCA, the median ALP was 1.2 (IQR 0.9–1.6) and median TB was 0.5 (IQR 0.4–0.7). During a median follow-up duration of 8.3 years (IQR 4.0–13.5), 74 (2.4%) patients underwent LT and 522 (16.9%) died (all-cause mortality). In multivariable analyses, both log ALP (aHR 1.8 95% CI 1.5–2.1, p < 0.001) and log TB (aHR 3.0, 95% CI 2.5–3.6, p < 0.001) were associated with the hazard of LT or death. The cumulative 10-year LTFS was 77.4% (95% CI 73.2–81.8), 84.4% (95% CI 82.1–86.7), and

88.4% (95% CI 86.2–90.9) in those with ALP >2 (n = 489), ALP 1–2 (n = 1500) or ALP≤1 (n = 1056), respectively (p < 0.001). The 10-year LTFS was 56.8% (95% CI 50.5–63.9), 83.2% (95% CI 80.0–86.6), and 89.5% (95% CI 87.7–91.4) in those with TB >1 (n = 267), TB 0.6–1 (n = 694) or TB≤0.6 (n = 1811), respectively (p < 0.001). Patients with an ALP≤1.5 and normal TB at one year (1781/2758, 64.6%; of whom 95.2% also had an AST≤1.5) showed a 10-year LTFS of 88.7% (95% CI 86.8–90.6). Among the 642/2758 (23.3%) patients with ALP≤1.0 and a TB≤0.6 (deep response) the 10-year LTFS was 91.0% (95% CI 88.2–93.9).
Conclusion: In this nationwide cohort, including every patient with PBC from all Dutch treatment centers, ALP and TB after one year of UDCA were independently associated with clinical outcome. Almost a quarter of patients reach a deep response to UDCA alone, which was associated with the best LT-free survival.

THU-300
Long term efficacy, effectiveness and side effects of third line therapies in autoimmune hepatitis
Ilkay Ergenc[1], Alexandra Frolkis[1], Yooyun Chung[1], Yoh Zen[1], Deepak Joshi[1], Michael Heneghan[1]. [1]*Institute of Liver Studies, King's College Hospital, London, United Kingdom*
Email: ergencilkay@gmail.com

Background and aims: Evidence demonstrating the long-term efficacy and safety of third-line agents is limited. We aimed to evaluate the long-term outcomes of autoimmune hepatitis (AIH) patients treated with third-line agents.
Method: We conducted a retrospective review of 704 AIH patients treated at our tertiary liver centre between 1975 and May 2024. Patients who received third-line therapy for at least six months were included in the analysis. Clinical event-free survival was defined as the absence of ascites, variceal bleeding, hepatic encephalopathy, hepatorenal syndrome, hepatocellular carcinoma, liver transplantation, or death.
Results: Of the 93 included patients, 74 (79.6%) were female, with a median age of 47 years (IQR 30–63.7). Twenty-seven percent of patients were cirrhotic at diagnosis. Ninety patients (96.8%) received steroid maintenance therapy (12% budesonide; 88% prednisolone). Sixty-six patients (71%) were treated with azathioprine (AZA); 46 discontinued due to side effects, 13 due to lack of efficacy, one achieved remission. Nine patients were treated with mercaptopurine (MP) (10.1%) as first/second line therapy; all of whom discontinued due to side effects. Twenty-eight percent of patients did not receive AZA or MP. Mycophenolate mofetil (MMF) was initiated in 68 patients (73.1%). MMF treatment was discontinued in nine patients due to side effects, seven for family planning, and three due to lack of efficacy. In one patient, MMF was switched to rituximab to treat co-existing vasculitis. Median follow-up time on MMF was 168 months (23.1–168). Tacrolimus (TAC) was used in 51 patients (54.8%); four discontinued treatment (in one patient due clinical trial enrolment, one due to HPV-related cervical intraepithelial neoplasia, one for inefficacy, and one due to cytopenia), with a median follow-up time of 59.4 months (14.2–62.8). Rituximab was administered to six patients (6.5%). Triple therapy was used in 18 patients (19.4%), most commonly a combination of TAC, steroids, and MMF, with a median treatment duration of 62.4 months (26.4–139.6). Median ALT levels improved from 149 U/L (49–312) pre-third line treatment to 32 U/L (21–47) at last visit. Median IgG levels decreased from 17.5 g/L (12.6–24.3) pre-third line treatment to 13.8 g/L (11.2–17.9) post-treatment. Median clinical event-free survival was 148.3 months (48–189.3) in patients treated with MMF (n = 42, including 14 not exposed to AZA), 53.5 months (18.5–85.2) in patients treated with TAC (n = 33, including 5 not exposed to AZA) and 59.7 months (22.2–119.1) in patients treated with triple therapy (n = 18).
Conclusion: In this single-centre cohort, primarily comprising difficult-to-treat AIH patients, third-line therapies demonstrated favourable long-term clinical outcomes with significant improvement in biochemical parameters, prolonged clinical event-free survival, and a good safety profile.

Email: l.cristoferi@campus.unimib.it

Background and aims: Primary Sclerosing Cholangitis (PSC) is a chronic cholestatic liver disease with no effective medical treatment. EASL Guidelines recommend bezafibrate as a first-line treatment for pruritus. Preliminary evidence from small patient cohorts has suggested that bezafibrate and fenofibrate may improve liver function tests (LFTs), and a randomized clinical trial is currently underway in France to validate this. Data on the safety of fibrates in PSC remains limited. This study aimed to evaluate the safety profile and impact of fenofibrate and bezafibrate on LFTs and liver stiffness measurements (LSM) in a multicenter cohort of PSC patients across Europe and the United States.
Method: Patients with a confirmed diagnosis of PSC who were treated with either bezafibrate or fenofibrate at university hospitals in Monza, Milan, Yale, Hamburg, and Oxford, with at least six months of follow-up, were retrospectively included. LFTs and LSM were evaluated at baseline and during follow-up. Safety was assessed based on treatment discontinuation rates and the occurrence of adverse clinical outcomes (liver-related death, liver transplantation).
Results: Seventy-two PSC patients were included: 40 (55.6%) received bezafibrate, 32 (44.4%) fenofibrate; 70 (97.3%) were already on ursodeoxycholic acid therapy. The median age at diagnosis was 30.5 years (IQR 23.8–45.3); 48 (66.7%) were male. Fifty-two (72.2%) had IBD, and 14 (9.4%) had a variant with autoimmune hepatitis. The primary indication for therapy was cholestasis (58.3%), pruritus (31.9%), or both (9.7%). Over a median follow-up of 20.1 months (IQR 12.1–43.8) ALP levels showed a significant median reduction of 42.9% at six months (IQR 12.1–54.2, p < 0.0001) and remained stable thereafter. ALP normalization was achieved by 30.0%, 32.6%, and 33.3% of patients at six, 12, and 24 months, respectively. No significant differences in ALP reduction over time were observed between bezafibrate and fenofibrate (p = 0.6262). Median LSM at baseline was 8.9 kPa [IQR 6.77, 11.45] and remained stable after 12 months (p > 0.05). Twenty patients (27.8%) discontinued treatment: 7 (35%) due to inefficacy (3 on pruritus, 3 on cholestasis improvement, 1 on both), 5 (25%) due to adverse events, 5 (25%) due to clinical outcomes, and 3 (15%) by personal choice or inclusion in clinical trials. Among them, 12 (60%) and 3 (15%) discontinued treatment after 6 and 12 months, respectively.
Conclusion: In PSC patients, fibrates demonstrated significant ALP reduction, with 30.0% of patients achieving normalization in 6 months with no difference between fenofibrates and bezafibrate.

LSM remained stable at 12 months. Safety was acceptable, with discontinuation driven mainly by inefficacy and in the first 6 months of treatment. Fibrates may be valuable for improving cholestasis in addition to pruritus in PSC, warranting further prospective studies.

Background and aims: Social Determinants of Health (SDOH) are conditions in which people grow, work, and age. Studies highlight the influence of SDOH on the development and progression of various chronic diseases. However, little is known about the influence of SDOH on autoimmune liver disease (AILD). We aim to explore the relation between SDOH and quality of care, treatment and outcome parameters of AILD.

Method: An international multicentre cross-sectional questionnaire is distributed among adults with AILD between October 2024 and January 2025. The questionnaire covers well-established instruments evaluating SDOH as defined by the World Health Organization, including sociodemographics, income, education, work environment, food insecurity, housing, early childhood development, social support and access to health services. As outcome variables, parameters of treatment and disease progression were assessed. The questionnaire was revised by patient representatives of ERN RARE-LIVER. Data collection will be completed by January 2025. Regression models will be employed to analyze the association between SDOH and AILD.

Results: After 7 weeks of data acquisition, 957 patients from 15 European countries answered the questionnaire. 176 (19%) of the patients had primary sclerosing cholangitis, 309 (33%) had autoimmune hepatitis, 380 (40%) had primary biliary cholangitis, and 81 (9%) had variant syndromes. 741 (77%) were female, and most were between 50 and 60 years old. Overall, 95 (11%) participants screened positive for food insecurity. Of those, 60 (63%) and 33 (33%) reported additional expenses for liver medication and additional private health insurance, respectively. In total, 141 (16%) individuals reported having liver cirrhosis. The prevalence of cirrhosis was 29% (25/89) among those who primarily spoke a non-native language at home, and 14% (116/798) among those who spoke the dominant language of their country ($p = 0.001$).

Conclusion: This interim analysis highlights the high prevalence of food insecurity and out-of-pocket expenses for liver-related healthcare among patients with AILD and suggests significant negative health outcomes in individuals facing language barriers. These findings emphasize the necessity to address SDOH in clinical practice to reduce health inequities and improve clinical outcomes in AILD care.

Email: g.weijsters@erasmusmc.nl

Background and aims: Primary Biliary Cholangitis (PBC) is associated with several extrahepatic autoimmune diseases (EHAID), but reliable prevalence estimates are scarce. We aimed to assess the occurrence and impact of EHAID in a nation-wide population with PBC.

Method: The retrospective Dutch PBC Cohort Study (DPCS) includes every identifiable patient with PBC in the Netherlands from 1990 up to last data collection (2019–2023) in all 71 Dutch hospitals. Clinical data were obtained through medical chart review. Logistic regression and survival analyses were used to assess whether EHAID is associated with biochemical response and liver transplant-free survival among patients who were treated with ursodeoxycholic acid (UDCA) alone. Multivariate analyses were adjusted for age at diagnosis, cirrhosis at baseline, use of immunosuppressive drugs, sex, year of diagnosis and biochemical parameters.

Results: In total, 4293 patients were included of whom 1239 (28.8%) were diagnosed with EHAID during the course of disease, 138 (3.2%) patients underwent LT and 806 (18.8%) patients died during a median follow-up of 8.3 years (IQR 3.7–14.3). Hypothyroidism was the most

prevalent EHAID 428/1239 (34.5%), followed by Sjögren's Syndrome 217/1239 (17.5%). EHAID was already present at baseline in 932/1239 (75.2%) patients. Patients with EHAID at baseline were more frequently female (91.6% vs 87.0%, p < 0.001) and had cirrhosis less frequently (5.5% vs 7.3%, p = 0.046) as compared to those without EHAID, while median age (56.7 years, IQR 49.0–66.7 vs 56.8 years, IQR 48.3–66.4, p = 0.548), median ALP (1.83×ULN, IQR 1.27–2.99 vs 1.94×ULN, IQR 1.31–3.23, p = 0.202) and median AST (1.52×ULN, IQR 1.03–2.26 vs 1.53×ULN, IQR 1.06–2.33, p = 0.682) were similar. After one year on UDCA alone, the PARIS-II response rate was 391/595 (65.7%) among patients with baseline EHAID vs 1329/2265 (58.7%) in those without EHAID (p = 0.002), but EHAID was not independently associated with the UDCA response (PARIS-II) (aOR 0.93, 95CI% 0.72–1.20, p = 0.564). Among 3243 patients with at least 6 months follow-up, the 10-year LT-free survival was 85.7% (95% CI 82.2–88.9) in those with EHAID at baseline vs 85.5% (95% CI 83.9–87.1) in those without (p = 0.758). This absent association between EHAID and long-term clinical outcome remained in multivariable Cox regression analysis (aHR 1.08, 95%CI 0.84–1.39, p = 0.554).

Conclusion: In this nationwide cohort, almost 30% of patients with PBC are affected by extrahepatic autoimmune diseases (EHAID), which are observed more frequently in females. At PBC diagnosis, cirrhosis was less common in patients with EHAID, suggesting EHAID may contribute to earlier diagnosis. Presence of EHAID was not related to the biochemical response to UDCA or the long-term clinical outcome of PBC.

Email: cristina.rigamonti@uniupo.it

Background and aims: Primary biliary cholangitis (PBC) is a progressive cholestatic disease that can lead to portal hypertension. PBC patients with compensated advanced chronic liver disease (cACLD), defined according to the Baveno VI criteria based on a liver stiffness measurement (LSM) ≥10 kPa, are at risk of developing clinically significant portal hypertension (CSPH). Identifying cACLD patients with CSPH is essential for implementing therapeutic strategies. We aimed to non-invasively stratify the CSPH risk in PBC patients with cACLD using the Baveno VII criteria, also implementing spleen stiffness measurement (SSM), and the NICER model (PMID 39326431).

Method: Multicentric study including 88 PBC patients with cACLD from 5 tertiary centres for liver diseases (Novara, Milan, Palermo, Istanbul, Vienna) who underwent vibration-controlled transient elastography (VCTE)-based LSM and SSM. The Baveno VII criteria were applied, along with the single SSM cut-off (≤40 kPa vs. >40 kPa) and the dual SSM cut-offs (≤25 kPa and SSM ≥55 kPa). The NICER model was computed as published: Logit = –6.40032480 + ln(SSM) × 1.96952565 + ln(LSM) × 1.83093447 – BMI × 0.12882190 – platelets (PLT) × 0.01850461. Esophagogastroduodenoscopy (EGD) was performed per Baveno VI recommendations and proposed to all patients with SSM > 40 kPa.

Results: Among the 88 PBC patients, 72 (82%) were women, 79 (90%) on ursodesoxycholic acid monotherapy, median age was 65 (IQR 55–74) years, median BMI 25.1 (IQR 23.1–26.9) kg/m2, median disease duration 3.4 (IQR 1.3–10.3) years, median ALP 1.3 (IQR 1.0–2.3) × ULN, median total bilirubin 0.7 (IQR 0.5–1.1) mg/dL, median LSM 17.3 kPa (IQR 11.9–35.8), median SSM 51.5 kPa (IQR 32.8–68.7). Thirty-seven (51%) out of the 73 patients with available EGD had oesophageal varices, of which 15 (20%) had high-risk oesophageal varices. Applying the Baveno VII criteria: CSPH was ruled-out in 30 (34%) and ruled-in in 29 (33%) patients, while 29 (33%) remained in the grey zone. Using the Baveno VII-SSM criteria with a single cut-off: 38 (43%) patients were at low risk for CSPH, 44 (50%) at high risk, 6 (7%) in the grey zone. Using the Baveno VII-SSM with dual cut-offs: 31 (35%) patients were classified as low risk, 36 (41%) as high risk, and 21 (24%) in the grey zone. Based on the NICER model, CSPH risk distribution was: <25% 36 patients (41%), > 75% 48 patients (54%). Among the 73 patients who underwent EGD, esophageal varices were found in 1 (1%) of patients with a CSPH risk <25% and in 34 (46%) of patients with a CSPH risk > 75% (p < 0.001).

Conclusion: The addition of SSM to the Baveno VII criteria reduces the diagnostic grey zone in PBC patients with cACLD, particularly using the single-SSM cut-off at > 40 kPa. The SSM-containing NICER model provides valuable and accurate non-invasive CSPH risk assessment information also in PBC patients.

THU-305

Quantitative morphometric analysis via artificial intelligence-driven image analysis in autoimmune hepatitis: a multi-center study

Giorgio Cazzaniga[1], Elisa Merelli[2], Bastian Engel[3,4], Francesca Bolis[2,5], Alberto Marini[2], Eugenia Nofit[6], Laura Cristoferi[6], Davide Bernasconi[7], Federica Malinverno[6], Raffaella Viganò[5], Richard Taubert[3,8], Gaia Chiarello[1], Mario Livio Pietro Camozzi[9], Fabio Pagni[1], Marco Carbone[2,5], Pietro Invernizzi[2,6], Alessio Gerussi[2,6]. *[1]Department of Medicine and Surgery, Pathology, Fondazione IRCCS San Gerardo dei Tintori, University of Milano-Bicocca, Monza, Italy; [2]Department of Medicine and Surgery, University of Milano-Bicocca, Monza, Italy; [3]Department of Gastroenterology, Hepatology, Infectious Diseases and Endocrinology, Hannover Medical School, Hannover, Germany, Hannover, Germany; [4]European Reference Network on Hepatological Diseases (ERN RARE-LIVER), Hamburg, Germany; [5]Hepatology and Gastroenterology Unit, ASST Grande Ospedale Metropolitano Niguarda, Milano, Italy; [6]Division of Gastroenterology, Center for Autoimmune Liver Diseases, European Reference Network on Hepatological Diseases (ERN RARE-LIVER), Fondazione IRCCS San Gerardo dei Tintori, Monza, Italy; [7]Bicocca Bioinformatics Biostatistics and Bioimaging Centre - B4 School of Medicine and Surgery, University of Milano-Bicocca, Monza, Italy; [8]European Reference Network on Hepatological Diseases (ERN RARE-LIVER), Hamburg, Italy; [9]Unit of Surgical Pathology, ASST Grande Ospedale Metropolitano Niguarda, Milano, Italy*
Email: giorgio9cazzaniga@gmail.com

Background and aims: Clinical-pathological correlations in autoimmune hepatitis (AIH) remain challenging due to significant variability in clinical and pathological presentations and diverse subtypes. This study employed computer vision on digital slides to derive quantitative morphometric parameters, aiming to improve diagnostic accuracy and strengthen correlations with clinical markers.

Method: Clinical data and hematoxylin and eosin (H&E)-stained histological slides from diagnosis were collected from two Italian and one German tertiary referral centers. Images were processed with tissue and portal tract segmentation, and a nucleus classifier to differentiate hepatocytes and inflammatory cells. For each case, ten morphometric parameters, six classical histological metrics (mhAI and Ishak fibrosis scores), and over fifty clinical parameters were analyzed.
Results: The study includes a cohort of 128 patients with confirmed AIH; mean age at diagnosis was 54 ± 17 years, with 66% females. After feature selection, the following morphometric parameters were prioritized for clinico-pathological correlations: 'inflammatory cell-to-hepatocyte ratio', 'mean distance between inflammatory cells', 'functional liver area' and 'cell density in portal tracts'. The 'inflammatory cell-to-hepatocyte ratio' in the lobule ($p < 0.01$) and the 'mean distance between inflammatory cells' ($p < 0.01$) showed strong correlations with mhAI score. When compared to traditional histological mHAI and Ishak Fibrosis scores, morphometric parameters demonstrated stronger correlations with AST and ALT levels in multiple linear regression. Patients with higher values of AST and ALT at diagnosis showed significantly higher values of 'inflammatory cell-to-hepatocyte ratio' ($p < 0.001$) and lower values of 'mean distance between inflammatory cells' ($p = 0.02$). The 'functional liver area' and 'cell density in portal tracts' were higher in patients with lower platelets ($p < 0.01$ and $p = 0.01$, respectively).
Conclusion: Artificial intelligence-driven image analysis enables more reproducible quantification of histological parameters and enhances the correlation with clinical findings, complementing existing semi-quantitative scoring systems.

THU-306
Efficacy and safety of odevixibat in adult patients with progressive familial intrahepatic cholestasis: results from the 72-week PEDFIC2 phase III, open-label study

Henkjan J. Verkade[1], Janis M. Stoll[2], Florence Lacaille[3], Bertrand Roquelaure[4], Eyal Shteyer[5], Heng Zou[6], Alejandra Ramirez-Santiago[6], Fatine Elaraki[7]. *[1]Department of Pediatrics, University of Groningen, Beatrix Children's Hospital/ University Medical Center Groningen, Groningen, Netherlands; [2]Department of Pediatrics, Washington University School of Medicine, St. Louis, MO, United States; [3]Pediatric Gastroenterology-Hepatology-Nutrition Unit, Hôpital Universitaire Necker-Enfants Malades, Paris, France; [4]APHM, Service de Pédiatrie Multidisciplinaire, Hôpital de la Timone Enfants, Marseille, France; [5]Hebrew University of Jerusalem, Shaare Zedek Medical Center, Jerusalem, Israel; [6]Ipsen, Cambridge, MA, United States; [7]Ipsen Pharma, Boulogne-Billancourt, France*
Email: h.j.verkade@umcg.nl

Background and aims: Long-term treatment with odevixibat (ODX) was well tolerated and led to sustained and clinically meaningful improvements in pruritus, as well as reductions in serum bile acid (sBA) levels in patients of any age across progressive familial intrahepatic cholestasis (PFIC) types in the PEDFIC 2 study (NCT03659916) [1]. We conducted an analysis focusing on patients > 18 years of age to further characterize the clinical benefit of long-term ODX therapy in adults with any PFIC type.
Method: PEDFIC 2 included enrolment of patients of any age and PFIC type. Patients received ODX 40 µg/kg/day or 120 µg/kg/day. Efficacy endpoints: change from baseline (BL) in sBA to last assessment; sBA response (≤70 µmol/L or reduced ≥70% from BL) at Week 72; and patient-reported pruritus response (scratching score ≤1 or ≥1-point drop in pruritus score from baseline to a given time point). Long-term safety was evaluated throughout the study.
Results: 7 adult patients received ODX in PEDFIC 2 (120 µg/kg/day, n = 6; 40 µg/kg/day, n = 1) with 5 completing 72 weeks treatment (median treatment duration: 84 weeks [range, 24–119 weeks]). Ages ranged from 18 to 26 years at BL; 3/7 patients had FIC1 deficiency, 2/7 had BSEP deficiency, and 2/7 had episodic cholestasis. At last assessment, 5/5 patients (FIC1 deficiency, n = 3) and BSEP deficiency, n = 2) had reductions in sBA with ODX. At Week 72, sBA response was reported in 2/5 patients (FIC1 deficiency, n = 1 and episodic cholestasis, n = 1). 3/5 patients (FIC1 deficiency, n = 2) and BSEP deficiency, n = 1) achieved a pruritus response with ODX (BL itching score: 3 vs ≤1 at last assessment); in 2/5 patients itching score was similar to BL at the last assessment. 2 patients with episodic cholestasis had low sBA and minimal pruritus at BL; neither patient reported a symptom flare during treatment with ODX (treatment exposure: 14 and 20 months, respectively). Patient level data will be presented at the congress. 5/7 patients transitioned to commercial product, 1 patient withdrew consent to participate after 6 months of treatment, and 1 patient was lost to follow-up. Most treatment-emergent adverse events were mild/moderate in severity and assessed as unrelated to ODX; most common was diarrhea (n/N = 3/7) and vitamin D deficiency (n/N = 3/7). 2/7 patients had mild GI disturbances considered possibly/probably related to ODX and 3/7 patients had serious AEs (SAEs), i.e., streptococcal septic arthritis, gastroenteritis-induced dehydration, and acute pancreatitis. All SAEs were assessed as unrelated to ODX.
Conclusion: Clinically meaningful improvements in pruritus and reductions in sBA were achieved with long-term ODX in adults with PFIC. Although based on a small sample size, present data indicate the efficacy and safety profile of ODX in adults with PFIC is consistent with previous results and that additional clinical investigation in this population is warranted.

THU-307
Analysis of histopathological diagnosis and clinical diagnosis of 1,752 patients undergoing liver biopsy

Airong Hu[1], Suwen Jiang[1], Jialan Wang[2], Ken Lin[3], Ying Fan[4], Menghan Jin[3], Haojin Zhang[4], Shiqi Yang[2], Shiyang Fang[4]. *[1]Liver Diseases Center, Ningbo Institute of Liver Diseases, Ningbo No. 2 Hospital, Ningbo, China; [2]Wenzhou Medical University, Wenzhou, China; [3]Ningbo University Health Science Center, Ningbo, China; [4]School of Medicine, Shaoxing University, Shaoxing, China*
Email: huairong@ucas.edu.cn

Background and aims: To investigate the histopathological diagnosis, clinicopathological features and etiological components of liver biopsy, and to provide guiding value for clinical diagnosis and treatment.
Method: The clinicopathological data of 1,752 patients who underwent liver biopsy in Ningbo No. 2 Hospital from January 2015 to December 2023 were included in this study. The consistency of demographic traits, clinical diagnosis, pathological diagnosis, and the severity of liver histopathology were analyzed.
Results: Among the 1,752 patients, 1,589 (90.70%) had a definite diagnosis of the disease, and the top three were hepatitis B virus (HBV) infection (45.04%), metabolic dysfunction-associated steatotic liver disease (MASLD) (12.61%), autoimmune liver diseases (11.64%), and 163 cases (9.30%) without a clear disease diagnosis, involving 22 diseases. Multiple liver illnesses were present concurrently, such as autoimmune liver disease and drug-induced liver damage (DILI), autoimmune liver disease and MASLD, HBV infection and MASLD, etc. and with HBV infection combined with MASLD being the most predominant (67.14%). Hepatic occupations were mainly liver primary or metastatic malignant tumors of the liver (3.82%). The patients with HBV infection, concomitant combination of two or more liver diseases, and liver primary or metastatic malignant tumors were mainly males, while the patients with MASLD, autoimmune liver disease, DILI, and undiagnosed diseases were mainly females, and the composition was statistically significant ($P < 0.001$), and the statistical differences between the two were significant ($P < 0.05$). There was a significant statistically significant difference in age

between the groups ($P < 0.001$), with the lowest age of patients with HBV infection and the highest age of patients with primary or metastatic hepatic malignancies. Except for 2017, the composition of diseases was dominated by HBV infection until 2021, whereas the composition ratio of non-infectious liver diseases showed a yearly increasing trend from 2022 onwards, reaching 96.82% in 2023 (especially for MASLD, which reached 44.09%). The autoimmune liver disease group had the most severe hepatic pathological damage, including the mean Ridit value of liver inflammation grade and fibrosis stage, and the composition ratio of significant hepatic inflammation (≥G2)/significant hepatic fibrosis (≥S2)/cirrhosis (S4), especially in patients with autoimmune hepatitis-primary biliary cholangitis overlap syndrome.

Conclusion: The etiology and clinicopathological features of liver diseases are highly heterogeneous, and the demand for liver pathology caused by HBV infection is gradually decreasing, while liver pathological diagnosis is necessary for non-infectious liver diseases, especially autoimmune liver diseases.

THU-308-YI

Long-term evaluation of controlled attenuation parameter for steatosis monitoring in autoimmune hepatitis

Ignasi Olivas[1,2], Pinelopi Arvaniti[1,2,3], María Del Barrio[4,5], Paula Esteban[6], Helena Hernández Evole[1,2], Marlene Padilla[1,2], Mar Riveiro Barciela[6], Álvaro Díaz-González[4,5], Sergio Rodriguez-Tajes[1,2,7], María Carlota Londoño. *[1]Liver Unit, Hospital Clínic Barcelona, Barcelona, Spain; [2]Fundació de Recerca Clínic Barcelona-Institut d'Investigacions Biomèdiques August Pi i Sunyer (FRCB-IDIBAPS), Barcelona, Spain; [3]European Reference Network on Hepatological Diseases (ERN RARE-LIVER), Barcelona, Spain; [4]Gastroenterology and Hepatology Department, Marqués de Valdecilla University Hospital, Santander, Spain; [5]Clinical and Translational Research in Digestive Diseases Group, Valdecilla Research Institute (IDIVAL), Santander, Spain; [6]Liver Unit, Internal Medicine Department, Hospital Universitari Vall d'Hebron, Vall d'Hebron Barcelona Hospital Campus, Universitat Autònoma de Barcelona, Barcelona, Spain; [7]Centro de investigación biomédica en red. Enfermedades Hepáticas y Digestivas (CIBEREHD), Barcelona, Spain*
Email: ignasiolivasalberch@gmail.com

Background and aims: The controlled attenuation parameter (CAP) has demonstrated usefulness in detecting steatosis in individuals with autoimmune hepatitis (AIH), but its role in long-term monitoring of these patients remains unclear. The aims of this study were: 1) to evaluate the utility of CAP for detecting steatosis during follow-up; 2) to identify predictive factors for steatosis development; and 3) to assess the effects of corticosteroids (CS) and metabolic comorbidities on steatosis progression in AIH patients.

Method: This was a retrospective, multicenter study that included 293 patients with biopsy-confirmed AIH who had undergone at least one CAP measurement. Patients with concomitant liver diseases or AIH variants were excluded. A CAP threshold of 275 dB/m was used to confirm the presence of steatosis. To assess longitudinal changes in CAP during follow-up, a mixed-effects model for repeated measures (MMRM) was applied. Predictive factors for cirrhosis development, as well as event-free survival (EFS) related to decompensation, death, or transplantation, were also analyzed.

Results: The cohort consisted mainly of women (n = 206, 70%), with a median age of 55 years (IQR: 42–64). At the time of AIH diagnosis, 64 patients (22%) had dyslipidemia, 33 (11%) had diabetes mellitus (DM), and 27 (9%) had a body mass index (BMI) ≥30 kg/m². Sixty patients (20%) had steatosis as identified by liver biopsy and/or abdominal ultrasound at baseline, and 73% of these met the criteria for metabolic-associated steatotic liver disease (MASLD). Among those with steatosis, there was a higher prevalence of DM (23% vs. 9%, p = 0.004) and a higher BMI (30 vs. 25 kg/m², p < 0.01). Of the 234 patients without steatosis at baseline, 31 (14%) developed steatosis (CAP ≥275 dB/m) after a median follow-up of 9 years (IQR 6–13). These patients had a higher CAP value (242 vs. 205 dB/m, p <0.01) at the first transient elastography (TE) performed at a median of 24 months (IQR 5–71), and there was a significant increase in CAP values during follow-up, as determined by MMRM ($F_{(1, 208)} = 58.44$, $p < 0.01$). BMI (OR 1.54, p = 0.05) and CAP value (OR 1.01, p < 0.01) at the time of the first TE were significant predictors of steatosis development. The initial dose and duration of CS treatment were not correlated with BMI and were not linked to an increased risk of steatosis. The presence of steatosis, DM, or MASLD at diagnosis or during follow-up did not correlate with poorer treatment response or an increased risk of cirrhosis development. The low number of events in this cohort prevented further evaluation of the impact of steatosis on EFS.

Conclusion: CAP is a valuable tool for detecting steatosis in AIH. Corticosteroid dose, treatment duration, and metabolic comorbidities did not contribute to the development of steatosis. Elevated BMI and CAP emerged as the most significant predictors of steatosis development in AIH patients during follow-up.

THU-309-YI

Liver steatosis prevalence in primary sclerosing cholangitis

Imante Lasyte[1,2], Johannes R. Hov[3,4,5,6], Lina Lindström[1,7], Michael Ingre[1,8], Fredrik Rorsman[9], Nils Nyhlin[10], Antonio Molinaro[11], Stergios Kechagias[12], Annika Bergquist[1,8]. *[1]Department of Medicine, Huddinge, Karolinska Institutet, Stockholm, Sweden; [2]Division of Gastroenterology, Department of Medicine, Central Hospital, Stockholm, Sweden; [3]Institute of Clinical Medicine, Faculty of Medicine, University of Oslo, Oslo, Norway; [4]Research Institute of Internal Medicine, Division of Surgery and Specialized Medicine, Oslo University Hospital, Oslo, Norway; [5]Norwegian PSC Research Center, Department of Transplantation Medicine, Oslo University Hospital, Oslo, Norway; [6]Section of Gastroenterology, Department of Transplantation Medicine, Oslo University Hospital, Oslo, Norway; [7]Department of Gastroenterology, Dermatovenereology and Rheumatology, Centre for Digestive Health, Stockholm, Sweden; [8]Division of Hepatology, Department of Upper GI, Karolinska University Hospital, Stockholm, Sweden; [9]Department of Gastroenterology and Hepatology, Akademiska University Hospital, Uppsala, Sweden; [10]Department of Gastroenterology, Faculty of Medicine and Health, Orebro University, Orebro, Sweden; [11]Department of Clinical and Molecular Medicine, Gothenburg University, Gothenburg, Sweden; [12]Department of Health, Medicine and Caring Sciences, Linköping University, Linkoping, Linkoping, Sweden*
Email: imante.lasyte@ki.se

Background and aims: The rising prevalence of metabolic dysfunction-associated steatotic liver disease (MASLD), driven by the obesity epidemic, has made its co-occurrence with other primary liver diseases increasingly common. Primary sclerosing cholangitis (PSC) is a rare immune-mediated cholestatic liver disease, and there is a gap in research aiming to evaluate the prevalence and impact of liver steatosis in PSC. We aimed to evaluate the prevalence of liver steatosis in patients with PSC using controlled attenuation parameter (CAP) measurements, acquired during transient elastography.

Method: Patients with PSC were enrolled from an ongoing multicenter phase III study of simvastatin (PiSCATIN). Clinical, laboratory, liver MRI data, CAP and liver stiffness measurement (LSM) values (Fibroscan, Echosens, Paris, France) were collected at baseline. Liver steatosis was defined by a median CAP value of ≥254 dB/m, as validated by Steinman et al. in their study on CAP accuracy for detecting steatosis in autoimmune liver diseases. Baseline characteristics were compared between non-steatotic and steatotic patient groups using frequencies or median and IQR. The association between CAP values and these parameters was assessed with uni- and multivariable linear regression models. A 2-tail significance level of p < 0.05 was chosen.

Results: A total of 220 patients with valid CAP values were included, 153 (69.5%) males. The median CAP was 227 dB/m (IQR 80) with a point prevalence of liver steatosis (CAP ≥254 dB/m) of 29% (95% CI 23–35). Patients' age, sex, PSC type or duration did not differ significantly between steatotic and non-steatotic groups. In both groups the prevalence of IBD was 80%, IBD duration did not differ significantly. Median body mass index (BMI) was 24.1 kg/m² (IQR 5.3) in the non-steatotic group and 27.8 kg/m² (IQR 5.8) in the steatotic group, with fewer lean individuals (BMI <25) in the steatotic group (17% vs. 55%, $p < 0.05$). Cholesterol and triglyceride levels were higher ($p < 0.05$) in steatotic group, with medians of 5.5 mmol/L (IQR 1.25) and 1.2 mmol/L (IQR 0.7), compared to 5 mmol/L (IQR 1.6) and 0.9 mmol/L (IQR 0.45) in the non-steatotic group. The median LSM value was 6.9 kPa (IQR 5.3), with no significant association between CAP and LSM values ($p > 0.05$). Multivariable linear regression showed BMI, triglycerides, and diabetes independently associated with CAP ($p < 0.05$), but no significant association was found between CAP and MRI findings of advanced liver disease (e.g., liver deformity, ascites, spleen enlargement, and varices).
Conclusion: Although the potential importance of steatosis in PSC prognosis is yet to be determined, the prevalence of liver steatosis in patients with PSC was within the range expected in the general population. Higher BMI and plasma triglyceride levels, but not a more advanced disease stage, are associated significantly with higher CAP values.

THU-310

Pruritus is not a clinical feature of early-onset primary sclerosing cholangitis during late teenage years

Jeremy Nayagam[1], Samantha Campbell[1], Sophie Cant[2], Jenny Yerlett[2], Marianne Samyn[2], Deepak Joshi[1]. *[1]Institute of Liver Studies, King's College Hospital, London, United Kingdom; [2]Paediatric Liver, GI and Nutrition Centre, King's College Hospital, London, United Kingdom*
Email: j.nayagam@nhs.net

Background and aims: Primary sclerosing cholangitis (PSC) is a rare chronic liver disease which can present at any age, including during childhood, adolescence and early adulthood. Earlier age at diagnosis of PSC is often initially associated with overlapping autoimmune features and patients can develop a dominant biliary phenotype over time, although the natural history and symptom burden of subgroup is not well characterized. There are no licensed treatments for PSC, and in the United Kingdom the currently accessible clinical trial is for patients with PSC and severe pruritus. We sought to describe the prevalence of pruritus in early-onset PSC, and factors associated with pruritus.
Method: This was a single centre retrospective study of patients with PSC who attended our clinical service over a 1-year period. We included patients with PSC aged 16–28 years, and excluded patients who did not attend or who had undergone liver transplantation. We collected variables including demographics, clinical parameters, presence of pruritus, and blood tests.
Results: We identified 107 patients with PSC. There were 58 males (54.2%) and median age at appointment was 23.2 years (IQR, 20.2–25.8). The median age at diagnosis was 13.9 years (IQR, 10.4–17.3), and 78 (72.9%) had overlapping autoimmune features. Ursodeoxycholic acid (UDCA) was used in 71 (66.4%). Current pruritus was noted in 19 (17.8%) of the cohort: 2 (1.9%) were on rifampicin for pruritus, 1 (0.9%) was on a clinical trial for pruritus, no patients were on bezafibrate. Pruritus was reported in 0/13 patients aged 16–18, 8/48 (16.7%) aged 19–23, and 11/46 (23.9%) aged 24–28. Pruritus was more common in males (27.6% v 6.1%, $p = 0.004$) and in patients without overlapping autoimmune features (34.5% v 11.5%, $p = 0.006$). In patients with pruritus there was a trend towards older age at diagnosis (15.2 v 13.9 years, $p = 0.09$) and current age (24.8 v 23.1 years, $p = 0.08$). They had higher alkaline phosphatase (488 v 102, $p < 0.001$) and gamma glutamyl transferase (426 v 57, $p < 0.001$), but there was no difference in platelet count (261 v 277, $p = 0.73$).
Conclusion: In our cohort of patients with early-onset PSC, pruritus was not a significant symptom in patients in their late teenage years, but was more common during early adulthood. Pruritus was associated with biochemical markers of biliary damage, suggesting it develops in more advanced stages of cholangiopathy. Further work is required to fully characterize this subgroup of patients, and to discover therapeutic options to ideally prevent progressive cholangiopathy.

THU-311-YI

Uncovering novel therapeutic targets for autoimmune hepatitis (AIH): detection via omics integration and validation in proof-of-concept clinical trial

Yang Xu[1], Jan Philipp Weltzsch[1], Christoph Kilian[1], Babett Steglich[1], Christina Weiler-Normann[1], Michael Dudek[2], Laura Liebig[3], Johannes Hartl[1], Marcial Sebode[1], Joseph Tintelnot[1], Malte Wehmeyer[1], Silja Steinmann[1], Ida Schregel[1], Jenny Krause[1], Marius Böttcher[1], Ludwig J. Horst[1], Alena Laschtowitz[4], Maria Rosa Bono[5], Guido Rattay[1], Ruba Al Shonikat[1], Adrian Sagebiel[1], Jonas Wagner[1], Varshi Sivayoganathan[1], Christian Casar[1], Sören Alexander Weidemann[1], Ning Song[1], Nico Kaiser[1], Manuela Kolster[1], Christian F. Email: y.xu@uke.de

Background and aims: Standard immunosuppression for autoimmune hepatitis (AIH) is non-specific with corticosteroids as drug of choice for remission induction. An improved understanding of the underlying pathophysiology is needed and could enable a tailored therapeutic approach and avoid side effects associated with standard therapy. This study aims to provide insight into the inflammatory network by identifying key players and their interactions as well as to evaluate them in the clinical context of AIH.
Method: Liver biopsies from patients with AIH and PBC were analyzed by mRNA sequencing. Transaminase levels and histological features were correlated with gene expression. Key immune contributors of this inflammatory signature within AIH were further characterized by single cell and spatial sequencing. Functional validation was performed using ex vivo cytotoxicity assays. Results were further evaluated in the clinical context as part of a phase II, proof-of-concept trial, assessing the effect of infliximab, a monoclonal antibody targeting TNF, in patients with previously untreated AIH.
Results: In livers of patients with AIH, activated transcription factor modules such as NFKB1/STAT1, along with pathways like TNF, exhibit differential expression and correlate with transaminase levels and histological inflammation. Computational and functional analyses reveal that IL-15, produced by dendritic cells and macrophages, enhances the cytotoxic potential of liver-resident CD8+ T cells. This cytotoxic pathway is fully activated by TNF, secreted by clonally expanded tissue-resident CD4+ T cells. In AIH, hepatocytes increase the expression of adhesion molecules for CD8+ T cells and MHC class II molecules in response to TNF, rendering them vulnerable to damage from both CD8+ and CD4+ T cells, thereby sustaining the inflammatory cycle. Steroid-free blockade of TNF using infliximab in patients with previously untreated AIH markedly reduces serum ALT levels and liver stiffness, indicating an amelioration of the inflammatory activity in vivo.
Conclusion: This study provides a comprehensive and unique insight into the cellular and molecular basis of AIH pathogenesis. Targeting TNF, one of the key players identified, is a feasible therapeutic

alternative to corticosteroid-based standard therapy in patients with untreated AIH.

Clinical outcomes of primary sclerosing cholangitis associated with inflammatory bowel disease after liver transplantation: a systematic review and meta-analysis

Jiangrong Zhou[1], Dennis Sneek[1], Bettina E. Hansen[2], Caroline den Hoed[1,3], Marin de Jong[1], Qiuwei Pan[1], Adriaan J. van der Meer[1,3], Pengfei Li[1], Annemarie de Vries[1].
[1]Department of Gastroenterology and Hepatology, Erasmus MC, Rotterdam, Netherlands; [2]Department of Epidemiology and Biostatistics, Erasmus MC, Rotterdam, Netherlands; [3]Erasmus MC Transplant Institute, Erasmus MC, Rotterdam, Netherlands
Email: j.zhou.1@erasmusmc.nl

Background and aims: Primary sclerosing cholangitis (PSC) can recur after liver transplantation (LT), and its association with inflammatory bowel disease (IBD) adds complexity to clinical outcomes, given the variable course of IBD post-LT. This study aims to comprehensively estimate the incidence rates (IR) of key outcomes in PSC-IBD patients following LT, including recurrent PSC (rPSC), colorectal cancer (CRC) or high-grade dysplasia (HGD), bowel surgeries, IBD exacerbations, and newly diagnosed IBD.
Method: Online databases were searched from January 2000 till October 2024 for studies reporting on patients who underwent LT for PSC with IBD diagnosed either before or after LT. The pooled IR were calculated with the "meta" package (R Studio [V.4.2.764]) using a random effects model.
Results: Of 4,381 studies initially identified, 80 underwent full-text review, and 27 retrospective cohort studies were included in the meta-analysis. These cohorts reported on 3,425 patients underwent LT for PSC, of whom 65% had concomitant IBD at the time of LT. The mean follow-up period across studies ranged widely from 3 years to 17 years. The recurrence rate of PSC in PSC-IBD patients, based on data from 18 studies, was 30.8 cases per 1,000 person-years (95% CI 23.4–38.2), compared to 23.8 cases per 1,000 person-years (95% CI 8.6–39.1) in PSC-only patients from 7 studies. Though the recurrence rate was higher in PSC-IBD patients, the difference was not statistically significant ($p = 0.42$). A pooled analysis of 12 studies reporting on colorectal neoplasia in PSC-IBD patients post LT reported an overall IR of CRC/HGD of 6.1 cases per 1,000 person-years (95% CI 3.7–8.4). The rate of IBD clinical exacerbation, defined as worsening of IBD symptoms, increased inflammatory activity at endoscopy, or required optimization of IBD treatment post-transplantation, was 35.8 cases per 1,000 person-years (95% CI 22.7–48.9), though heterogeneity was high ($I^2 = 80\%$). The overall bowel surgery rate post-LT was 19.5 cases per 1,000 person-years (95% CI 16.1–22.9) within 17 studies. Additionally, 12 studies reported on newly diagnosed IBD in PSC patients without pre-existing IBD at LT, with pooled IR of 16.7 cases per 1,000 person-years (95% CI 10.4–22.9).
Conclusion: This meta-analysis reveals that the IR of rPSC is considerable among PSC patients with and without concomitant IBD. In patients with PSC-IBD, strict endoscopic surveillance post LT is indicated to mitigate the risk of CRC/HGD. Furthermore, PSC-only patients remain at risk of developing IBD after LT. These findings underscore the need for a tailored follow-up strategy involving both hepatologists and gastroenterologists to optimize care for PSC patients post-transplantation.

Treatment with elafibranor has no impact on bone health in patients with primary biliary cholangitis

Jörn M. Schattenberg[1], Pietro Andreone[2], Michael Heneghan[3], Cynthia Levy[4,5], Nuno Antunes[6], Darren Asquith[7], Valeria Cranham[8], Hugo Gomes da Silva[8], Marlyn J. Mayo[9]. *[1]Department of Internal Medicine II, Saarland University Medical Center, Homburg, Germany; [2]Medicina Interna Metabolica, Baggiovara Hospital, Azienda Ospedaliero-Universitaria di Modena and Università di Modena e Reggio Emilia, Modena, Italy; [3]Institute of Liver Studies, King's College Hospital NHS Foundation Trust, London, United Kingdom; [4]Division of Digestive Health and Liver Diseases, University of Miami School of Medicine, Miami, Florida, United States; [5]Schiff Center for Liver Diseases, University of Miami, Miami, Florida, United States; [6]Ipsen, Cambridge, Massachusetts, United States; [7]Ipsen, London, United Kingdom; [8]Ipsen, Boulogne-Billancourt, France; [9]Division of Digestive and Liver Diseases, University of Texas Southwestern Medical Center, Dallas, Texas, United States*
Email: valeria.cranham@ipsen.com

Background and aims: Patients (pts) with primary biliary cholangitis (PBC), a rare, cholestatic liver disease, have a higher risk of osteoporosis and fractures. Risk of fracture is noted for peroxisome proliferator-activated receptor agonists. We present bone mineral density (BMD) and bone serum biomarkers assessed to Week (Wk) 52 in the phase III ELATIVE® trial.
Method: In ELATIVE® (NCT04526665), 161 pts with PBC were randomised 2:1 to elafibranor 80 mg or placebo. The frequency of bone fractures was assessed. BMD was assessed by dual energy X-ray absorptiometry (DEXA) scan for the femoral neck, lumbar spine and total hip regions, reported as T scores. Bone turnover was assessed via two serum biomarkers: carboxy terminal crosslinked telopeptides of type 1 collagen (CTX), a marker of bone resorption, and type 1 procollagen peptide (P1NP), a marker of bone formation. Changes from baseline (CfB) in BMD T scores and CTX and P1NP levels were assessed to Wk 52.
Results: In total, 63, 64 and 59 pts receiving elafibranor and 27, 26 and 24 pts receiving placebo had baseline and Wk 52 BMD T scores for the femoral neck, lumbar and total hip regions, respectively. Distribution of BMD T scores at baseline suggested osteopenia and osteoporosis in both groups, particularly in patients who received elafibranor. Imbalances were also seen in the underlying medical history for osteoporosis (elafibranor: 19.4%; placebo: 3.8%) and osteopenia (elafibranor: 19.4%; placebo: 17.0%) for the overall trial population. No significant differences were seen in CfB of mean BMD T scores in the femoral neck and lumbar spine regions. A significant difference in CfB of BMD T scores in the total hip regions was seen between the elafibranor and placebo groups (Least Square [LS] means: elafibranor: 0.020; placebo: −0.305 $p = 0.0186$). Overall, 81 pts receiving elafibranor and 32 pts receiving placebo had baseline and Wk 52 CTX and P1NP data. An increase in CTX and a decrease in P1NP was observed in both groups; no meaningful between-group differences were reported for either marker. The increase in CTX in the elafibranor group was numerically smaller than in the placebo group (LS means difference vs placebo: −11.0 pg/mL [95% confidence interval (CI): −91.3; 69.3]; $p = 0.787$). The decrease in P1NP in the elafibranor group was numerically smaller than in the placebo group (LS means difference vs placebo: 3.5 µg/L [95% CI: −6.7; 13.7]; $p = 0.495$). Seven (6.4%) pts receiving elafibranor and no patients receiving placebo had bone fractures. Six of the pts with bone fractures had an associated accidental fall and all pts had a confounding medical history.
Conclusion: Biomarkers of bone turnover and rates of fractures in patients with PBC receiving elafibranor or placebo suggest that elafibranor has no negative impact on bone health. Elafibranor's efficacy and safety profile favours its use in the treatment of PBC.

THU-314

The Mayo-risk model predicts postsurgical transplant-free survival in patients with Primary sclerosing cholangitis

Johannes Chang[1], Mona Burtz[1], Leona Dold[1], Philipp Lutz[1], Hanno Matthaei[2], Steffen Manekeller[2], Christian Strassburg[1], Taotao Zhou[1], Tobias Weismüller[3]. *[1]University Hospital Bonn, Department of Internal Medicine I, Bonn, Germany; [2]University Hospital Bonn, Department of Surgery, Bonn, Germany; [3]Department of Gastroenterology, Vivantes Humboldt Hospital, Berlin, Germany*
Email: johannes.chang@ukbonn.de

Background and aims: Primary sclerosing cholangitis (PSC) is a devastating chronic liver disease. The pathogenesis is not fully understood and considered to be multifactorial. The Mayo-Risk Score (MRS) and Amsterdam-Oxford Score (AOS) have been established to estimate progression and outcome. Due to chronic inflammation in bile ducts and high prevalence of inflammatory bowel disease in PSC patients, risk of tumor development is high. Thus, surgery is often indicated in these patients. However, data on surgical risk and postsurgical outcomes with associated predictors are scarce.
Methods: In this single-cohort, retrospective study, 257 consecutive patients from 2004 to 2023 with PSC, treated in a specialized tertiary center for autoimmune liver diseases, were screened. 72 patients were identified that underwent a non-transplantation, surgical procedure. The time of index surgery was defined as baseline. Detailed data on surgery type, postoperative complications and follow-up were recorded. Primary endpoint was transplant-free survival. Predictors for outcome were assessed using cox regression. The whole cohort of 257 patients was then stratified in two propensity matched cohorts at the time of first diagnosis of PSC at our center; a cohort undergoing non-transplantation surgery at any time at follow-up within 5 years vs. a cohort without. Survival analysis was performed between the two cohorts.
Results: 72 patients were included into the analysis, 27 with liver cirrhosis. IBD was present in 80%. Most patients (82%) were treated with ursodeoxycholic acid. 60% received visceral procedures, with partial hepatectomies and cholecystectomies as predominant surgery types, followed by IBD associated surgery. Regression analysis revealed that cirrhosis was a strong predictor for postsurgical 1-year TFS. AOS (HR 3.59; 95% CI 1.88–6.87; $p \leq 0.001$) and MRS (HR 2.04; 95% CI 1.49–2.87, $p \leq 0.001$) were strongly associated to postsurgical TFS with excellent AUC in ROC-analysis (AOS: AUC 0.821 and MRS 0.896; $p \leq 0.001$ respectively) with MRS performing superior to AOS and MELD (AUC 0.824, $p \leq 0.001$). In the propensity matched cohorts, non-cirrhotic patients undergoing surgery at any timepoint within 5 years of first diagnosis did not have impaired survival vs. non-cirrhotic patients with no surgery at follow-up.
Conclusion: Cirrhosis is a strong predictor for postsurgical 1-year TFS in patients with PSC. Predictive scores in the context of PSC (MRS/AOS) excellently performed in predicting 1-year TFS, with the MRS performing superior to AOS and MELD. The use of MRS/AOS may be considered as predictors for preoperative risk stratification. If non-cirrhotic, patients with PSC receiving surgery seem not to have an impaired survival compared to PSC patients without any surgical procedure within 5 years.

Email: johannes.wiegand@medizin.uni-leipzig.de

Background and aims: In patients with primary biliary cholangitis (PBC) ursodeoxycholic acid (UDCA) treatment response is classified after 12 months by Paris II criteria (alkaline phosphatase (ALP) and aspartate-aminotransferase (AST) ≤1.5× upper limit of normal (ULN), with bilirubin <1 mg/dL). The German PBC registry recruited patients into sub-groups of UDCA adequate and inadequate Paris II responders. We analyzed how frequently clinical judgement and Paris II criteria aligned and how many cases were misclassified.
Method: Clinical judgement of UDCA treatment response was compared to formal assessment of Paris II criteria. Differences were tested by Fisher's Exact or Mann-Whitney U tests.
Results: Clinical judgement and formal definition differed in 48/383 (12.5%) cases: 4/130 (3.1%) were falsely classified as inadequate UDCA responders, 44/253 (17.4%) as adequate although being inadequate responders with ALP or AST levels > 1.5 × ULN in 57% and 23%, and bilirubin > 1 mg/dL in 28% after 12 months of therapy. Incorrectly classified responders occurred in 22/168 (13%) and 22/85 (26%) cases at academic and non-academic centers ($p = 0.014$). At non-academia, ALP levels at diagnosis were 3.6 ± 3.0 × ULN vs. 1.7 ± 0.9 × ULN in incorrectly vs. correctly classified responders ($p < 0.001$). They declined to 2.3 ± 1.2 × ULN vs. 0.9 ± 0.3 × ULN after 12 months of therapy ($p < 0.001$). Differences of minor extent were also observed for AST ($p = 0.029$ and 0.019) or bilirubin after 12 months of UDCA ($p = 0.031$). At academia, AST levels at diagnosis were 5.1 ± 9.2 × ULN vs. 2.4 ± 5.9 × ULN in incorrectly vs. correctly classified responders ($p = 0.008$). They declined to 1.2 ± 0.7 × ULN vs. 0.8 ± 0.2 × ULN after 12 months ($p = 0.001$). Bilirubin levels at diagnosis were 1.8 ± 3.3 × ULN vs. 0.9 ± 2.7 × ULN in incorrectly vs. correctly classified responders ($p < 0.001$). They declined to 1.2 ± 1.8 × ULN vs. 0.4 ± 0.2 × ULN ($p < 0.001$). No relevant differences in ALP levels were observed.
Incorrectly and correctly classified responders did not differ in terms of cirrhosis, transient elastography > 8 kPa, age <62 years at PBC diagnosis, or mean UDCA dosage after 12 months of therapy.
Conclusion: Clinical judgement of UDCA treatment response and Paris II criteria differ in a relevant proportion of cases, especially at non-academic centers. Higher baseline ALP levels and ALP kinetics may lead to assumption of adequate treatment response although Paris II criteria are formally not met.

Background and aims: Autoimmune liver diseases (AILDs) present significant management challenges, given their complex manifestations. Following our initial evaluation of Large Language Models (LLMs) in AILD management, which demonstrated promising but limited capabilities, we developed and assessed three specialized Retrieval-Augmented Generation (RAG) systems. They incorporated comprehensive clinical guidelines and medication safety information to enhance decision-support accuracy. Our aim was to evaluate the effectiveness of RAG-AI systems in providing evidence-based recommendations for AILD management.
Method: We engineered three RAG systems: HepaChat (customGPT from the OpenAI platform), RAG-ChatGPT (Model: gpt4o), and RAG-Claude (Model: claude 3.5 sonnet). Each system integrated 13 international clinical guidelines, including protocols from EASL, AASLD, AWMF, APASL, and BSG, spanning autoimmune hepatitis (AIH), primary biliary cholangitis (PBC), and primary sclerosing cholangitis (PSC) management. Additionally, we incorporated a comprehensive database containing 12,465 FDA medication warnings to ensure safety. Ten liver specialists (six European, four American) evaluated system responses to 56 standardized clinical questions using a 1–10 Likert scale. Questions addressed disease comprehension, therapeutic approaches, and clinical decision-making across all three major AILDs.
Results: Our analysis showed HepaChat's better performance (mean score 7.70 ± 1.37) with 35 best-rated responses, compared to RAG-ChatGPT (7.38 ± 1.51, 20 best-rated) and RAG-Claude (7.31 ± 1.44, 9 best-rated). Geographic stratification unveiled variations in evaluation patterns (Americas: 8.01 vs Europe: 6.79). Disease-specific analysis demonstrated HepaChat's suitability in AIH (Europe: 7.20, Americas: 8.33) and PSC (7.34 and 8.31, respectively), and AIH in America (8.42), only surpassed by RAG-ChatGPT for PBC in Europe (7.11 vs 7.01). All three systems showed marked advancement over conventional LLMs (2023 benchmark: 6.93 ± 1.53).
Conclusion: This study demonstrates that custom chatbots and RAG systems incorporating clinical guidelines could enhance AILD management. HepaChat's performance and accessibility through the OpenAI platform offers accessible support for healthcare providers in underserved communities; the use of chain-of-thought reasoning may explain its advantage over standard RAG architectures. Geographic variations in assessment highlight the importance of regional clinical perspectives in AI development. These findings establish a foundation for novel clinical support tools, potentially incorporating multi-modal data integration and specialized agent architectures. Future developments should focus on clinical workflow integration and adaptation to various healthcare settings while maintaining safety protocols.

THU-317-YI
The differential, but significant, burden of pruritus, fatigue, and sicca across cholestatic liver diseases

Kristel Leung[1], Rebecca Sole[2], Aisha Alawi[2], Bettina E. Hansen[3], Lauren Lapointe-Shaw[4], Aliya Gulamhusein[1], Gideon M. Hirschfield[2].
[1]Autoimmune and Rare Liver Disease Programme, University Health Network, University of Toronto, Toronto, Canada; [2]Autoimmune and Rare Liver Disease Programme, University Health Network, Toronto, Canada; [3]Erasmus Medical Center, Rotterdam, Netherlands; [4]Department of Medicine, University Health Network, Women's College Hospital, Toronto, Canada
Email: gideon.hirschfield@uhn.ca

Background and aims: Primary biliary cholangitis (PBC) and primary sclerosing cholangitis (PSC) are cholestatic liver diseases with a high symptom burden. We sought to explore symptom profiles and their associations.
Method: English-speaking adults with PBC or PSC at the Autoimmune and Rare Liver Disease programme in Toronto, Canada were prospectively recruited to self-administer electronic surveys on socioeconomic details, symptoms, and quality of life with clinic visits. Liver stiffness measurements by transient elastography as a disease stage surrogate were recorded. Surveys included the numeric rating scale (NRS), 5-D itch scale, visual analog fatigue scale (VAFS), modified fatigue impact scale (MFIS), and Primary Sjogren's Symptom Quality of Life (PSS-QoL). Comparisons were made with Kruskal-Wallis for continuous values and Chi-square/Fisher's Exact for categories. Spearman's rank (R) correlation coefficients were calculated.
Results: A total of 221 consented individuals completed baseline surveys (106 PBC [95% women], 115 PSC [62% men]). Daily itch (by NRS) was experienced by two-thirds of PBC and half of PSC respondents. More women experienced moderate-severe itch (24% women vs. 0% men in PBC; 23% women vs. 5.6% men in PSC, $p = 0.008$). Itch localization (by 5-D) differentially affected those with PBC compared to PSC. Moderate-severe fatigue affected 90% of women in both diseases, contrasting to 69% of PSC ($p = 0.022$) and 50% of PBC men ($p = 0.017$). Worse physical fatigue subscores (by MFIS) were seen in PBC than PSC; no differences were seen in cognitive or psychosocial subscores. No differences in itch or fatigue were noted amongst same gendered individuals stratified by disease. Moderate-severe Sjogren's symptoms (by PSS-QoL) was noted in 53% of PBC and 50% of PSC women; this contrasted to 0% of PBC ($p = 0.002$) and 26% of PSC men ($p = 0.036$). PSC men experienced higher Sjogren's symptom severity than PBC men ($p < 0.001$). Sicca was prevalent in PBC with skin (63%), eye (60%), and mouth dryness (58%). In PSC, sicca was common, with skin (47%), mouth (35%), and eye dryness (30%). Fatigue (by VAFS) and Sjogren's (by PSS-QOL) had the strongest correlation (R 0.68); itch (by NRS) and Sjogren's had moderate correlation (R 0.45), while itch and fatigue had weak correlation (R 0.32; $p < 0.001$ for all). Minimal to very weak correlations existed between symptom burden with household income, marital status, and education. Liver stiffness was weakly correlated with fatigue (by VAFS) (R 0.30, $p = 0.005$) and Sjogren's (by PSS-QoL) (R 0.34, $p = 0.001$) amongst PBC but not in PSC; there were no correlations with pruritus (by NRS).
Conclusion: Across cholestatic liver diseases, women experience higher symptom burden and severity than men. Fatigue and Sjogren' symptom scores are strongly correlated. Symptoms do not correlate with socio-economic status and are only weakly correlated with liver stiffness.

Epidemiological trends of autoimmune hepatitis in South Korea: a population-based study from 2010 to 2023

Kyung-Ah Kim[1], Hwa Young Choi[2]. [1]*Inje University Ilsan Paik Hospital, Goyang, Korea, Rep. of South;* [2]*Department of Cancer Control and Policy, Graduate School of Cancer Science and Policy, National Cancer Center, Goyang, Korea, Rep. of South*
Email: kakim@paik.ac.kr

Background and aims: The epidemiology of autoimmune hepatitis (AIH) has shown geographic and temporal variation. There are few longitudinal studies on the epidemiology of AIH in Korea. This study aimed to identify temporal trends in the epidemiology and outcomes of AIH in Korea from 2010 to 2023.
Method: We obtained data from the Korean National Health Insurance Service database and the Rare Intractable Disease Registry for AIH, identified by the International Classification of Diseases, 10th Revision code K75.4, from 2010 to 2023. We calculated the prevalence and incidence of AIH by age and sex, and analyzed temporal trends using Joinpoint regression.
Results: During 2010–2023, a total of 10,055 patients aged 20 years and older were newly identified with AIH (female-to-male ratio 5.3, mean age 59 years). The average age- and sex-adjusted incidence rate from 2010 to 2023 was 17.7 per million per year, and the annual incidence rate tended to increase with an average percent change of 6.5% until 2017, when it plateaued. During the COVID-19 pandemic, from 2020 to 2022, AIH incidence rates were stable. The increasing trend in AIH incidence was consistent among both sexes and in the 30+ age group, and was more pronounced in the 70+ age group. Age- and sex-adjusted prevalence rates increased from 92.3 per million population in 2010 to 284.8 in 2023, an average percent change of 10.8%. The increasing trend in AIH prevalence was more pronounced in those aged 70 years and older. The annual case-fatality ratio was 1.95%, significantly higher in men than women (2.72% vs 1.81%).
Conclusion: From 2010 to 2023, the average incidence of AIH was 17.7 per million per year, with an upward trend that has recently plateaued. The prevalence of AIH in South Korea has increased to 284.8 per million in 2023, which is comparable to the prevalence of AIH reported in Western countries.

THU-319

Sebepliase alfa improves lipid metabolism and liver outcomes in pediatric patients with lysosomal acid lipase deficiency

William Balistreri[1], Lorenzo D'Antiga[2], Jennifer Evans[3], Florian Abel[3], Don Wilson[4]. [1]*Cincinnati Children's Hospital Medical Center, Cincinnati, United States;* [2]*University of Milano–Bicocca, Hospital Papa Giovanni XXIII, Milan, Italy;* [3]*Alexion, AstraZeneca Rare Disease, Boston, United States;* [4]*Cook Children's Medical Center, Fort Worth, United States*
Email: william.balistreri@cchmc.org

Background and aims: Lysosomal acid lipase deficiency (LAL-D) is a lipid metabolism disorder that causes substantial liver damage. Children and adults with LAL-D present with dyslipidemia, indicated by abnormal low- and high-density lipoprotein cholesterol levels (LDL-C, HDL-C) and elevated serum alanine and aspartate aminotransferase (ALT, AST) levels. The aim of this analysis was to quantify baseline lipid and liver parameters in patients with LAL-D and examine if these values changed in patients treated with the LAL enzyme replacement therapy sebelipase alfa (SA).
Method: This observational analysis included patients enrolled in the International LAL-D Registry (NCT01633489) who were alive at enrollment, including a subset who were diagnosed with LAL-D before 18 years of age. Patients were included in the registry regardless of whether they were treated with SA. Patients were excluded if they started SA treatment at <6 months of age (indicating rapidly progressive LAL-D) or used lipid-modifying medications during the analysis period.
Results: A total of 310 patients were enrolled in the International LAL-D Registry. Of 99 patients included in the pediatric subset analysis, 88 were treated with SA. Among 71 patients with both lipid and liver results, 68 (96%) had abnormalities in both lipid and liver parameters at baseline. Median (interquartile range) baseline concentrations of LDL-C and HDL-C were 210 mg/dL (158, 236; n = 80) and 35 mg/dL (29, 44; n = 78), respectively. Among 83 patients with both ALT and AST results, 2 (2%) had both values within normal limits (WNL) and 72 (87%) had elevations in both measures at baseline. Among 86 patients with ALT results, 22 (26%) had ALT results > 3 × the upper limit of normal at baseline. Among treated patients with LDL-C results at baseline and at least one follow-up, median LDL-C concentrations were 212, 151, 179, and 169 mg/dL at baseline and 1, 2, and 3 years of follow-up, respectively. Median HDL-C concentrations improved continuously from 35 mg/dL at baseline to 42 mg/dL at 3 years. Sixty treated patients had ALT results at baseline and at least one follow-up measure. ALT levels were WNL in 3 of 60 (5%) patients at baseline and in 21 of 46 (46%) patients at 1 year, 19 of 51 (37%) patients at 2 years, and 16 of 45 (36%) patients at 3 years of follow-up; AST results were similar over time. Among treated patients, 66% reported ≥1 adverse events, most of which were mild or moderate. Fourteen patients experienced serious adverse events (SAEs), including one death (roadway accident). All SAEs were deemed unrelated to treatment.
Conclusion: Patients with LAL-D diagnosed before age 18 years had substantial signs of liver injury and dysregulation of lipid metabolism, with ~75% of patients meeting the LDL-C criterion of familial hypercholesterolemia. Treatment with SA may improve lipid metabolism (LDL-C, HDL-C) and parameters of liver injury (ALT, AST) in this population.

THU-320

Diagnostic distribution of patients positive for anti-mitochondrial antibodies (subtype), anti-sp100, and anti-gp210: pathological examination is necessary of PBC diagnosis: a retrospective study based on liver biopsy

Hongli Liu[1,2], Xing Liu[3], Yi-Fan Hu[4], Sha-Sha Li[5], Xi-Xuan Wang[1,2], Yi-Jun Bao[6], Yu Zhang[1,2,4], Li Wang[4], Zhi-Xiang Du[4], Miao-Yang Chen[4], Qing-Fang Xiong[4], Yan-Dan Zhong[4], Cai-Yun Zhang[3], Du-Xian Liu[7], Ping Huang[4], Wen-Quan Zeng[4], Min Ai[4], Kai Zhang[3], Yongfeng Yang[1,2,4,5]. Email: yangyongfeng@njucm.edu.cn

Background and aims: Primary biliary cholangitis (PBC) is the most common chronic cholestatic autoimmune disease with an increasing prevalence worldwide. Serum biomarkers including anti-mitochondrial antibodies (AMAs) AMA-M2, anti-gp210 and anti-sp100, are the classical diagnostic antibodies for PBC in clinic. However, these antibodies also exist in other autoimmune diseases, and antibodies-positive patients with transient elevations in alkaline phosphatase (ALP) are insufficient for PBC diagnosis. In this condition, pathological examination may be necessary for PBC diagnosis. The aim of this study is to explore the diagnostic distribution of antibodies-positive patients in the cohort of patients who underwent liver biopsy, especially those who did not meet the PBC diagnostic criteria at baseline according to APASL.

Method: A retrospective analysis was conducted at the Second Hospital of Nanjing, between January 2017 and December 2023. Patients (n = 745) underwent liver biopsy, and the relation of serum antibodies including AMA/AMA-M2, AMA-M4, AMA-M9, anti-gp210, and anti-sp100, and the final PBC diagnosis were examined.
Results: A total of 745 patients were included, and 780 liver biopsies performed in this study. Among them, 713 patients underwent a single biopsy (713 biopsies), and 32 patients underwent repeated biopsies (67 biopsies), including 29 patients with two biopsies (58 biopsies) and 3 patients with three biopsies (9 biopsies). The serum diagnostic distribution of patients positive for anti-mitochondrial antibodies (AMAs) and its subtypes (AMA-M2, AMA-M4, AMA-M9), anti-gp210, and anti-sp100 was analyzed. Among the single biopsy group, 562 patients (78.8%) were diagnosed with PBC, while 151 patients (21.2%) were non-PBC. In the repeated biopsy group, 58 of 67 biopsies (corresponding to 30 patients) confirmed PBC, while 9 biopsies (corresponding to 5 patients) identified as non-PBC. Among these, 3 non-PBC patients were later diagnosed with PBC during follow-up after repeated biopsies. Overall, 592 patients (79.4%) were diagnosed with PBC after liver biopsy, including 4 patients confirmed during follow-up. Analysis of antibody distribution among the 780 liver biopsies showed 526 AMA-positive cases, 491 AMA-M2-positive cases, 241 anti-gp210-positive cases, 188 anti-sp100-positive cases, 9 AMA-M4-positive cases, and 5 AMA-M9-positive cases. Among non-AMA/AMA-M2/AMA-M4/AMA-M9-positive patients (148 cases), 40 were anti-gp210-positive (14 non-PBC, 2 later diagnosed as PBC during follow-up), and 77 were anti-sp100-positive (39 non-PBC). All 5 cases with dual positivity for anti-gp210 and anti-sp100 were diagnosed with PBC, while all 4 cases with triple positivity for AMA, anti-gp210, and anti-sp100 were non-PBC.
Conclusion: Antibody positivity alone is insufficient for PBC diagnosis. Comprehensive evaluation, including liver biopsy pathology, alkaline phosphatase levels, and other clinical indicators, is essential to avoid misdiagnosis.

Real-world assessment of standard of care trends in primary biliary cholangitis and cholestatic pruritus in Europe

Kaitlin Hagan[1], Lina Titievsky[1], Atif Adam[2], James Brash[2], Petter Egger[2], Frank Tacke[3], Christophe Corpechot[4], Marco Carbone[5], Alexander Cobitz[1], Anna Halliday[6], Megan McLaughlin[1]. *[1]GSK, Collegeville, PA, United States; [2]IQVIA LTD, London, United Kingdom; [3]Charité - Universitätsmedizin Berlin, Berlin, Germany; [4]Hôpital Saint-Antoine, Paris, France; [5]University of Milano-Bicocca, Milan, Italy; [6]GSK, London, United Kingdom*
Email: kaitlin.a.hagan@gsk.com

Background and aims: Primary biliary cholangitis (PBC) is a chronic, progressive liver disease characterised by the immune-mediated destruction of intrahepatic bile ducts, leading to cholestasis and subsequent liver fibrosis. One of the most challenging and distressing symptoms experienced by patients with PBC is pruritus, which affects up to 89% of patients and is clinically significant in up to 53% of patients. Despite the prevalence of pruritus and its significant impact on patients' quality of life, it is often undertreated. There are limited real-world data from Europe regarding the use of medications for cholestatic pruritus. This study assessed the use of medications related to PBC and cholestatic pruritus among patients with PBC in France, Germany, Italy and Spain from 2015 to 2023/4.
Method: This study was a multinational retrospective study of patients (>18 years) with PBC using existing electronic medical record data from France, Germany, Italy and Spain. All databases were standardised to the Observational Medical Outcomes Partnership (OMOP) Common Data Model. Patients with PBC were identified based on two or more diagnosis codes for PBC on separate clinical visits within a 1-year period. We evaluated prescriptions for PBC-specific therapies (ursodeoxycholic acid [UDCA], obeticholic acid [OCA], fibrates) and guideline-suggested medications for cholestatic pruritus (cholestyramine, rifampicin, oral opiate antagonists, selective serotonin reuptake inhibitors [SSRIs], gabapentin). All analyses were descriptive, and results are reported overall and stratified by country.
Results: Overall, 2612 patients with PBC were identified (France: 583; Germany: 891; Italy: 752; Spain: 386). Mean age at baseline was 63.1 years and 83.5% of the cohort was female. Documented pruritus was present in 2.3% of patients. Most patients (85.2%) had a prescription for UDCA over the study period; there was a declining trend in UDCA prescriptions over the years across all countries, most pronounced in Germany (92.1%– 66.7%). Few patients reported OCA (<2%) or fibrates use (6.7%). Use of guideline-suggested antipruritic medications across all countries over the study period was low (cholestyramine 4.9%; rifampicin 0.8%; oral opiate antagonists <1%; SSRIs 12.1%; gabapentin 2.7%).
Conclusion: These analyses, based on a typical cohort of patients with PBC, demonstrate low real-world usage of guideline-suggested therapies for cholestatic pruritus. The proportion of patients with documented pruritus was low, suggesting underreporting of this symptom. Given that prior literature shows that most patients with PBC experience pruritus at some point in their disease, a considerable proportion of patients are not receiving guideline-suggested pruritus therapies. This underscores a clear unmet patient need for licensed treatments to address cholestatic pruritus in PBC.

The risk of psychiatric disorders in patients with autoimmune hepatitis: a nationwide registry-based follow-up study

Lisbet Groenbaek[1,2], Thomas Damgaard Sandahl[2], Peter Jepsen[2,3]. *[1]Department of Medicine, Regional Hospital Horsens, Horsens, Denmark; [2]Department of Hepatology and Gastroenterology, Aarhus University Hospital, Aarhus, Denmark; [3]Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark*
Email: lisbet.groenbaek@clin.au.dk

Background and aims: Patients with autoimmune hepatitis (AIH) may have impaired quality of life and symptoms of depression and anxiety. Little is known about the long-term risk for psychiatric disorders. We conducted a population-based follow-up study on the risk of psychiatric disorders in patients with AIH and compared with the general population.
Method: From nationwide registries we identified all Danish patients diagnosed with AIH, 1994–2022, and matched population comparators. Based on hospital diagnoses and medical prescription data, we estimated the prevalence of psychiatric disorders at AIH diagnosis. Patients and comparators were followed through 2022, and we compared the risk of subsequent diagnoses of psychiatric disorders.
Results: We included 1371 patients with AIH and 13,556 comparators with a median age of 54 years at AIH diagnosis. In the patients with AIH, 207 developed a psychiatric disorder during 13,798.6 years of follow-up (median follow-up: 8.8 years). One third of these patients developed more than one psychiatric disorder. The absolute risk for overall psychiatric disorders was 12.4% (95% confidence interval [CI] 10.6–14.4) 10 years after AIH diagnosis. Depressive and anxiety disorders comprised the highest 10-year risk of 11.4% and 3.6%, respectively, and the same pattern applied to comparators. The overall 10-year risk of psychiatric disorders was similar in patients and comparators with an adjusted relative risk of 1.0 (95% CI 0.7–1.6), and this was the case for all psychiatric disorders.
Conclusion: This nationwide study showed that the risk for psychiatric disorders was similar in patients with AIH and in population comparators.

THU-323

A larger decline of IgG after initiation of treatment in patients with AIH is associated with complete biochemical response despite having normal baseline IgG levels

Lorenz Grossar[1], Sarah Raevens[2], Anja Geerts[3], Christophe Van Steenkiste[4], Isabelle Colle[5], Charlotte De Vloo[6], Hans Orlent[7], Jeoffrey Schouten[8], Marie Gallant[9], Annelien Van Driessche[10], Hans Van Vlierberghe[2], Xavier Verhelst[2]. *[1]Ghent University Hospital, Department of Internal Medicine and Paediatrics, Liver Research Center Ghent, Ghent University, Ghent, Belgium; [2]Ghent University Hospital, Department of Gastroenterology and Hepatology, Liver Research Center Ghent, Ghent University, Ghent, Belgium; [3]Ghent University Hospital, Department of Gastroenterology and Hepatology, Ghent, Belgium; [4]AZ Maria Middelares, Department of Gastroenterology and Hepatology, University hospital Antwerp, Ghent, Belgium; [5]ASZ Aalst, Department of Gastroenterology and Hepatology, Aalst, Belgium; [6]AZ Delta, Department of Gastroenterology and Hepatology, Roeselare, Belgium; [7]AZ Sint-Jan, department of Gastroenterology and Hepatology, Brugge, Belgium; [8]VITAZ, Department of Gastroenterology and Hepatology, Sint-Niklaas, Belgium; [9]Jan Ypermanziekenhuis, Department of Gastroenterology and Hepatology, Ieper, Belgium; [10]AZ Glorieux, Department of Gastroenterology and Hepatology, Ronse, Belgium*
Email: lorenz.grossar@ugent.be

Background and aims: A minority of patients with autoimmune hepatitis (AIH) present without elevation of immunoglobulin G (IgG) levels at diagnosis. The International Autoimmune Hepatitis Group (IAIHG) consensus criteria define complete biochemical response (CBR) as normalisation of both transaminases and IgG within the first six months of treatment, and this intermediate endpoint correlates with superior liver-related survival. In AIH patients presenting without elevation of IgG at diagnosis, determination of CBR thus mainly relies on normalisation of transaminases alone. We aimed to investigate differences in IgG evolution under immunosuppression according to biochemical response status.
Method: We investigated the evolution of IgG values at baseline before treatment and after 6 months of treatment in subjects with IgG within normal range at diagnosis, from a multicentric cohort in Belgium consisting of one tertiary care centre and seven secondary care centres. Mean differences of IgG at baseline versus after 6 months of treatment were then compared between subjects attaining CBR and those with insufficient response (IR).
Results: Out of 213 AIH patients in our cohort, 49 (23.0%) presented without IgG elevation at presentation. No difference was recorded between this group and the rest of the cohort in terms of baseline demographic and biochemical variables except for IgG. In the subgroup without IgG elevation, mean IgG value at baseline was 12.15 (±2.38) g/L. Thirty-five subjects (71.4%) achieved CBR and showed a mean IgG decline after six months of 2.43 (±2.57) g/L, whereas the remaining fourteen subjects demonstrated a mean IgG decline of 0.24 (±3.46) g/L ($p = 0.019$).
Conclusion: We demonstrate that AIH patients without IgG elevation at diagnosis achieving CBR have a substantially larger IgG decline after six months of treatment. Further investigation of this finding in larger studies of this particular subset of AIH patients could elucidate the value of IgG decline and its potential relationship to survival endpoints.

Background and aims: Steatotic liver disease (SLD) affects over one-third of the global population. The controlled attenuation parameter (CAP) by vibration-controlled transient elastography (VCTE) is a reliable measure to assess the presence of SLD. Elevated alkaline phosphatase (ALP) is associated with more advanced fibrosis in patients with SLD and primary biliary cholangitis (PBC). This international multicentre study aimed to determine whether SLD can influence treatment response and clinical outcomes in patients with PBC.
Method: From an international registry of the GLOBAL PBC, 820 patients with at least one CAP value were retrospectively analyzed. SLD was defined as CAP≥280 dB/m. Patients with prior liver transplantation (LT) or hepatocellular carcinoma (HCC) were excluded. The biochemical response was based on conventional criteria (Paris-2, Toronto, GLOBE score), and the deep response was defined as normal ALP and Bilirubin<0.6xULN. The influence of SLD on clinical outcomes (hepatic decompensation (HD), HCC, LT or death) was estimated using Cox regression analysis, allowing for non-linear associations with restricted cubic splines.
Results: Among the patients included, 729 were females (88.9%), the mean age was 61.6 ± 12.0 years, and 186 (22.7%) had SLD. Patients with SLD had a higher BMI (31.7 ± 6.4 vs. 25.6 ± 5.0 kg/m^2, p < 0.001) and higher frequencies of diabetes mellitus (25.8% vs. 7.9%, p < 0.001) and hypertension (45.8% vs 26.8%, p < 0.001). Patients with SLD had similar liver stiffness measurement (LSM, 13.7 ± 14.5 vs. 11.4 ± 12.1, p = 0.073) and frequency of cirrhosis by VCTE (LSM≥14.0 kPa, 24.5% vs. 19.0%, p = 0.129), but had lower FIB-4 and APRI scores (1.6 ± 1.3 vs. 2.1 ± 1.9, p = 0.001, and 0.52 ± 0.48 vs. 0.72 ± 0.99, p < 0.001, respectively) compared to those without SLD. A higher proportion of patients with SLD achieved treatment response according to Paris-2 (62.9% vs 47.1%, p = 0.001), and Toronto criteria (70.8% vs 53.5%, p < 0.001), GLOBE score (79.0% vs. 69.6%, p = 0.032), ALP normalization (43.8% vs 30.6%, p = 0.001), and deep response (30.2% vs 17.0%, p < 0.001). Over a median follow-up of 7.6 ± 6.4 years, 6.0% (n = 49) developed HD, 0.2% (n = 2) HCC, 2.0% (n = 16) required a LT and 3.9% (n = 32) died. SLD was not associated with a higher risk of HD (HR 0.26, 95%CI 0.06–1.18, p = 0.082) or need for LT and mortality (HR 0.85, 95%CI 0.41–1.75, p = 0.654).
Conclusion: In PBC patients, the presence of SLD evaluated with CAP by VCTE is common but does not seem to have a negative impact on response to treatment and clinical outcomes. Future studies with a larger sample size are warranted.

Email: marco.carbone@unimib.it

Background and aims: Sclerosing cholangitis is a chronic cholestatic biliary disease, characterised by inflammation and fibrosis of the bile ducts, stricture formation and progressive destruction of the biliary tree leading to biliary cirrhosis. It may be primary (immune-mediated) or secondary to a variety of insults. Diagnostic uncertainty between the aetiology can impact on cancer surveillance, clinical trial validity, and patient outcomes. This study aimed to develop and validate a clinical diagnostic model to help differentiate PSC from SSC.
Method: Retrospective review of 388 adult clinical case records with sclerosing cholangitis. Derivation cohort from three tertiary liver centres in Italy; validation cohort from one tertiary centre in the UK. Patients were classified as PSC or SSC according to EASL guidelines. We performed a multivariate logistic regression analysis in the derivation cohort to identify predictors of PSC diagnosis and validated it in the external cohort.
Results: In the derivation cohort of 244 patients (159 PSC and 85 SSC), six variables were associated with an increased likelihood of PSC over SSC. These were younger age (p < 0.0001), presence of IBD (p < 0.0001), no history of abdominal surgery (p < 0.0001), absence of pancreatic involvement (p = 0.0508), presence of autoimmune comorbidities (p = 0.0393), and a family history of autoimmune diseases (p = 0.0202). The variables were used to develop a predictive model for PSC diagnosis (PSC-DM) with an area under the receiver operating characteristic curve (AUROC) of 0.98 (95% confidence interval (CI) 0.97–0.99). In the external cohort of 144 patients (99 PSC and 45 SSC), the AUROC of the model was 0.95 (95% CI 0.92–0.98).
Conclusion: We derived and externally validated a model based on routinely available clinical parameters that accurately discriminate between patients with PSC and SSC. This would enhance patient's referral, tailored management and appropriate selection for clinical trials.

Email: magdalena.salcedo@salud.madrid.org

Background and aims: Primary Sclerosing Cholangitis (PSC) is a rare immune-mediated liver disease strongly associated with inflammatory bowel disease (IBD) and exhibiting a higher prevalence in men. Unlike other autoimmune liver disorders, there is a lack of updated, gender-specific epidemiological and clinical data on PSC in Spain. Additionally, prior studies suggest that the association between PSC and IBD in Spain may be weaker compared to northern Europe. Aims: To compare the epidemiological and demographic characteristics, IBD association, and clinical progression of PSC between men and women in Spain.
Method: This observational, cross-sectional, multicenter study included prevalent cases of PSC across 47 Spanish hospitals. A total of 697 patients were analyzed using anonymized surveys and data from the Spanish Registry of Cholestatic and Immune Liver Diseases (COLHAI).
Results: The cohort included 697 PSC patients, of whom 428 were men (61.4%) and 269 were women (38.6%), with median current ages of 50.3 and 53.6 years, respectively. Among them, 458 (65.8%) had IBD (50% ulcerative colitis, 13.5% Crohn's disease, and 2.4% indeterminate colitis). Diagnosis of IBD preceded PSC in 52.5% of cases, occurred simultaneously in 32.7%, and followed PSC in 14.7%, with no gender-based differences. PSC was diagnosed at a younger mean age in patients with IBD compared to those without (37.7 vs. 46.2 years; $p < 0.001$). Men reported a higher frequency of active alcohol consumption (9.7% vs. 1.5%, $p < 0.001$). At diagnosis, jaundice was more common in men (24.1% vs. 16.8%; $p = 0.03$), whereas fatigue was more frequent in women (25% vs. 15.9%; $p = 0.04$). No significant differences were observed in cholestasis, pruritus, or other digestive symptoms. IBD prevalence was significantly higher in men (70.6% vs. 58.2%, $p < 0.001$). Hepatic decompensation (ascites, encephalopathy, or upper gastrointestinal bleeding due to portal hypertension) occurred more frequently in men than in women (13.8% vs. 7.1%; $p = 0.006$), although the time from PSC diagnosis to decompensation did not differ significantly (7.35 years for men vs. 9.5 years for women). Approximately 14.6% of patients experienced cholangitis, with no gender-based differences. During follow-up, 133 patients underwent liver transplantation (95 men and 38 women; 22.2% vs. 14.1%, $p = 0.01$), with a comparable mean time from PSC diagnosis to transplantation (9.4 years in men vs. 8.7 years in women; p = NS).
Conclusion: This study highlights significant gender differences in the clinical course of PSC, with men exhibiting a worse prognosis, higher risk of complications, and greater need for liver transplantation. These findings underscore the importance of considering gender in risk stratification and management of PSC and emphasize the need for longitudinal studies to further investigate gender-based differences in disease progression.

Email: mar.riveiro@vallhebron.cat

Background and aims: data on safety and efficacy of third-line therapies for autoimmune hepatitis (AIH) is scarce. Recently, results from patients treated with rituximab or infliximab have been published, but the number of cirrhotic patients was limited, despite the fact that 1/2 of children and 1/3 of adults have cirrhosis at AIH diagnosis. Our aim was to analyse the impact of rituximab treatment in cirrhotic patients with AIH.
Method: retrospective study that included all patients from the ColHai registry and IAIHG hospitals with AIH diagnosed by biopsy (simplified criteria ≥6), who had cirrhosis and received rituximab. Biochemical response (BR) was defined as normal AST and ALT, and complete biochemical response (CBR) if IgG was also normal.
Results: 29 cirrhotic adults from 12 hospitals were included, 24 (82.8%) were women with a median age of 46 (IQR 33–61) years, 26 AIH and 3 AIH variants (1 PBC and 2 PSC). Criteria for rituximab was: 24 (82.8%) refractory AIH, 3 (10.3%) intolerance to prior treatments and 2 (10%) concomitant systemic/haematological disorder. Nineteen (65.5%) patients had cirrhosis at diagnosis and 10 developed cirrhosis during follow-up (FU). At the start of rituximab, 4 (14.2%) patients were decompensated, 20 (69.0%) had signs of portal hypertension, including 5 (17.2%) with oesophageal varices. Overall, MELD score was 10 (7–13). Only 2 (6.9%) patients achieved CBR before starting rituximab that was prescribed due to a concomitant disorder. After rituximab, 22 (75.9%) patients achieved CBR within a median time of 8 (IQR 3–13) months. Seven out of 22 (31.8%) patients who achieved CBR presented ≥1 flare, with no cases of ACLF. However, 1 (3.4%) patient required liver transplantation due to decompensation. Flares were managed by increasing or restarting corticosteroids and in 4/7

patients a new cycle of rituximab. Overall, 4 (14.8%) patients developed adverse reactions, 11 (37.9%) infections, and 2 (7.1%) skin tumours. Two (6.9%) patients died due no-related liver causes.
The majority of patients (24, 85.7%) underwent periodical doses of rituximab. Median doses of rituximab were 2 (1–5). Rituximab was associated with a reduction in corticosteroid doses in 20 (71.4%) patients and suspension of ≥1 immunosuppressant in 13 (46.5%). Median FU was 23 (13–37) months. At last FU, 15 (51.7%) patients were still on rituximab, 21 (72.4%) in BR, and 15 (55.2%) in CBR. The comparison between pre-rituximab and last FU showed an improvement in all liver tests, including a significant improvement in MELD score (10.8 vs 8.8, p = 0.006).
Conclusion: rituximab is an effective treatment for AIH cirrhosis with 3 out of every 4 patients achieving CBR. Besides, its use is associated with an improvement in liver functions tests, including MELD. AIH flares were not associated with any case of ACLF, and managed with corticosteroids and new doses of rituximab.

Email: marlenepadillamd@gmail.com

Background and aims: Baveno VII (BVII) guidelines recommend performing endoscopy for variceal screening in patients intolerant or with contraindications to beta-blockers, and liver stiffness (LS) ≥20 kPa, platelet count ≤150,000, or splenic stiffness (SS) ≥40 kPa. However, these criteria have not been validated in patients with autoimmune hepatitis (AIH) or primary biliary cholangitis (PBC). This study aimed to evaluate the ability of SS and the BVII criteria in predicting varices needing treatment (VNT) in AIH and PBC patients.
Method: This multicenter, cross-sectional study included 70 AIH and 45 PBC patients with cirrhosis, confirmed by liver biopsy and/or ultrasound (nodular margins and/or signs of portal hypertension). All patients underwent LS and SS measurement using Fibroscan®. Laboratory and endoscopic data (±12 months) were collected. Sensitivity (S), specificity (Sp), and accuracy (AUC) of BVII criteria and SS in predicting VNT were analyzed, along with the false-negative rate (FNR), which represents the percentage of missed VNT cases.
Results: Most patients were female (PBC 87%; AIH 71%), with median ages of 66 years (IQR 58–75) for PBC and 63 years (IQR 53–70) for AIH and were in biochemical response at SS measurement (PBC 66%; AIH 77%). In PBC patients, median LS and SS were 15 kPa (IQR 11–24) and 42 kPa (IQR 32–57), respectively. Eleven patients (24%) had VNT, with a median LS and SS of 16 kPa and 62 kPa, respectively. BVII criteria showed moderate accuracy in predicting VNT (AUC 0.66; S 100%; Sp 32%; FNR 0%). Among the BVII components, platelet count (AUC 0.86; S 100%; Sp 41%; FNR 0%) outperformed LS (AUC 0.68; S 36%; Sp 65%; FNR 12%). SS (AUC 0.87; S 100%; Sp 56%; FNR 0%) showed better predictive ability than BVII but was comparable to platelets. Combining platelets and SS yielded the best predictive capacity (AUC 0.94; S 100%; Sp 71%; FNR 0%). In AIH patients, median LS and SS were 10 kPa (IQR 7–14) and 32 kPa (IQR 26–41). Thirteen patients (19%) had VNT, with median LS and SS in these patients being 15 kPa and 43 kPa, respectively. BVII criteria showed good accuracy in predicting VNT (AUC 0.86; S 92%; Sp 65%; FNR 8%), mainly due to the strong predictive capacity of platelet count (AUC 0.88; S 92%; Sp 70%; FNR 8%). In contrast, LS and SS showed moderate predictive capacities with AUCs of 0.76 (S 38%; Sp 88%; FNR 14%) and 0.75 (S 66%; Sp 77%; FNR 10%), respectively. Adding SS to the platelet count did not enhance its predictive capacity (AUC 0.90; S 54%; Sp 88%; FNR 11%).
Conclusion: AIH patients with VNT had lower LS and SS values than PBC patients. BVII criteria effectively predicted VNT in patients with PBC and AIH. However, in PBC, the combination of platelet count ≤150,000 and SS ≥40 kPa provided excellent accuracy and enhanced BVII criteria for predicting VNT. In AIH, a platelet count ≤150,000 was the most reliable predictor of VNT, outperforming SS, LS, and BVII criteria, which showed low sensitivity and higher FNR.

Email: marlyn.mayo@utsouthwestern.edu

Background and aims: Primary biliary cholangitis (PBC), a rare cholestatic liver disease, causes progressive biliary fibrosis. Liver stiffness measurements (LSM) and Enhanced Liver Fibrosis (ELF) are non-invasive tests (NITs) for fibrosis. The phase III ELATIVE® trial (NCT04526665) assessed elafibranor, a peroxisome proliferator-activated receptor (PPAR) agonist exerting effects on PPAR alpha

and delta, in patients (pts) with PBC. PPAR alpha activation has been associated with positive effects on fibrosis. LSM and ELF in pts treated with elafibranor and placebo in ELATIVE® to 52 weeks have been reported previously. Here, we assess the effect of elafibranor on NITs for fibrosis and biochemical markers in ELATIVE® to Week 104; NITs are also stratified by disease stage.

Method: In pts with LSM and ELF from baseline (BL) to Wk 104, proportions of pts with LSM > 8 kPa and > 10 kPa and changes ≥0.5 kPa, and ELF ≥7.7 and ≥9.8 and changes ≥0.19, were assessed at visits to Wk 104. LSM and ELF changes were assessed in early and advanced stage disease; advanced disease was defined as BL LSM > 10 kPa and/or advanced fibrosis/cirrhosis on histology. Changes from BL (CfB) to Wk 104 were assessed for alkaline phosphatase (ALP), total bilirubin (TB), albumin (ALB), alanine aminotransferase (ALT), aspartate transaminase (AST) and gamma-glutamyl transferase (GGT).

Results: At data cutoff, 48 pts receiving elafibranor in ELATIVE® had LSM and 41 had ELF from BL to Wk 104. LSM increased and decreased by ≥0.5 kPa in similar proportions of pts across study visits to Wk 104 (36.2–40.0% and 42.6–47.9%). A consistent proportion of patients had LSM > 8 kPa and > 10 kPa from BL (54.2% and 33.3%) to Wk 104 (50.0% and 29.2%). Of the 16 pts with LSM > 10 kPa at BL, 6 (37.5%) had LSM ≤10 kPa at Wk 104; of the 32 with LSM ≤10 kPa at BL, 4 (12.5%) had LSM > 10 kPa at Wk 104. ELF increased and decreased by ≥0.19 in similar proportions of pts across visits to Wk 104 (24.4–41.5% and 32.5–41.5%). All pts had ELF ≥7.7 at every visit. Comparable proportions of pts had ELF ≥9.8 at BL and Wk 104 (48.8% vs 39.0%). At Wk 104, in pts with early stage disease, LSM increased and decreased by ≥0.5 kPa in 35.5% and 45.2% of pts, and ELF increased and decreased by ≥0.19 in 44.4% and 37.0% of pts. In pts with advanced stage disease, LSM increased and decreased by ≥0.5 kPa in 47.1% and 52.9%, and ELF increased and decreased by ≥0.19 in 35.7% and 50.0% of pts. In pts with LSM, mean CfB in ALP and GGT to Wk 104 were −124.0 U/L and −25.1 U/L, respectively. In pts with ELF, CfB in ALP and GGT to Wk 104 were −116.9 U/L and −22.8 U/L, respectively. TB, ALT, AST and ALB were relatively stable in both subsets. Elafibranor was well-tolerated in this subset to Wk 104, consistent with the overall safety profile in ELATIVE®.

Conclusion: With two years of elafibranor treatment, predictors of liver fibrosis and key biochemical markers remain stable in pts with PBC, including those with advanced stage disease.

THU-334

Cholestasis as a predictor of PSC in inflammatory bowel disease: insights from a romanian cohort study

Matei Mandea[1,2], Dragos Oancea[3,4], Razvan Iacob[5,6], Speranta Iacob[4,5], Mihaela Ghioca[3], Cristian Gheorghe[3], Liana Gheorghe[3]. *[1]Fundeni Clinical Institute, Gastroenterology and Hepatology Clinic, Carol Davila University of Medicine and Pharmacy, Department of Internal Medicine, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Department of Internal Medicine, Bucharest, Romania; [3]Gastroenterology and Hepatology clinic, Fundeni Clinical Institute, Bucharest, Romania; [4]Department of Internal Medicine, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [5]Gastroenterology and Hepatology clinic, Fundeni Clinical Institute, Bucharest, Romania, Bucharest, Romania; [6]Department of Internal Medicine, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, Bucharest, Romania*
Email: matei.mandea@drd.umfcd.ro

Background and aims: Primary sclerosing cholangitis (PSC) and inflammatory bowel diseases (IBD) often coexist, with PSC prevalence in IBD patients ranging from 3–8%. Approximately 80% of PSC patients also have IBD. Thus, chronic cholestasis in an IBD patient necessitates further investigation. The study aimed to evaluate the significance of cholestasis syndrome in patients with IBD.

Method: We conducted a retrospective study at Fundeni Clinical Institute, evaluating 3,767 patients suspected of ulcerative colitis (UC) or Crohn's disease (CD) from 2011 to 2022. Of these, 1,386 had confirmed UC, and 1,116 had confirmed CD. PSC was diagnosed in 1.37% (19) of UC patients and 1.34% (15) of CD patients. Data included IBD type, disease severity, extent, treatment, age at IBD and PSC diagnosis, liver disease presence, biochemical cholestasis (ALP > 120 U/L or GGT > 55 U/L), and MRCP performance.

Results: Biochemical cholestasis was observed in 14.4% of IBD patients, with mean ALP levels of 142 U/L in UC and 187 U/L in CD, and mean GGT levels of 121 U/L in UC and 125 U/L in CD. Among these, 65% of UC patients and 78% of CD patients underwent MRCP for PSC diagnosis/exclusion. Liver disease was present in 21% of cholestatic UC patients and 47.8% of cholestatic CD patients. Diagnoses included cholangiocarcinoma (3.2%), hepatocellular carcinoma (3 patients), PSC (9%), primary biliary cholangitis (2 patients), and liver cirrhosis (9%). Mean ALP and GGT levels were significantly elevated in PSC patients compared to cholestatic non-PSC patients (mean ALP: 308.8 U/L vs. 144.2 U/L, $p < 0.001$; mean GGT: 243 U/L vs. 108.4 U/L, $p < 0.001$). In the PSC-UC group, 15 of 19 patients had pancolitis (Montreal classification E3), 3 had left-sided colitis (E2), and 1 had proctitis (E1). Severe disease activity was observed in 2 patients, with 3 requiring biologics. Among PSC-CD patients, 11 of 15 exhibited severe disease activity, and 9 required biologic treatment.

Conclusion: Cholestasis in IBD patients does not always indicate PSC, as other liver diseases may be involved. The phenotypic characteristics of this cohort displayed some variation compared to published data. This is the largest monocentric study in Romania examining IBD patients for PSC diagnosis. PSC prevalence in our long-term IBD cohort was lower than expected. PSC patients exhibited ALP and GGT levels exceeding twice the upper normal limit.

CM-101 impacts disease biomarkers in primary sclerosing cholangitis: assessment of the SPRING study pharmacokinetics and pharmacodynamics

Matthew Frankel[1], John Lawler[1], Ilan Vaknin[1], Adi Mor[1]. *[1]Chemomab Therapeutics Ltd, Tel Aviv, Israel*
Email: adi.mor@chemomab.com

Background and aims: CM-101, a novel monoclonal antibody targeting CCL24, was shown in the SPRING study to be well tolerated and exhibited anti-inflammatory, anti-fibrotic, and anti-cholestatic activities in patients with primary sclerosing cholangitis (PSC). Here we analyze the pharmacokinetics (PK) and pharmacodynamics (PD) data and explore their relationships with biomarkers of efficacy.

Method: The SPRING study was a phase 2, randomized, double-blind, placebo-controlled study of PSC patients. The study design and clinical data have been presented. Patients received 5 doses of CM-101 (either 10 mg/kg or 20 mg/kg) or placebo IV every 3 weeks for 15 weeks. PK parameters were assessed, and target engagement of CCL24 was quantified using a ligand binding assay for total (CM-101-bound and unbound) serum CCL24. PK parameters were correlated with clinical markers of the liver enzymes alanine transaminase (ALT) and alkaline phosphatase (ALP), and liver stiffness as measured by transient elastography (TE).

Results: PK analyses indicated dose-proportional increases in CM-101 concentration with steady-state levels achieved after the fourth dose, resulting in mean C_{trough} values of 63.45 µg/mL when patients were dosed at 10 mg/kg, and 141 µg/mL when patients were dosed at 20 mg/kg. The steady state was maintained throughout the double-blind treatment period (week 15). Increases in C_{max}, $AUC_{0\text{-}168h}$, and AUC_{last} were dose-proportional for both Dose 1 and Dose 5 of CM-101. Total CCL24 levels rose 3.3-fold and 6.7-fold for the 10 mg/kg and 20 mg/kg groups, respectively, and remained elevated throughout the double-blind treatment period. This increase, which was evident only in the CM-101 treated groups, reflects effective antibody-target engagement, and was dose-dependent between the 10 mg/kg and 20 mg/kg groups. The increase in serum CCL24 levels corresponded to the increase in serum CM-101 levels. Linear regression analyses

found trends between increasing exposure (as measured by C_{trough}, C_{max}, and $AUC_{0\text{-}168h}$ parameters) and decreasing TE, ALT and ALP.
Conclusion: CM-101 demonstrates two-compartment, dose-dependent PK with high target engagement in patients with PSC. A dose-dependent trend between the higher dose and reductions in TE and ALP is encouraging. Additional data is expected following a planned phase 3.

THU-336-YI
Direct nerve fiber recordings reveal functional alterations in cutaneous C-fibers linked to itch severity in cholestatic liver diseases

Miriam M. Düll[1,2], Hannah Kleinlein[1,2], Fabienne Falter[1,2], Anne Bauer[1,2], Markus F. Neurath[1,3], Sonja Ständer[4], Aysenur Süer[4,5], Martin Schmelz[6], Peter Dietrich[1,7], Andreas E. Kremer[8], Barbara Namer[2,9,10]. *[1]Department of Medicine 1, University Hospital Erlangen and Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany; [2]Institute of Physiology and Pathophysiology, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany; [3]Deutsches Zentrum Immuntherapie DZI, Erlangen, Germany; [4]Department of Dermatology and Center for Chronic Pruritus, University Hospital Münster, Münster, Germany; [5]Institute of Medical Informatics, University of Münster, Germany, Münster, Germany; [6]Department of Experimental Pain Research Mannheim, University of Heidelberg, Mannheim, Germany; [7]Institute of Biochemistry, Emil-Fischer-Zentrum, Friedrich-Alexander-University Erlangen-Nürnberg, Erlangen, Germany; [8]Department of Gastroenterology and Hepatology, University Hospital Zürich, University of Zürich, Zürich, Switzerland; [9]Research group Neuroscience, Interdisciplinary Centre for Clinical Research within the faculty of Medicine at the RWTH Aachen University, Germany, Aachen, Germany; [10]Institute of Physiology, Aachen, Germany*
Email: miriam.duell@uk-erlangen.de

Background and aims: Chronic pruritus is a common and sometimes difficult-to-treat symptom associated with cholestatic liver diseases that significantly affects patients` quality of life. While several potential pruritogens have been identified, the functional properties and alterations of cutaneous C-fibers mediating pruritic stimuli remain poorly understood. This aim of this study was to objectively assess functionality of C-fibers in patients with and without chronic cholestatic pruritus using microneurography (MNG), a technique for direct recording of nerve fibers.
Method: Sixteen patients with cholestatic liver diseases (primary biliary cholangitis [PBC], n = 7; primary/secondary sclerosing cholangitis [PSC/SSC], n = 4; other causes of chronic cholestasis, n = 5) participated in the study. Validated pruritus questionnaires, including mean itch intensity measured on a numeric rating scale (NRS), were administered. MNG recordings of single C-fibers were obtained via a ultra-thin electrode inserted into the superficial peroneal nerve at ankle level. Standardized mechanical and electrical stimulation protocols as well as chemical stimulation with either lysophosphatidic acid (LPA, 0.1 mM) or a bile acid pool (deoxycholic acid, glycocholic acid, ursodeoxycholic acid) were used to classify C-fibers.
Results: Patients were stratified into high-pruritus (NRS ≥3) and low-pruritus (NRS <3) groups, with no significant differences between the groups in term of age, gender, laboratory parameters, or disease stage. A total of 72 C-fibers were recorded. The high-pruritus group exhibited a greater proportion of functionally abnormal C-fibers (57%) compared to the low-pruritus group (33%). Notably, 50% of patients with high pruritus had more than 50% of their C-fibers classified as pathologically altered, whereas no patients in the low-pruritus group exceeded this threshold. Spontaneous activity, a marker of hyper-reactivity, was observed in 38% of high-pruritus patients but was completely absent in the low-pruritus group. No significant differences were identified in C-fiber activation following stimulation with LPA or the bile acid pool.
Conclusion: Patients with cholestatic liver diseases and high-intensity pruritus exhibit a higher proportion of functionally altered C-fibers, suggesting that chronic cholestasis causes long-term changes in the functionality of cutaneous nerve fibers.

THU-337
Is the POISE really valid as a surrogate endpoint for patients with PBC treated with UDCA and PPAR agonist? – a retrospective validation study from the real-world data in Japan

Ryo Miura[1], Katsunori Yoshida[2], Masanori Abe[3], Tadashi Namisaki[4], Kyoko Oura[5], Kazuhito Kawata[6], Chiaki Maeyashiki[7], Yasuaki Kuwata[8], Atsushi Takahashi[9], Tatehiro Kagawa[10], Atsushi Fukunaga[11], Shiho Miyase[12], Tomokazu Kawaoka[13], Kosuke Matsumoto[1], Akihito Takeuchi[1], Shinji Shimoda[14], Yoshitaka Arase[10], Hiromasa Ohira[9], Kaoru Tsuchiya[7], Tsutomu Masaki[5], Hitoshi Yoshiji[4], Noriyo Yamashiki[2], Yuki Kugiyama[15], Toshiaki Nakano[14], Atsumasa Komori[15], Atsushi Tanaka[1]. *[1]Teikyo Univercity School of Medicine, Tokyo, Japan; [2]Kansai Medical University Medical Center, Moriguchi, Japan; [3]Ehime University Graduate School of Medicine, Toon, Japan; [4]Nara Medical University, Kashihara, Japan; [5]Department of Gastroenterology and Neurology, Kagawa University, kita-gun, Japan; [6]Hamamatsu University School of Medicine, Hamamatsu, Japan; [7]Patient Orientated Musashino Red Cross, Musashino, Japan; [8]Sapporo-Kosei General Hospital, Sapporo, Japan; [9]Fukushima Medical University School of Medicine, Fukushima, Japan; [10]Tokai University School of Medicine, Isehara, Japan; [11]Fukuoka University, Faculty of Medicine, Fukuoka, Japan; [12]Kumamoto Shinto General Hospital, Kumamoto, Japan; [13]Graduate School of Biomedical and Health Sciences, Hiroshima University, Hiroshima, Japan; [14]Kansai Medical University, Hirakata, Japan; [15]National Hospital Organization Nagasaki Medical Center, Omura, Japan*
Email: a-tanaka@med.teikyo-u.ac.jp

Background and aims: In clinical trials evaluating PPAR agonists for primary biliary cholangitis (PBC) with an incomplete response to ursodeoxycholic acid (UDCA), the POISE criteria are commonly used as the primary endpoint. These criteria are defined as achieving an alkaline phosphatase (ALP) level <1.67× the upper limit of normal (ULN) with a ≥15% reduction from baseline, and bilirubin levels within the ULN after one year of treatment. However, the POISE criteria were originally established as a predictor of favorable long-term prognosis in patients treated with UDCA monotherapy, and it remains an area of uncertainty whether these criteria are similarly associated with long-term prognosis in patients receiving combination therapy with UDCA and PPAR agonists. This study aimed to retrospectively evaluate whether the POISE criteria are predictive of long-term outcomes in patients treated with UDCA and bezafibrate (BZF) based on the real-world data from a nationwide survey of PBC in Japan.
Method: We utilized clinical data from the 17th nationwide survey on PBC conducted during 2023–2024, in which 2,051 patients with PBC were registered. Among them, we included patients without missing data on medical treatment or prognosis, and those who received BZF as an add-on therapy to UDCA, had ALP ≥1.5× ULN at the initiation of BZF therapy, and had been followed for at least one year after starting BZF. We excluded patients with concomitant hepatitis B, hepatitis C, or autoimmune hepatitis. Enrolled patients were categorized based on whether they met the POISE criteria one year after initiating BZF therapy. We statistically compared the incidence of liver transplantation (LT) or all-cause mortality, as well as a composite endpoint including LT, all-cause mortality, decompensated events (ascites, edema, hepatic encephalopathy, gastrointestinal bleeding) and hepatocellular carcinoma between the groups.
Results: Of the 2,051 PBC cases, 226 met the inclusion criteria (male/female, 46:180; mean age at BZF initiation, 57.7 ± 12.8 years; mean follow-up duration after BZF initiation, 8.7 ± 5.0 years). Among these, 92 patients met the POISE criteria (POISE-in), while 134 did not (POISE-out). LT or all-cause mortality occurred in 4 POISE-in patients and 16 POISE-out patients, with incidence rates of 5.76 and 9.81 per 10,000 person-years, respectively. The incidence of events including decompensated cirrhosis and HCC was 5 cases in the POISE-in group

and 32 cases in the POISE-out group, corresponding to rates of 4.9 and 28.6 per 10,000 person-years, respectively. Kaplan-Meier analysis showed significant differences between POISE-in and POISE-out for both LT/all-cause mortality (p = 0.032) and the composite endpoint (p = 0.002).
Conclusion: These findings demonstrate that achieving the POISE criteria is significantly associated with improved long-term prognosis in patients receiving UDCA and BZF, strongly supporting the use of the POISE in clinical trials evaluating UDCA and PPAR agonist combination therapy.

THU-338-YI
Health-related quality of life and well-being of young patients with autoimmune hepatitis during transition of care from paediatric to adult site
Maciej Janik[1], Weronika Marcinkowska[1], Joanna Łącz[1], Joanna Raszeja-Wyszomirska[1], Piotr Milkiewicz[1,2]. *[1]Medical University of Warsaw, Warszawa, Poland; [2]Pomeranian Medical University, Szczecin, Poland*
Email: mjanik24@gmail.com

Background and aims: Autoimmune hepatitis (AIH) is a chronic liver disease that, in the majority of patients, requires lifelong maintenance therapy. AIH treatment may impact health-related quality of life (HRQoL) and patients' well-being. Treatment adherence is presumed to be lower during the transition of care from paediatric to adult sites. Here, we assessed HRQoL in young adults with AIH during the transition of care in the reference liver diseases adult centre.
Method: Sixty-six patients (66% female) with AIH diagnosed in childhood were assessed at the first visit to the adult centre and during mean follow-up of 4.5 ± 2.2 years. HRQoL was evaluated by SF-12 (generic HRQoL tool), PHQ-9 (depression), and MFIS (fatigue). The HRQoL was compared using paired observation from the first and the follow-up visit at the adult centre. Additionally, the patient's HRQoL at the follow-up visit (66% female, mean age 24.4 ± 3.0 years) was evaluated to sex- and age-matched healthy volunteers (67% female, mean age 25.6 ± 3.1 years).
Results: On the first visit to the adult centre, patients presented at a mean age of 19.8 ± 2.3 years, 18 (27%) patients were referred after the age of 20. At the first visit, mean ALT was 74 ± 80 U/l, IgG 1538 ± 561 mg/dL, and complete biochemical response (CBR) was seen in 33% of patients. During follow-up, mean ALT was 45 ± 51 U/l, IgG was 1517 ± 658 mg/dL, and complete biochemical response (CBR) was achieved in 62% of patients. Compared to the first visit, CBR was achieved more frequently (p < 0.001). During the 4.5 years of follow-up, there were no differences in the physical component scale (PCS, p = 0.059), but the mental component scale (MCS) of HRQoL was lower at the follow-up visit (p = 0.003). The PHQ-9 results were comparable between both time points (p = 0.394), but moderate depression (PHQ-9≥10 points) was found in 28% and 43% of patients during the first and the follow-up visit, respectively. Half of the patients declared psychiatric consultation in medical history, but only 23% received any psychiatric drug. There were no differences in overall fatigue (total MFIS) as well as MFIS subdomains. During the follow-up, there were no differences in HRQoL (PCS and MCS), depression signs and fatigue in terms of liver cirrhosis, steroids use and CBR achievement (all p > 0.05) Compared to controls, young people with AIH had impaired HRQoL in terms of physical (PCS, p = 0.01), mental (MCS, p < 0.001) as well as depressive signs (PHQ-9, p < 0.001), but not overall fatigue and its cognitive subscale in MFIS. Screening for moderate-severe depression (PHQ-9≥15 points) was positive in 25.4% of patients, compared to 10.6% in controls (p = 0.036).
Conclusion: Young adults with AIH are at risk of significant deterioration of HRQoL as well as a higher risk of depression than in the general population. Beside improvement in laboratory result and achieving CBR, HRQoL remained impaired or, in terms of mental aspects, deteriorated. These findings stress the need for psychological consultation during the transition of care, also in adult clinics.

THU-339-YI
UK validation of the simple cholestatic complaints score: a patient reported outcomes measure in primary sclerosing cholangitis
Nasir Hussain[1], Nadir Abbas[1], Khushpreet Bhandal[1], Penelope Rogers[1], Emma Burke[1], Diana Hull[1], Martine Walmsley[2], Paula Hanford[2], James Ferguson[1], Palak J. Trivedi[1]. *[1]University of Birmingham, Birmingham, United Kingdom; [2]PSC Support, Manchester, United Kingdom*
Email: n.hussain@doctors.org.uk

Background and aims: Primary sclerosing cholangitis (PSC) is a rare cholestatic disease with significant symptom burden. A reliable patient reported outcome measure (PROM) is of key importance in the development of symptom-directed therapies. The Simple Cholestatic Complaints Score (SCCS) was developed as a 4-item questionnaire that is quick and easy to complete, assessing principal cholestatic symptoms (pruritus, fatigue, abdominal pain and fever). The SCCS has been tested and validated in a Dutch cohort of PSC patients. The aim of this cross-sectional study was to externally validate the SCCS in a cohort of PSC patients from the UK.
Method: Adults with PSC (aged > 16, non-transplant) were invited to complete the SCCS questionnaire alongside additional health related quality of life (QoL) assessments: the chronic liver disease questionnaire (CLDQ), EuroQol-5 Dimension 5-level (EQ-5D 5L) questionnaire, the 5D itch score and the itch numerical rating scale (NRS). Clinical and laboratory data were captured in parallel at the same timepoint. Validity was determined using Spearman correlation coefficient between SCCS and other QoL assessment tools, where both overall and item specific scores were compared.
Results: Between Nov 2022 and Feb 2023, 139 patients with PSC were recruited (median age 40yrs, 79 men, median MELD score 7.0), of whom 91% (127/139) had large duct disease, 94% (130/139) had inflammatory bowel disease (IBD) and 17% (23/139) had cirrhosis. Total SCCS was greater in those with more advanced liver disease (3.0 in cirrhosis vs 2.0 in no cirrhosis, p = 0.002) and those with a history of acute cholangitis (5.0 vs 2.0, p = 0.003), alongside positive correlations with MELD scores (rho 0.30, p = 0.001) and transient elastography (rho 0.21, p = 0.022). No significant differences in total SCCS were seen between sexes, presence of IBD, and extent of ductal involvement. The total SCCS values exhibited strong negative correlations with overall CLDQ scores (rho −0.76, p < 0.001) and EQ-5D 5L VAS scores (rho −0.65, p < 0.001) and index values (rho −0.65, p < 0.001). With respect to item specific scores, the pruritus domain of the SCCS very strongly and positively correlated with the 5D itch score (rho 0.86, p < 0.001) and itch worst NRS (rho 0.89, p < 0.001). The fatigue domain of SCCS exhibited strong correlation to the CLDQ fatigue domain (rho −0.78, p < 0.001); and the abdominal pain SCCS item a strong correlation with the abdominal symptom domain of CLDQ (rho −0.60, p < 0.001).
Conclusion: Herein, we show that the SCCS is reliable in capturing the impact of item specific symptoms, consistent with what is reported in other QoL assessments. The SCCS provides a quick, simple and easy to use PROM, which should be utilized in both clinical care and as an outcome measure in symptom specific PSC clinical trials.

THU-340
Validation of the clinical global impression severity scale for primary biliary cholangitis: a clinical trials outcome tool
Nasir Hussain[1,2], Rachel Smith[3], Sarah Barnum[4], Nadir Abbas[2], Sarah Al Shakhshir[1], Geraldine Carroll[5], Laura Jopson[5], Jessica Leighton[5], George Mells[3], Mo Christie[6], Robert Mitchell-Thain[6], Aaron Wetten[5], Jessica Dyson[7], James Neuberger[2], Magnus Doverskog[8], Palak J. Trivedi[1,2], Judith Jaeger[4], David Jones[7]. *[1]University of Birmingham, Birmingham, United Kingdom; [2]Liver Unit, University Hospitals Birmingham NHS Trust, Birmingham, United Kingdom; [3]Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom; [4]CognitionMetrics LLC, Connecticut, United States; [5]Newcastle upon Tyne Hospitals NHS*

Email: n.hussain@doctors.org.uk

Background and aims: Primary biliary cholangitis (PBC) is a cholestatic disease that can cause disabling symptoms such as fatigue, cognitive dysfunction and emotional distress. These symptoms are captured by patient reported outcome measures (PROM) such as the PBC-40. However, for clinical research, PROMs are limited by personality or contextual influences causing bias (under or over reporting of symptoms). In contrast the Clinical Global Impression (CGI) scale utilizes expert judgement on syndrome severity to provide objective ratings following comprehensive symptom evaluation. CGIs are widely used in CNS indications and accepted by regulators as a primary efficacy endpoint. The newly developed CGI-S-PBC™ consists of a semi-structured interview covering the 6 symptom domains in the PBC – 40 (itch, fatigue, subjective cognition, psychosocial, emotional and somatic symptoms). This validation study aims to measure interrater agreement of the CGI-S-PBC™ among expert hepatologists and its correlation with the PBC-40.
Method: Adults with PBC (n = 13, all female) completed PBC-40 questionnaires and were then interviewed remotely (online) regarding symptoms, by a trained hepatologist. The videoed interviews were then rated independently by n = 12 blinded expert hepatologists. Raters used the CGI-S-PBC™ anchors to score symptoms on a Likert scale (1–7) for each symptom domain and provide a global rating. Statistical analyses (Krippendorf alpha) measured the level of rater agreement between expert ratings. The ratings and their association with the self-completed PBC - 40 scores were also examined (Spearman correlation).
Results: There was strong interrater agreement found amongst most domains, with the highest agreement for itch (alpha 0.93 (95% CI 0.92–0.95) and limited agreement seen for the somatic symptom domain (alpha 0.65, 95% CI 0.61–0.69). Strong agreement was exhibited for fatigue (alpha 0.82, 95% CI 0.80–0.84), subjective cognition (alpha 0.80, 95% CI 0.77–0.82), psychosocial (alpha 0.79, 95% CI 0.76–0.82), emotional (alpha 0.90, 95% CI 0.89–0.92) and the overall global score (alpha 0.81, 95% CI 0.78–0.84). The average score amongst raters had significant strong positive correlations with the PBC - 40 measures. The correlation coefficients were 0.90 for itch, 0.65 for fatigue, 0.79 for subjective cognition, 0.86 for psychosocial, 0.95 for emotional, 0.79 for somatic symptoms, and 0.88 for the overall global score ($p < 0.01$ for all).
Conclusion: The CGI-S-PBC™ is a valid and reliable rating instrument for PBC symptoms, crucial in really understanding the impact on patients. It is an integral tool for the approval of treatments that aim to improve symptoms, critical due to the number of novel symptom-directed therapies in development presently. The CGI-S-PBC™ is currently being used in training PBC-expert hepatologists for application in a randomized controlled trial.

Implementation of a clinical global impression severity scale for primary biliary cirrhosis: results of a hepatologist focussed training programme

Nasir Hussain[1,2], Sarah Barnum[3], Mo Christie[4], Robert Mitchell-Thain[4], James Neuberger[2], Andreas E. Kremer[5], Magnus Doverskog[6], Palak Trivedi[1,2], Judith Jaeger[3], David E. Jones[7].

Email: n.hussain@doctors.org.uk

Background and aims: Primary Biliary Cholangitis (PBC) is a cholestatic liver disease with high symptom burden. Symptoms such as fatigue and cognitive concerns are not captured by laboratory measures, and therefore additional tools are needed to facilitate the testing of symptom directed therapies. A Clinical Global Impression Severity scale for PBC (CGI-S-PBC™) was recently developed and validated, expanding on the PBC-40 patient reported outcome measure. Commonly used in other disease areas, the use and application of CGI scales is a novel concept in hepatology. Herein we report the application of a CGI training programme developed and administered to hepatologists with PBC expertise, allowing them to apply the tool in clinical trials.
Method: A training programme was developed by clinical hepatologists alongside clinical psychologists with extensive experience in CGI scale development. The training programme consisted of 3 interactive sessions involving education on the CGI scale using didactic instruction, video modelling, interactive discussion, and in vivo practice interviewing. Between each live session and following the final session, trainees watched and scored pre-recorded CGI interviews with PBC patients. Trainees were required to demonstrate >80% accuracy in their scoring against pre-determined gold standards, in order to be certified as successful raters.
Results: To date, 26 hepatologists (19 male) from 8 European countries have completed the training programme. Training sessions were completed in 5 cohorts (maximum of 8 trainees per group). 88% (23/26) achieved ≥80% reliability after the third training session. Only 2 trainees required an additional 1 to 1 training session, following which all trainees achieved >80% reliability on subsequent ratings. Across trainees, the average accuracy of scoring was 86% (cohort 1: 89%, cohort 2: 85%, cohort 3: 85%, cohort 4: 90%, cohort 5: 90%).
Conclusion: This dedicated training programme for the CGI-S-PBC™ scale is proven to be effective and successful in training hepatologists to reliably score PBC specific CGI interviews. Approved raters from this programme are currently participating as central raters in an ongoing phase 2 study of an investigational medication where interrater reliability will be studied in a real-world setting. This training programme complements the recently validated CGI-S-PBC™ scale, for use internationally, where there is an essential need for regulator approved symptom outcome measures, that can be used in clinical trials for novel symptom directed therapeutics in PBC.

Email: nadia.ovchinsky@nyulangone.org

Background and aims: Robust, long-term data from ASSERT phase III randomized controlled trial (NCT04674761) and ASSERT-EXT

(NCT05035030) open-label extension demonstrate sustained efficacy and tolerability in patients with Alagille syndrome (ALGS) of any age treated with odevixibat (ODX) for ≤96 weeks [1,2]. ODX is US and EU approved for cholestatic pruritus in patients with ALGS aged ≥12 months and ≥6 months, respectively. Here we analyzed efficacy and safety outcomes for patients aged ≥10 years from ASSERT and ASSERT-EXT to characterize the clinical benefit of long-term ODX in older patients.

Method: Patients received ODX PBO for 24 weeks in ASSERT; those who completed were eligible for the 72-week ASSERT-EXT. All patients received ODX 120 μg/kg/day (≤96 weeks for patients randomized to ODX in ASSERT). This integrated analysis includes patients aged ≥10 to <18 years at baseline (BL). Endpoints include mean scratching score (patient-reported); mean serum bile acid (sBA) levels; proportion of patients with clinically meaningful improvement in pruritus (≥1-point reduction); sleep parameters; and growth up to Week 72 timepoint. Safety was evaluated throughout.

Results: 10 patients aged ≥10 years received ODX (PBO/ODX n = 4; ODX/ODX n = 6); median age at BL: 12.2 years (range, 10.9–15.5). 6/10 patients completed ≤96 weeks treatment (median duration: 74 weeks [range, 16–129]); 2 patients withdrew consent prior to Week 72, 1 patient discontinued due to elevated bilirubin, and 1 patient had liver transplant after 110 days of ODX. Pooled mean (SD) pruritus scores at BL (n = 10) and Weeks 69 –72 (n = 4) of ASSERT-EXT were 2.1 (0.8) and 0.4 (0.6), respectively. At Weeks 69–72, 3 patients achieved a ≥1-point reduction in scratching score. Pooled mean (SD) sBAs at BL (n = 10) and Week 72 (n = 6) of ASSERT-EXT were 211.6 (113.4) and 76.8 (50.5) μmol/L, respectively. ODX was associated with improved sleep (mean change [SD] from BL to Week 72 timepoint in difficulty falling asleep: −1.6 [1.5]; difficulty staying asleep: −1.2 [1.2]; and daytime tiredness: −0.9 [1.6]). Height and weight increased over time (mean change [SD] from BL to Week 72 timepoint in height z-score: 0.07 [0.2]; weight z-score: −0.03 [0.4]). Patient-level data will be presented. Most TEAEs were mild/moderate in severity; most common were vitamin D deficiency (n/N = 4/10) and influenza (n/N = 3/10). 3 patients had GI disturbances considered probably related to ODX, 3 had elevated transaminases, and 3 had serious AEs, all unrelated to ODX. 2 patients had diarrhea (n = 1 related to ODX); neither were serious nor led to dose interruption or treatment discontinuation.

Conclusion: ODX was well tolerated with clinically meaningful improvements in pruritus, reductions in sBA, and improvements in sleep outcomes in patients with ALGS aged ≥10 years. Despite sample size, present data indicate the efficacy and safety profile of ODX in this subset of patients is consistent with previous results.

Combination obeticholic acid (OCA) and fibrate therapy is associated with greater probability of biochemical response than switching from OCA to a fibrate in primary biliary cholangitis

Nadir Abbas[1], Emma Culver[2], Rachel Smith[3], Douglas Thorburn[4], Neil Halliday[5], Nadia Eden[5], James Ferguson[1], Jessica Dyson[6], George Mells[6], David E. Jones[6], Palak J. Trivedi[7]. *[1]National Institute for Health and Care Research (NIHR) Birmingham, Biomedical Research Centre (BRC), Centre for Liver and Gastrointestinal Research, University of Birmingham, Birmingham, UK, Liver Unit, University Hospitals Birmingham Queen Elizabeth, Birmingham, UK, Birmingham, United Kingdom; [2]Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom; [3]Academic Department of Medical Genetics, University of Cambridge, Cambridge, UK, Cambridge Liver Unit, Cambridge University Hospitals NHS Foundation Trust, Cambridge, UK, Cambridge, United Kingdom; [4]Department of Hepatology and Liver Transplantation, Royal Free Hospital NHS Foundation Trust, London, UK, London, United Kingdom; [5]Department of Hepatology and Liver Transplantation, Royal Free Hospital NHS Foundation Trust, London, United Kingdom; [6]Liver Unit, Newcastle Upon Tyne Hospitals NHS Foundation Trust, Newcastle, UK, NIHR Newcastle Biomedical Research Centre, Newcastle University, Newcastle, UK, Newcastle, United Kingdom; [7]National Institute for Health and Care Research (NIHR) Birmingham, Biomedical Research Centre (BRC), Centre for Liver and Gastrointestinal Research, University of Birmingham, Birmingham, UK, Liver Unit, University Hospitals Birmingham Queen Elizabeth, Birmingham, UK, Institute of Immunology, Immunology and Infection, Birmingham, United Kingdom*
Email: p.j.trivedi@bham.ac.uk

Background and aims: Approximately 40% of patients (pts) with primary biliary cholangitis (PBC) are non-responders to ursodeoxycholic acid (UDCA) and candidates for second-line therapy (SLT). Until recently, the latter consisted of licensed treatment with obeticholic acid (OCA), or off-licensed bezafibrate/fenofibrate (fibrates). Unfortunately, >50% of pts inadequately respond to historic SLT paradigms. Emerging data suggests that combination therapy (OCA+fibrates) is associated with a greater biochemical response rate, although it is not known if 'switching' between SLTs can achieve the same, desired effect. The goal of this study was to compare biochemical response rates combination SLT, to that of a 'switch' regimen, wherein OCA was stopped and substituted for a fibrate in biochemical non-responders.

Method: We conducted a multicentre study across five high volume liver centres in the UK. Our cohort consisted of PBC pts who initiated OCA between 2017–19 with follow-up continuing to 2023. Rates of OCA discontinuation, dates of fibrate initiation, treatment regimen (permutations and combinations of UDCA, OCA and fibrates) were captured; alongside rates of biochemical response according to POISE criteria (alkaline phosphatase values [ALP] <1.67× the upper limit of normal, ALP reduction by >15% of pre-treatment values, and a normal bilirubin). Secondary outcomes included ALP normalisation and the incidence of liver-related clinical events (decompensation, hepatocellular carcinoma, referral for transplantation, death).

Results: In all, we accrued data from 240 pts who initiated OCA as an SLT (median age 46y, n = 48 with cirrhosis). Observing 4-years of follow-up, n = 45 initiated fibrates as add-on therapy to OCA (defined as group 1: n = 31 taking UDCA; n = 41 on OCA+bezafibrate; n = 4 on OCA+fenofibrate). In turn, n = 74 switched from OCA to a fibrate (defined as group 2: n = 51 taking UDCA; n = 57 on bezafibrate; n = 17 on fenofibrate). Follow up of 1, 2, 3, and 4 years was completed by 29, 25, 21 and 22 pts in group 1, respectively, and 57, 47, 38 and 37 in group 2. Biochemical response according to POISE criteria was met in 31%, 44%, 85% and 91% of pts at 1, 2, 3, and 4 yrs, respectively, in group 1. This compared to 16%, 34%, 42% and 43% in group 2 ($P < 0.001$ for all time comparisons). ALP normalisation rates in group 1 vs. group 2 were 3% vs. 0% (p = ns), 4% vs. 7% (p = ns), 25% vs. 13% ($p = 0.01$) and 52% vs. 35% ($p < 0.001$), at 1, 2, 3 and 4 yrs, respectively. A non-significant trend toward greater normalisation rates in all biochemical parameters was observed in group 1 vs group 2: 0% vs. 3%; 7% vs. 3%, 13% vs. 5% and 35% vs. 8%. Five (11%) pts in group 1 experienced a clinical event vs four (5%) in group 2 (hazard ratio: 2.2; IQR 0.5–8.6).

Conclusion: Biochemical response rates under OCA+fibrate treatment are greater than stopping/switching from OCA to fibrates as part of a SLT regimen. Our data support the need for ongoing studies of combination SLT, alongside treatment paradigms associated with greater probability of biochemical response in PBC.

THU-344

Clinical characteristics of a large cohort of primary sclerosing cholangitis patients undergoing liver transplant for primary sclerosing cholangitis and biochemical predictors of recurrence

Natcha Cheewasereechon[1], Aisha Alawi[1], Shani Nagler[1], Leila Amiri[1], Nazia Selzner[1], Gideon M. Hirschfield[1], Aliya Gulamhusein[1]. *[1]Toronto General Hospital, University of Toronto, Toronto, Canada*
Email: natchachee@hotmail.com

Background and aims: Primary sclerosing cholangitis (PSC) is a rare, chronic and progressive cholestatic liver disease, that may progress to liver failure requiring liver transplantation (LT) 10–15 years after diagnosis. Recurrent PSC (rPSC) is a devastating complication that occurs in up to 30% of patients 10 years post LT and is associated with graft loss, need for re-transplantation, and reduced survival. We aimed to describe characteristics of a large PSC cohort undergoing LT and report biochemical predictors of rPSC.
Method: A retrospective cohort study was conducted at the University Health Network in Toronto. 247 PSC patients post LT were identified between January 1, 2000 to December 31,2022. Descriptive statistics were used to define the characteristics of the cohort. Qualitative variables were summarized as proportions and continuous variables as means with standard deviations and medians with interquartile ranges. 174 patients with sufficient data were included in a time-dependent Cox Proportional Hazards model to identify biochemical risk factors for rPSC. A p-value <0.05 was considered statistically significant.
Results: 247 patients with PSC were transplanted during the study period. Mean age at diagnosis was 34.5 (SD 13) years and median follow up time was 16 (IQR 10–20) years. The majority were male (67%, n = 165), had large duct PSC (88.7%, n = 218), associated IBD (79%, n = 194) and were treated with UDCA pre-transplant (70%, n = 174). Mean age at transplant was 43.6 (SD 13.5) years and median MELD was 19 (IQR 13–26). Living donor LT (LDLT) was the most frequent donor type (54%, n = 133) followed by donation after brainstem death (DBD) (44%, n = 103) with donation after cardiac death (DCD) (0.4%, n = 1) and split grafts (1.2%, n = 3) being rarely used. Male (48%, n = 119) and female (49%, n = 122) donors were equally used. The vast majority of patients had a Roux-en-Y hepaticojejunostomy (92%, n = 227). Unidentified cancer pre-transplant was seen on explant in 11% (n = 28) with 4.9% (n = 12) with cholangiocarcinoma, 5.7% (n = 14) with hepatocellular carcinoma and 5% (n = 2) with gallbladder cancer. Biopsy proven rejection episodes were frequent with early (within 1 month) acute cellular rejection (ACR) occurring in 29% (n = 72), late (≥1 month) ACR in 28% (n = 70), and chronic rejection in 6.5% (n = 16). Anastomotic strictures occurred in 19% (n = 46) and rPSC was diagnosed in 26% (n = 63) with median time to rPSC of 3.5 years (IQR 2.3–5.1). Ursodeoxycholic acid (UDCA) was used post-LT in 53% (n = 132). Immunosuppression within the first year was most commonly with tacrolimus (93%, n = 229) and mycophenolate (79%, n = 194), the combination of which continued in the majority beyond 1 year. Higher ALP (HR 1.002, 95% CI 1.0003–1.004, p = 0.02) and creatinine (HR 1.017, 95% CI 1.002–1.031, p = 0.02) were identified as biochemical predictors of rPSC.
Conclusion: rPSC is a frequent complication post-LT and may be predicted by elevated ALP and creatinine. Further evaluation of reliable predictors of rPSC is urgently needed.

THU-349

Risk factors for post-liver transplantation patient and graft survival in autoimmune hepatitis: pioneering insights from a south american cohort

Pedro Passos[1,2], Maria Eduarda Souza dos Santos[2], Maria Julya Albuquerque Parente[2], Mateus Mendes Santos Freire[2], Clebia de Lima[2,3], Isabel Bastos de Medeiros[4,5], Tiago Franco David[4,5], Rodrigo Motta[6], Gabriel Gomes de Araújo[2], Joathan de Souza Silva[2], Ana Clara Sales de Souza[2], Letícia Pinheiro Amorim[2], Lívia Melo Carone Linhares[3], Elodie Hyppolito[3,7], Gustavo Rego Coelho[2,3], José Huygens Parente Garcia[2,3,8]. *[1]Centre of Research and Drug Development (NPDM), Federal University of Ceara, Fortaleza, Brazil; [2]Department of Surgery, Federal University of Ceará, Fortaleza, Brazil; [3]Walter Cantídio University Hospital, Fortaleza, Brazil; [4]Liver Transplant Fellowship Program, Federal University of Ceará, Fortaleza, Brazil; [5]Federal University of Pará, Belém, Brazil; [6]Translational Gastroenterology and Liver Unit, University of Oxford, Oxford, United Kingdom; [7]Postgraduate Program in Public Health, Federal University of Ceará, Fortaleza, Brazil; [8]Postgraduate Program in Pharmacology, Federal University of Ceará, Fortaleza, Brazil*
Email: pedropassos@alu.ufc.br

Background and aims: Autoimmune hepatitis (AIH) is a rare liver disease with regional variations in presentation and genetic associations. About 10% of AIH patients require liver transplantation (LT). Limited studies in non-European cohorts highlight the need for regional data. This study addresses this gap by examining risk factors for post-LT patient and graft survival in a Brazilian cohort.
Method: We conducted a retrospective cohort at a single Brazilian reference center, including AIH LT patients between 2004 and 2024. We excluded patients younger than 14 years-old, those with acute-on-chronic liver failure, and those with fulminant hepatitis. We utilized Kaplan-Meier (KM) estimates for both patient and graft survival post-LT, considering graft loss as either retransplantation or death. Univariate Cox proportional hazards (PH) regression was applied to all relevant variables for predicting patient or graft survival at 5 years, and those with p value <0.05 were further analyzed in a multivariate Cox PH model.
Results: The study included 132 predominantly female (79%) and mixed-race (78%) patients, with a median age of 28.1 years. The most common post-LT immunosuppressive regimen was the combination of an antimetabolite, a calcineurin inhibitor, and a glucocorticoid (52%). The KM survival estimates for patients were 77.5%, 75.2%, and 75.2% at 1, 3, and 5 years post-LT, respectively, while graft survival were 75.6%, 71.3%, and 71.3% at the same intervals. In the univariate analysis for patient survival, higher pre-LT MELD scores (hazard ratio [HR]: 1.1, 95% confidence interval [CI]: 1.0–1.2) was associated with worse outcomes. Conversely, a greater number of immunosuppressive agents (IMSa) was protective (HR: 0.3, 95% CI: 0.2–0.7), as well as the use of any antimetabolite (HR: 0.2, 95% CI: 0.1–0.6). In multivariate analysis, only IMSa number remained a significant predictor of patient survival (HR: 0.2, 95% CI: 0.1–0.8). For graft survival, univariate analysis revealed similar trends, with higher MELD scores (HR: 1.1, 95% CI: 1.0–1.2) negatively associated with outcomes, while a greater number of IMSa (HR: 0.4, 95% CI: 0.2–0.8) and the use of an antimetabolite (HR: 0.2, 95% CI: 0.1–0.6) were protective. Again, in multivariate analysis, only the number of IMSa was a significant predictor (HR: 0.3, 95% CI: 0.1–0.9). Further KM analyses were performed by stratifying patients into those receiving fewer than 3 IMSa and those receiving 3 or more IMSa. Patients receiving at least 3 IMSa had significantly better outcomes, with 5-year patient and graft survival of 92.0% and 90.1%, respectively, compared to 70.6% and 64.7% for patients receiving fewer than 3 IMSa (both p < 0.01).
Conclusion: As far as we know, this is the largest South American cohort of AIH patients undergoing LT reported to date. Given the regional variations in AIH, insights gained from this cohort provide essential data for improving LT strategies in South America.

Email: peni.arvaniti@gmail.com

Background and aims: Although the classic phenotype of primary biliary cholangitis (PBC) has slow progression and favorable response to treatment, other disease phenotypes characterized histologically by portal inflammation and/or ductopenia are associated with worse prognosis. In this study, we aimed to: 1) catalog the non-classical phenotypes of PBC according to biochemical parameters at diagnosis, 2) identify the impact of non-classical phenotypes on treatment response and disease prognosis, and 3) study the specific prognostic factors in each PBC phenotype.
Method: This multicenter retrospective study included 505 PBC patients who received second-line treatment (2LT) with bezafibrate and/or obeticholic acid. Data were exported from the ColHai registry (Spanish Registry for Autoimmune and Cholestatic Liver Diseases). Patients with PBC variants were excluded from the study. Included patients were classified into 3 groups (G) according to biochemical parameters at diagnosis. G1: alkaline phosphatase (ALP) <4 × upper limit of normal (ULN) and alanine aminotransferase (ALT) <2 × ULN; G2: ALP <4 × ULN and ALT ≥2 × ULN; and G3: ALP ≥4 × ULN. Event-free survival (EFS), defined as absence of decompensation, death or liver transplantation was calculated. The factors associated with prognosis were analyzed in each group.
Results: Most patients (n = 444, 88%) were female, with a median age of 51 years (IQR: 43–58). Sixty-one percent (n = 308) belonged to G1, 33% (n = 163) to G2, and 7% (n = 34) to G3. At diagnosis, G2 and G3 had higher liver stiffness measurements (G1: 5.8, G2: 7.8, and G3: 9.8; p < 0.001) and a higher frequency of pruritus (G1: 28%, G2: 46%, G3: 42%; p < 0.001). At the last follow-up, the percentage of patients with ALP <1 × ULN (G1: 48%, G2: 40%, G3: 20%, p < 0.001), 1.5 × ULN (G1 80%, G2 68%, G3 38%; p < 0.001) and 1.67 × ULN (G1 82%, G2 72%, G3 47%, p < 0.001) were significantly lower in G2 and G3 patients. After a median follow-up of 110 months (IQR: 65–174), G2 patients had lower EFS compared to G1 (p = 0.002). Unlike G1 patients, in G2 patients, ALP was not independently associated with EFS. In this subgroup (G2), only AST (HR: 1.047, p < 0.001 and HR: 1.034, p = 0.027) and platelets (HR: 1.001, p = 0.006 and HR: 1.001, p < 0.001) before and after the initiation of 2LT were independently associated with EFS. In G3, the results were similar to those of G2, but the low number of events prevented multivariate analysis.
Conclusion: Non-classical PBC phenotypes have worse long-term prognosis and lower response to treatment. In patients with PBC and elevated transaminase levels (G2), AST and platelet counts are the main factors associated with prognosis. Further studies are needed to determine the impact of AST normalization on the prognosis of these patients.

THU-351

Advancements in autoimmune hepatitis epidemiology, treatment and complication – a 15-year retrospective study

Mifleh Tatour[1], Rawi Hazzan[2], Fadi Abu Baker[3], Tarek Saadi[4]. *[1]Clalit Health Services, Northern Region, Israel, Department of Family Medicine, Clalit Health Services, Northern Region, Israel, Afula, Israel, Israel; [2]Department of Gastroenterology and Hepatology, Hillel Yaffe medical center, Hadera, Israel, Bruce Rappaport Faculty of Medicine, Technion – Israel Institute of Technology, Haifa, Israel, Hadera, Israel; [3]Department of Gastroenterology and Hepatology, Hillel Yaffe medical center, Hadera, Israel, Hadera, Israel; [4]Liver Unit, Rambam Health Care Campus, Haifa, Israel, Bruce Rappaport Faculty of Medicine, Technion – Israel Institute of Technology, Haifa, Israel, Haifa, Israel*
Email: Mifleh.rt.1989@gmail.com

Background and aims: Autoimmune hepatitis (AIH) is a rare, heterogeneous liver disease marked by autoantibodies, hypergammaglobulinemia, and distinct histological features. Predominantly affecting women, its incidence and prevalence show significant regional variability globally. Therefore, our aim is to examine the trends of AIH and to assess its demographics, management, and disease progression using an extensive population-based database.
Method: This retrospective, population-based study analyzed data from 2.7 million adults in Clalit Health Services, focusing on autoimmune hepatitis (AIH) diagnoses between 2009 and 2023. Data reordered included demographics, clinical details, and treatment regimens. Key outcomes tracked were the development of cirrhosis and its complications.
Results: This study included 992 AIH patients with a median age of 51.5 years, 80.4% female, and a median follow-up of 6.1 years. Obesity was present in 23.2%, and 10.9% had thyroid disease. At diagnosis, 22.9% had cirrhosis, and an additional 137 patients developed cirrhosis during follow-up, leading to a total prevalence of 36.5%. Among cirrhotic patients, 29.9% experienced decompensation, 25.3% developed ascites, 9.3% had variceal bleeding, and 10.4% developed hepatic encephalopathy. Hepatocellular carcinoma (HCC) occurred in 5.24% of cirrhotic patients, with an incidence rate of 6.32 cases per

1000 patient-years. Overall, 11.2% of cirrhotic patients underwent liver transplantation. The proportion of AIH patients diagnosed with cirrhosis at the time of diagnosis significantly decreased over the study period (p = 0.0028).
Conclusion: This study demonstrates a decreasing trend in AIH patients diagnosed with cirrhosis, suggesting earlier detection and improved management, alongside a lower documented incidence of HCC.

THU-352
The histological activity index is associated with disease severity and treatment response in patients with immune mediated liver injury from checkpoint inhibitors
Robert Fontana[1], Lucy Meunier[2,3], David E Kleiner[4], Benjamin Riviere[5], Dominique Larrey[2], Vincent Chen[1], Jiezhun Gu[6], Huiman Barnhart[6], Alisa Likhitsup[1], Lina Hountondji[2]. *[1]University of Michigan, Ann Arbor, Ann Arbor, United States; [2]Montpellier School of Medicine, Montpellier, France; [3]IRB-INSERM-1183, Montpellier, France; [4]National Cancer Institute, Bethesda, United States; [5]University of Montpellier, Montpellier, France; [6]Duke University, Durham, United States*
Email: rfontana@med.umich.edu

Background and aims: Immune mediated liver injury from checkpoint inhibitors (ILICI) is a common adverse event that may require early ICI discontinuation and/or immunomodulatory therapy. The aim of our study was to identify clinical correlates of histological features in ILICI patients seen at a US Drug-Induced Liver Injury Network (DILIN) site and Montpellier, France.
Method: 45 histological features of 67 ILICI patients were scored by 2 expert hepatopathologists. Since the baseline features of the 34 French and 33 DILIN patients were generally similar, the data were merged for analysis. We investigated if hepatic steatosis (>5%), histology activity index (HAI) >5 and granulomas were associated with clinical features, DILIN severity score (1 to 5) and 6-month treatment outcomes.
Results: Median age was 62.5 years, 63% male, 84% Caucasian. Suspect drugs included Ipilimumab/ nivolumab (24%), pembrolizumab (45%) and other ICIs (31%). At ILICI onset, the median drug latency was 72 days, ALT 346 IU/l, Alk P 207 IU/l, T bili 0.8 mg/dl; 52% hepatocellular, 19% mixed, and 28% cholestatic. Biopsy was obtained at a median of 106 days after ICI initiation and prior to corticosteroid initiation in 54%. During follow-up, 92% received corticosteroids, 30% ursodiol, and 27% mycophenolate/ azathioprine; 34% had chronic DILI while 43% died but only 4% from liver failure. Biopsies demonstrated 42% with HAI > 5, 30% with steatosis and 37% with granulomas. Those with HAI > 5 had significantly more granulomas, plasma cells, bridging necrosis and canalicular cholestasis on biopsy ($p < 0.05$). They also had higher initial and peak serum ALT, T bili and INR levels, higher DILIN severity score and were more likely to receive antimetabolites ($p < 0.05$). In contrast, those with histological steatosis were less likely to have severe hepatitis but more likely to have cirrhosis and higher BMI suggesting that the steatosis may have been a pre-existing feature ($p < 0.05$). Histological granulomas were associated with younger patient age, male sex, higher BMI, and lower peak bilirubin levels ($p < 0.05$).
Conclusion: Moderate inflammation, hepatic steatosis and hepatic granulomas are common in ILICI patients. Patients with more severe histological inflammation have higher ALT, bilirubin and INR levels and are more likely to be refractory to corticosteroids. Going forward, liver biopsy data may help clinicians determine optimal management strategies for ILICI patients.

Comprehensive exploration of disease-specific autoantigen candidates in autoimmune hepatitis through immunocomplexome analysis
Satoshi Matsuo[1], Satoshi Miuma[1], Satoshi Ishida[1], Yasuhiko Nakao, Masanori Fukushima[1], Ryu Sasaki[1], Masafumi Haraguchi, Hisamitsu Miyaaki[1]. *[1]Department of Gastroenterology and Hepatology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan*
Email: s.matsuo41@nagasaki-u.ac.jp

Background and aims: The disease specific antigens for autoimmune hepatitis (AIH) remain unidentified, yet their discovery could significantly contribute to AIH diagnosis and treatment. Unlike array analysis, this study utilizes immune complexome analysis, which comprehensively examines immune complexes formed in vivo, to identify AIH-specific disease antigens.
Method: This study targeted 53 AIH cases (AIH group) and 64 metabolic dysfunction-associated steatotic liver disease (MASLD) cases (MASLD group), diagnosed through liver biopsy between May 2008 and May 2022. AIH diagnosis was based on pathological evaluation and an international AIH group diagnostic score of ≥11. Using Protein A/G, immune complexes were comprehensively collected from stored serum, then digested into peptides for identification via nano-LC-MS/MS and database searches. Relative antigen abundance was quantified through label-free quantification. Candidates specific to AIH were extracted by comparing the results to the MASLD group, setting the MASLD group's abundance +3SD as the positive antigen cutoff. Relative autoantibody levels against these candidates were analyzed using the Luciferase Immunoprecipitation System (LIPS) assay.
Results: The AIH group had a median age of 62 years, with 42 women (79.3%). Liver fibrosis staging revealed 18/15/6/8 cases at stages F1/2/3/4, respectively. Immune complexome analysis identified 1,218 and 1,216 immune complex-forming antigens in the AIH and MASLD groups, respectively. Setting the MASLD group's cutoff at +3SD, antigens with a significantly higher positive rate in the AIH group, reported expression in hepatocytes, and abundance over 2.5 times the cutoff were selected as autoantigen candidates. Three candidates, SKIL (positive in 22.6% of AIH cases), STAT4 (18.9%), and MAGE-D2 (26.4%), were identified as AIH-specific autoantigen candidates. Furthermore, LIPS assay confirmed increased autoantibody levels against these antigens in AIH-positive cases. AIH cases positive for SKIL and STAT4 exhibited significantly higher AST, ALT, and IgG levels compared to negative cases.
Conclusion: SKIL, STAT4, and MAGE-D2 were identified as novel AIH-specific antigen candidates in a subset of AIH cases. Detailed analysis of these antigens' characteristics as autoantigens, including immunohistochemistry, is ongoing.

Predictors of response to steroids in children and adolescents with treatment naïve severe autoimmune hepatitis
Samannay Das[1], Tamoghna Biswas[1], Rajeev Khanna[1], Vikrant Sood[1], Bikrant Bihari Lal[1], Seema Alam[1], Anmol Anmol[1]. *[1]ILBS, New Delhi, India*
Email: samannay393@gmail.com

Background and aims: Steroids are indicated in severe autoimmune hepatitis (AIH) to avert liver transplantation (LT). There is limited paediatric data on prediction of response to steroids. The present study was conducted to identify predictors of response to steroids in children and adolescents with severe AIH.
Method: In this retrospective analysis of prospectively maintained database, children and adolescents below 18 years from January 2011 to May 2024 with severe AIH who received steroids were enrolled. Outcome was studied in terms of response to steroids which was defined clinically in terms of survival with native liver (SNL) or not (LT or death) by Day 28.

Results: Fifty children (31 females) with a median age of 11.9 (6.5, 15) years were studied. There were 9 deaths and 3 LT, while 38 (76%) had SNL. On Multivariate cox regression analysis, advance HE (HR 5.2, p = 0.024) and SURFASA score (HR = 1.2, p = 0.029) predicted poor response. SURFASA (AUROC 0.872) and AAPS scores (AUROC 0.827) were found to be superior to CLIF-SOFA (AUROC 0.798) and PELD (AUROC 0.773). A cut-off of SURFASA score of –2.3 differentiated patients with good or poor response.
Conclusion: Response to steroids is seen in three-fourths of children and adolescents with severe AIH. Advance HE and SURFASA score predicted poor response. SURFASA score >/ = –2.3 help in identifying patients in urgent need for LT.

THU-356
Extra-intestinal autoimmune conditions in patients with primary sclerosing cholangitis – does age matter?
Samantha Campbell[1], Alexandra Frolkis[1], Marianne Samyn[1], Deepak Joshi[1], Jeremy Nayagam[1]. [1]*King's College Hospital, Institute of Liver Studies, London, United Kingdom*
Email: samantha.campbell8@nhs.net

Background and aims: Primary sclerosing cholangitis (PSC) is an immune-mediated liver disease with a genetic predisposition. PSC is associated with inflammatory bowel disease (IBD) and extra-intestinal autoimmune (EIA) conditions, and first-degree relatives also have an increased risk of autoimmune conditions. We aim to evaluate if the phenotype of PSC, including PSC and autoimmune hepatitis overlap (PSC-AIH), presence of IBD and age at diagnosis, is associated with EIA disorders.
Method: All consecutive patients attending Young Adult and Hepatobiliary Medicine clinic with PSC at our centre from October 2023 to August 2024 were identified using electronic patient records. Retrospective data was collected, including phenotype of PSC, age at diagnosis of liver disease, presence of EIA, and family history of autoimmune disorders. Patients with a liver transplant and other cholangiopathies were excluded. Chi-squared tests were used to assess associations between categorical variables. Kruskal wallis was used for non-parametric continuous variables. Logistic regression was used to explore the association between EIAs and liver disease adjusting for confounders (IBD, age, sex).
Results: We included 286 individuals with PSC, with a male predominance of 60.4% and median age at liver disease diagnosis was 26.5 years (Q1: 15.5, Q3: 43). Phenotypes of PSC were: 71% large-duct PSC, 24.8% PSC-AIH and 4.2% small duct PSC. There were 216 (75.5%) patients with IBD, with no significant difference in prevalence based on phenotype (p = 0.25). There were 59 (20.7%) who had an EIA, and the most common EIAs were autoimmune joint condition and thyroid conditions. There was no difference in EIAs based on IBD diagnosis (p = 0.86). After confounder adjustment, there was no significant difference in EIAs by PSC phenotype (odds ratio 0.69; 95% confidence interval 0.31–1.58). For every year increase in age, the odds of having an EIA increased (odds ratio 1.03; 95% confidence interval 1.01–1.05). Of the 231 with available family history, 32 (13.9%) had a first-degree relative with an autoimmune condition. The most common autoimmune disorders in family members were IBD and autoimmune liver disease.
Conclusion: Our results are in line with current literature, and we demonstrated that 21% of patients with PSC had an EIA, and almost 14% had a first-degree relative with an autoimmune condition. The phenotype of PSC with regards to PSC-AIH and PSC-IBD was not associated with presence of EIAs; but increasing age may be a factor. A limitation of our study is the exclusion of patients with more advanced liver disease who underwent liver transplantation. Further work is required to understand which patients with PSC require investigation for EIAs and the potential genetic risk loci underpinning PSC and the association with other autoimmune conditions.

THU-357
The spectrum of adult cholestatic liver diseases related to ABCB4 gene mutations: genotype-phenotype correlation
Sandra Ribeiro Correia[1], Jorge Diogo Da Silva[2,3,4,5], Tiago Pereira Guedes[1,4,6], Luís Azevedo Maia[1], José Manuel Ferreira[1], Ana Rita Soares[2,5,6], Isabel Pedroto[1,6]. [1]*Department of Gastroenterology, Unidade Local de Saúde de Santo António, Porto, Portugal;* [2]*Unidade de Genética Médica, Centro de Genética Médica Doutor Jacinto Magalhães, Unidade Local de Saúde de Santo António, Porto, Portugal;* [3]*Life and Health Sciences Research Institute (ICVS), School of Medicine, University of Minho, Braga, Portugal;* [4]*Unit for Multidisciplinary Research in Biomedicine, Abel Salazar Biomedical Sciences Institute, Porto, Portugal;* [5]*Genetyca-ICM, Atrys, Porto, Portugal;* [6]*School of Medicine and Biomedical Sciences, University of Porto, Porto, Portugal*
Email: sandra.ines.correia@gmail.com

Background and aims: Progressive Familial Intrahepatic Cholestasis Type 3 (PFIC3) is an autosomal recessive disorder caused by variants in the ABCB4 gene. PFIC3 is characterized by biallelic variants in ABCB4 that lead to severe gene defects. The presence of monoallelic pathogenic genetic variants of ABCB4 is associated with a range of clinical manifestations such as Low Phospholipid-associated Cholelithiasis (LPAC), Intrahepatic Cholestasis of Pregnancy (ICP), Drug-induced cholestasis Liver Injury (DILI) or recurrent liver biochemistry abnormalities. We aim to characterize patients diagnosed with cholestatic liver diseases (CLD) related to the ABCB4 gene, including genotype-phenotype correlations.
Method: We conducted a retrospective study that included patients with CLD related to the ABCB4 gene mutation diagnosed between 2015 and 2024 in a tertiary care centre. Non-genetic aetiologies were excluded in all patients.
Results: We included 44 adult patients, 26 females, from 38 families with CLD related to ABCB4 gene mutations. The median age at diagnosis was 41 years. The most common initial clinical presentation was recurrent abdominal pain (n = 12) and pruritus (n = 4). Related to phenotype, patients presented PFIC 3 (n = 1), ICP (n = 10), LPAC (n = 14), DILI (n = 2), and recurrent cholestasis or isolated elevation of Gamma-glutamyl transpeptidase (n = 19). Twenty-two patients underwent cholecystectomy, with a median age of 29 years. One patient had cirrhosis and underwent liver transplantation. We identified 17 unique ABCB4 variants and 6 polymorphic susceptibility SNPs; 32 patients had a monoallelic (23 rare, 9 susceptibility SNP) and 12 had a biallelic variant (4 rare, 8 susceptibility SNP). In 7 cases, the rare ABCB4 variant was of uncertain significance but tending towards pathogenicity (VUS-high). We observed no differences in cholestasis or liver injury marker levels when comparing carriers of either monoallelic versus biallelic or rare versus susceptibility variants. When assessing the main phenotype, monoallelic variants were more common in patients with ICP or asymptomatic (either with or without recurrent biochemical changes) (p = 0.040). Susceptibility SNPs (mono or biallelic) were more common in asymptomatic patients, while rare variants were more frequent in ICP and LPAC cases (p = 0.001). Finally, a complete ursodeoxycholic acid (UDCA) response was more common in patients with rare than SNP variants (p = 0.048), suggesting additional genetic/environmental factors that contribute to the phenotype in SNP cases that UDCA does not revert.
Conclusion: Our results indicate that polymorphic susceptibility ABCB4 variants are typically not associated with disease and that monoallelic variants are associated with no disease or ICP, indicating a less severe phenotype. This work establishes for the first time genotype-phenotype correlations for ABCB4 that include both highly penetrant and common susceptibility variants.

THU-358-YI

Epidemiology of primary sclerosing cholangitis in Canterbury, New Zealand, a population-based study

Samantha Benson-Pope[1], Catherine Stedman, Jeffrey Ngu[1,2]. [1]*Te Whatu Ora Waitaha Canterbury, Christchurch, New Zealand;* [2]*University of Otago, Christchurch, Christchurch, New Zealand*
Email: sbensonpope@gmail.com

Background and aims: Primary sclerosing cholangitis (PSC) is an immune-mediated chronic liver disease characterised by inflammation and fibrosis of intrahepatic and extrahepatic bile ducts leading to cirrhosis and its complications. Previous epidemiological studies have shown that the incidence and prevalence of PSC in Canterbury, New Zealand, are among the highest reported worldwide (1)(2). A nationwide population census was conducted in New Zealand in 2023. Therefore, we aimed to report the latest epidemiology of PSC in Canterbury based on the Census 2023 population data.
Method: Patients with a diagnosis of PSC were added to our existing database. Radiology and histopathology reports were also searched to ensure all PSC cases were captured. Those with radiological or histological diagnoses of sclerosing cholangitis without other identifiable causes were included. Incidence and prevalence rates were calculated using Census population data from Statistics New Zealand.
Results: Our database included 142 PSC patients as of 31st December 2023. From 2017 to 2023, 35 new PSC cases were diagnosed in Canterbury. The average annual incidence of PSC for this period was 0.77/100,000 (95% CI 0.10–1.45/100,000). Excluding patients who had moved away from the region and deceased, there were 82 prevalent cases in 2023. The point prevalence of PSC in Canterbury on 31st December 2023 was 12.6/100,000 (95% CI 9.87–15.32/100,000). Ethnicity-specific prevalence showed that PSC prevalence was significantly higher in ethnic European (14.35/100,000; 95% CI 11.11–17.60/100,000) compared to non-European (5.45/100,000; 95% CI 1.41–9.48/100,000). The majority (66%) had a concurrent diagnosis of inflammatory bowel disease. Most (91%) had large duct PSC; 56% of cases had both intra- and extra-hepatic bile duct involvement at diagnosis, 33% intrahepatic duct involvement only and 2% extrahepatic duct involvement only. The median age of diagnosis was 52 years, and 60% were male.
Conclusion: Our population-based study showed that the incidence and prevalence of PSC in Canterbury were comparable to our previous reports, suggesting that the frequency and burden of PSC in Canterbury remained high. This study also demonstrated a significant difference in the prevalence of PSC among different ethnic groups living within the same geographical region, with the population of European descent having a significantly higher prevalence. It showed that ethnicity influences susceptibility to PSC and suggests a genetic predisposition to the development of the disease.

THU-359

Atherosclerosis in primary biliary cholangitis – more common than previously thought

Suzanne Elshafey[1], Sonal Kumar[1], Russell Rosenblatt[1]. [1]*Weill Cornell Medical Center, New York, United States*
Email: rur9017@med.cornell.edu

Background and aims: Hyperlipidemia (HL) is present in up to 80% of patients with primary biliary cholangitis (PBC) but does not appear to increase the risk of atherosclerotic cardiovascular disease (ASCVD). Guidelines recommend the use of statins in only those patients with independent risk factors for ASCVD. Given rising obesity prevalence, many patients with PBC may benefit from cardiovascular risk reduction with statins. New tools, such as coronary artery calcium scoring (CACS), have emerged to help risk stratify patients with HL. Our hypothesis is that the prevalence of ASCVD in patients with PBC who undergo a CT chest or CACS is high, and as a result, HL may be undertreated in this patient population.
Method: We retrospectively reviewed charts of PBC patients, as diagnosed by EASL guidelines, and included adults with CACS or CT for non-cardiac indications. Patients were followed from time of PBC diagnosis to last available clinical follow-up or liver transplantation. Primary outcome was the presence of ASCVD as defined by the presence of coronary calcification on imaging. Secondary outcomes included the prevalence of statin use in patients with strong indications (ASCVD by imaging or personal history of ASCVD), new ASCVD and all-cause mortality. Outcomes were assessed by multivariable regression and included *a priori* covariates (age, sex and presence of advanced fibrosis).
Results: 94 patients with PBC were included. The median age was 60 years and majority were female (92%) and White (55%). 42% were active or former smokers, 44% had hypertension, 11% had diabetes, and 12% had ASCVD diagnosed prior to PBC diagnosis. Steatotic liver disease was present in 12% of patients diagnosed by either liver biopsy or imaging. 84 patients had CT scans for noncardiac reasons. CT scans (or CACS) were performed a median of 5.8 years after PBC diagnosis. 50% of patients had coronary calcification on CT. Of the 58 patients with strong indications for statins, only 28% and 59% were prescribed a statin at time of PBC diagnosis and end of the study, respectively. 23% of patients were on statins at the time of PBC diagnosis and 40% by last follow up. Patients on statins at PBC diagnosis were male, older, and more likely to have metabolic dysfunction associated steatotic liver disease (MASLD) (all $p < 0.05$). 11 patients had new ASCVD events after diagnosis of PBC – 4 myocardial infarctions, 7 strokes, 3 with peripheral arterial disease. Statin use was not associated with ASCVD, death, or fibrosis (all $p > 0.05$). On multivariable analysis, age (OR 1.04, 1.01–1.07) and prior ASCVD (OR 20.33, 1.34–309.52) were associated with new ASCVD. Only advanced fibrosis (HR 6.80, 1.37–33.62) was associated with increased mortality.
Conclusion: ASCVD prevalence is higher in PBC patients than previously thought and likely undertreated. Further studies are needed to better identify those with ASCVD and PBC.

THU-360

Optimization of corticosteroid treatment for acute severe autoimmune hepatitis: slow simmering shows better prognosis

Rui Wang[1], Qiuxiang Lin[2], Xiong Ma[1], Min Lian[1]. [1]*Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China;* [2]*Mengchao Hepatobiliary Hospital, Fujian Medical University, Fuzhou, China*
Email: sophialian24@163.com

Background and aims: Uncertainties persist regarding the optimal management of acute severe autoimmune hepatitis (AS-AIH), including the use of corticosteroids. This study aimed to compare the effectiveness and safety of rapid versus slow corticosteroid tapering in AS-AIH.
Method: A multicenter study involving patients with acute AIH was conducted. We defined acute AIH as an acute presentation (<30 days) with AIH and exhibiting no evidence of pre-existing liver diseases. Initially, corticosteroid treatment and overall outcomes were reported. Subsequently, the role of corticosteroid tapering rate in modifying outcomes across subgroups was investigated. For patients with an initial corticosteroid dose of 20 mg/day or higher, we further classified patients into rapid tapering group (duration until dose of prednisone <20 mg/day <3 weeks) and slow tapering group (duration until dose of prednisone <20 mg/day ≥3 weeks). Adverse events were defined with any of the following events, progression (e.g., acute icteric AIH progression to AS-AIH or AIH-ALF, AS-AIH progression to AIH-ALF, non-cirrhotic progression to cirrhosis, compensated cirrhosis progression to decompensation), LT, and liver-related death.
Results: This retrospective cohort study enrolled 237 patients, with 109 presenting acute icteric AIH, 97 with AS-AIH, and 31 with AIH-acute liver failure (ALF). Among patients with acute icteric AIH, slow tapering significantly improved adverse outcome-free survival compared to rapid tapering (99% *vs.* 71%, $P < 0.0001$). Similarly, in

AS-AIH patients, slow tapering resulted in notably higher adverse outcome-free survival rates compared to rapid tapering (92% *vs.* 54%, $P < 0.001$). Slow tapering independently predicted fewer adverse events (OR 0.144; 95% CI 0.037–0.562; $P = 0.005$). However, in AIH-acute liver failure (ALF) patients, tapering rate did not significantly affect adverse outcome-free survival (38% *vs.* 50%, $P = 0.590$). Overall, there were no significant differences in osteoporosis or infection occurrence between tapering groups in the entire acute AIH cohort.
Conclusion: A slow corticosteroid tapering reduced adverse outcomes in acute AIH patients, particularly in acute icteric AIH and AS-AIH.

THU-365

Fibrosis stage is an independent predictor of liver-related complications in primary biliary cholangitis

Tadashi Namisaki[1], Hiroyuki Masuda[1], Norihisa Nishimura[1], Shinya Sato[1], Kosuke Kaji[1], Hitoshi Yoshiji[1]. [1]*Nara medical university, Kashihara, Japan*
Email: tadashin@naramed-u.ac.jp

Background and aims: This study aimed to clarify the predictive ability of histological stage (HS) in comparison with biochemical response to ursodeoxycholic Acid (UDCA) (BR) for the development of complications in patients with primary biliary cholangitis (PBC).
Method: A total of 226 patients were diagnosed with serologically and histologically confirmed PBC. All the patients with asymptomatic PBC were treated with UDCA continuously for at least 1 year after the diagnosis were enrolled. Pathological staging was performed in accordance with the Scheuer and Nakanuma classifications (SC and NC). NC comprises grading for liver fibrosis (F) and bile duct loss (S). Nakanuma F and S scores were assessed on a four-point scale (F0–F3 and B0–B3). BR was evaluated according to three previously published definitions: the Nara criteria (NaC), Paris II criteria (PC), and Barcelona criteria (BC). This study investigated the relationship of the development of complications with HS and BR. PBC complications include pruritus, esophageal varices, ascites and jaundice.
Results: The distribution of patients in stage I, II, III, and IV based on the SC was 70/102/51/3. The distribution of patients in stage I, II, III, and IV based on the Nakanuma classification was 20/89/107/10. The cumulative complication rates (CCR) were significantly higher in the advanced stages (Scheuer III/IV and Nakanuma III/IV) than in the early stages (Scheuer I/II and Nakanuma I/II), respectively. CCR were significantly higher in the advanced Nakanuma F scores (Score 2/3) and Nakanuma B scores (Score 2/3) than the early Nakanuma F scores (Score 0/1) and Nakanuma B scores (Score 0/1), respectively. However, there was no differences in CCR between the favorite and poor response groups based on NaC, PC or BC. CCR for the four groups of early stages/favorable response (Group A: GA), advanced stages/favorable response (GB), early stages /poor response (GC) and advanced stages/poor response (GD) was estimated by combining histological stages based on HS and BR, defined as (1) SC/NaC, (2) SC/PC, (3) SC/BC, (4) NC/NaC, (5) NC/PC, (6) NC/BC, (7) F/NaC, (8) F/PC, (9) F/BC, (10) B/NaC, (11) B/PC, and (12) B/BC. CCR for (2) SC/PC, (3) SC/BC, (4) SC/NaC, (5) NC/PC, (6) NC/BC, (9) F/BC, and (11) B/PC were significantly higher in GB than in GA. CCR for (1) SC/NaC, (3) SC/BC, (4) NC/NaC, (6) NC/BC, (7) F/NaC, (8) F/PC, and (9) F/BC were significantly higher in GD than in GC. These findings suggest that CCR increase with progression of HS, regardless of BR. The multivariate COX regression analysis showed that the advanced Nakanuma stage was confirmed as independent factor associated with the development of complications in patients with PBC.
Conclusion: Both HS and BR play a pivotal role in the development of complications of PBC. HS is associated with a higher risk for the development of complications than BR in patients with PBC.

THU-366

Early assessment of treatment response in primary biliary cholangitis: key to timely management

Tomáš Koky[1], Sylvia Dražilová[1], Martin Janičko[1], Dominika Toporcerová[1], Jakub Gazda[1], Peter Jarčuška[1]. [1]*University of Pavol Jozef Šafárik, Faculty of medicine, Košice, Košice, Slovakia*
Email: tomaskoky1@gmail.com

Background and aims: Primary biliary cholangitis (PBC) is an autoimmune liver disease that leads to destruction of the bile ducts and liver fibrosis. The goal of PBC treatment is to achieve a biochemical, histological and clinical remission. The drug of choice for PBC patients is UDCA. Second line PBC treatment for UDCA non-responders is available. The aim of our study was to explore predictive factors associated with compete biochemical response (CBR - both normal bilirubin and ALP levels) in primary biliary cholangitis (PBC) patients treated with ursodeoxycholic acid (UDCA) at month 12 and the end of follow-up. Overall aim of the research is to identify and refine early predictors of the treatment response to allow the inclusion of potential non-responders into second line treatment or clinical trials.
Method: We conducted a multicenter retrospective study of PBC patients. We enrolled patients with PBC treated with UDCA between 1999 and 2024 in 2 hepatology centers in Eastern Slovakia. At inclusion following variables were collected from the patient documentation: total bilirubin, AST, ALT, GGT, ALP, albumin, platelets, prothrombin time (INR) and CRP. Patients were followed every 6 months as is the standard of care for PBC both centers. At follow-up visits, further values of total bilirubine and ALP were collected. We determined the response to the treatment three times during follow-up. After 6 months of UDCA treatment, we assessed therapeutic response according to the modified Toronto criteria; defined as ALP $\leq 1.67 \times$ ULN and total bilirubin $\leq 2 \times$ ULN 13. After 12 months of UDCA treatment and at last check-up, we assessed CBR (ALP $\leq$ULN and total bilirubin $\leq$ULN). Primary outcome was defined as the proportion of patients that achieved CBR, defined as normal bilirubine and normal ALP levels, at last check-up. We had several secondary outcomes as well.
Results: A total 51 of 155 patients included in this study (32.9%) achieved complete biochemical response (CBR) at the end of follow-up. Among patients responding to treatment at month 6 according to Toronto criteria, 44.7% achieved CBR, while only 2.6% of non-responders did. Toronto response at month 6 was the strongest predictor of CBR at 12 months and overall survival. Patients achieving a Toronto response at month 6 had an 81% chance of achieving CBR and a significantly lower risk of decompensation and death compared to non-responders.
Conclusion: Patients with complete biochemical response last check-up had very low chance of hepatic decompensation or liver-related death during follow-up. None of the patients who did not achieve biochemical response at month 6 by Toronto criteria, had CBR at the end of follow-up. For non-responders by Toronto criteria at month 6, initiation of second line treatment should be considered after half a year of treatment.

THU-367

Prognosis of primary sclerosing cholangitis (PSC) in Hungary is independent of coexisting inflammatory bowel disease (IBD) and prognostic ability of the currently used PSC risk scores are limited

David Tornai[1], Peter Ven[2], Bence Toth[1], Zsuzsanna Vitalis[1], Istvan Tornai[3], Tamas Tornai[4], Gabriella Pár[5], Istvan Altorjay[1], Maria Papp[1]. Medicine, Faculty of Medicine, University of Debrecen, European Reference Network on Hepatological Diseases, ERN RARE-LIVER, Debrecen, Hungary; [4]Institute of Pancreatic Diseases, Semmelweis University, Budapest, Hungary; [5]Division of Gastroenterology, First Department of Medicine, University of Pécs, Pécs, Hungary
Email: tornai.david@med.unideb.hu

Background and aims: Primary sclerosing cholangitis (PSC) is a rare, chronic disorder of the intra- and extrahepatic biliary tree characterized by cholestasis, periductal inflammation and fibrosis. Currently, there is very limited epidemiological data from the Central-Eastern European region. We assessed disease characteristics and natural history of PSC in a bicentre Hungarian cohort and compared its outcome with respect to co-existing inflammatory bowel disease (IBD).
Method: Imaging, laboratory and clinical data including presence of IBD, variant syndrome, disease course and outcome were prospectively collected in two large Hungarian Clinical Centre Patients were followed on a yearly basis. Median diseases follow-up (FUP) time was 8.82 (IQR: 5.2–13.5) years. A wide range of clinical scoring systems were applied. Poor disease outcome was defined as orthotopic liver transplantation (LT) and/or liver-related death during the FUP.
Results: Of 135 patients (57.8% males; median age at diagnosis: 31 [IQR: 20–47] yrs) with confirmed PSC, 73 (54.1%) had coexisting IBD. Nineteen patients already had cirrhosis at diagnosis and 31 more developed it during the FUP. A total of 21 (15.6%) patients died of which 85.7% were liver-related deaths. Twenty-five patients (18.5%) underwent liver transplantation (LT). Twenty-three (17%) patients developed malignancy (9 cholangiocarcinoma, 3 hepatocellular carcinoma, 6 colorectal carcinoma and 6 non-gastrointestinal malignancy) during the FUP. Patients with IBD were younger and had higher Mayo and Amsterdam-Oxford scores at diagnosis compared to those without, however there was no difference in disease outcomes in these groups ($p = 0.133$). Clinical scores at diagnosis had moderate prognostic ability for poor disease outcome (AUROC [95%CI], Mayo score: 0.637 [0.521–0.753]; $p = 0.018$; Amsterdam-Oxford: 0.687 [0.576–0.798]; $p = 0.002$; $p < 0.001$; UK-long: 0.695 [0.588–0.803]; $p < 0.001$), except UK-short PSC risk score (0.745 [0.643–0.847]). Persistent alkaline phosphatase (ALP) increase, despite ursodeoxycholic acid (UDCA) treatment, especially within the first two years of diagnosis had good prognostic ability (AUROC [95% CI], at diagnosis: 0.656 [0.556–0.757], $p = 0.006$; after one year: 0.724 [0.602–0.847], $p < 0.001$; after two years: 0.746 [0.617–0.875], $p < 0.001$).
Conclusion: Prognosis of PSC is independent of coexisting IBD in our large Hungarian prospective PSC cohort. Prognostic ability of the currently used PSC risk scores is limited. The UK-short PSC risk score and early ALP response to UDCA treatment showed to have the best accuracy.

THU-368
Unveiling the cholangiopathy of critical COVID-19: unique imaging patterns on magnetic resonance cholangiography

Valéria Borges[1,2], Michelle Damian[2], Cláudia Silva[2], Helma Pinchemel Cotrim[1]. *[1]Universidade Federal da Bahia, Salvador, Brazil; [2]Universidade Federal de Uberlândia, Uberlândia, Brazil*
Email: valeriafaborges@gmail.com

Background and aims: COVID-19-related cholangiopathy, considered a variant of secondary sclerosing cholangitis in critically ill patients (SSC-CIP), represents a progressive cholestatic complication frequently associated with a high risk of progression to cirrhosis, the need for liver transplantation, or death. Diagnosis cannot rely solely on clinical and laboratory findings; therefore, imaging techniques such as magnetic resonance cholangiography (MRC) are essential. This study aimed to describe the imaging findings of COVID-19-related SSC on MRC.
Method: We studied a cohort of 42 adult patients who were mechanically ventilated and confirmed to have COVID-19 through molecular testing between June 2020 and September 2021. These patients had no history of liver disease and were observed until November 2024. A single radiologist reevaluated the MRC studies using a standardised protocol.
Results: Nineteen patients were included, with a median age of 60 [interquartile range (IQR) 51–63], of whom 11 were male (58%). A total of 27 MRCs were performed, with a median interval of 162 days [IQR 78–648.5] after the positive SARS-CoV-2 test. Of these, 24 (88.9%) were conducted prior to any biliary intervention via ERC (endoscopic retrograde cholangiography). In all 26 technically adequate studies, intrahepatic bile duct strictures were identified, with 65.4% presenting with upstream dilation, 81% displaying a "beaded" appearance, and 96% revealing periportal and peribiliary signal alterations without lobar predominance. Intrabiliary casts in the extrahepatic bile ducts were observed in five cases (19.2%). Hepatic morphological changes were detected in 58% of patients. In all follow-up examinations, there was either a worsening in the extent of strictures, an increase in the severity of narrowing, or a progression of upstream dilation. Over a median period of 934 days [IQR 551–1199], eight (42%) developed signs of advanced chronic liver disease, and six patients (32%) died. Significant associations were observed between the severity of MRC findings, age, and the duration of hospitalisation for ARDS (acute respiratory distress syndrome), $p < 0.05$.
Conclusion: COVID-19-related SSC demonstrates multiple intrahepatic bile duct strictures on MRC, with a characteristic "beaded" appearance and thickening of the bile duct walls, accompanied by enhancement and no lobar predominance. The extrahepatic biliary system is generally spared. These findings underscore the critical role of MRC in diagnosing and monitoring this condition.

Direct visualization of fibroblast activation protein inhibitor expression in primary sclerosing cholangitis – a novel biomarker for disease activity and inflammation?

Laura Muana Wilhelm[1], Desiree Weiberg[2], Tim Felgenhauer[3], Frank Bengel[2], Heiner Wedemeyer[1], Thomas Wirth[1]. *[1]Department of Gastroenterology, Hepatology, Infectiology and Endocrinology, Hannover Medical School, Hannover, Germany, Hanover, Germany; [2]Department of Nuclear Medicine, Hannover Medical School, Hannover, Germany, Hanover, Germany; [3]Department of Radiation Protection and Medical Physics, Hannover Medical School, Hannover, Germany, Hanover, Germany*
Email: wilhelm.laura@mh-hannover.de

Background and aims: Primary sclerosing cholangitis (PSC) is a chronic cholestatic disease marked by fibrosis and strictures, with high cholangiocarcinoma (CCC) risk. Limited diagnostic tools hinder early tumor detection, worsening prognosis. Recently, ^{68}Ga-FAPI-PET/CT has emerged as a promising imaging modality for CCC detection. This study aimed to assess the diagnostic efficacy of the novel ^{68}Ga-FAPI-PET/CT in PSC, with a particular focus on early CCC detection.
Method: Eleven PSC patients, seven with histologically confirmed CCC, two with both PSC and CCC, and five controls without hepatic disease underwent ^{68}Ga-FAPI-PET/CT. For PET analysis, physiological liver uptake was defined as mean SUVpeak of all controls, plus 2 SD. FAP liver volume above physiologic uptake (FAP-livo) was calculated. Results were compared to endoscopic retrograde cholangiopancreatography (ERCP), laboratory parameters and Fibrosis-4 (FIB-4) score.
Results: Transaminase levels were highest in PSC patients (ALT median: PSC 87 U/L; AST median: PSC 86 U/L). CRP was highest in CCC (median: CCC 30.2 mg/L). Cholestasis markers were elevated across all groups with significant bilirubin elevation only in CCC (median:

CCC 92 µmol/L). Liver synthesis markers, CHE and INR, were mostly preserved, with slight CHE reduction in PSC/CCC and marked reduction in three CCC cases. FIB-4 predicted advanced fibrosis in three CCC cases. CA19.9 was elevated mainly in CCC patients, with high variability (median 171 kU/L; range 6–16,925 kU/L). Physiological liver FAP uptake in controls was homogeneous with a SUVpeak of 1.5 ± 0.2. FAP-livo was elevated in PSC, CCC and PSC/CCC patients (mean ± SD, 1267 ± 843 ml vs. 1362 ± 1302 ml vs. 1990 ± 1921 ml). Lesion SUVpeak did not differ between PSC and CCC (mean ± SD, 9.9 ± 3.9 vs.14.3 ± 5.8, p = 0.07). Due to the high level of diffuse FAP signal elevation in active PSC regions, additional detection of focal lesions typical for CCC was not feasible. However, PSC mainly exhibited diffuse regional uptake along bile ducts, while CCC showed mainly focal uptake. Furthermore, in PSC FAP expression corresponded with ERCP findings near dominant strictures, and FAP-livo correlated with FIB-4 and white blood cell count in PSC (p = 0.03 each), suggesting association to disease activity and fibrosis.

Conclusion: Our findings suggest that ^{68}Ga-FAPI-PET/CT effectively characterizes disease patterns and may aid in assessing fibrosis risk in PSC patients. Although FAP uptake was elevated in both PSC and CCC, limiting its utility for CCC detection in PSC patients, the correlation between FAP-livo, FIB-4 score, and white blood cell count in PSC suggests that ^{68}Ga-FAPI-PET/CT could still be a valuable tool for monitoring disease activity and inflammation in PSC.

Liver development and regeneration

The reelin signaling pathway in lymphatic endothelial cells is a key driver of ductular reaction during liver injury

Aarti Sharma[1], Pinky Juneja[1], Juliet Luft[2], Deepika Jakhar[1], Jayesh Kumar Sevak[1], Kexin Kong[2], Ashwini Vasudevan[1], Dinesh Mani Tripathi[1], Archana Rastogi[1], Prakash Ramachandran[2], Shiv Kumar Sarin[1], Savneet Kaur[1]. *[1]Institute of Liver and Biliary Sciences, New Delhi, India; [2]Centre For Inflammation Research, Institute for Regeneration and Repair, University of Edinburgh, Edinburgh, United Kingdom*
Email: savykaur@gmail.com

Background and aims: Ductular reaction (DR) exhibiting histologically as proliferating ductal and hepatic progenitor cells (HPC) plays a crucial role in regeneration during liver injury. Mechanisms underlying DR during regeneration in injured liver remains poorly studied. We characterized vascular niche factors governing DR and HPC proliferation in liver injury models.

Method: To study liver regeneration in injury, 2-Acetyaminoflourene (2-AAF) followed by 70% PHx (AAF-PHx) models were developed along with AAF-sham. All analyses were performed from 12 h to D21 post AAF-PHx. Ov6+EpCAM+/CK19+ HPC and ductal cells, CD31+ liver sinusoidal endothelial cell (LSEC) and CD31+PDPN+ lymphatic endothelial cell (LyEC) were studied by Flow Cytometry and immunofluorescence. Proteomic analysis was performed on sorted LSEC and LyEC and differentially expressed proteins and pathways were identified. A single cell RNA seq (scRNA seq) atlas of fibrotic human livers was analysed to identify LyEC ligands expressed in human disease. LyEC:ductal cell co-cultures were employed to validate effect of identified protein and pathway on cell proliferation. Inhibition studies were done using CRISPR-Cas9 mediated transfection of ductal cells with DNA plasmids encoding guide RNA targeting specific genes.

Results: Ductular cells and HPC increased from D4 with maximum increase at D8 and D15 post AAF-PHx. Maximum increase in LSEC and LyEC were observed at D8 and D15. Confocal imaging of liver tissues revealed close association between LyEC and CK19+ ductal cells in portal areas. In-vivo inhibition via MAZ51, a vegfr3 lymphangiogenesis inhibitor led to decline in LVs number and LyEC (60%) along with ductal cells (50%) at D8 post AAF-PHx. Compared to sham, LSEC and LyEC from D8 showed an enrichment and activation of common cell proliferation pathways like Wnt/β-catenin, Ras/MAPK, PI3 K/Akt, actin etc. From rodent proteomics data, human liver scRNA seq and ELISA, we identified reelin (Reln) in LyEC as one of the significant upregulated secretory protein. A high gene expression of Reln and two of its receptors (ITGB1 and ITGA3) was seen on LyEC and ductal cells of AAF-PHx models respectively. Compared to control, treatment of ductal organoids with LyEC-conditioned media and recombinant Reln led to their increased diameter (12 ± 2 vs 21 ± 3 and 19 ± 2)µm. Compared to control cultures, inhibition of ITGB1 and ITGA3 on 2D ductal cell cultures significantly reduced subsequent organoid numbers in 3D cultures (27 ± 2 vs 17 ± 4 and 15 ± 3) and also decreased expression of downstream pathway proteins, pAkt (2fold) and pERK (1.5fold).

Conclusion: Our study suggest that LyEC contribute to ductular proliferation via Reelin-ITGB1/ITGA3 pathway during liver injury. Understanding of mechanisms involved in liver regeneration by HPCs holds promise for potential development of novel therapeutic approaches to life-threatening liver diseases.

Harnessing antioxidant nano-chimeras for combining targeted transforming growth factor β receptor I degradation and transforming growth factor β reduction to attenuate liver fibrosis

Hanshu Liu[1], Hongxia Liang[1], Huan Min[2], Longdi Wang[3]. *[1]the First Affiliated Hospital of Zhengzhou University, Zhengzhou City, Henan Province, China; [2]Enan Institute of Advanced Technology, Zhengzhou University, Department of Pharmacology, School of Basic Medical Sciences, Zhengzhou University, Zhengzhou City, Henan Province, China; [3]Henan Institute of Advanced Technology, Zhengzhou University, Zhengzhou City, Henan Province, China*
Email: 13569939521@163.com

Background and aims: Polydopamine nanoparticles (PDA NPs) have manifested reactive oxygen species (ROS) scavenging capabilities to alleviate the progression of liver fibrosis. Targeting the transforming growth factor β (TGF-β) receptor I (ALK5) to disrupt the TGF-β -Smad2/3 signaling pathway emerges as a potent therapeutic strategy for liver fibrosis. Lysosomal targeting chimeras (LYTACs) technology particularly utilizes various cell membrane receptors to redirect both secretory and membrane-associated target proteins towards lysosomal degradation. Notably, CI-M6PR is a transmembrane receptor highly expressed on the surface of activated hepatic stellate cells (HSCs) that transports mannose-6-phosphate (M6P)-tagged cargos to lysosomes. The aim of the study was to ascertain whether LYTAC constructed with M6P, ALK5 small molecule inhibitor and PDA NPs, which called MAPs, could exert a good role in anti-liver fibrosis.

Method: MAPs' effects of reducing the expression of TGF-β and degrading ALK5 by lysosome to alleviate the activation of HSCs were respectively assessed in H_2O_2-treated mouse monocyte - macrophage leukemia cells (RAW264.7) and TGF-β-induced human hepatic stellate cells (LX-2) by western blot and qPCR. The therapeutic potential of MAPs against liver fibrosis was further evaluated in a CCl_4-induced murine liver fibrosis model, mice were intragastric administrated CCl_4 twice weekly for 1 month, and received treatment of MAPs via the caudal vein every other day from the third week of model construction.

Results: MAPs efficiently scavenged ROS within the macrophages, thereby reducing both the transcriptional and protein levels of TGF-β, and utilized the high affinity of M6P for the CI-M6PR to target activated HSCs for lysosomal degradation of ALK5, leading to

impairment of the TGF-β-Smad2/3 pathway and a decline in the secretion of the ECM in HSCs. In the CCl_4-induced murine liver fibrosis model, MAPs located in liver mostly, reduced fibrotic biomarkers and alleviated liver fibrosis. In addition, CCl_4 treatment robustly augmented phosphorylation levels of Smad2 and Smad3, while MAPs treatment led to significant decreases, thereby markedly dampening the TGF-β-Smad2/3 signaling pathway.
Conclusion: Our research developed an innovative LYTAC system, MAPs, using antioxidative PDA nanoparticle as the core, with R268712 as the ALK5 targeting ligand and M6P as the CI-M6PR targeting ligand, which effectively reduced TGF-β production by scavenging ROS and downregulated ALK5 expression through lysosomal degradation. These dual mechanisms synergistically inhibit the activation of the TGF-β-Smad2/3 signaling pathway in HSCs, effectively reducing ECM expression and alleviating the progression of liver fibrosis. Our work pioneers the use of LYTAC technology in the therapeutic landscape of liver fibrosis, expanding the potential treatment modalities.

Knockout of DDX3X promotes liver regeneration through CD36-mediated hepatic lipid accumulation
Ling Xu[1], Zhenzhen Pan[1], Zihao Fan[1], Yaling Cao[1], Xiangying Zhang[1], Feng Ren[1]. [1]*Beijing Institute of Hepatology/Beijing Youan Hospital, Capital Medical University, Beijing, China*
Email: 15764235913@163.com

Background and aims: The liver possesses a unique regenerative capacity, which is indispensable for the recovery process following liver resection and the management of various liver diseases. Accumulation of lipids in hepatocytes has been recognized as a pivotal factor during liver regeneration, yet the intricate mechanisms underlying this process remain elusive. This study endeavors to elucidate the mechanism through which DDX3X mediates lipid accumulation during liver regeneration.
Method: We collected serum samples from patients at various time points post-hepatectomy. A liver regeneration model in C57BL/6 mice was established by performing a two-thirds partial hepatectomy (PH). Hepatocyte-specific DDX3X knockout (DDX3XΔhep) mice were generated using CRISPR/Cas9/Cre-LoxP technology to investigate the pivotal role of DDX3X in liver regeneration. High-throughput RNA sequencing was conducted to dissect the downstream signaling pathways in DDX3XΔhep mice during liver regeneration. Oil Red O staining was utilized to visualize liver lipid accumulation. qPCR and Western blotting were employed to assess the expression levels of target genes and proteins, respectively.
Results: Patients undergoing PH exhibited a progressive decrease in serum DDX3X levels. In the mouse liver regeneration model, hepatic DDX3X expression initially surged (0–12 hours) and subsequently declined (24–96 hours). Following two-thirds PH, DDX3XΔhep mice demonstrated a significantly augmented regenerative capacity compared to controls, accompanied by a marked increase in liver lipid levels. RNA sequencing revealed enhanced fatty acid uptake in DDX3XΔhep mice during liver regeneration. Notably, knockdown of the key fatty acid receptor CD36 significantly reduced hepatocyte lipid accumulation and impeded liver regeneration in DDX3XΔhep mice.
Conclusion: During liver regeneration, hepatocyte DDX3X deficiency promotes hepatocyte proliferation by augmenting liver lipid accumulation through CD36 regulation. Our findings offer novel insights into the mechanisms underlying liver regeneration and identify potential targets for accelerating postsurgical recovery in patients.

Echinococcus multilocularis infection induces pathological angiogenesis in mouse liver via PDGFR/PI3 K/AKT/FAK signaling pathway
Xiaojuan Bi[1], Ning Yang[1], Guodong Lyu[1], Renyong Lin[1]. [1]*the First Affiliated Hospital of Xinjiang Medical University, Urumqi, Xinjiang, China*
Email: renyonglin@xjmu.edu.cn

Background and aims: Alveolar echinococcosis (AE) is a globally prevalent zoonotic disease caused by Echinococcus multilocularis (E. multilocularis) infection, characterized by the formation of tumor-like growths primarily in the liver, with the potential to spread to other organs. Similar to tumors, E. multilocularis infection is accompanied by pathological angiogenesis, suggesting that the implementation of anti-angiogenic therapeutic strategies may also have promising applications in the treatment of AE. However, the mechanism of angiogenesis in AE remains unclear and needs to be clarified.
Method: To investigate the mechanism of pathological angiogenesis induced by E. multilocularis infection, we established a mouse infection model by inoculating protoscoleces via the hepatic portal vein. Mice were sacrificed at different time points post-infection (2, 4, 10, and 12 weeks) for histopathological and gene expression analyses. Liver tissues were subjected to hematoxylin and eosin (H&E) staining, periodic acid-Schiff (PAS) staining, Sirius red staining, and immunohistochemistry (IHC) to assess pathological changes and angiogenesis. Quantitative real-time PCR (qRT-PCR) was performed to measure the expression levels of angiogenesis-related genes. In vitro experiments were conducted using human umbilical vein endothelial cells (HUVECs) to explore the angiogenic effects of E. multilocularis protoscoleces protein (EmP). Various signaling pathway inhibitors, including PDGFR-β inhibitor AG1296, PI3 K inhibitor LY294002, AKT inhibitor MK2206, and FAK inhibitor Y15, were utilized to elucidate the underlying signaling pathway. Cell viability, migration, and pseudocapillary formation assays were conducted to assess the functional effects of EmP on HUVECs.
Results: In this study, we discovered that angiogenesis related genes are significant up-regulated in the mouse model of E. multilocularis infection and pathological angiogenesis around the lesion was significantly increased at 10–12 weeks after infection compared to the control group. Interventions utilizing a range of inhibitors at the in vitro level, including the PDGFR-β inhibitor AG1296, the PI3 K inhibitor LY294002, the AKT inhibitor MK2206, and the FAK inhibitor Y15, demonstrated that E. multilocularis protoscoleces protein (EmP) induces angiogenesis through PDGFR/PI3 K/AKT/FAK signaling pathway.
Conclusion: Our findings provide new perspectives on how E. multilocularis infection triggers pathological angiogenesis in the host liver, and may provide a novel anti-angiogenic therapeutic strategy against E. multilocularis infection.

SAT-056
Regulation of interleukin-6- and epidermal growth factor receptor-dependent pathways by augmenter of liver regeneration is mediated by activation of ADAM17
Christoph Voigt[1], Sophie Menzel[1], Marion Kubitza[1], Rania Dayoub[1], Michael Melter[1], Prof. Dr. Thomas Weiß[1]. [1]*Children's University Hospital Regensburg (KUNO), Regensburg, Germany*
Email: christoph.voigt@ukr.de

Background and aims: Liver regeneration is a process that is tightly regulated by several cytokines and growth factors. Augmenter of liver regeneration (ALR), a ubiquitously expressed anti-apoptotic, anti-oxidative and anti-inflammatory co-mitogen, is known for its hepatotrophic properties, especially during regenerative processes. Despite its established role in supporting liver regeneration, the molecular mechanisms by which ALR influences cell proliferation and inflammation remain poorly understood. This study seeks to

elucidate ALR's molecular effects on key signaling pathways involved in liver regeneration, providing deeper insights into its regulatory functions.
Method: Hepatoma cell lines and primary mouse hepatocytes were treated with recombinant human ALR (rALR) and/or various specific inhibitors, and the respective signaling pathways were analyzed by immunoprecipitation, Western Blot, qRT-PCR and ELISA techniques.
Results: Our findings reveal that rALR plays a multifaceted role in modulating molecular pathways. It phosphorylates EGFR at cytoplasmic sites independent of direct receptor binding, activating downstream mediators ERK1/2 and Akt. rALR also suppresses IL-6-induced JAK1 and STAT3 phosphorylation, reducing STAT3 target genes involved in inflammation (e.g. ICAM-1) and iron homeostasis (e.g. hepcidin, transferrin receptor, ZIP14). This occurs independently of EGFR activation and without the involvement of regulatory proteins such as SOCS1/3, PIAS, or SHP1/2. Additionally, rALR enhances membrane-bound ADAM17/TACE expression and activity, promoting the release of EGFR ligands and IL-6 receptor (IL-6R) subunit alpha. Mechanistically, rALR activates a GPCR, triggering src and PKC, which induces ADAM17. These findings underscore ALR's intricate role in regulating cell proliferation and inflammation.
Conclusion: In conclusion, rALR modulates key signaling processes by activating the sheddase ADAM17/TACE via GPCR, PKC, and src pathways. This activation promotes the release of EGFR ligands and IL-6R subunit alpha, with EGFR ligands triggering MAPK and PI3 K/Akt pathways to drive cell proliferation. By inducing IL-6R shedding, rALR reduces the functional IL-6 receptor complex, suppressing STAT3 target gene expression in hepatocytes and mitigating inflammation. These actions highlight ALR's broad regulatory impact, influencing EGFR transactivaiton, IL-6R shedding, and potentially other ADAM17-mediated pathways.

SAT-057

Time-restricted feeding modulates genes involved in liver regeneration and damage regression processes in a rat model treated with diethylnitrosamine

Christian Molina-Aguilar[1], Felipe Castañeda[1], Fernanda Guadalupe Arriaga-González[2], Julieta Berenice Rivera-Zavala[1,3], Melany Vivanco Valenzuela[4], Martín del Castillo Velasco-Herrera[2], Kenya Contreras[1], Valeria Martínez Cuevas[1], David J. Adams[2], Mauricio Díaz-Muñoz[5], Carla Daniela Robles-Espinoza[1,2]. *[1]International Laboratory for Human Genome Research - UNAM, Querétaro, Mexico; [2]Wellcome Sanger Institute, Hinxton, Cambridgeshire, CB10 1SA, United Kingdom; [3]Instituto Tecnológico de Estudios Superiores de Monterrey (ITESM), Querétaro, Mexico; [4]Hospital General de México, Ciudad de México, Mexico; [5]Neurobiology Institute - UNAM, 76230, Mexico*
Email: cmolina@liigh.unam.mx

Background and aims: Chronic liver damage can lead to various pathologies ranging from early, reversible conditions like fibrosis and steatosis to irreversible, life-threatening diseases such as cirrhosis and hepatocellular carcinoma. The relationship between inflammation, fibrosis, and regeneration processes is crucial in the progression of damage, and thus, clinical intervention at early stages is critical to prevent its progression. However, the mechanisms driving this progression remain poorly understood, as these stages are subclinical. Time-restricted feeding (T-RF) protocols have shown protective effects against liver damage in both animal models and human clinical studies. By promoting reversible and regenerative processes, T-RF serves as a potentially significant intervention for patients with early-stage liver disease. In this study, we investigated the protective mechanisms of T-RF against chronic inflammation and fibrosis while promoting hepatic regeneration using a rat model treated with the hepatotoxic diethylnitrosamine (DEN).
Method: Forty males Wistar rats were randomly divided into four groups: A) AL group: Untreated rats with 24 hours (h) of food access (Ad libitum). B) AL+DEN group: Rats treated with DEN and Ad Libitum food access. C) T-RF group: Untreated rats with only 2 h of food access per day. D) T-RF+DEN group: Rats treated with DEN and 2 h of food access per day. After 8 weeks of DEN treatment (50 mg/kg), followed by 2 weeks of hepatotoxic depuration, the regression effects induced by T-RF were assessed through blood markers of inflammation and hepatic damage, histopathology, immunohistochemistry technique, and bulk RNA-seq analysis.
Results: Signs of damage were shown in groups treated with DEN but with differential signs of regression pathways. Histopathological evaluation using the Ishak ratio determined, that the liver in both groups AL+DEN and T-RF+DEN underwent regression and regenerative processes, albeit through different mechanisms. In the T-RF+DEN group, chronic inflammation markers were significantly reduced; total leukocytes and lymphocytes count were 34% and 40% lower compared with the AL+DEN group, indicating a significant decrease in systemic chronic inflammation. Additionally, by immunohistochemistry the TNF-alpha levels were significantly lower in the T-RF +DEN group with 1.1 of arbitrary units (AU) compared to the AL+DEN group with 4.8 AU. Through RNA-seq, in AL+DEN group presented 7649 down regulated and 7176 up regulated genes, while T-RF induced 10% upper and 54% downer regulated genes compared with AL+DEN. Also, we identified 53 key genes involved in regeneration and regression processes. The top five of up regulated genes in the T-RF+DEN group compared to the AL+DEN group were STAT6, SP1, SMARCA4, IL6R, and NFkB1, which are associated with regeneration.
Conclusion: The T-RF protocol improved the liver regeneration process by avoiding the establishment of chronic inflammation and favouring regenerative processes.

SAT-058-YI

MAIT cells mediate liver tissue repair via VEGF and VIM secretion

Katia Sayaf[1], Hossain Delowar Akther[2], Martin J. Lett[3], Aneesha Bhandari[3], Lucy C. Garner[3], Narayan Ramamurthy[2], Carl-Philipp Hackstein[4], Francesco Paolo Russo[1], Paul Klenerman[5]. *[1]Department of Surgery, Oncology, and Gastroenterology, Padova, Italy; [2]Peter Medawar Building for Pathogen Research, South Parks Road, Oxford OX1 3SY, UK, Oxford, United Kingdom; [3]Translational Gastroenterology Unit, Nuffield Department of Medicine, University of Oxford, Oxford OX3 9DU, UK, Oxford, United Kingdom; [4]Center for Infection Prevention, Technical University of Munich, 85354, Freising, Germany; [5]Peter Medawar Building for Pathogen Research, South Parks Road, Oxford OX1 3SY, UK, Translational Gastroenterology Unit, Nuffield Department of Medicine, University of Oxford, Oxford OX3 9DU, UK, NIHR Biomedical Research Centre, John Radcliffe Hospital, Oxford OX3 9DU, UK, Oxford, United Kingdom*
Email: katia.sayaf@studenti.unipd.it

Background and aims: Mucosal-associated invariant T (MAIT) cells are highly abundant in the human liver, comprising 20–50% of intrahepatic T cells. MAIT cells express transcriptional signatures linked to tissue repair, but the specific factors driving this function in human tissues remain undefined. The aim of our study is to identify such factors and examine their in vivo relevance, especially in the liver.
Method: Peripheral MAIT cells were isolated from healthy donors and activated using TCR ligands and cytokines. The production of growth factors and vimentin (VIM) was assessed via flow cytometry or in cell culture supernatants using LEGENDplex and Western blot techniques. To evaluate the role of MAIT cells in tissue repair, supernatants were applied to hepatocyte (HHL12) and epithelial (Caco-2) monolayers in wound-healing assays. The role of VEGF/VIM signaling inhibition in repair-associated processes was investigated by blocking VEGFR2 and VIM. To corroborate the relevance of these findings in vivo, single-cell RNA-sequencing data from human liver injury models were analyzed.
Results: Activated MAIT cells were found to produced VEGF and PDGF-AA, with VEGF levels notably higher than those produced by conventional naïve, central memory, and effector memory T cells.

Further, we discovered that activated MAIT cells also secrete VIM, a structural protein that can function as an alternate ligand of VEGFR2. Functionally, supernatants from MAIT cells accelerated wound closure, an effect that was blocked by VEGFR2 and VIM inhibition. Analysis of liver injury models further revealed that MAIT cell-derived VEGF and VIM expression was prominently upregulated in regenerating liver tissue, underscoring their role in tissue repair in vivo.
Conclusion: Our findings demonstrate that MAIT cells play a critical role in tissue repair through the secretion of pro-proliferative factors like VEGF and VIM. For the first time, we provided evidence that by producing VEGF and VIM, MAIT cells drive tissue regeneration via VEGFR2. These results highlight MAIT cells as key mediators in tissue repair, particularly liver regeneration.

SAT-059-YI
A comprehensive study on acute and chronic liver injury response in Acomys (Spiny mice): insights into the role of p21 in liver regeneration
Karen Ching[1], Tak Yung Man[1], Rhona E. Aird[1], Christos Spanos[2], Sofia Ferreira-Gonzalez[1], Stuart J. Forbes[1]. [1]*Institute for Regeneration and Repair, University of Edinburgh, Edinburgh, United Kingdom;* [2]*School of Biological Sciences, University of Edinburgh, Edinburgh, United Kingdom*
Email: kc.karenching@ed.ac.uk

Background and aims: Although mammalian livers possess remarkable regenerative abilities, sustained injury leads to fibrosis and eventual cirrhosis. The genus *Acomys* has emerged as a promising model for studying mammalian regeneration. They demonstrated regenerative capabilities across multiple organ systems, including the central nervous, renal, musculoskeletal, and cardiac systems. Based on these consistent outcomes, we hypothesize that *Acomys* livers exhibit accelerated, scarless regeneration. This project aims to investigate whether *Acomys* livers regenerate efficiently with minimal fibrosis following acute and chronic injury.
Method: We employed 1) surgical model of 2/3 partial hepatectomy (PHx), 2) acute injury model of acetaminophen (APAP) overdosing, and 3) chronic fibrosis-inducing model of carbon tetrachloride (CCl4). Liver samples were processed for histological analysis. Mass spectrometry-based proteomics was carried out in PHx model.
Results: In all models, irrespective of the mode of injury, *Acomys* consistently displayed an increase in p21+ hepatocytes at injury sites, a response that was absent in *Mus*. In PHx model, *Acomys* restored liver function within 48 hours and achieved complete liver mass regeneration within 7 days (n = 7). A significant increase in p21+ hepatocytes was observed in the PHx compared to the sham group (20.47% vs 0.57%; p = 0.002). Despite the upregulation of cell cycle inhibitor, the remnant livers remained proliferative (median BrdU+ hepatocyte: 2.94%). Proteomic analysis also confirmed an upregulation of cell cycle-associated proteins in regenerating liver tissues (Sham n = 2; PHx n = 3). In APAP model, *Acomys* demonstrated higher tolerance than *Mus* (median necrotic area: 6.05% vs 31.02%; p = 0.029). Time-course studies revealed a transient increase in p21 in *Acomys*, which then resolved as liver regenerated (median p21+ hepatocyte: 40.20% vs 0.30%). Interestingly, those cells predominantly localized around the portal vein, forming a distinct boundary from the central vein. In CCl4 model, *Acomys* exhibited no significant elevation in liver damage markers, despite pronounced histopathological changes (n = 7). While *Mus* displayed a significant increase in fibrotic tissue between control and injured groups (median fibrotic area: 1.58% vs. 3.29%; p = 0.027), *Acomys* exhibited minimal fibrotic tissue accumulation (2.93% vs. 3.13%; p = 0.81).
Conclusion: A key finding across all models was the consistent p21 overexpression coincided with injury and resolved during the regeneration process. This precise regulation of p21 appears to facilitate the initiation of the repair cascade while minimizing senescence-associated damage. Investigating the molecular mechanisms underlying *Acomys*' ability to resolve cell cycle arrest and re-enter proliferation holds potential for advancing tissue repair and regenerative medicine, particularly in the context of age-related diseases where cellular senescence plays a significant role.

SAT-060
Extending the lifespan of human chemically derived hepatic progenitors by treating with Drug A
Seunghee Kim[1], Elsy Soraya Salas Silva[1], Ji Hyun Shin[1], Dongho Choi[1]. [1]*Hanyang university, Seoul, Korea, Rep. of South*
Email: ksh000925@naver.com

Background and aims: In clinical trials, mature hepatocyte transplantation has shown potential as an alternative to organ transplantation. However, this approach faces challenges, including limited cell engraftment efficiency, maintenance of function, and long-term *in vitro* culture. To address these issues, we developed human chemically derived hepatic progenitors (hCdHs) capable of differentiating into hepatocytes and cholangiocytes using small molecules to reprogram human primary hepatocytes (hPHs), as demonstrated in previous studies. Despite this progress, variability in cell characteristics among patients and the difficulty of maintaining stem cell properties during long-term culture remain significant obstacles. To overcome these limitations, we identified Drug A to enable prolonged culture while preserving stem cell properties.
Method: Drug A-treated hCdHs (Drug A-hCdHs) were generated by reprogramming hPHs isolated from liver tissue using a medium containing HGF, A83-01, CHIR99021 (referred to as HAC), and Drug A for 8–12 days. hCdHs generated from HAC-containing reprogramming medium without Drug A served as control. The generation of Drug A-hCdHs was confirmed through qPCR and immunofluorescence (IF). To induce cholangiocyte differentiation, Drug A-hCdHs were treated with HAC medium supplemented with EGF, HGF, and CHIR99021 (referred to as CDM). Additionally, Drug A-hCdHs were plated on Matrigel to generate organoids.The organoids generation was observed at day 3 of culture. Drug A-organoids were divided in the day 7 of culture or when the organoids reached the 100 um.
Results: We successfully generated Drug A-hCdHs, and we assessed the mRNA and protein expression of hepatic progenitor cell markers using qPCR and IF. We found that the expression of hepatic progenitor cell markers was maintained at higher levels in Drug A-hCdHs compared to hCdHs as passages increased. Additionally, we confirmed through qPCR analysis that the expression of hepatic stellate cell (HSC) markers increased in hCdHs with prolonged culture, while Drug A-hCdHs did not show them. Furthermore, the results from western blot using PCNA marker indicated that treatment with Drug A enhanced the cell proliferation capacity. Drug A-hCdHs were shown to be capable of differentiating into cholangiocytes. Finally, we successfully generated organoids using Drug A-hCdHs in 3D culture.
Conclusion: These results demonstrated that Drug A regulates the lifespan of cells while preventing HSC-like properties and maintaining hepatic progenitor cell characteristics. Additionally, we showed that Drug A-hCdHs can differentiate into cholangiocytes, and furthermore, can generate organoids.

Background and aims: Liver aging involves a series of cellular and molecular changes that impair liver function and affect the ability to maintain metabolic homeostasis. This process is characterized by an increase in cellular senescence, where cells lose their ability to divide and proliferate, but remain metabolically active, secreting inflammatory and pro-fibrotic factors that contribute to a pro-inflammatory microenvironment. This environment promotes progressive deterioration of liver tissue. With aging, energy metabolism is altered, particularly in the pathways related to lipid and glucose processing. These changes not only reduce the energy efficiency of liver cells, but also predispose the liver to pathologies such as metabolic dysfunction-associated fatty liver disease, which is common in older individuals. NEDDylation, a post-translational modification that regulates the activity of various proteins, plays a key role in liver metabolic processes. Its dysregulation affects glucose and lipid metabolism and interferes with signaling pathways and protein stability. Consequently, NEDDylation may act as a "driver" of liver aging, contributing to the prosenescent and inflammatory state observed in the aging liver. This study aimed to identify the key changes in the NEDDylation process associated with aging.
Method: We conducted an in-depth analysis of NEDDylation in liver samples from murine aging models, including Progeria and SAMR1/SAMP8 models, as well as mice of different ages. Additionally, we performed experiments involving NEDP1 overexpression in the livers of mice of varying ages to further investigate its role in aging-related processes.
Results: Our findings revealed progressive dysregulation of key molecules involved in NEDDylation, which correlated with aging. This suggests that this post-translational modification is intrinsically linked to liver aging. Notably, we observed significant alterations in the level and activity of NEDP1, a critical regulator of NEDDylation, underscoring its potential role in driving age-related changes in the liver. Preliminary results from NEDP1 overexpression experiments indicated that this manipulation induces senescence markers and disrupts metabolism and mitochondrial function. These findings highlight the impact of NEDDylation dysregulation on liver aging and its contribution to the pro-senescent and inflammatory state in aged liver tissue.
Conclusion: Our study underscores the critical role of NEDDylation in liver aging, linking its dysregulation to the key metabolic and cellular changes associated with this process. The observed effects of NEDP1 overexpression on senescence markers and mitochondrial function further emphasized the importance of NEDDylation as a potential therapeutic target. Exploring strategies to modulate NEDDylation could pave the way for novel approaches to address chronic liver diseases and promote health at an advanced age.

SAT-062

Generation and functional profiling of injury-resistant ductal organoids with biliary tree networks optimized by genipin

Shiwen Ma[1], Jiaxian Chen[1], Meiqian Hu[1], Jiaojiao Xin[1], Jing Jiang[1], Dongyan Shi[1], Jun Li[1]. [1]*State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, National Clinical Research Center for Infectious Diseases, National Medical Center for Infectious Diseases, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China*
Email: lijun2009@zju.edu.cn

Background and aims: Cholangiocytes may suffer from oxidative stress injury and mitochondrial dysfunction during the construction of functional ductal organoids (FDOs) for liver regenerative medicine, which limits the functional performance and application potential of the organoids. We aimed to construct injury-resistant FDOs with biliary tree networks.
Method: We used genipin, a crosslinking agent with anti-inflammatory and antioxidant properties, to optimize rat decellularized liver scaffolds (DLSs) and reconstructed FDOs with primary cholangiocytes isolated from mouse bile ducts. The genipin-crosslinked FDOs (GNP-FDOs) were characterized through functional assays and transcriptomics. Hepatotoxic drug chlorpromazine was used to assess the injury-resistance ability of GNP-FDOs.
Results: We observed that genipin-crosslinked DLSs exhibited improved resistance to degradation, showing a degradation rate of about 60% after 120 hours of treatment with collagenase, while non-crosslinked DLSs were completely degraded. Calcein-AM/PI double staining revealed that GNP-FDOs formed a continuous and multi-branch biliary tree network at 7 days. JC-1 staining showed that cholangiocytes in GNP-FDOs had stable mitochondrial potential at day 7 compared with non-crosslinked FDOs. The primary cilia in biliary lumen of GNP-FDOs was observed at day 7 with scanning electron microscopy and immunostaining for acetylated α-tubulin. The rhodamine 123 transport assay exhibited the mature functions of bile secretion and transportation in GNP-FDOs by day 7. Transcriptomic analysis of GNP-FDOs cultured for 1, 7, and 14 days revealed that anti-apoptotic genes were significantly upregulated, while apoptosis-related genes were downregulated at days 7 and 14. Enrichment analysis of 1,014 differentially expressed genes between days 1 and 7 demonstrated that GNP-FDOs exhibited enrichment in gene sets related to primary cilia at 7 days. Pathways related to bile synthesis and secretion, drug metabolism, lipid metabolism, and retinol metabolism were significantly activated at day 7 and remained activated at day 14. The GNP-FDOs upregulated Muc5ac and Lcn2 expression by the IL-17 signaling pathway, exerting antibacterial effects and protecting cells from injury. After exposure to the hepatotoxic drug chlorpromazine for 24 hours, Calcein-AM/PI double staining and JC-1 staining revealed that the GNP-FDOs cultured for 7 days maintained high cell viability and preserved the stability of biliary trees. The expression of apoptosis- and inflammation-related genes in GNP-FDOs were significantly suppressed in response to chlorpromazine exposure.
Conclusion: Such GNP-FDOs with the specific functions of bile secretion and drug metabolism exhibit high resistance to injury, providing promising potential for future clinical therapeutic applications in biliary diseases.

SAT-065-YI

Engineered extracellular vesicles derived from mesenchymal stem cell carrying insulin-like growth factor I to promote liver regeneration after partial hepatectomy

Mailín Casadei[1], María José Cantero[1], Bárbara Bueloni[1], Fatima Huaman[1], Lucia Lameroli Mauriz[1], Natalia Pacienza[2], Catalina Atorrasagasti[1], Juan Bayo Fina[1], Guillermo Mazzolini[1], Esteban Fiore[1]. Universidad Favaloro-CONICET, Ciudad Autónoma de Buenos Aires, Argentina
Email: mcasadei@austral.edu.ar

Background and aims: Liver transplantation is currently the only curative treatment for end-stage liver diseases. Impaired regeneration after liver resection may cause liver failure. Because extracellular vesicles (EV) derived from mesenchymal stem cells (MSC) largely reproduce their immunomodulatory, cytoprotective, and pro-regenerative effect, they are proposed as an alternative to cell therapy. Furthermore, EV are also emerging as a strategy to deliver therapeutic genes. We have recently demonstrated in experimental models that the anti-fibrotic effect of MSC from the umbilical cord (human umbilical cord perivascular cells, HUCPVC), genetically modified to express the hepatoprotective and pro-regenerative factor IGF-I (insulin-like growth factor I), is mediated by EV carrying IGF-I. The aim of this study was to evaluate the effect on liver regeneration of EV carrying IGF-I on partial hepatectomy (PH) model in mice.
Method: EV were isolated by ion exchange chromatography from supernatants of HUCPVC infected with adenoviruses codifying for green fluorescent protein (GFP-HUCPVC-EV) or IGF-I (IGF-I-HUCPVC-EV). EV phenotype was evaluated by flow cytometry for CD63, CD9, CD81 markers and nanoparticle tracking analysis was used to determine EV concentration and size distribution. EV´s biological function was assessed by anti-inflammatory assay on macrophages J774 cells. PH of 66% of liver mass were performed on adult C57BL6 mice by surgical removal of right and left lobes (2/3 of total liver mass). After 1 hour of PH, vehicle (saline solution); GFP-HUCPVC-EV; or IGF-I-HUCPVC-EV were administered by tail vein (1 dose, 50 microgram/mice) and 3 days later animals were euthanized to liver sample collect (n = 6/group). Liver index was calculated as ratio of liver/body weight and liver regeneration rate (LRR) as % of recovered liver mass. qPCR and histological analysis, including mitotic index and PCNA immunohistochemistry for cell proliferation were performed on liver sample.
Results: IGF-I-HUCPVC-EV were able to load and deliver IGF-I while keeping their phenotype, size and biological function. Also, in vivo treatment with IGF-I-HUCPVC-EV led to a higher LI and LRR compared to control groups. An increase in PCNA+ cells following IGF-I-HUCPVC-EV administration indicated enhanced liver regeneration. Moreover, IGF-I-HUCPVC-EV treatment upregulated markers associated with hepatocyte proliferation, such as PCNA, HGF, and cyclin D1, as well as IGF-I, a marker of hepatocyte function. In contrast, the treatment with IGF-I-HUCPVC-EV reduced the expression of pro-inflammatory genes such as IL-1beta, TNF-alpha and iNOS.
Conclusion: Our findings provide experimental evidence supporting IGF-I-HUCPVC-EV as a promising therapeutic agent for enhancing liver regeneration following surgical injury.

SAT-066
A 3D human liver organoid model to study the impact of ischemia-reperfusion injury on liver regeneration during transplantation

Maura Cimino[1], Rosaria Tinnirello[2], Riccardo Perriera[1], Andrea Orlando[1], Pier Giulio Conaldi[1], Massimo Pinzani[2], Giovanni Zito[2], Vitale Miceli[1]. *[1]Ismett- Istituto Mediterraneo per i Trapianti Ismett IRCCS, Palermo, Italy; [2]Ismett- Istituto Mediterraneo per i Trapianti Ismett IRCCS, Palermo, Italy*
Email: vmiceli@ismett.edu

Background and aims: End-stage liver disease (ESLD) is a major global health burden, with liver cirrhosis and hepatocellular carcinoma (HCC) as leading causes of mortality. Liver transplantation (LTx) is the only treatment for ESLD, offering the best chance for survival, but its success is often limited by ischemia-reperfusion injury (IRI), a key cause of graft failure. Stem/progenitor cell-derived organoids, including liver organoids, are 3D *in vitro* models replicating native organ functions. These systems are promising tools for studying liver function, disease modeling, and regenerative medicine. Here, we implemented a 3D human liver organoid (hLiO) model to investigate the impact of IRI on liver regeneration.
Method: We isolated EpCAM+ liver progenitor cells from healthy liver biopsies using enzyme digestion, and seeded them in basal membrane extract (BME) to expand undifferentiated hLiO in a tailored expansion medium. Organoids were characterized by assessing liver progenitor markers (LGR5, EpCAM) via RT-PCR and immunofluorescence. To evaluate the differentiation potential of hLiO, we used a specific medium to differentiate hLiO into hepatocytes. Differentiation was confirmed by mature hepatocyte marker expression (HNF4A, CYP3A4) and albumin secretion (ELISA). Finally, undifferentiated hLiO were used to model ischemic injury through cold storage at 4°C for varying durations (4 to 20 hours), with cell viability assessed at each time point.
Results: We first analyzed undifferentiated hLiO, which expressed higher levels of LGR5 and EpCAM but lower levels of albumin, HNF4A, and CYP3A4 compared to iPSC-derived hepatocytes and primary hepatocytes. Following the differentiation protocol, hLiO exhibited increased albumin secretion and higher expression of CYP3A4 and HNF4A compared to hLiO maintained in expansion medium. Our hLiO model effectively mimics the liver regeneration process through a straightforward *in vitro* differentiation protocol over 11 days. We then evaluated the impact of cold ischemia on undifferentiated hLiO. Our data showed mortality rates of 47 ± 15% at 13 hours, 75 ± 11% at 17 hours, and 84 ± 10% at 20 hours, while no significant effects were detected after 4 hours of cold ischemia.
Conclusion: We presented hLiO as a valid 3D model capable of recapitulating liver regeneration capacity. Consequently, hLiO can serve as a robust model to study the impact of IRI on liver regeneration. We preliminarily evaluated the effects of ischemia on undifferentiated hLiO, but further studies are required to investigate the mechanisms underlying ischemic liver injury, the effects of reperfusion following cold ischemia, and their implications for liver regeneration. This work reveals a promising approach to studying the impact of IRI on liver regeneration, with the ultimate goal of improving liver recovery and regeneration outcomes after transplantation.

SAT-067
3D assembloid model as a useful in vitro tool to study acute and chronic liver diseases

Riccardo Perriera[1], Maura Cimino[1], Cinzia Chinnici[2], Pier Giulio Conaldi[1], Massimo Pinzani[1], Vitale Miceli[1], Giovanni Zito[1]. *[1]IRCCS ISMETT, Palermo, Italy; [2]Fondazione Ri.MED, Palermo, Italy*
Email: gzito@ismett.edu

Background and aims: The study of acute and chronic liver diseases in vitro relied on 2D cell cultures, which often failed to capture the complexity of the in vivo liver environment. In contrast, 3D cultures more accurately replicate liver architecture, and cell-to-cell interactions, enabling a more physiologically relevant representation of liver functions. 3D assembloids, composed of multiple cell types in a spatially organized structure, more closely mimic in vivo conditions, providing a scalable and human-relevant platform for preclinical testing. 3D assembloids can derive from hiPSCs, offering greater reproducibility and consistency than primary cells. hiPSCs are ideal for creating functional liver assembloids due to their plasticity and ability to self-organize into 3D spheroids. As proof of concept, our preliminary study aims to generate a multicellular 3D liver assembloid composed of hiPSC-HEPs and HUVEC endothelial cells.
Method: Human dermal fibroblasts were reprogrammed into hiPSCs using the CytoTune-iPS 2.0 Sendai Reprogramming Kit, and their pluripotency was assessed through gene and protein expression

analysis (qRT-PCR and IF). 2D hiPSC-HEPs were generated using the STEMdiff™ Hepatocyte Kit. For 3D hepatocyte cultures, the differentiation protocol was adapted for non-adherent conditions. HEP differentiation was evaluated via marker expression and albumin release. 3D liver assembloids were created by combining 3D hiPSC-HEPs and HUVEC endothelial cells in a specific ratio, and the assembloids were analyzed for the expression of cell-specific markers.

Results: We generated functional 2D hiPSC-HEPs, characterized by the expression of specific markers and albumin production and secretion. We also optimized a protocol to create mature hepatocyte organoids that expressed the same markers. While differentiation protocols for hiPSC-derived liver sinusoidal endothelial cells (LSECs) and Kupffer cells (KCs) are still in progress, we initiated a proof-of-concept approach to create a 3D multicellular system by combining 3D hiPSC-HEps and HUVEC endothelial cells. Over 14 days, we monitored assembloid formation and performed IFs for HEPs and HUVEC-specific proteins. Whole-mount staining revealed a multicellular system positive for CK18 (hepatocyte marker) and CD31 (endothelial marker), with HUVECs exhibiting a typical elongated, organized arrangement around the hepatocytes, a characteristic behavior of endothelial cells in 3D models.

Conclusion: Our preliminary data support the feasibility of generating hiPSC-HEP organoids that express cell-specific markers and exhibit hepatocyte functions in vitro. While differentiation protocols for LSECs and KCs are still under development, our findings suggest that 3D liver assembloids can be generated to recreate the liver lobule niche, highlighting important cellular crosstalk in physiological and pathophysiological contexts.

SAT-068-YI

Room for improvement in female authorships across leading medical journals

Sara Hauskov[1], Camilla Dalby Hansen[2], Eva Hansen[1], Johanne Kragh Hansen[1], Nikolaj Torp[1], Katrine Lindvig[1], Peter Andersen[1], Stine Johansen[1], Ida Falk Villesen[1], Katrine Bech[1], Katrine Thorhauge[1], Helle Schnefeld[1], Mads Israelsen[1], Maja Thiele[1], Aleksander Krag[1], Maru Rinella[3]. *[1]Centre for Liver Research, Odense, Denmark; [2]Centre for Liver Research, Odense C, Denmark; [3]The faculty of the Section of Gastroenterology, Hepatology & Nutrition, Chicago, United States*

Email: sara.tonder.hauskov@rsyd.dk

Background and aims: The field of hepatology is undergoing a pivotal transformation with emerging medical treatments for steatotic liver disease (SLD). Randomized controlled trials (RCTs) remain the gold standard for evaluating clinical interventions, and prominent authorship positions—particularly first, second, and last authors—are key indicators of academic leadership and influence. However, gender equity in these positions remains a concern.

Method: The current analysis focused on RCTs across all specialties published on PubMed in four major journals: *The Lancet*, *The New England Journal of Medicine* (NEJM), *The British Medical Journal* (BMJ), and *The Journal of the American Medical Association* (JAMA), starting from January 1, 1965. Article metadata were retrieved from PubMed on October 30, 2024, and included variables such as title, authors, year of publication, and identifiers. Data were processed and analyzed in Python 3.10.9. Author first names were extracted from various web sources and used for binary gender classification using a pre-trained machine learning model. Starting in 2005, journals were required to disclose funding sources, which were categorized into two groups: pharmaceutical-sponsored and non-sponsored. The final dataset included 8,872 articles, representing 79% of the original dataset.

Results: A total of 8,872 RCTs were analyzed, comprising 1,261 (BMJ), 2,535 (The Lancet), 3,781 (NEJM), and 1,295 (JAMA). Since 1990, an average of 223 RCTs have been published annually, with the proportion of women across all authorship positions increasing steadily by approximately 5 percent per decade—from 25.6% (1990–1995) to 40.2% (2019–2024). Women as first authors increased from 20% (1990–1995) to 33.5% (2019–2024), while women as last authors increased from 21.5% to 29% respectively. In the past five years NEJM had the lowest representation, with 27.4% of first authors and 26.0% of last authors being women (BMJ with 49.3% and 32.3%). Over the decades, NEJM exhibited only a 5 percent point increase in women as last authors, rising from 20.3% (1990–1995) to 26.0% (2019–2024). Pharmaceutical-sponsored RCTs showed lower female representation compared to non-sponsored studies in the past five years. In pharmaceutical-sponsored publications, women comprised 25.6% of first authors and 26.3% of last authors, compared to 38.9% and 30.5%, respectively, in non-sponsored studies. Across all authorship positions, women accounted for 36.8% in pharmaceutical-sponsored RCTs versus 42.6% in non-sponsored RCTs.

Conclusion: There is still room for improvement in female representation in RCT authorship, despite significant progress over time across all journals. NEJM has shown a notably slower rate of advancement compared to its peers. Last authorship positions have not kept pace with the broader increases in female authorship. Additionally, pharmaceutical-sponsored RCTs continue to show low female representation in both first and last author roles compared to non-sponsored studies.

Cathepsin L inhibitor enhances liver regeneration in fibrotic liver

Shunhei Yamashina[1], Masahiro Tada[1], Kei Ishizuka[1], Hiroo Fukada[1], Akira Uchiyama[1], Reiko Yaginuma[1], Kyoko Fukuhara[1], Kazuyoshi Kon[1], Kenichi Ikejima[1]. *[1]Department of Gastroenterology, Juntendo University School of Medicine, Tokyo, Japan*

Email: syamashi@juntendo.ac.jp

Background and aims: Impaired liver regeneration in fibrotic liver is a well-documented clinical phenomenon. While collagenolytic cathepsins, including cathepsin L (CTSL), show enhanced activity in CCl4-induced fibrotic liver, lysosomal proteolysis and cathepsin biosynthesis are suppressed following partial hepatectomy (PH). Our previous studies demonstrated that CTSL deficiency enhances liver regeneration after PH. This study investigated whether CTSL inhibition could improve regenerative capacity in fibrotic liver.

Method: Male C57BL/6 mice were administered CTSL inhibitor (Z-FY-CHO, 10 mg/kg/day) or vehicle intraperitoneally for 3 days before undergoing 70% PH. Liver regeneration was assessed by measuring wet weight of the remaining liver at 2 and 5 days post-PH, expressed as a percentage of calculated pre-hepatectomy liver weight. To evaluate CTSL inhibition in fibrotic liver, mice were first treated with CCl4 (0.25 mg/g body weight in olive oil) intraperitoneally every 3 days for 2 weeks, followed by CTSL inhibitor or vehicle administration for 3 days. Hepatocyte proliferation was assessed by bromodeoxyuridine (BrdU) immunostaining, and cyclin D1 expression was evaluated by Western blot analysis.

Results: CTSL inhibitor treatment significantly enhanced liver mass restoration at 5 days post-PH compared to controls. BrdU-positive hepatocytes increased from 14.86 ± 0.9% in controls to 23.74 ± 0.8% in CTSL inhibitor-treated mice at 48 hours post-PH. Cyclin D1 expression showed approximately 2-fold elevation in the CTSL inhibitor group compared to controls. In CCl4-induced fibrotic liver, CTSL inhibition increased BrdU-positive hepatocytes from 2.16 ± 0.3% to 8.92 ± 2.3% and upregulated cyclin D1 expression, indicating enhanced regenerative response.

Conclusion: This study demonstrates that CTSL inhibition accelerates liver regeneration after PH, supporting our hypothesis that decreased CTSL activity plays a crucial role in liver regeneration. Furthermore, CTSL inhibition enhanced hepatocyte proliferation in fibrotic liver,

suggesting that the elevated CTSL activity observed in CCl4-induced fibrotic liver may contribute to impaired regeneration. These findings identify CTSL as a potential therapeutic target for addressing regenerative disorders in hepatic cirrhosis.

SAT-070

Extracellular matrix protein 1 (ECM1) as a dual regulator of liver regeneration via HGF/c-MET and TGF-β signaling pathways

Ye Yao[1], Yujia Li[1], Hoehme Stefan[2], Chenjun Huang[3], Seddik Hammad[1], Elisa Holstein[4], Laura Danielczyk[1], Roman Liebe[5], Chunfang Gao[6], Matthias Ebert[7], Honglei Weng[1], Ursula Klingmüller[4], Peter ten Dijke[8], Steven Dooley[1], Sai Wang[1]. *[1]Department of Medicine II, University Medical Center Mannheim, Medical Faculty Mannheim, Heidelberg University, Mannheim, Germany; [2]Interdisciplinary Centre for Bioinformatics, University of Leipzig, Leipzig, Germany; [3]Department of Medicine II, University Medical Center Mannheim, Medical Faculty Mannheim, Heidelberg University, Department of Clinical Laboratory Medicine Center, Yueyang Hospital of Integrated Traditional Chinese and Western Medicine, Shanghai University of Traditional Chinese Medicine, Mannheim, Germany; [4]DKFZ, German Cancer Research Center, Heidelberg, Germany; [5]Clinic of Gastroenterology, Hepatology and Infectious Diseases, Otto-von-Guericke-University, Magdeburg, Germany; [6]Department of Clinical Laboratory Medicine Center, Yueyang Hospital of Integrated Traditional Chinese and Western Medicine, Shanghai University of Traditional Chinese Medicine, Shanghai, China; [7]Department of Medicine II, University Medical Center Mannheim, Medical Faculty Mannheim, Heidelberg University, Molecular Medicine Partnership Unit, European Molecular Biology Laboratory, DKFZ-Hector Cancer Institute at the University Medical Center, Mannheim, Germany; [8]Oncode Institute and Department of Cell and Chemical Biology, Leiden University Medical Center, Leiden, Netherlands*
Email: steven.dooley@medma.uni-heidelberg.de

Background and aims: Extracellular matrix protein 1 (ECM1) is crucial for liver homeostasis and negatively correlates with chronic liver disease (CLD) progression. However, its role in acute liver injury and regeneration (LR) remains unclear. This study investigates ECM1's impact on LR and its underlying mechanisms.
Method: Ecm1-tdTomato mice were administered adeno-associated virus 8 (AAV8)-ECM1 seven days before 70% partial hepatectomy (PHx). Hepatic gene expression was analyzed with RNA sequencing. Functional assays were done with hepatocytes, mouse liver tissue and patient samples.
Results: ECM1 is downregulated during LR after PHx. Interference with ECM1 downregulation by AAV8-ECM1 delays proliferation and liver mass gain at days 2 and 4, but catches up by day 8, as indicated by the liver-to-body weight ratio and immunostaining of PCNA and Ki67. Mechanistically, in early-stages of LR (days 0–4), downregulation of ECM1 is required for efficient HGF/c-MET/ERK/MYC signaling to mediate cell cycle progression, including CyclinA2, B1, B2, and Birc5 expression. In the late stage (days 4–8), overexpression of ECM1 inhibits latent TGF-β activation, therefore interfering with TGF-β-induced cell cycle kinase inhibitors p15, p16, p18, and p19, required for regeneration termination, which finally restores the liver mass. Additionally, Myc overexpression in hepatocytes rescues ECM1 mediated proliferation inhibition. In liver tissue of patients, ECM1-positive hepatocytes display reduced nuclear Myc expression.
Conclusion: ECM1 regulates liver regeneration by modulating HGF/c-MET/ERK/MYC and TGF-β/SMAD pathways. We hypothesize that for patients requiring liver regeneration, ECM1 downregulation benefits hepatocyte proliferation and liver function restoration. However, its inhibitory effect on TGF-β signaling should also be considered.

Integrated single-cell transcriptome and protein analysis unveils long-lasting liver NK cell dysfunction in NUC-treated chronic HBV

Boris Beudeker[1], Arda Karaoglu[1], Gertine Oord[1], Anthony Grooshuismink[1], Harmen van de Werken[1], Robert J. de Knegt[1], Andre Boonstra[1]. *[1]Erasmus Medical Center, Rotterdam, Netherlands*
Email: borisbeudeker@live.nl

Background and aims: Chronic hepatitis B virus (HBV) infection is a leading cause of cirrhosis and hepatocellular carcinoma. While nucleos(t)ide analogues (NUCs) suppress replication, they require lifelong therapy. The immune landscape in NUC-HBV is rarely biopsied and remains understudied, though it has potential to reveal therapeutic targets, as long-term NUC therapy reduces inflammation-related confounders, enabling identification of immune dysfunctions. Liver fine-needle aspiration (FNA) combined with single-cell RNA sequencing (scRNA-seq) has revolutionized access to NUC-HBV livers. CXCR6+ hepatic NK cells, key mediators of antiviral defense, emerge as a critical focus. This study aimed to define immune alterations and identify therapeutic targets in NUC-HBV livers.
Method: HBeAg-negative patients on long-term tenofovir or entecavir therapy with normal transaminases and no fibrosis (F0-F1) were included (n = 18). Blood and paired liver FNAs were sequenced using 10X Genomics scRNA-seq and integrated with healthy liver and blood datasets. Bioinformatic analyses included unsupervised clustering, differential gene expression (DEG), and cell-cell interaction mapping. Multiplex flow cytometry (n = 54) and multicolor immunofluorescent staining of liver biopsies (n = 19) validated findings.
Results: Unsupervised clustering of 221,383 immune cells identified 24,517 NK cells (11.1%) across four clusters. CXCR6+ NK cells, the dominant hepatic subset, were significantly reduced in NUC-HBV livers compared to controls (22% vs. 5% of immune cells, p = 0.002). These cells exhibited the highest IFN-γ gene expression, alongside hallmark genes *XCL1, GZMK, TNFSF10* (TRAIL), and *TIGIT*. Transcriptional profiling revealed 84 DEGs, with downregulated cytokines (e.g., *IFNG, XCL1, CCL3, CCL4*). Cytotoxicity pathways were intact, and exhaustion genes (e.g., *PDCD1* [PD1]) remained low. Immunofluorescence confirmed significant depletion of CXCR6+ NK cells (9% vs. 2% of hepatic cells) and severe loss of in situ IFN-γ production (24.2% vs. 0.2% of CXCR6+ NK cells). Hepatic IFN-γ production was not compensated by CD56dim or CD3+ T cells. Blood NK cells showed minimal changes, supported by extensive flow cytometry. Receptor-ligand analyses revealed a TGF-β-enriched liver microenvironment in NUC-HBV, alongside reduced Kupffer cell responsiveness to IFN-γ (e.g., downregulated *IFNGR1/2*).
Conclusion: Even after years of NUC therapy, CXCR6+ hepatic NK cells remain profoundly suppressed in their ability to produce IFN-γ and other key cytokines, while retaining cytotoxic capacity. The TGF-β-enriched hepatic milieu, rather than IL-10 or exhaustion, is associated with impaired NK immunity. Prolonged IFN-γ suppression by CXCR6+ NK cells may affect non-cytolytic viral control and cccDNA integrity. Restoring liver-resident NK cell functionality could represent a promising immune-based strategy to boost intrahepatic antiviral responses targeting infected hepatocytes.

Human cirrhotic ascites contains myeloid reprogrammed T-cells capable of enhancing peritoneal immune surveillance

Erich Freyer[1,2,3,4,5], Daniel Brown Romero[1], George Finney[1], Anandita Mathur[1], Lucy Cooper[1], Bethany H. James[1], Anke R.M. Kraft[2,3,4,5], Mala Maini[1], Markus Cornberg[2,3,4,5], Laura J. Pallett[1]. [1]*Institute of Immunity and Transplantation, Division of Infection and Immunity, University College London, London, United Kingdom;* [2]*Department of Gastroenterology, Hepatology, Infectious Diseases and Endocrinology, Hannover Medical School (MHH), Hannover, Germany;* [3]*German Center for Infection Research (DZIF), Partner-site Hannover-Braunschweig, Hannover, Germany;* [4]*Centre for Individualised Infection Medicine (CiiM), a joint venture between the Helmholtz Centre for Infection Research (HZI) and Hannover Medical School (MHH), Hannover, Germany;* [5]*Twincore, Centre for Experimental and Clinical Infection Research, a joint venture between the Helmholtz Centre for Infection Research (HZI) and Hannover Medical School (MHH), Hannover, Germany*
Email: freyer.erich@mh-hannover.de

Background and aims: Peritoneal leukocytes are essential for immunoregulation, tissue homeostasis and repair. When peritoneal homeostasis is disturbed leukocytes are recruited to help restore balance. Previously we described the reprogramming of liver-resident CD8$^+$T-cells upon interaction with neighbouring myeloid cells (Pallett et al. Nature 2023). Upon interaction, hepatic CD8$^+$T-cells can 'steal' fragments of the plasma membrane acquiring constitutive immunomodulatory features at rest and enhanced antiviral/anti-tumour functionality. We hypothesised that myeloid cells within the peritoneal cavity reprogramme CD8$^+$T-cells to help maintain peritoneal homeostasis, providing local antiviral/anti-tumour immunosurveillance.
Method: Using spectral flow cytometry and confocal imaging we assessed the phenotype and function of myeloid instructed T-cells, detected by co-staining for CD8 and CD14. For this, leukocytes were isolated from fluid accumulation (ascites) in the abdominal cavity of patients with chronic liver disease.
Results: Here we show myeloid-instructed CD8$^+$T-cells accumulate in ascites, correlating positively with acute-phase-protein (CRP) and negatively with disease severity (MELD). Using a short-term T-cell receptor (TCR; anti-CD3/CD28) stimulation protocol we demonstrate myeloid reprogramming substantially impacts effector function. Peritoneal CD14$^+$CD8$^+$T-cells become 'super-responders' to TCR stimulation with significantly increased production of anti-microbial cytokines and chemokines. We further show that CD14$^+$CD8$^+$T-cells respond to viral peptide stimulation (CMV/EBV/Flu), with increased numbers of polyfunctional dual-cytokine producing (IFNg$^+$TNF$^+$) CD8$^+$T-cells. Furthermore, these cells produce more autocrine IL-2, likely to support their own proliferation and can better mobilise cytotoxic granules (CD107a) upon antigenic encounter. Stealing of the LPS-receptor from the surface of myeloid cells also allows CD14$^+$CD8$^+$T-cells to respond directly to local bacteria. We confirmed LPS-receptor internalisation, indicating that some T-cells may be sensing LPS *in vivo*. Peritoneal CD14$^+$CD8$^+$T-cells take up significantly more LPS than their CD14-negative counterparts in an LBP-dependent manner, indicating a role for the physiological environment of the ascites which is rich in LBP.
Conclusion: As a result of their improved effector functionality, myeloid-instructed CD8$^+$T-cells likely contribute to the maintenance of peritoneal homeostasis, representing an important immune sentinel providing critical antiviral/antitumour and antibacterial immunosurveillance. Targeting myeloid reprogramming may provide an effective approach to controlling chronic inflammation while also addressing the immune dysregulation that contributes to the high mortality rates associated with ascites.

TIGIT blockade on CD8+T cells induces hepatocyte apoptosis

Amber Bozward, Scott Davies, Rémi Fiancette[1], Grace Wootton, Sian Faustini[2], Hin Fai Kwok[2], Naomi Richardson[1], Sean Morris[1], Kayani Kayani[1], Ye Htun Oo. [1]*Institute of Immunology and Immunotherapy, University of Birmingham, Birmingham, United Kingdom;* [2]*Clinical Immunology, University of Birmingham, Birmingham, United Kingdom*
Email: a.g.bozward@bham.ac.uk

Background and aims: TIGIT blockade has recently undergone a phase III trial for the treatment of small-cell lung cancer (SKCRAPER-02), however, the potential adverse effects of TIGIT blockade therapy on the liver is unknown. TIGIT has an inhibitory effect on cytotoxic effector T cells, and blocking TIGIT enhances CD8$^+$ T cell effector functions in tumour-bearing mice. To address this in humans, we investigated the phenotype and function of TIGIT$^+$effector T cells in the liver and their effect on hepatocytes with and without TIGIT blockade.
Method: Liver infiltrating and peripheral TIGIT$^+$effector T cells were phenotyped by flow cytometry, and their localisation was examined by immunohistochemistry. TIGIT$^+$effector T cell-induced primary hepatocyte apoptosis was investigated using co-culture experiments and blocking assays using a TIGIT neutralised antibody and imaged over a 24 h period.
Results: TIGIT$^+$effector T cells expressed CXCR3 and VLA-4 and localised around hepatocytes expressing TIGIT ligand CD155 and CXCL10, VCMA-1 on hepatic sinusoids. TIGIT-expressing CD8$^+$ T cells contain significantly higher granzyme B than non-TIGIT-expressing CD8$^+$ T cells. Additionally, perforin expression is significantly increased in TIGIT$^+$CD8$^+$ T cells compared to TIGIT$^-$CD8$^+$ T cells in controls. We then cocultured primary human hepatocytes (PHH) with TIGIT$^+$ or TIGIT$^-$ CD8$^+$ T cells with or without blocking TIGIT. Our results showed hepatocytes undergo apoptosis at a higher frequency when co-cultured with TIGIT$^-$CD8 T cells than when co-cultured with TIGIT$^+$CD8$^+$ T cells. TIGIT blockade restored PHH killing by TIGIT$^+$CD8$^+$ T cells.
Conclusion: TIGIT+ CD8 cells can recruit to liver via sinusoids and localise around hepatocytes. By blocking TIGIT, inhibition of TIGIT$^+$CD8 T cells is lost, leading to activation and hepatocyte apoptosis. Thus, we reason that anti-TIGIT therapies can potentially induce hepatitis by releasing inhibition of TIGIT$^+$CD8 T cells. These findings serve as a caution on the potential untoward side effects of using TIGIT-blocking therapies, which could lead to checkpoint-induced liver injury.

Transplantation Medicine, Division of Surgery, Inflammatory Diseases and Transplantation, Oslo University Hospital, Institute of Clinical Medicine, Faculty of Medicine, University of Oslo, Research Institute of Internal Medicine, Division of Surgery, Inflammatory Diseases and Transplantation, Oslo University Hospital, Oslo, Norway; [10]Department of Transplantation Medicine, Division of Surgery and Specialized Medicine Oslo University Hospital Rikshospitalet, Oslo, Norway; [11]Department of Gastroenterology, Oslo University Hospital, Institute of Clinical Medicine, Faculty of Medicine, University of Oslo, Oslo, Norway
Email: a.mahdy@ikmb.uni-kiel.de

Background and aims: Primary sclerosing cholangitis (PSC) is a rarer liver disease where chronic inflammation coupled with fibrosis leads to a narrowing of the bile duct, which impedes the flow of bile. A large subset of patients with PSC has concurrent inflammatory bowel disease (IBD)-like that is characterized by a right-sided predominance, rectal sparing, and backwash ileitis. While the complete etiological understanding of PSC or IBD is currently still lacking, we have previously identified a group of type II invariant natural killer T cells that were significantly expanded in a subset of Crohn's disease (CD) patients, hence, we named this subset CAIT cells. These cells recognize non-peptide antigens presented by CD1d. While CAIT cells were more expanded primarily in CD compared to healthy controls and other subsets of IBD, *e.g.,* ulcerative colitis (UC), their expansion and potential pathogenic role in individuals with PSC was not studied yet.
Method: We profiled the T cell receptor alpha (TRA) chain repertoire of 154 individuals with PSC and 64 healthy controls in addition to 855 individuals with IBD or suspension of IBD from the Norwegian inception cohort IBSEN-III. Specifically, 246 symptomatic controls, 228 treatment-naïve CD and 357 UC patients, and 176 and 329 treated CD and UC patients were analyzed.
Results: The expansion of CAIT cells was comparable in individuals with PSC relative to healthy controls, suggesting that these cells are not implicated in the pathogenesis of PSC. By analyzing the repertoire of individuals with IBD, we observed that CAIT cells are significantly expanded in CD (P-value = 5.4×10^{-4}) and that 10.9% of CD patients had a significantly increased CAIT level, particularly in patients with ileal and ileocolonic involvement. Furthermore, the expansion of these clonotypes was higher in individuals with stricturing or penetrating disease behavior.
Conclusion: Our findings indicate that CAIT cells are not implicated in PSC, however, we could replicate that these cells are specifically expanded in individuals with CD, predominantly with ileal and ileocolonic involvement. Although a large subset of PSC patients has a backwash ileitis, this ileal inflammation did not correlate with the expansion of CAIT cells. These findings strengthen the notions that distinct pathophysiological mechanisms, and potentially antigens, are causative for PSC and different IBD subtypes.

FRI-035
The role of FOXP3+ regulatory T (Treg) cells in mouse models of liver disease

Caitlin Abbott[1], Violette Mouro[2], Chiara Perucchini[3], Donato Inverso[2,3], Matteo Iannacone[2,3]. *[1]Dynamics of Immune Responses Unit, San Raffaele Hospital, Milan, Italy; [2]San Raffaele University, Milan, Italy; [3]San Raffaele Hospital, Milan, Italy*
Email: abbott.caitlin@hsr.it

Background and aims: Chronic liver diseases such as viral hepatitis and metabolic associated steatotic liver disease (MASLD) are associated with inflammation and dysregulated immune responses. The contribution of Treg cells to these liver conditions is only partially understood. This study aims to elucidate the role of Treg in the regulation of immune responses in the liver and determine whether they can be targeted for therapeutic benefit. To address this, the phenotypes and kinetics of Treg cells in the liver during both chronic Hepatitis B virus (HBV) infection and MASLD required establishment, in order to elucidate the function of these cells in inflammation and immune dysregulation.
Method: A transgenic mouse model of replication competent Hepatitis B virus (HBV-Tg) was used to mimic the chronic infection setting with transfer of naïve $CD8^+$ HBV Antigen (Ag)-specific T cells not leading to viral clearance but a dysfunctional immune response. To model MASLD mice were fed a choline-deficient high fat diet, western diet, or normal chow from 8 weeks of age and monitored for disease progression up to 1 year. Plasma biochemistry (ALT, total cholesterol, and triglycerides) was used to assess the inflammation in each setting and Treg phenotypes were measured with spectral flow cytometry.
Results: In HBV-Tg mice, transfer of naïve viral Ag-specific $CD8^+$ T cells resulted in an increased percentage and number of liver Treg and specifically favored expansion of Treg expressing CD25 and the receptor for IL-33 (ST2). During MASLD progression, multiple phases of inflammation and resolution were observed with expansion of Treg cells corresponding to increases in effector T cells within the liver. This was distinct from the phenotype in the visceral adipose tissue in which Treg increased after four weeks of diet and proceeded to dramatically decline, highlighting the distinctive nature of the liver environment. Flow cytometry analysis revealed differences in the phenotype of Treg cells between diets and timepoints identifying PD-1^+ $CD25^-$ and $ST2^+$ $CD25^+$ activated and proliferative populations as increased within the liver.
Conclusion: Treg cells were increased in the liver both in the context of dysregulated viral antigen-specific T cell responses in HBV-Tg mice, and during MASLD progression. This study identifies significant changes in Treg populations corresponding to disease stage in each model and is positioned to identify how to manipulate these cells for therapeutic benefit. To further investigate the role of Treg cells, $FOXP3^{DTR\text{-}eGFP}$ mice will be used for depletion of Treg in both models. By depletion of Treg prior to Ag-specific T cell transfer in HBV-Tg mice, this stands to reveal the contribution of Treg cells to the development of dysfunctional $CD8^+$T cell responses in chronic HBV infection. In contrast, Treg depletion will be conducted at defined disease stages in MASLD to increase our understanding of their influence on disease progression.

FRI-036
Single nucleotide polymorphisms of the vitamin D receptor and their impact on vitamin D- and Interleukin-6 levels in liver cirrhosis and acute-on-chronic-liver failure

Alina Bauschen[1], Mona-May Langer[1], Birte Möhlendick[2], Sabrina Guckenbiehl[3], Christian M. Lange. *[1]Department of Internal Medicine II LMU University Hospital, Munich, Germany; [2]Institute of Pharmacogenetics, University Hospital and University of Duisburg-Essen, Essen, Germany; [3]Department for Gastroenterology and Hepatology, University Hospital and University of Duisburg-Essen, Essen, Germany*
Email: alina.bauschen@med.uni-muenchen.de

Background and aims: Vitamin D ($25(OH)D_3$) is a regulator of both adaptive and innate immune system. It has anti-inflammatory, anti-fibrotic and immunomodulatory properties. Therefore, it is important in cirrhosis-associated systemic inflammation. Simultaneously, 25 $(OH)D_3$-deficiency is a frequent phenomenon in chronic liver disease. This study investigated what impact single nucleotide polymorphisms (SNPs) within the Vitamin D receptor (VDR) have on $25(OH)D_3$-status and $25(OH)D_3$-mediated immunological effects in liver cirrhosis and acute-on-chronic liver failure (ACLF).
Method: Clinical data were analysed of patients with compensated and decompensated liver cirrhosis with or without ACLF that were enrolled prospectively from a monocentric cohort study (n = 355). Pyrosequencing was performed to examine VDR for defined SNPs (rs7968585, rs731236, rs7975232, rs2239179, rs2228570). Interleukin-6 (IL-6) levels were quantified using Enzyme-Linked

Immunosorbent Assay (ELISA) and 25(OH)D_3 plasma-concentrations were assessed by ADVIA Centaur® Immunoassay.
Results: Severe 25(OH)D_3-deficiency was frequent in the overall cohort with mean 25(OH)D_3-concentrations at 15.3 ng/mL. As cirrhosis progressed, 25(OH)D_3-levels decreased significantly (compensated vs. ACLF: $p = 0.007$). Likewise, concentrations of inflammatory molecules, for example IL-6, increased with aggravation of liver cirrhosis (compensated vs. ACLF: $p < 0.0001$). In total, 25(OH)D_3- and IL-6-levels showed inverse correlation. 25(OH)D_3-supplementation could significantly increase 25(OH)D_3-status in compensated and decompensated cirrhosis, while in ACLF, 25(OH)D_3-levels were unaffected by supplementary therapies (ACLF supplemented vs. unsupplemented: $p > 0.9999$). Notably, a trend indicating an opposing association between the genotype of the VDR haplotype rs731236/rs7975232/rs7968585 as well as rs2239179 and IL-6-concentrations was observed in both compensated liver cirrhosis and ACLF. Finally, the GG-genotype of the rs2239179 variant showed significant lower expression in ACLF as compared to other patients ($p = 0.0003$) and was associated with 25(OH)D_3-levels in the overall cohort (AG vs. GG: $p = 0.002$).
Conclusion: These data prove the VDR-genotype to affect 25(OH)D_3-status, the efficacy of a supplementary therapy and inflammatory markers in liver cirrhosis. Taking these aspects into account, future analyses should study further immunological effects of 25(OH)D_3, patient outcomes and different supplementation strategies in subgroups of specific VDR-variants.

FRI-037-YI
miRNA/mRNA signature of mouse Kupffer cells during the progression of chronic liver disease from fibrosis to hepatocellular carcinoma

Ananya Ajith[1], Jonathan Evraerts[1], Joachim Ravau[1], Francoise Smets[1], Etienne Sokal[1], Mustapha Najimi[1]. *[1]UCLouvain, Brussels, Belgium*
Email: ananya.ajith@uclouvain.be

Background and aims: Chronic liver disease (CLD) progression from fibrosis to hepatocellular carcinoma (HCC) involves profound immune dysregulation, with Kupffer cells (KCs) playing a pivotal role. KCs are liver resident macrophages that form the primary line of defence in liver. An imbalance in the hepatic macrophage population becomes evident during CLD progression from liver fibrosis to HCC. This study aims to explore the deregulated (DE) miRNA and mRNA profiles in mouse KCs to elucidate key molecular mechanisms driving liver fibrosis and HCC.
Method: C3H mice were given a single injection of diethylnitrosamine (DEN) at 4 weeks of age, followed by continuous injections of carbon tetrachloride (CCl4) for 6 and 21 weeks to induce liver fibrosis and HCC. KCs were isolated by fluorescence-activated cell sorting (FACS) from the non-parenchymal cell fraction of enzymatically digested liver (Collagenase P- Roche), and total RNA was extracted using miRNeasy micro kit (Qiagen), for sequencing. Differential expression and functional enrichment analyses were performed to identify key pathways and biological processes.
Results: For both miRNA and mRNA sequencing, the fold change and p value threshold were set at | logFC | > 1 and p value <0.05. In-depth miRNA sequencing identified 7 DE-miRNAs in fibrosis and 15 in HCC compared to naïve controls. Among the miRNAs analyzed, mmu-miR-210-3p, was uniquely expressed in fibrosis and mmu-miR-126a-5p, mmu-miR-3082-5p, mmu-miR-199a-5p, mmu-miR-125b-5p, mmu-miR-29c-3p, mmu-miR-5128, mmu-miR-714, mmu-miR-709, mmu-miR-362-3p expressed only in HCC, compared to the naïve liver. Notably, mmu-miR-199b-5p was upregulated 4-fold in both conditions. Transcriptomic analysis revealed 140 downregulated and 686 upregulated DEGs in fibrosis, and 243 downregulated and 1,068 upregulated DEGs in HCC compared to naïve controls, and 56 unique to HCC compared to fibrosis. Gene set enrichment analysis highlighted dysregulation of pathways related to immune response, cytokine-chemokine signalling, and inflammatory processes in both fibrosis and HCC groups. DE-genes of the cytokine pathways include Ccr2, Irf4, Il20rb in fibrosis and Cxcl13, ccl12 in HCC. Inflammatory genes include Ednrb, Il33, Il2ra in fibrosis and CCl5, Ilr12 in HCC.
Conclusion: Our study identified distinct DE-miRNAs and DE-genes in KCs during liver fibrosis and HCC, compared to naïve group. These findings highlight the critical role of KCs driving inflammation and immune modulations during CLD progression to tumorigenesis, offering potential therapeutic targets.

FRI-038
Unraveling the liver immune rheostat: How contact-dependent regulation causes dysfunction of antigen-specific CD8 T cells over the course of chronic hepatitis B

Anna Fürst[1], Vincent Steinbacher[2], Hannah Wintersteller[1], Miriam Bosch[2], Ulrike Protzer[3], Dirk Wohlleber[2], Percy A. Knolle[2]. *[1]1Institute of Molecular Immunology, TUM School of Medicine and Health, Technical University of Munich, Germany, Munich, Germany; [2]Institute of Molecular Immunology, TUM School of Medicine and Health, Technical University of Munich, Germany, Munich, Germany; [3]Institute of Virology, Technical University of Munich, Germany, Munich, Germany*
Email: anna.fuerst@tum.de

Background and aims: While acute hepatitis B virus (HBV) infections are controlled by a robust, antiviral CD8 T cell response, CD8 T cells are scarce and dysfunctional in chronic HBV infections. Recently, we showed that the liver immune rheostat is the underlying mechanism that is responsible for the functional inhibition of CD8 T cells during persistent hepatic infections. Here we demonstrate the effect of the microenvironment of the liver on CD8 T cells over the course of infection.
Method: To analyze the liver immune rheostat, we utilized a preclinical model system based on hepatotropic, recombinant adenoviruses to transfer the HBV genome into hepatocytes, thereby inducing acute-resolving or persistent infections. Subsequently, we conducted analysis on these tissues by using confocal microscopy, flow cytometry using isolated CD8 T cells or hepatic cells and by RNA sequencing. Using *in vitro* co-cultures, we could further investigate interactions between hepatic cells and CD8 T cells.
Results: During persistent infection, antigen-specific $CXCR6^+$ CD8 T cells exhibit sustained loss of effector function and dysfunctionality imposed by the liver immune rheostat. Analysis of hepatic interaction partners revealed an extensive contact with $CXCL16^+$ LSECs over the course of persistent infections. Further, complementary *in vitro* studies phenocopied increased PKA phosphorylation and expression of CXCR6, and revealed molecule transfer between LSECs and CD8 T cells.
Conclusion: Our findings reveal that extensive interactions with LSECs induce dysfunction in antigen-specific CXCR6+ CD8 T cells. Further they suggest, that by molecule transfer and signaling changes LSECs could establish the liver immune rheostat and thus contribute to immune modulation during chronic infection.

Single-cell profiling of hepatic dendritic cells in metabolic-associated steatotic liver disease

Camilla Klaimi[1], Pauline Jacquemain[1], Kevin Ory[1], Anne-sophie Jenequin[1], Charlène Pourpe[2], Ghania Hounana Kara Ali[1], Zouriatou Gouda[1], Marine Huillet[1], Nathalie Hennuyer[1], Arnaud Carrier[2], Alexandre Pelletier[2], Fabien Delahaye[2], Amelie Bonnefond[2], David Dombrowicz[1], Bart Staels[1], Delphine Eberlé[1], Joel Haas[1]. *[1]Univ. Lille, Inserm, CHU Lille, Institut Pasteur Lille, U1011-EGID, Lille, France; [2]Univ.Lille, Inserm, CHU Lille, Institut Pasteur Lille, U1283-UMR8199-EGID, Lille, France*
Email: camilla.klaimi@pasteur-lille.fr

Background and aims: Metabolic dysfunction-associated Steatotic Liver Disease (MASLD) is a prevalent chronic liver disease, with increasing incidence linked to rising obesity rates. MASLD can

progress to Metabolic dysfunction-associated Steatohepatitis (MASH), characterized by hepatic necroinflammation and fibrosis. Previous studies, including work from our group, have shown alterations in hepatic conventional dendritic cells (cDCs) in MASH, with a reduced cDC1-to-cDC2 ratio in both humans and mice. However, the role of cDC subtypes in MASH pathophysiology is still unclear. In this study, we aimed to characterize the spectrum of hepatic cDC phenotypes present in MASLD and determine the metabolic and immune signals that induce these signatures.

Method: Single-cell RNA sequencing (scRNA-seq) was performed on sorted cDCs from the livers of chow-fed and MASH-diet-fed mice, with regression after 24 weeks of diet. *In vitro*, bone marrow-derived progenitors (BMDCs) were differentiated into cDC1- or cDC2-like cells using FLT3L+GMCSF or GMCSF alone, respectively. BMDCs were cultured under various conditions and analyzed for gene expression by RT-qPCR and metabolic phenotype by single-cell energetic metabolism by profiling translation inhibition (SCENITH).

Results: Our scRNA-seq analysis identified 9 cDC clusters in the livers of chow- and MASH-fed mice. Cluster 4 was significantly enriched in MASH-fed mice (1.7% in chow vs. 10.7% in MASH) and showed high expression of migratory dendritic cell markers, including *Ccr7*. This cluster's gene expression profile resembled mregDC, a phenotype associated with the tumor microenvironment. In a MASH regression model, we observed a decrease in hepatic mregDC levels after 4 weeks, though levels did not return to those in chow-fed mice. Gene expression in BMDCs showed that mregDC markers were induced by TLR stimulation and further upregulated by free fatty acid treatment.

Conclusion: Our findings suggest that metabolic changes during MASLD drive the mregDC transcriptional program. Further research is needed to identify the signals regulating mregDC induction and their role in MASLD progression or regression.

Email: cboni@ao.pr.it

Background and aims: In chronic HBV infection, HBV-specific CD8 T cells consist of a heterogeneous cell population composed of different subsets which display variable degrees of dysfunction or attenuation of their antiviral functions in relation to the stage of disease/infection and to the specificity for distinct HBV antigens. In particular, simultaneous staining with exhaustion (PD-1) and memory (CD127) markers identifies two main subsets of HBV-specific CD8 T cells ($PD1^{hi}CD127^{low/-}$ and $PD1^{+}CD127^{+}$) variably distributed in individual patients with HBeAg negative chronic hepatitis. Aim of the study was to characterize the transcriptional profiling and functional features of HBV-specific CD8 T cell subsets in patients with HBeAg negative untreated chronic active hepatitis (CH) and in CH patients who achieved HBsAg clearance either spontaneously or by NUC therapy (Re) to better understand their role in HBV pathogenesis and to identify intracellular pathways relevant for HBV functional cure.

Method: Gene expression profiles of individual HBV $core^{18-27}$-specific CD8 T cell subsets sorted by PD-1 and CD127 co-staining were analyzed by Nanostring, adapted for low-input samples (e.g. 1–10 cells) in 5 HBeAg negative CH patients and in 6 Re patients. The analysis of checkpoint/differentiation molecules (CD39, Bcl-2), transcription factors (TOX, TCF1) and cytokines (TNF-alpha and IFN-gamma) by flow cytometry was performed in an expanded cohort of 21 CH and 19 Re patients.

Results: Transcriptional analysis of HBV-specific CD8 T cell subsets shows an enrichment in exhaustion-related genes in the $PD1^{hi}CD127^{low/-}$ subset as compared to $PD1^{+}CD127^{+}$ memory like (ML) cells in CH patients, which is even more significant when the comparison focuses on $PD1^{+}CD127^{+}$ ML cells of Re patients. A signature of 13 genes identifies the progressive transition from the more exhaustion-oriented $PD1^{hi}CD127^{low/-}$ CD8 T cells of CH patients to the intermediate phenotype of $PD1^{+}CD127^{+}$ T cells of CH patients and the more memory-oriented $PD1^{+}CD127^{+}$ ML T cells of Re HBsAg negative patients.

Conclusion: Our study identifies distinct exhaustion signatures in the different HBV-specific CD8 T cell subsets that coexist at different ratios in the distinct phases of the disease and that may guide individualized transcriptional/functional correction therapies for CHB patients.

Enhancing restorative macrophage functions through genetic modification improves liver fibrosis in MASH models

Christopher Sloas[1], Hongxue Shi[2], Xiaobo Wang[2], Yumi Ohtani[1], Julia Smith[1], MacKenzie Villano[1], Nancy Carson[1], Angela Mosebarger[1], James Montgomery[1], Linara Cornell[1], Jordan Reff[1], Sascha Abramson[1], Daniel Blumenthal[1], Thomas Condamine[1], Ira Tabas[2], Michael Klichinsky[1], Brad Zinker[1]. *[1]Carisma Therapeutics, Inc., Philadelphia, United States; [2]Department of Medicine, Columbia University Irving Medical Center, New York, United States*
Email: christopher.sloas@carismatx.com

Background and aims: Liver fibrosis is a central pathway in multiple liver diseases, including metabolic dysfunction-associated steatohepatitis (MASH). Treatment options remain few for severe MASH patients, and current therapies have minimal direct impact on fibrosis. Macrophage-based therapies represent an opportunity to target fibrosis in liver diseases. Macrophages are innate immune cells that support fibrosis resolution by regulating tissue remodeling and inflammation. Here, we sought to augment macrophages' pro-restorative capabilities by engineering them to express fibrosis-modifying transgenes. We demonstrate that macrophages can be rationally engineered to express proteins that target distinct liver disease pathways by reducing inflammation, inhibiting fibrosis, and clearing apoptotic hepatocytes. We then assessed the therapeutic benefit of macrophage engineering in multiple murine MASH models.

Method: Human and murine macrophages were engineered to overexpress newly identified fibrosis-modifying transgenes including IL-10, relaxin, and TIM-4. *In vitro* assays demonstrated the ability of each transgene to promote pro-restorative macrophage functions, such as efferocytosis and fibroblast inactivation. The *in vivo* efficacy of engineered murine macrophages was evaluated using diet-induced models of liver fibrosis: a 26-week westernized diet (WD) with low-dose CCl_4 (WD-MASH; cells dosed IV at weeks 21, 23, 25) and a 6-week CDAHFD model (cells dosed IV at week 4). The CDAHFD model was additionally implemented in immunodeficient NSG mice, using human macrophages expressing human transgene sequences.

Results: Engineered macrophages successfully expressed newly identified anti-fibrotic transgenes both *in vitro* and *in vivo*. In one embodiment, macrophages were engineered to co-express IL-10 and relaxin. Systemically administered engineered cells reduced fibrotic

area in both the WD-MASH and CDAHFD models (45% and 69% vs. control, respectively). In an additional approach, macrophages were engineered to express the efferocytosis receptor TIM-4. In the context of both murine and human TIM-4, a single dose of engineered cells reduced fibrotic area in CDAHFD models (69% and 58% vs. control, respectively). Importantly, the anti-fibrotic efficacy of engineered cells was superior to that of non-engineered cells in all studies. Multiple fibrosis-modifying transgenes and macrophage engineering strategies were analyzed *in vitro* and *in vivo* to expand the utility of this approach.
Conclusion: Macrophages engineered to express fibrosis-modifying transgenes improved liver fibrosis in multiple MASH models. These results demonstrate preclinical proof-of-concept for using engineered macrophage therapies to treat liver fibrosis. The approach represents a platform technology that has the potential to address key underlying pathologies driving liver fibrosis as an off-the-shelf therapy.

Defining the role of tissue-resident Kupffer cells in the pathogenesis of chronic liver disease
Fabio Colella[1], Eleni Papachristoforou[1], Ravinder Parhar[1], Elena Sutherland[1], Xintong Zhang[1], Ben Higgins[1], Amy Board[1], Taylor McGilvaray[1], Tom Collings[1], Neil Henderson[1], Prakash Ramachandran[1]. [1]*University of Edinburgh, Edinburgh, United Kingdom*
Email: fcolell2@ed.ac.uk

Background and aims: Cells of the innate immune system are crucial mediators of fibrosis progression in chronic liver disease (CLD) and have gained attention as putative therapeutic targets. However, whilst the role of monocyte-derived macrophages, specifically $TREM2^+CD9^+SPP1^+GPNMB^+$ scar-associated (SAMac)/ lipid associated macrophages (LAM), in fibrosis pathogenesis are now well described, the functional role of embryologically-derived liver resident Kupffer cells (KCs) in disease progression remains largely unknown. To address this, we developed a new transgenic mouse model which is deficient in KCs and investigated the impact on CLD pathogenesis.
Method: Clec4f-Cre;$Csf1r^{flox/flox}$ mice were generated, exploiting the early expression of Clec4f during KC development and essential role of Csf1r signalling for macrophage survival. Clec4f-$Cre^{-/-}$;$Csf1r^{F/F}$ (Cre^{neg}), Clec4f-$Cre^{+/-}$;$Csf1r^{F/F}$ (Cre^{het}) and Clec4f-$Cre^{+/+}$;$Csf1r^{F/F}$ (Cre^{hom}) mice were bred and characterised in homeostasis and following induction of CLD by either twice-weekly carbon tetrachloride (CCl4) injections for six weeks or administration of the choline-deficient amino acid-defined high-fat diet (CDAHFD) for five weeks. Flow cytometry and multiplex immunofluorescence (IF) staining were used to quantify hepatic macrophage subpopulations in different genotypes and conditions. Fibrosis and steatosis levels were quantitated histologically by picrosirius red staining followed by machine learning analysis using QuPath.
Results: Using spectral flow cytometry and IF, significant depletion of $TIMD4^+$ KC was observed in Cre^{het} and Cre^{hom} animals in both healthy liver tissue and following the induction of CLD. However, overall macrophage number was not different between genotypes, indicating replenishment of the liver with $TIMD4^-$ macrophages in Cre^{het} and Cre^{hom} animals. Ly-$6C^{hi}$ monocytes and SAMac/LAMs expanded in CLD liver tissue compared to healthy but no significant difference was observed in hepatic Ly-$6C^{hi}$ monocyte or SAMac/LAM numbers between genotypes. Histological analysis showed that $TIMD4^+$ KC depletion had no effect on the degree of hepatic steatosis in CDAHFD model or on the levels of liver fibrosis in either CCl4 or CDAHFD-treated mice.
Conclusion: We present a new model which enables assessment of the functional consequences of chronic depletion of embryologically-derived $TIMD4^+$ KCs. Our data indicate a functionally redundant role for $TIMD4^+$ KCs in the development of liver fibrosis, with $TIMD4^-$ macrophages replenishing this population following depletion and maintaining similar tissue responses to chronic injury. Hence, therapeutic interventions aimed at targeting macrophages in CLD should be focussed on modulating monocyte-derived macrophages rather than embryologically-derived $TIMD4^+$ KCs.

Safety and efficacy of everolimus in autoimmune hepatitis – a single center retrospective analysis
Florian Seltsam[1], Georgios Konstantis[1], Martina Daniel[1], Sabrina Guckenbiehl[1], Sebastian Wiener[1], Marcin Krawczyk[1], Hartmut Schmidt[1], Claudia Veltkamp[1]. [1]*University Hospital Essen, University of Duisburg-Essen, Essen, Germany*
Email: florianalexander.seltsam@uk-essen.de

Background and aims: Autoimmune hepatitis (AIH) is a rare autoimmune liver disease that is typically managed with standard steroid- and immunosuppressive regimens including azathioprine, mycofenolate mofetil, tacrolimus or cyclosporine. However, some patients fail to respond to these therapies or develop treatment-related skin cancer and require alternative treatments. Mammalian target of rapamycin (mTOR) inhibitors have been reported as potential alternatives, but available data are sparse, with limited patient number and conflicting outcomes. This study aims to evaluate the safety and efficacy of the mTOR – inhibitor everolimus in AIH.
Method: We performed a retrospective analysis of patients with AIH treated at our center from January 2020 to October 2024. AIH was diagnosed by specific autoantibodies, increased IgG concentrations, histological demonstration of interface hepatitis and periportal necrosis as well as prompt response to corticosteroids. Patients who received everolimus either due to non-response to other immunosuppressive therapy or due to a *de novo* skin cancer under the therapy were included in the analysis. We documented side effects of everolimus and analysed its effects on liver status. Changes in liver function tests under the therapy with everolimus were analysed using paired student t-test of unequal variance.
Results: From our collective (about 500 patient contacts per year) a total of 18 patients (14 women, median age 60 years, age range 28–77 years, nine with cirrhosis) received everolimus due to non-response to immunosuppressive therapy (n = 12) and/or skin cancer (n = 11). Fourteen patients (78%) reported no side effects from everolimus, while four experienced mild side effects during the first month, leading to therapy discontinuation. Among 12 patients who received everolimus for lack of disease control, nine (75%) demonstrated significant ALT reduction at three (p = 0.01) and six months (p = 0.03). Everolimus was discontinued in two patients due to non-response and in one patient due to mild side effects. Among six patients with skin cancer, three discontinued the therapy due to side effects of everolimus, while the remaining three achieved sustained remission with persistent normalization of serum AST, ALT, AP, GGT and immunoglobulin G (IgG). Side effects reported in the entire cohort included pruritus and apthae in mouth (1/18 (5.5%)), mild pancytopenia (1/18 (5.5%)), mild depressive symptoms (1/18 (5.5%)) and mild face swelling (1/18 (5.5%)), completely resolving after treatment discontinuation. No severe side effects such as infection, pneumonitis, hepatitis B reinfection, Pneumocystis-jirovecii-pneumonia (PCP), kidney injury and amenorrhea were observed.
Conclusion: Everolimus appears to be a safe and effective therapy for AIH in most cases. Larger prospective studies are warranted to confirm these findings and further asses in role in the therapy of AIH.

Email: freyer.erich@mh-hannover.de

Background and aims: Hepatitis E virus (HEV) is the leading cause of viral hepatitis worldwide, typically resulting in an acute, self-limiting infection in immunocompetent individuals. However, in immunocompromised individuals, HEV can cause chronic hepatitis. γδ T cells, a unique population of T cells abundant in the liver, play a crucial role in bridging innate and adaptive immunity. Several subsets of γδ T cells have been identified as key regulators in chronic infections. This study aims to investigate the role of γδ T cells at different stages of HEV infection, focusing on their phenotypic and functional adaptations.
Method: We analysed 53 patients (23 immunocompetent, 30 immunocompromised) with acute, chronic or resolved HEV infections and 15 healthy controls. Peripheral blood mononuclear cells (PBMCs) were analysed by high-parameter flow cytometry to characterise the ex vivo phenotype of γδ T cells. Intracellular cytokine assays were performed following in vitro stimulation of PBMCs to assess functional responses.
Results: Using dimensionality reduction of high-parameter flow cytometry data, we identified a distinct subset of γδ T cells - specifically CD8-positive γδ T cells - that differed between acute and chronic HEV cases. In chronic HEV, $CD8^+$γδ T cells were skewed towards Vδ1 and non-Vδ1Vδ2 subsets compared to acute infections. These cells displayed a robust effector phenotype, characterised by increased activation markers (CD38, CD69) and antiviral mediators (perforin, granzyme B, T-bet) compared to CD8-negative γδ T cells. Effector memory $CD8^+$γδ T cells (CCR7-/CD45RA-) were positively correlated with liver inflammation (ALT) in chronic HEV infection ($r = 0.67$, $p < 0.05$). In addition, $CD8^+$γδ T cells expressed higher levels of CD16, suggesting enhanced antibody-dependent cellular cytotoxicity (ADCC). However, prolonged infection was associated with reduced CD16 expression in chronic cases. In chronic HEV, $CD8^+$γδ T cells produced less IFNγ after TCR stimulation and exhibited a weaker pro-inflammatory (IL-17A) and anti-inflammatory (IL-10) cytokine response after IL-12/IL-18 stimulation in vitro compared to acute HEV cases.
Conclusion: $CD8^+$γδ T cells represent a distinct effector immune cell subset that adapts dynamically during acute and chronic HEV infection. In chronic infection, their skewed effector phenotype and reduced regulatory functions may contribute to impaired antiviral responses and increased inflammation, thereby promoting disease progression, making them potential biomarkers or therapeutic targets for chronic HEV infection.

FRI-045-YI
Hepatic stellate cells orchestrate the retention and functional impairment of tissue-resident CD8+ T-cells in the fibrotic human liver

George Finney[1], Stephanie Kucykowicz[1], Daniel Brown Romero[1], Bethany H. James[1], Ginevra Pistocchi[1], Anandita Mathur[1], Niamah Nishan[1], Giulia Lupo[2], Maria Castanho Martins[2], Walid Al-Akkad[2], Mala Maini[1], Prakash Ramachandran[3], Krista Rombouts[2], Laura J. Pallett[1]. *[1]Institute of Immunity and Transplantation, Division of Infection and Immunity, University College London, London, United Kingdom; [2]Institute for Liver and Digestive Health, Division of Medicine, University College London, London, United Kingdom; [3]Centre for Inflammation Research, Queen's Medical Research Institute, University of Edinburgh, Edinburgh, United Kingdom*
Email: laura.pallett@ucl.ac.uk

Background and aims: Stromal cells regulate tissue homeostasis, orchestrating local immunity by imprinting cell fate, producing immunomodulatory mediators, promoting leukocyte tethering and altering immune cell function. Here we explored the capacity of primary hepatic stellate cells (HSCs) - resident non-parenchymal pericytes - to dictate the derivation and function of tissue-resident $CD8^+$T-cells (T_{RM}) in the human liver.
Results: Transdifferentiated HSCs (proliferative myofibroblasts secreting TGF-beta and retinoic acid) induce expression of prototypic tissue retention signals (CD69/CD103/CD49a) on peripheral $CD8^+$T-cells in 2D co-cultures and HSC-repopulated 3D decellularised liver scaffolds. Interestingly, HSC repopulating 3D scaffolds obtained from the healthy liver, compared to the fibrotic liver, exhibit a less activated, more quiescent phenotype. Associated with this, the frequency of 'induced T_{RM}' ($CD69^+CD103^+$) T-cells is significantly reduced. In support of our *in vitro* findings, the proportion of hepatic $CD8^+T_{RM}$ ($CD69^+CD103^+$) increase in individuals with fibrosis as a consequence of a range of chronic liver diseases, where HSC are highly activated *in vivo*. A previous study in mice has suggested that T_{RM} may play an anti-fibrotic role by eliminating activated HSCs. Therefore, we assessed the functionality of healthy and fibrotic T_{RM} by stimulating (anti-CD3/CD28) intrahepatic leukocytes for 4 hours. T_{RM} from both the healthy and fibrotic liver produced equivalently high levels of IL-2, characteristic of hepatic T_{RM}. In contrast, the amount of anti-fibrotic IFN-gamma and the ability to mobilise cytotoxic granules (CD107a) was significantly impaired in fibrotic T_{RM}. In line with their reduced functionality, fibrotic $CD8^+T_{RM}$ express higher levels of co-inhibitory receptors (PD-1/TIGIT) and less co-stimulatory molecules (CD28) *ex vivo*, despite comparable levels of activation (HLA-DR/CD38/CD44). Finally, we demonstrate that HSCs upregulate the corresponding co-inhibitory ligands (PD-L1/CD155) in fibrosis and directly suppress hepatic T_{RM} IFN-gamma production when co-cultured. Remarkably, pre-treatment of transdifferentiated HSCs with anti-PD-L1/L2 antibodies restored the ability of T_{RM} to secrete IFN-gamma.
Conclusion: We demonstrated that HSCs imprint a tissue-residency program on hepatic T-cells and directly limit effector function. Critically our data suggest treatment with checkpoint inhibitors such as PD1/PD-L1 may reduce the extent of fibrosis and subsequent disease sequalae by reinvigorating the anti-fibrotic potential of well positioned, long-lived T_{RM} effector cells.

FRI-046-YI
Fine needle aspiration reveals immunotherapy biomarkers and targets compartmentalised within hepatocellular carcinoma

Gloryanne Aidoo-Micah[1,2], Stephanie Kucykowicz[1], Vishnu Naidu[3], Sayani Khara[3], Tate McKinnon-Snell[1], Rushabh Shah[2], Daniel Brown Romero[1], Yiya Zhong[1], Upkar Gill[4], Nathalie Schmidt[1], Mariana Diniz[1], Laura J. Pallett[1], Edward Green[2], Alexa Childs[2], Tim Meyer[2,5], Mala Maini[1]. *[1]University College London, London, United Kingdom; [2]Royal Free London NHS Foundation Trust, London, United Kingdom; [3]Royal Free London NHS Trust, London, United Kingdom; [4]Queen Mary University of London, London, United Kingdom; [5]UniversityCollege London, London, United Kingdom*
Email: g.micah@ucl.ac.uk

Background and aims: Harnessing tissue-resident immunity for tumour clearance requires approaches that rescue local effector CD8+ T cells from intrinsic dysfunction, while overcoming extrinsic suppression by regulatory immune counterparts within the tumour niche. Thus, sampling immune cells sequestered in tumours is critical to the discovery of targetable regulatory pathways and subsets. In hepatocellular carcinoma (HCC), diagnostic biopsies often contain a mixture of immune cells from HCC and surrounding non-tumoural liver, and their invasive nature and requirement for tissue processing has restricted their application. We hypothesized that fine needle aspiration (FNA) of liver tumours would offer a minimally invasive method to monitor local tissue-compartmentalised immune

responses to dissect primary and secondary immunotherapy resistance mechanisms.
Method: Patients with advanced HCC were consented to provide matched blood, FNA and biopsy. Peripheral blood mononuclear cells (PBMC) from blood (n = 25) and tumour infiltrating leukocytes (TIL) from FNA (n = 25) and biopsy (n = 15) were isolated for *ex-vivo* spectral multi-parameter flow cytometric and *in vitro* functional characterisation of effector and regulatory immune populations.
Results: FNA reproducibly sampled a broad range of viable immune subsets local to the tumour microenvironment (TME) and yielded significantly more leukocytes than biopsies (mean 73% v 27% of all live cells, $p < 0.001$). Crucially, FNA were able to extract tissue-resident $CD8^+$ T cells ($T_{RM,}$ $CD69^+CD103^+CD8$) that could not be sampled in blood (10% v 0.1% of total CD8+ cells, $p < 0.0001$). The majority of tumour $CD8^+T_{RM}$ sampled before immunotherapy expressed multiple immune checkpoints including PD-1, Tim-3 and 2B4, accounting for significantly higher expression of these therapeutic targets on the global $CD8^+$ T cells extracted from FNA or biopsies than from blood. Within the myeloid compartment, dendritic cells were reduced whereas functionally suppressive neutrophils with a granulocytic/polymorphonuclear myeloid derived suppressor cell phenotype (g-MDSC/PMN-MDSC) were markedly expanded in tumour FNA compared to blood, allowing characterisation of their dominant homing and immunoregulatory mechanisms to define novel therapeutic targets.
Conclusion: We show that minimally invasive FNAs are capable of comprehensively sampling the distinct immune landscape of HCC compartmentalised at the site of disease, including the presence of key immunotherapeutic targets (T-cell checkpoints and g-MDSC). The resulting data have allowed characterisation of immunotherapeutic targets paving the way for future personalised refinement of targeted immunotherapy to overcome tumour immune escape.

Low-dose lipopolysaccharide administration improves the survival rate of septic shock by enhancing the bactericidal activity of Kupffer cells and reducing hepatic infiltration of pro-inflammatory monocyte-derived macrophages in mice

Hiroyuki Nakashima[1], Bradley Kearney[1], Manabu Kinoshita[1].
[1]*Department of Immunology and Microbiology, National Defense Medical College, Tokorozawa Saitama, Japan*
Email: hiro1618@ndmc.ac.jp

Background and aims: Lipopolysaccharide (LPS) administration induces a severe inflammatory response in experimental animals. However, repeated administration of low-dose LPS effectively stimulates innate immune cells and improves survival rates in the septic shock model, called LPS preconditioning (LPS precon, DOI: 10.1159/000475931). Kupffer cells, a special macrophage found in the liver, eliminate blood-borne bacteria and are essential to survive septic shock. In this study, we sought to elucidate the impact of LPS precon on Kupffer cells.
Method: Male C57BL/6 mice were preconditioned with LPS by daily intraperitoneal injection of various concentrations of sub-lethal LPS for three consecutive days. We isolated liver non-parenchymal cells 24 hours after the final injection for flow cytometry analysis. The bactericidal activity of Kupffer cells was assessed *in vitro* by pH-rodo labeled *Escherichia coli* (*E. coli*) and *Staphylococcus aureus* (*S. aureus*). The subset analysis of $F4/80^{low}$ monocyte-derived macrophages (MdMphs) was performed according to our previous study (DOI: 10.1002/cyto.a.24783).
Results: LPS precon upregulated the expression of CD11b on Kupffer cells, suggesting the activation of these cells. *In vitro*, bactericidal activity was up-regulated not only against *E. coli* but against *S. aureus* as well. Interestingly, only Kupffer cells showed a significant dose-dependence between bactericidal activity and LPS dosage, whereas MdMphs or neutrophils did not. Although the cell number of MdMphs increases after the treatment, the percentage of pro-inflammatory MdMphs decreased, which suggested that immune-suppressive monocytes are recruited to reduce the inflammatory reactions in subsequent sepsis induction.
Conclusion: LPS precon dramatically impacted Kupffer cells and augmented bactericidal activity against both gram-positive and negative bacteria. We propose that the enhanced bacterial clearance by Kupffer cells and recruitment of immunosuppressive monocytes are crucial mechanisms of the improved survival rate of sepsis in LPS precon mice.

FRI-048-YI

Establishing an optimised method for single-cell RNA-seq based immunophenotyping from cryopreserved human liver needle biopsies

Juliet Luft[1], Fabio Colella[1], Holly King[2], Craig Lammert[2], Naga Chalasani[2], Prakash Ramachandran[1]. [1]*Centre for Inflammation Research, Institute for Regeneration and Repair, University of Edinburgh, Edinburgh, United Kingdom;* [2]*Division of Gastroenterology & Hepatology, Indiana University School of Medicine, Indianapolis, United States*
Email: jluft@ed.ac.uk

Background and aims: Single-cell RNA-seq (scRNAseq) has transformed our understanding of immune cell heterogeneity in chronic liver diseases (CLD). However, due to fresh human liver tissue availability, most scRNAseq studies focus on end-stage liver disease, a point at which pharmacological interventions are unlikely to be effective. In contrast, single-cell or single-nucleus (snRNAseq) profiling of liver needle biopsies have the capacity to define the immune landscape during CLD evolution, yielding more tractable therapeutic targets. To take advantage of these samples, better methods are required to comprehensively profile all immune and non-immune cell types from small archival liver needle biopsies. Consequently, we performed benchmarking of five single-cell approaches to define the optimal strategy for immune profiling in human liver needle biopsies.
Method: Human liver biopsy tissue was obtained from the University of Edinburgh or Indiana University with ethical approval. We compared single-cell data from five methods: (a) Fresh scRNAseq (10X Genomics) on FACS-enriched viable cells following enzymatic dissociation of fresh liver biopsies (n = 2). (b) Publicly available fresh snRNAseq data (10X Genomics) from cryopreserved liver biopsy tissue (n = 9). (c) Fixed snRNAseq (Parse Biosciences) on cryopreserved liver biopsies (n = 5). (d) Fixed snRNAseq (10X Genomics Flex) on cryopreserved liver biopsies (n = 4). (e) Fixed scRNAseq (10X Genomics Flex) on cryopreserved liver biopsies following fixation and enzymatic dissociation (n = 6). Comparative bioinformatic analysis was performed using R.
Results: Fresh scRNAseq (method a) yielded the fewest cells and failed to capture non-immune cells. Fixed snRNAseq sequenced using Parse Biosciences (method c) had the worst immune cell coverage, with low cell and transcript counts preventing full characterisation. The impact of ambient RNA was apparent in all snRNAseq methods (methods b-d), resulting in low confidence annotation of cell types. In contrast, fixed scRNAseq using the 10X Flex protocol (method e) captured the full repertoire of immune and non-immune cells from each cryopreserved biopsy sample, with lower ambient RNA contamination and mitochondrial gene detection, improving cluster separation and enabling high-confidence annotation of myeloid and lymphoid subtypes.
Conclusion: We describe a fixed scRNAseq approach which can be applied to cryopreserved human liver needle biopsies, capturing immune and non-immune cells from a single small sample and facilitating robust subclustering and annotation. Importantly, this approach generates high quality immune cell data at lower per sample cost, due to sample multiplexing and reduced sequencing depth. Application of this method to study early-stage liver biopsies

offers the opportunity to define new therapeutic targets for immune-mediated CLD.

Influence of T cell exhaustion versus senescence in the development of spontaneous operational tolerance following liver transplantation

Jorge Torres[1], Julien Vionnet[2], Elena Perpiñán[1], Elisavet Codela[1], Niloufar Safinia[1], Alberto Sanchez-Fueyo[1]. [1]*Institute of Liver Studies, Liver Sciences Department, School of Life Sciences & Medicine, King's College London University, London, United Kingdom;* [2]*Centre de Transplantation d'Organes (CTO) et Service de Gastro-entérologie et d'Hépatologie (GLG), Centre Hospitalier Universitaire Vaudois (CHUV), Lausanne, Switzerland*
Email: jorge.torres_yaguana@kcl.ac.uk

Background and aims: In the setting of transplantation the liver exerts unique immunoregulatory properties, which accounts for the feasibility of completely discontinuing maintenance immunosuppression in a small subset of patients (spontaneous operational tolerance). The gradual exhaustion of alloreactive T cell clones as a result of the high antigenic load provided by the liver allograft has been proposed as a potential mechanism to account for this phenomenon. However, to date this has only been investigated in recipients with chronic hepatitis C infection. In contrast to exhaustion, T cell senescence is associated with increased inflammatory markers and reduced immunological tolerance, but its role in clinical liver transplantation remains to be investigated. Here we report the results of immunophenotypig studies conducted on sequentially collected blood samples from liver transplant recipients enrolled in a multi-centre European immunosuppression withdrawal trial (LIFT trial, NCT02498977).
Method: Out of the 82 patients who initiated drug withdrawal, 13 (16.3%) met the primary end-point of spontaneous operational tolerance and 54 (67.5%) either rejected or developed sub-clinical histological changes. We analysed PBMC samples from 10 tolerant (TOL) and 10 rejecting (Non-TOL) recipients before the initiation of weaning (baseline), 6–9 months after, and 12 months after having completely stopped immunosuppression. We combined multi-parameter spectral cytometry (25 phenotypic parameters) and time-of-flight mass cytometry (CyTOF; 28 phenotypic/metabolic parameters) to assess the phenotype and metabolic state of circulating T-cells and their association with the development of tolerance.
Results: TOL and Non-TOL patients differed in the proportion of exhausted and senescent T-cells. TOL patients displayed increased exhausted CD8+ CD45RA+ effector memory T-cells (TEMRA), which positively correlated with recipient age (but not with time post-transplant). In contrast, in Non-TOL we observed increased senescent CD8+ TEMRA, which negatively correlated with circulating levels of telomerase. Metabolic profiling revealed that both CD4+ and CD8+ effector memory T-cells from TOL were metabolically quiescent, whereas CD8+ TEMRA from Non-TOL exhibited a highly metabolically active state.
Conclusion: Our findings suggest that immunological outcomes following liver transplantation (rejection versus tolerance) are orchestrated by a finely tuned balance between T-cell exhaustion and senescence.

FRI-050-YI

CD155 blockade modulates monocyte responses in acute-on-chronic liver failure

Joseph Delo[1,2], Daniel Forton, Evangelos Triantafyllou[3], Arjuna Singanayagam[1,2]. [1]*Institute of Infection and Immunity, City St George's, University of London, London, United Kingdom;* [2]*Department of Gastroenterology and Hepatology, St George's University Hospital, London, United Kingdom;* [3]*Department of Metabolism, Digestion and Reproduction, Imperial, London, United Kingdom*
Email: joseph.delo@gmail.com

Background and aims: Monocytes play a critical role as a first-line defence against bacterial infections. In acute-on-chronic liver failure (ACLF) however, monocytes adopt an immunosuppressive phenotype characterised by increased anti-inflammatory cytokine secretion and impaired phagocytosis. CD155, an immune checkpoint expressed on monocytes, binds to the inhibitory receptor CD96 on T cells. CD155 signalling has been shown to drive macrophages toward an M2-like, immunosuppressive state in tumours and reduce their ability to activate T cells during antigen presentation. This study investigates the role of CD155 in monocyte dysfunction in ACLF and its therapeutic potential as an immunomodulatory target.
Method: Participants included healthy controls (HC, n = 33), patients with compensated cirrhosis (n = 7), stable decompensated cirrhosis (n = 11), acute decompensated cirrhosis (n = 21), and ACLF (n = 20), recruited within 48 hours of hospital admission. Peripheral monocyte CD155 expression was assessed via flow cytometry. Peripheral blood mononuclear cells (PBMCs) from HCs were conditioned with patient-derived plasma for 48 hours, and CD155 or CD96 were blocked using monoclonal antibodies. Monocyte function was evaluated by analysing activation/exhaustion markers (CD86, HLA-DR, MERTK, CD206, PDL1), phagocytosis (pHrodo *E. coli* BioParticles), and cytokine production (IL-6, IL-10, TNF-alpha, IL-1beta) after lipopolysaccharide (LPS) stimulation.
Results: A higher proportion of CD14+CD16+ monocytes expressed CD155 in ACLF patients compared to HCs (61.1% vs. 28.9%, p = 0.003), with expression correlating positively with Child-Pugh (r = 0.28, p = 0.03) and MELD scores (r = 0.34, p = 0.01). Conditioning HC PBMCs with ACLF plasma upregulated CD155 expression on monocytes (54.3% to 83.0%, p = 0.001) and recapitulated the immunosuppressive phenotype observed in ACLF with increased MERTK and PDL1 expression, elevated IL-10 production, and reduced phagocytosis. Blocking CD155 completely reversed suppressive marker expression to HC levels (MERTK MFI 26300 to 7600, p < 0.001; PDL1 MFI 7400 to 4700, p = 0.001) and ameliorated the increase in IL-10 production (5.67% to 3.50% IL-10 positive, p = 0.02). However, blocking CD155 did not restore phagocytic capacity.
Conclusion: This study highlights CD155 as a mediator of monocyte dysregulation in ACLF. Targeting CD155 could modulate monocyte function, enhance antibacterial immunity, and reduce dependence on antibiotics in ACLF patients.

FRI-055-YI

Inhibition of the lysophatidylcholine-autotaxin-lysophosphatidic acid axis restores monocytic pro-inflammatory cytokine production in patients with acute-on-chronic liver failure

Joseph Wilson[1,2], Roosey Sheth[1,2], Francesca Trovato[1,2], Rima Abdalla[T,2], Evangelos Triantafyllou[3], Mark Mcphail[1,2]. [1]*Institute for Liver Studies, Department of Inflammation Biology, King's College London, London, United Kingdom;* [2]*King's College Hospital NHS Foundation Trust, London, United Kingdom;* [3]*Department of Metabolism, Digestion and Reproduction, Imperial College London, London, United Kingdom*
Email: joseph.wilson10@nhs.net

Background and aims: Acute-on-chronic liver failure (ACLF) is a life-threatening syndrome characterised by monocytic immunoparesis, leading to systemic bacterial infection and high rates of sepsis. Autotaxin (ATX) hydrolyses lysophosphatidylcholine (LPC) to lysophosphatidic acid (LPA) and is upregulated in liver failure and is associated with increased mortality. The mechanistic role of the individual lipids of the LPC-ATX-LPA axis in modulating monocyte capabilities are unclear. We hypothesise that ATX inhibition restores monocyte-specific cytokine production, surface phenotype, and phagocytic capacity.
Method: Fifteen ACLF patients and seventeen healthy controls (HC) were prospectively recruited. Whole blood was cultured with LPA

16:0 (30uM), LPC 16:0 (30uM), ATX inhibitor HA130 (100nM), or LPC in combination with HA130. Monocyte-specific cell surface immunophenotyping (CD163, HLA-DR, MerTK, PD-L1), and intracellular cytokine staining (IFNg, IL-1b, IL-6, TNFa, IL-10) following stimulation with lipopolysaccharide (LPS), was assessed by flow cytometry gating for CD14+ monocytes. Monocyte phagocytic capacity was measured by uptake of GFP-tagged *E. coli* with flow cytometry.

Results: Incubation with LPA downregulated monocytic MerTK and PD-L1 expression in ACLF (p = 0.0057; p = 0.0312 respectively) and impaired intracellular expression of pro-inflammatory cytokines IFNg and IL-1b in ACLF (p = 0.03; p = 0.06) and HC (p = 0.02; p = 0.005). In HCs, LPA also suppressed IL-6 production (p = 0.02). LPA-induced IFNg suppression was restored with ATX inhibition in both HC and ACLF (p = 0.005; p = 0.09). ATX inhibition also restored IL-6 expression in HC (p = 0.03). Interestingly, LPA and ATX inhibitor treatment yielded no differences in TNFa and IL-10 production in either cohort. LPC incubation significantly abrogated expression of CD163 in both ACLF and HC (p = 0.049; p = 0.064), and HLA-DR, and MerTK in HC (p = 0.031; p = 0.037). None of these phenomena were reversed with LPC and ATX inhibitor co-incubation, thus suggesting LPC-dependent suppression. In HC, LPA significantly impaired phagocytic capacity vs LPC and ATX inhibitor co-incubation (p = 0.0121) but not in ACLF, indicative of LPA driving monocytic function. LPC incubation did not alter intracellular cytokine production in either cohort.

Conclusion: ATX inhibition restores LPA-induced suppression of monocyte-derived pro-inflammatory cytokines in both ACLF and HC, and phagocytic capacity in HC. Pro-inflammatory cell surface proteins appear downregulated in an LPC-dependent fashion in both ACLF and HC. The LPC-ATX-LPA axis is a promising immunomodulatory target warranting further investigation in liver failure syndromes.

FRI-056

Investigating macrophage- phenotype and organ injury in acute-on-chronic liver failure

Juan Wang[1], Mohsin Hassan[1], Marlene Kohlhepp[1], Felix Heymann[1], Moritz Peiseler[1], Nicola Wilck[2], Frank Tacke[1], Pavitra Kumar[1], Cornelius Engelmann[1]. [1]*Department of Hepatology and Gastroenterology, Campus Virchow-Klinikum and Campus Charité Mitte, Charité - Universitätsmedizin Berlin, Berlin, Germany;* [2]*Charité-Universitätsmedizin Berlin, Berlin, Germany*
Email: cornelius.engelmann@charite.de

Background and aims: Acute-on-chronic liver failure (ACLF) is characterized by acute decompensation of liver cirrhosis, accompanied by multi-organ failure. Kidney failure is the most common extrahepatic complication. Changes in immune cell subsets including macrophages, neutrophils, and lymphocytes, may drive systemic inflammation and organ injury. However, the dynamics of immune cells, especially macrophages, in ACLF progression remain unclear. This study aims to investigate immune cell dynamics, focusing on macrophage patterns in ACLF models and their role in liver and kidney injury.

Method: We performed two ACLF mouse models, 1) 10 weeks of intraperitoneal (*i.p.*) CCl4 followed by LPS *i.p.* injection 2) 4 weeks of Western diet (WD)+EtOH (10%) in drinking water and followed by EtOH binge. Sirius red was used to quantify fibrosis, TUNEL staining to detect cell death, and spectral flow cytometry to characterize immune cell subsets.

Results: CCl4 treatment induced fibrosis in both the liver and kidney which remained unchanged after LPS injection. WD + EtOH feeding provoked a mild fibrosis in the liver and significantly enhanced kidney fibrosis. Both chronic liver injury models induced cell death in the liver and kidney which was further exacerbated by an additional acute insult. CCl4 treatment increased CD45+ cells in both liver and kidney. LPS triggered a decline in B cells and a surge in neutrophils infiltrating both organs, while T cells remained unchanged. In the liver, LPS exposure increased monocytes and monocyte-derived macrophages (MoMFs) ($CD11b^{high}$, $F4/80^{+}$) along with an upregulation of *Ccl2*, *Tnf-α* and *IL-10* mRNA. LPS triggered a significant recruitment of MoMFs to the kidneys. Kupffer cells (KCs) ($CD11b^{low}$, $F4/80^{high}$, $Tim4^{+}$) remained stable in the liver after LPS, while kidney-resident macrophages (KRMs) ($CD11b^{low}$, $F4/80^{high}$, $CD11c^{+}$, $CX3CR1^{+}$) were markedly decreased after LPS. LPS induced a reduced TLR4 expression in KC, and an increased TLR2 expression in KRM. Both populations demonstrated an enhanced PD-L1 and SIRPα expression while MHC II expression decreased, suggesting a shift towards an immunosuppressive phenotype. In the WD+EtOH model, EtOH binge reduced T cells and B cells in the liver, alongside an increase in neutrophils and monocytes. Unexpectedly, KCs expanded while MoMFs decreased in the liver after binge, alongside an increase in *Ccl2* and *Tnf-α* gene expression. In the kidney, WD+EtOH reduced KRMs. EtOH binge further increased neutrophils and to a lesser extent MoMFs. Both liver and kidney macrophages demonstrated increased SIRPα expression after EtOH binge, and MoMFs in the liver showed reduced MHC II expression.

Conclusion: Both ACLF models showed immune dysregulation, macrophage expansion, and a shift towards an immunosuppressive macrophage phenotype. Gene expression analysis further revealed elevated levels of *Ccl2* and *Tnf-α*. Altogether, these findings suggest a key role for macrophages in ACLF pathogenesis.

FRI-057-YI

Mucosal-associated invariant T (MAIT) cells possess direct cytotoxic potential against HCC, but are rendered dysfunctional within the tumour microenvironment

Junika Pohl-Topcu[1], Alexandra Georgieva[1], Enric Redondo Monte[1], Sebastian Deschler[1], Juliane Kager[1], Sophia Erlacher[1], Joseph Zink[1], Anna-Marie Pedde[2], Anna Hirschberger[2], Jan P. Böttcher[2], Hanno Nieß[3], Melanie Laschinger[4], Norbert Hüser[4], Percy A. Knolle[2], Katrin Böttcher[1]. Email: katrin.boettcher@mri.tum.de

Background and aims: Hepatocellular carcinoma (HCC) is a major cause of cancer death worldwide and only a minority of patients with advanced HCC respond to currently available immunotherapy. Innate-like mucosal-associated invariant T (MAIT) cells are protective against HCC in murine models but are often rendered dysfunctional in human HCC patients for reasons that are incompletely understood. Here, we aim to unravel the molecular mechanisms of MAIT cell cytotoxicity and dysfunction within the tumour microenvironment in HCC in human patients with the aim to identify novel therapeutic strategies against HCC.

Method: MAIT cells were isolated from human liver tissue and peripheral blood. Primary MAIT cells were co-cultured with various HCC cell lines and primary human hepatocytes in vitro. MAIT cell phenotype and function were analysed by multi-colour flow cytometry. MAIT cell cytotoxicity was tested by real-time viability assays using xCelligence.

Results: Here, we uncover a so far unrecognised, direct cytotoxic capacity of human MAIT cells against HCC cells employing an in vitro co-culture system. Importantly, activated MAIT cells selectively killed HCC cells but not primary hepatocytes. T-cell-receptor-mediated activation of MAIT cells was indispensable for MAIT cell cytotoxicity, which was, however, independent of MHC class I-related protein 1 (MR1) signalling. Mechanistically, MAIT cell cytotoxicity required signalling via death receptors of the tumor necrosis factor superfamily and effector cytokines secreted by MAIT cells. In human HCC patients, MAIT cells are systemically reduced in frequency and excluded from HCC tumour tissue. Moreover, tumour-educated MAIT cells express a dysfunctional phenotype, which was induced

by HCC cells in a cell contact-dependent manner. Importantly, MAIT anti-tumour capacity could be enhanced by targeting the death receptor – cytokine axis we have identified.
Conclusion: Our results demonstrate a novel, direct cytotoxic capacity of human MAIT cells against HCC cells, which is dependent on death receptor signalling and MAIT cell cytokines. These findings suggest that enhancing the anti-tumour potential of MAIT cells could be harnessed to improve current immunotherapeutic strategies against HCC.

FRI-058-YI
Time-resolved liver fibrosis regression at single-cell resolution in a murine CCl4-cessation model

Email: katharina.bonitz@meduniwien.ac.at

Background and aims: Liver fibrosis can regress after removal of the primary trigger for liver injury. The molecular switch from a pro-fibrotic to a restorative phenotype in hepatic stellate cells, macrophages, hepatocytes, and endothelial cells remains poorly understood.
Method: Advanced fibrosis in mice was induced with carbon tetrachloride (CCl_4 for 12 weeks). Animals were sacrificed at peak injury (Peak), during regression at 3 (3dR), 7 (7dR) or 14 days (14dR) after CCl_4 cessation or olive oil treatment as controls (Ctrl) (n = 7–13 animals/group). Portal pressure (PP), collagen proportionate area (CPA), serum AST, ALT, and bilirubin levels were measured in a time-resolved manner. Hepatic single-cell suspensions were isolated using a two-step perfusion method (n = 3 mice per group). Parenchymal and non-parenchymal cells (ratio-mix: 1:19) were fixed and sequenced. The obtained single-cell dataset was analyzed using Seurat, interactions were evaluated using Nichenet.
Results: At Peak, fibrosis (CPA: Peak: 3.83 ± 0.61%; Ctrl: 0.53 ± 0.12%,), PP (Peak: 7.32 ± 0.49 mmHg; Ctrl: 4.75 ± 0.46 mmHg), and liver injury (Peak: AST: 1666 ± 2485 U/L; ALT: 1406 ± 3117 U/L; bilirubin: 0.31 ± 0.09 mg/dL; Ctrl: AST: 51 ± 20 U/L; ALT: 30 ± 8 U/L; bilirubin: 0.14 ± 0.05 mg/dL) were significantly induced (all $p < 0.05$ vs. Ctrl), confirming successful model induction. Liver disease regressed significantly after 14 days for CPA (2.89 ± 0.29%), PP (6.18 ± 0.38 mmHg), and liver injury markers (AST: 61 ± 13 U/L; ALT: 44 ± 11 U/L; bilirubin: 0.18 ± 0.5 mg/dL). After quality control, single-cell transcripts of 115286 cells (total cell number from all animals) – clustered in major hepatic cell types – were analyzed. Subclustering macrophages revealed three major sub-populations: embryonically derived (*Timd4+*, *Vsig4+*), scar-associated (SAM, *Trem2+*, *Cd9+*), and a novel Kupffer-cell derived macrophage populations during regression (*Clec4f+, Il10ra+, Cd5l+*). The relative abundance of SAMs (main source of matrix-metalloproteinase 12; *Mmp12)* was highest in Peak and decreased significantly during early regression (3dR). The decrease of *Trem2*, *Cd9,* and *Mmp12* during fibrosis regression was confirmed on liver-bulk RNA-Seq from an independent study with similar study design. Interestingly the main producers of *Mmp8* and *Mmp9* in our dataset were neutrophils with for highest *Mmp8*/*Mmp9* expression at 3dR and 7dR.
Conclusion: The murine CCl_4-cessation model allows to study liver fibrosis regression at a single-cell resolution. SAMs are depleted in the initial phase of regression, during which they represent the main secreters of MMPs. Other cell populations, such as neutrophils further produce MMPs during the intermediate phase of regression. Different myeloid cells thus display multiple roles in collagen degradation during fibrosis regression and will be further evaluated based on the hereby represented dataset.

FRI-059
Identification and characterization of tumor-reactive CD8 and CD4 T cells in hepatocellular carcinoma
Luc Magré[1], Yannick Rakké[1], Rachelle S. van Gemerden[1], Michail Doukas[1], Jan Ijzermans[1], Jaap Kwekkeboom[1], Sonja Buschow[1], Dave Sprengers[1]. *[1]Erasmus MC, Rotterdam, Netherlands*
Email: l.magre@erasmusmc.nl

Background and aims: Effective anti-tumor responses rely on the presence of tumor-reactive T cells in the tumor microenvironment (TME). Understanding the characteristics of these tumor-reactive T cells might reveal potential approaches for targeted immunotherapy. Most studies have been focusing on the identification of tumor-reactive CD8 T cells only, revealing CD39 as a potential marker for tumor reactivity in several tumor types. Recently, it has become clear that also a specific subset of CD4 T cells is capable of recognizing tumor antigens and may contribute to tumor clearance. In hepatocellular carcinoma (HCC) neither CD39 as a marker for tumor-reactive T cells nor the presence of tumor reactive CD4+ T cells has been studied. In this study we aimed to identify and phenotype CD39+ tumor reactive CD8 T cells in HCC and to study the presence and characteristics of tumor-reactive CD4 T cells.
Method: We used flow cytometry to phenotype tumor-infiltrating lymphocytes (TIL), peripheral blood mononuclear cells (PBMC) and tumor free lymphocytes (TFL) derived from HCC patients. Cancer germline antigen (CGA) and cytomegalovirus (CMV) peptide-loaded tetramers were used to identify tumor-reactive CD8 T cells and bystander T cells respectively. Using flow cytometry data Lineage tracing was performed to identify cell subsets with high phenotypic resemblance.
Results: Using flow cytometry we identified a population of CD8 T cells positive for CGA peptide-loaded tetramers. Analysis revealed that these specific CD8 T cells, in contrast to CMV peptide-loaded bystander T cells, have an enhanced activation status defined by increased 4-1BB expression as well as upregulation of CD39 and CD103. This specific population of tumor-reactive T cells was unique to the TME as it was absent in PBMC and tumor adjacent tissue. Using lineage tracing we were able to identify a possible tumor-reactive CD4 subset that phenotypically resembled the tumor-reactive CD8 T cell population.
Conclusion: To conclude, (I) we identified a unique HCC CD8 T cell population specific for tumor antigens characterized by CD39 and CD103 expression. (II) we identified a specific HCC CD4 T cell population with phenotypic resemblance to tumor-reactive CD8 T cells. Future functional analysis should determine the tumor-clearing capacity of these CD4 T cells.

FRI-060

Lnk/Sh2b3 regulates the development of hepatic memory CD8+ T cells via IL-15 signaling and suppresses the pathogenesis of MASLD

Taizo Mori[1], Taiji Yamazoe[2], Tatsuya Kanto[2], Sachiyo Yoshio[1].
[1]*Department of Human Immunology and Translational Research, National Center for Global Health Medicine, Tokyo, Japan;* [2]*Department of Liver Diseases, National Center for Global Health Medicine, Chiba, Japan*
Email: lbtmori@hospk.ncgm.go.jp

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) is closely linked to obesity, insulin resistance and can progress to cirrhosis and hepatocarcinoma under conditions of lipid stress and inflammation. A GWAS analysis of MASLD patients identified missense mutations in the Lnk/Sh2b3 (Lnk) gene associated with metabolic and inflammatory traits. We have previously shown that the intracellular adaptor protein Lnk suppresses $CD8^+$ T cell activation by regulating IL-15 signaling. However, the role of Lnk in MASLD pathogenesis remains unclear. This study aimed to investigate the functional role of Lnk in the development of MASLD and its underlying regulatory mechanisms.
Method: Lnk expression was analyzed in liver tissues from MASLD patients and mice models. MASLD was induced in Lnk-deficient ($Lnk^{-/-}$) and wild-type (WT) mice via a high-fat/high-cholesterol diet. The impact of Lnk deficiency on hepatic $CD8^+$ T cells was assessed using single-cell RNA sequencing and flow cytometry. IL-15 responsiveness in $Lnk^{-/-}$ $CD8^+$ T cells was evaluated in vitro. Additionally, $CD8^+$ T cell inhibition and IL-15 deficiency in $Lnk^{-/-}$ mice were analyzed for their effects on MASLD.
Results: Lnk expression was significantly reduced in the livers of both MASLD patients and animal models. $Lnk^{-/-}$ mice in the MASLD model exhibited markedly increased liver steatosis as well as more severe liver injury and fibrosis compared to WT mice. Bone marrow transplantation studies confirmed that $Lnk^{-/-}$ immune cells exacerbate MASLD progression. Lnk deficiency activated cytotoxicity-related pathways in T cells, promoting differentiation into effector/resident memory $CD8^+$ T cells. IL-15 stimulation of $Lnk^{-/-}$ $CD8^+$ T cells in vitro induced their differentiation into effector memory T cells, leading to increased production of inflammatory cytokines (IFN-γ, TNF-α) and cytotoxic factors (Gzmb, Perforin) with enhanced STAT5 phosphorylation, resulting in aggravated hepatocyte injury. Inhibition of $CD8^+$ T cells or genetic deficiency of IL-15 in $Lnk^{-/-}$ mice alleviated hepatic steatosis, injury, and fibrosis.
Conclusion: Hepatic steatosis induces IL-15 expression while downregulating Lnk, thereby exacerbating MASLD/MASH pathology. Lnk regulates IL-15 signaling in $CD8^+$ T cells, and this regulation plays a pivotal role in suppressing MASLD progression. Targeting Lnk-mediated IL-15 signaling may offer a potential therapeutic strategy for MASLD.

FRI-061

Glucocorticoid receptor inhibits Th2 immune responses by downregulating Pparg and Gata3 in schistosomiasis

Tao Sun[1], Guodong Lyu[1], Xiaojuan Bi[1], Ning Yang[1], Renyong Lin[1]. [1]*State Key Laboratory Of Pathogenesis, Prevention, And Treatment Of High Incidence Diseases In Central Asian, Urumqi, China*
Email: lgd_xj@xjmu.edu.cn

Background and aims: The Th2 immune response is pivotal in the pathogenesis of schistosomiasis, contributing to hepatic granuloma formation and fibrosis. Although the glucocorticoid receptor (GR) is a ubiquitously expressed nuclear receptor that mediates anti-inflammatory effects, its influence on Th2 responses in schistosomiasis remains underexplored. Therefore, this study aimed to investigate the potential effects of GR activation on the hepatic Th2 immune response in schistosomiasis using the synthetic glucocorticoid dexamethasone (DEX).
Method: Dexamethasone was administered to activate glucocorticoid receptors in Schistosoma japonicum-infected mice to investigate the potential effects of GR activation on the hepatic Th2 response. RNA sequencing (RNA-seq) was employed to analyze the transcription factors influenced by GR activation in Th2 cells. Single-cell sequencing analysis was conducted to identify the transcription factors that promote Th2 cell polarization in schistosomiasis.
Results: In vivo, GR activation significantly reduced the size of Schistosoma egg granulomas and substantially inhibited the transcription of key Th2-related cytokines, including IL-4, IL-5, and IL-13. In vitro, GR activation inhibited the transcription of IL-4, IL-5, and IL-13, as well as the secretion of IL-4 from Th2 cells. An integrated analysis of RNA sequencing and single-cell sequencing, complemented by gene expression validation, was performed to explore key transcription factors affected by GR activation during Th2 cell differentiation. The expression levels of two major transcription factors, namely Gata3 and Pparg, were significantly elevated in the livers of Schistosoma japonicum-infected mice but significantly decreased following dexamethasone treatment in both infected mouse livers and Th2 cells.
Conclusion: GR activation may suppress the Th2 immune response triggered by egg antigens by downregulating the expression of key transcription factors Gata3 and Pparg. Overall, these findings offer a novel therapeutic strategy for the treatment of schistosomiasis.

FRI-062

Trained human bone marrow mesenchymal stem cells enhance immunoregulatory responses and alleviate ConA-induced acute liver failure

Bingqi Li[1], Xiaofei Zeng[2], Jing Jiang[1], Jiaojiao Xin[1], Dongyan Shi[1], Xi Liang[1], Jun Li[1]. [1]*State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, National Clinical Research Center for Infectious Diseases, National Medical Center for Infectious Diseases, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China;* [2]*Department of Infectious Diseases, Guizhou Provincial People's Hospital, Zunyi Medical University of Medicine, Guiyang, China*
Email: lijun2009@zju.edu.cn

Background and aims: The immunoregulation of human bone marrow mesenchymal stem cells (hBMSC) plays an important role in treating liver failure. However, the complex in vivo disease microenvironment, including inflammatory cytokine storms, poses challenges to the survival and homing of hBMSC, thereby affecting their therapeutic efficacy. Trained immunity has been proven to exist in immune cells and non-immune cells such as epidermal stem cells. The immune memory enables trained cells to either activate or tolerate upon re-encountering inflammation. This study aims to enhance the immunoregulation of hBMSC by trained immunity to improve the therapeutic effect on liver failure, and to optimize stem cell therapy strategies.
Method: Trained hBMSC (T-hBMSC) were induced with pro-inflammatory cytokines IFN-gamma and TNF-alpha as "trainers" for 24 hours, and untrained-hBMSC (control group) were cultured with standard medium. Then same dosage "trainers" were used to restimulate hBMSC after a 48-hour washout period. Cell samples were collected to perform qRT-PCR and transcriptome analysis. Serum derived from patients with acute-on-chronic liver failure was used to simulate the pathological microenvironment and assess the immune response of T-hBMSC. Murine liver failure models were established in Balb/c mice via tail vein injection of concanavalin A (ConA). Mice were treated with either T-hBMSC or hBMSC via intrasplenic injection, with normal saline (NS) as control. Survival rates, liver function, and inflammatory factors were assessed. Liver tissues were harvested for histological staining, flow cytometry, and bulk RNA-seq to evaluate treatment efficacy.
Results: The stem cell markers and trilineage differentiation potential of hBMSC were preserved after training. The results showed that pro-inflammatory (IL1β, IL6, IL8) and immunoregulatory

genes (PDL-1, IDO) were significantly upregulated in T-hBMSC compared to hBMSC. Time trajectory analysis revealed different responses to restimulation, with T-hBMSC exhibiting distinct expression profiles, especially lower expression of pro-inflammatory genes (IL8, CXCL9) compared to hBMSC. Murine liver failure models were established via tail vein injection of ConA. The 14-day survival of T-hBMSC group was significantly higher than NS group, with improved ALT and AST post-transplantation. Histology showed reduced necrosis area and TUNEL-positive cells in T-hBMSC group. Gene set enrichment analysis revealed significant enrichment of pro-inflammatory TNF and IL17 pathways in hBMSC group compared to T-hBMSC, suggesting milder liver damage in T-hBMSC group.
Conclusion: T-hBMSC can alleviate liver failure by regulating the inflammatory response of immune cells, providing a novel approach to optimizing stem cell therapy strategies.

Understanding the impact of the liver microenvironment on regulatory T cells
Maegen Fleming[1], Elena Perpiñán[1], Nicolas Sompairac[2], Alberto Sanchez-Fueyo[1], Niloufar Safinia[1]. [1]*Roger William's Institute of Liver Studies, King's College London, London, United Kingdom;* [2]*Comprehensive Cancer Centre, King's College London, London, United Kingdom*
Email: maegen.fleming@kcl.ac.uk

Background and aims: To maintain tissue homeostasis, it is vital that the liver can mount inflammatory immune responses, necessary for pathogen clearance, whilst preventing chronic inflammation which could lead to hepatic injury and fibrosis. Unperturbed damage to the liver contributes to the progression of end-stage liver disease, for which there are limited treatment options. Given their key role in the suppression and resolution of immune responses, T regulatory cells (Tregs) are an attractive target for use in liver targeting immunotherapies. Despite classically being perceived as a tolerogenic organ, recent studies have shown that fewer Tregs persist within healthy liver tissue in contrast to other organs. Inversely, Treg numbers are increased within the hepatocellular carcinoma (HCC) tumour microenvironment. Why the healthy liver microenvironment is less favourable to Tregs is unknown. Identifying the factors influencing Treg survival is crucial to designing mechanisms to promote intrahepatic Treg persistence in cellular therapies. Therefore, our aim was to investigate the impact of the liver microenvironment on Tregs and isolate potential pathways that dictate intrahepatic Treg adaptation.
Method: Utilising single cell RNA (scRNA) data, it is possible to compare molecular differences between intrahepatic, circulatory and intratumoural Tregs. The scRNA dataset was comprised of Tregs and conventional $CD4^+$ T cells (Tconvs) isolated from histologically intact liver tissue, blood as well as background liver and tumour tissue from patients with HCC. Significant differentially expressed genes (DEGs) were classified as those with an adjusted p value of <0.05 and a log2 (fold change) >0.58.
Results: Intrahepatic Tregs differ on a transcriptomic level when compared to circulatory Tregs, with analysis showing 346 upregulated DEGs and 284 downregulated DEGs. Additionally, gene set enrichment analysis (GSEA) showed an upregulation of signaling pathways associated with IL-2/STAT5, mTORC1 and TNF-alpha. Apoptotic pathways were also enriched in intrahepatic Tregs. Annexin V staining and subsequent analysis by flow cytometry further supported that Tregs isolated from liver specimens were more apoptotic than those from blood. When compared to tumour derived Tregs, 292 DEGs were upregulated whilst 1040 DEGs were downregulated in intrahepatic Tregs. These DEGs were associated with cytokine signaling, mTOR regulation and metabolic pathways, suggesting that environmental stimuli drive genotypical differences between Tregs.
Conclusion: Exposure to the intrahepatic microenvironment leads to transcriptomic, signaling and metabolic changes that distinguishes liver-resident Tregs from their circulatory and tumour derived counterparts. These changes may contribute to the survival and function of intrahepatic Tregs.

FRI-064
MicroRNA-122 functions as a rheostat regulating liver tolerance, inflammation and fibrosis
Maytal Gefen[1], Shanny Layani[1], Emma Klahr[1], Zohar Shemuelian[1], Johannes Brandi[2], Thomas Jacobs[3], Christiane Steeg[3], Lorenz Adlung[4], Christoph Kilian[4], Merav Ordan[1], Oren Gordon[1], Nathalie Abudi[1,5], Rinat Abramovitch[1,5], Yuval Nevo[6], Shrona Elgavish[6], Hadar Benyamini[6], Jonathan Monin[6], Elina Zorde-Khavlevsky[1], Nofar Rosenberg[1], Aurelia Markezana[1], Dayana Yaish[1], Adi Sheena Yehezkel[1], Alina Simerzin[1], Mila Rivkin[1], Osher Amran[1], Daniel Goldenberg[1], Amnon Peled[1], Jonathan Axelrod[1], Jacob Rachmilewitz[1], Samuel Huber[4], Nicola Gagliani[4], Christoph Schramm[4], Sören Alexander Weidemann[4], Johannes Herkel[4], Antonella Carambia[4], Rifaat Safadi[7], Abed Khakayla[8], Achraf Imam[8], Danijela Heide[9], Jenny Hetzer[10], Stefan Rose-John[11], Mathias Heikenwälder[9,10], Hilla Giladi[1], Eithan Galun[1]. Email: maytalgefen@gmail.com

Background and aims: Chronic liver inflammation and fibrosis are hallmark features of liver diseases such as metabolic-dysfunction-associated steatohepatitis (MASH), chronic autoimmune liver diseases, and liver cancer. However, the interplay between these pathologies remains unclear. This study investigates the role of the liver-specific microRNA, miR-122, in regulating liver inflammation, fibrosis, and immune tolerance. Given its high abundance in hepatocytes, we hypothesized miR-122 is a key regulator of liver immune homeostasis, influencing both innate and adaptive immunity.
Method: A multi-faceted approach was employed, including mouse models with genetic deletion of miR-122, administration of miR-122 mimics and inhibitors (antagomirs), and comprehensive transcriptomic analyses such as RNA sequencing (RNAseq). We examined the effects of miR-122 modulation on immune and inflammatory pathways, including its direct regulation of targets like TLR3 and IRF2. To assess clinical relevance, we compared transcriptomic profiles from autoimmune hepatitis (AIH) patients to those of miR-122 knockout (KO) mice. Additionally, in vivo infection models for bacterial and malaria were utilized to evaluate immune activation in the absence of miR-122.
Results: MiR-122 expression was inversely correlated with liver inflammation and fibrosis in both mouse models and human AIH patients. Loss of miR-122 resulted in early-onset liver inflammation and fibrosis, accompanied by macrophage and lymphocyte infiltration and activation of pro-inflammatory cytokines such as TNFα, IL1β, and IL6. RNAseq revealed over 5,000 differentially expressed genes in miR-122 KO mice, highlighting an upregulation of chemokines, immune checkpoints, and pro-fibrotic pathways. Direct regulation of TLR3 by miR-122 via IRF2 was confirmed through luciferase assays

and in vivo antagomir experiments. miR-122 KO mice demonstrated enhanced resilience to bacterial (MRSA) and parasitic (malaria) infections, possibly due to increased activation of innate immune pathways and elevated erythropoietin levels.
Conclusion: MiR-122 serves as a critical regulator of liver immune tolerance, balancing inflammation and fibrosis through independent pathways. Its absence enhances innate immune activation and accelerates liver fibrosis, implicating miR-122 as a dual mediator of immune and fibrotic responses. These findings suggest that miR-122 is a promising therapeutic target, where its upregulation may suppress inflammation and fibrosis in autoimmune and chronic liver diseases, while its downregulation could bolster immune responses in infectious contexts.

FRI-065-YI
Non-neuronal role of immune cells in liver regeneration
Nastaran Fazel Modares[1]. [1]*University Health Network, Toronto, Canada*
Email: nastaran.fazel@gmail.com

Background and aims: Humans recover from hepatic injury largely by liver regeneration. This complicated process requires hepatocyte proliferation driven by collaboration amongst multiple hepatic cell types. Immune cells also contribute, with some producing mitogenic cytokines such as IL-6 but others damaging hepatocytes by secreting IFNγ. A better understanding of immune cell functions in liver regeneration is necessary to improve clinical interventions.
Method: ChAT+ B Cell deficient mice ($Chat^{flox;Mb1\text{-}Cre}$), α7 Knockout Mice ($Chrna7^{-/-}$) were used. To induce acute liver damage, we used 70% partial hepatectomy (70%PHX).
Results: Here, we demonstrate that B cells expressing choline acetyltransferase (ChAT), the enzyme synthesizing acetylcholine (ACh), are specifically required for liver regeneration. Mice lacking ChAT+ B cells subjected to partial hepatectomy (PHX) display greater mortality due to failed liver regeneration. We show that both Kupffer cells and hepatic CD8+ T cells express the α7 nicotinic ACh receptor (nAChR; encoded by *Chrna7*), and that liver regeneration is also disrupted in mice lacking α7 nAChR. Thus, two regulatory axes promoting hepatocyte proliferation operate following PHX:one where hepatic ChAT+ B cells and α7 nAChR+ Kupffer cells interact to drive IL-6 production by Kupffer cells, and another where ChAT+ B cells and α7 nAChR+ hepatic CD8+ T cells interact to reduce IFNγ production by CD8+ T cells. Our work offers novel insights into liver regeneration mechanisms that may point to new therapies for liver damage.
Conclusion: In summary, our results suggest the following scenario within hours after PHX, a population of ChAT+ B cells expands and begins to secrete ACh. This ACh signals directly to α7 nAChR-expressing CD8+ T cells and Kupffer cells to inhibit IFNγ production and induce IL-6 secretion, respectively. This modulation of these cytokines in turn limits cytotoxicity towards hepatocytes and promotes their proliferation, achieving the numbers needed to secure proper liver regeneration.

FRI-066
The tumor suppressor miR-122 regulates liver cancer stem cells immune evasion and proliferation through CD24
Nofar Rosenberg[1], Hilla Giladi[2], Emma Klahr[1], Christoph Schramm[3], Tania Roskams[4], Matthias Van Haele[5], Danijela Heide[6], Shiran Shapira[7], Nadir Arber[7], Pau Sancho-Bru[8], Gisa Tiegs[9], Mathias Heikenwälder[6], Eithan Galun[10]. Email: nofar.ros@gmail.com

Background and aims: We have previously shown that liver cancer stem cells are a source of primary liver cancer. New factors, in particular immunological, are essential for converting liver cancer cells to immune targets. CD24 characterizes tumor stem cell and is a driver of liver cancer and as a "don't-eat-me-signal," repelling an immune affect against the cells. However, it is not known what increases CD24 expression and how this increase affects hepatic tissue and enhances hepatocarcinogenesis.
Method: To unfold the mechanism of how hepatic cancer stem cells proliferation is regulated and escapes the anti-cancer immune response, we performed *in vitro* and *in vivo* experiments, including therapeutics *in vivo* and performed analysis of human liver cancer samples and samples from chronic disease patients.
Results: We found that in chronic liver inflammation, both autoimmune and MASH, ductular reaction (DR) develops and is dependent on CD24 expression and signalling. We show that liver tumor cell propagation is dependent on CD24 expression and that CD24 expression is increased in livers of both human and mouse pre-malignant conditions and CCA and mixed HCC-CCA samples. To determine how CD24 is regulated, we found that microRNA miR-122, also known to act as a tumor suppressor, regulates CD24 by repressing its expression by targeting the miR seed in its 3′-UTR. We found that increasing miR-122 expression with compounds that we developed, that act to increase the activity of RORà, a known activator of the miR-122 promoter, leads to suppression of CD24 and DR. In addition, miR-122 regulates the do-not-eat-me signal of CD24. Furthermore, treating Mdr2-KO mice with anti-CD24, exhibited a therapeutic effect against DR and liver fibrosis. In addition, we investigated what causes miR-122 levels to decrease and enable CD24 expression and the development of DR. We found that upon liver inflammation, pSTAT3 activates miR-24, which targets HNF4à, which is a transcription factor for miR-122 expression. Thus, upon inflammation, miR-122 can be decreased due to pSTAT3 signalling. Consequently, suppressing pSTAT3, leads to increased miR-122 expression level. We hypothesize that a small molecule that increases miR-122 activity, could be assessed as a therapeutic agent against pre-malignant and malignant liver conditions.
Conclusion: CD24, a cancer stem cell marker, is a direct target of miR-122. Thus, reducing CD24 levels with miR-122 will enable an immune attack on the hepatic cancer stem cells, and suppress cancer stem cell proliferation in the liver. We show a therapeutic benefit using anti-CD24 and pSTAT3 inhibitors.

Trust, Birmingham, United Kingdom
Email: r.b.fiancette@bham.ac.uk

Background and aims: Chronic hepatitis, mediated by $CD4^+$ and $CD8^+$ T cells, drives ongoing liver inflammation and disease progression towards liver cirrhosis and failure. T cell factor 1 (TCF-1) is a hallmark transcription factor denoting a T cell subset with stem-like properties which contribute to chronic inflammation. Their presence and functional role have been reported in various extra-hepatic autoimmune conditions. To our knowledge, there are no data on the presence, regulation or function of TCF-1^+ T cells in human liver. We explored the contribution of TCF-1^+ T cells to chronic hepatitis, and the role of peri-biliary lymphoid follicles in supporting their survival, activation and proliferation.
Method: By combining flow cytometric and microscopic analyses, we studied TCF-1 expression by T cell populations in peripheral blood and liver tissue of patients with inflammatory liver diseases and control individuals. Confocal microscopy allowed us to further investigate the exact localization of TCF-1^+ cells within liver tissue. In addition, we FACS-isolated and cultured T cells *in vitro* and stimulated them with anti-CD3/anti-CD28, or co-cultured them with antigen-loaded monocytes, and investigated their functional response, proliferation and degree of exhaustion.
Results: We identified intrahepatic (n = 11) and circulating (n = 8) TCF-1^+ T cells, predominantly in the CD127-expressing population. They expressed biliary homing chemokine receptors, integrin (n = 7) and effector molecules (n = 5). In PBC livers, they resided in peri-biliary lymphoid follicles with the PDC-E2 autoantigen and antigen-presenting cells. Stem-like TCF-1^+ T cells produced effector molecules and acquired an exhausted phenotype upon T cell receptor stimulation in the presence of IL-7 (n = 3). Furthermore, monocytes primed with the PBC pathognomonic self antigen PDC-E2 induced the proliferation of TCF-1^+ $CD4^+$ T cells which acquired effector properties (n = 2).
Conclusion: The novel identification of intrahepatic stem-like TCF-1^+ T cells provides a better understanding of the etiology of biliary diseases, and more generally of immune-induced chronic liver diseases. We propose that these cells represent a local source of antigen-specific T cells, which can proliferate and repopulate the pool of proinflammatory exhausted effector T cells, hence supporting persistent inflammation and sustaining biliary autoimmune diseases. Their functional characterization and the study of their interactions with other cell populations in their niche will help to elucidate how TCF-1^+ T cells can be modulated, and will open new avenues for targeted treatments of chronic inflammatory liver diseases.

FRI-068-YI
The role of T-cell immunoglobulin and mucin domain 3 (TIM-3) in immune dysregulation and infection in patients with decompensated cirrhosis and liver failure syndromes

Roosey Sheth[1], Francesca Trovato[2], Florent Artru[3], Joseph Wilson[4], Rima Abdalla[4], Evangelos Triantafyllou[5], Mark J. W. McPhail[2]. [1]*King's College London, King's College Hospital, Imperial College London, London, United Kingdom;* [2]*King's College London, King's College Hospital, London, United Kingdom;* [3]*King's College London, London, United Kingdom;* [4]*King's College Hospital, London, United Kingdom;* [5]*Imperial College London, London, United Kingdom*
Email: roosey.sheth@nhs.net

Background and aims: Decompensated cirrhosis (DC) and acute-on-chronic liver failure (ACLF) are life threatening syndromes with infection and sepsis are key drivers for mortality. Immune checkpoints have been implicated in immunoparesis and lipids may act as endogenous checkpoint activators. We hypothesise T-cell immunoglobulin and mucin domain 3 (TIM3) acts as a co-inhibitory immune checkpoint and together with active lipids leads to monocyte and macrophage dysfunction and increased risk of sepsis.
Method: Patients with DC, ACLF, acute liver failure (ALF), as a proinflammatory control, and healthy control (HC) were included. Plasma TIM3 expression was measured by ELISA. Monocyte immunophenotype was assessed by flow cytometry. Whole blood was cultured with TIM3 antibody or control and, following stimulation with lipopolysaccharide (LPS), intracellular monocyte-specific cytokines were assessed. Targeted lipidomics in HC, DC and ACLF were assessed by mass spectrometry and correlated with plasma TIM3 expression.
Results: The predominant aetiology of cirrhosis (30 ACLF, 17 DC) was alcohol related liver disease (70%, n = 33); 72% of these patients developed infections during the first 10 days of the admission. In ALF (n = 31), the main aetiology was drug-induced liver injury (73%, n = 22), 57% (n = 17) developed infections. Compared to HC (n = 13; 240.6 +/− 75.0 pg/ml), plasma TIM3 concentration was increased in DC (1101 +/− 390.4 pg/ml; p = 0.002), ACLF (1907 +/− 781.9 pg/ml; p < 0.0001) and ALF (2717 +/− 1270 pg/ml; p < 0.0001). In DC, patients with infection had increased plasma concentrations of TIM3 (unpaired t-test p = 0.03, AUROC = 0.739). Immunophenotyping monocoytes on whole blood demonstrated increased membrane bound TIM3 expression in DC vs HC (% of positive cells and MFI, p < 0.05), reduced HLA-DR (% of positive cells and MFI, p < 0.05) and increased PD-L1 (MFI p < 0.05). In DC, but not in HC or ALF, LPS stimulated monocytes treated with TIM3 antibodies produced more interferon-gamma compared to untreated cells (% of positive cells p < 0.05). The treatment did not affect IL-1b, IL-6, TNF-a or IL-10 production. Lysophosphatidylcholine and lysophosphoethanolamine lipid species were highly discriminant between DC and HC orthogonal partial least squares discriminant analysis (OPLS-DA; R2Y = 0.96, Q2 = 0.82). There was significant negative correlation in DC between plasma TIM-3 expression and LPC 16:0, LPC 18:0, LPC 18:1, LPE 16:0, LPE 18:0 and LPE 18:1 (Spearman-R p < 0.001 respectively).
Conclusion: Membrane-bound and plasma TIM3 expression is increased in patients with DC and ACLF and is associated with positive microbiology and infection. The pathway significantly correlates to bioactive lipid markers associated with immunoparesis in liver failure syndromes. Blockade of TIM3 increases interferon-gamma production and further investigation is warranted to explore if the TIM3 pathway can restore monocyte function in patients with cirrhosis.

FRI-069-YI
Scar-associated macrophages demonstrate phenotypic plasticity during the progression and regression of liver fibrosis

Ravi Parhar[1], Lily Jia[1], Feiyue Sun[1], Thomas Otto[2], Neil Henderson[1], Prakash Ramachandran[1]. [1]*University of Edinburgh, Edinburgh, United Kingdom;* [2]*University of Glasgow, Glasgow, United Kingdom*
Email: rparhar@hotmail.co.uk

Background and aims: Single-cell RNA-sequencing studies have identified monocyte-derived TREM2+ CD9+ scar-associated macrophages (SAMacs) (also known as lipid-associated macrophages, LAMs) as an attractive therapeutic target for liver fibrosis. However, SAMacs potentially have both pro-fibrotic and pro-resolution functions. It remains unknown whether the same SAMac subpopulation transitions between these functionally distinct states and how contrasting SAMac properties might be therapeutically manipulated. To address this, we aimed to dissect the temporal kinetics, plasticity and fate of SAMacs during the progression and regression of murine chronic liver disease (CLD), using novel fate mapping approaches.
Method: SAMac kinetics were assessed in murine CLD models including the choline-deficient, L-amino acid defined high fat diet (CDAHFD) model of liver fibrosis. Following a 5 week CLD induction, mice were analysed at serial timepoints (0, 1, 2 and 5 weeks) during ongoing injury (progression) or following the cessation of injury (regression). Monocyte fate mapping during progression and regression was performed by a single gavage of 5 mg tamoxifen in our newly developed transgenic system (Serpinb10-CreERT2 × Ai14 mice). SAMac kinetics were assessed by flow cytometry and

immunofluorescence. SAMac plasticity was characterised by transcriptional profiling (Nanostring nCounter) of FACS-sorted Ai14+ SAMacs during progression and regression.
Results: SAMac numbers increased significantly in CLD models, remained persistently expanded during progression but contracted during regression. Fate mapping enabled Ai14+ labelling of monocytes and SAMacs, with minimal labelling of resident TIMD4+ Kupffer cells using Serpinb10-CreERT2 mice. Labelled SAMacs accumulated in the liver fibrotic niche 2 days following tamoxifen. However, labelled SAMacs did not persist in the liver during CLD progression or regression over a 2 week period, indicating a rapid turnover of SAMacs. Transcriptomics of Ai14+ SAMacs confirmed significant plasticity over time, initially adopting a pro-inflammatory profibrogenic phenotype and then progressively switching into a pro-resolution matrix-degrading phenotype, even in the presence of ongoing liver injury. Ongoing work is focussed on identifying the signals which promote this SAMac reprogramming so it can be harnessed therapeutically.
Conclusion: SAMacs are a highly dynamic and plastic population in the fibrotic liver, being constantly replenished and switching from a pro-inflammatory to pro-resolution phenotype even in the presence of ongoing liver injury. These data suggest that the balance of SAMac subtypes is a crucial driver of disease pathogenesis and indicates that therapeutic manipulation should focus on enhancing SAMac reprogramming *in vivo* to limit fibrogenesis and promote scar degradation.

FRI-070-YI
p120 catenin expression by CD8+ T cells correlates with their frequency of invasion into cholangiocytes in autoimmune liver disease

Sofia Pat[1], Ye Htun Oo[1,2,3], Scott Davies[1,2]. [1]*Centre for Liver and Gastrointestinal, Institute of Biomedical Research, Department of Immunology and Immunotherapy, School of Infection, Inflammation and Immunology, College of Medicine and Health, University of Birmingham, Birmingham, United Kingdom;* [2]*NIHR Biomedical Research Centre, University of Birmingham and University Hospital Birmingham NHS Foundation Trust, Birmingham, United Kingdom;* [3]*Centre for Rare Diseases, European Reference Network on Hepatological Diseases (ERN-RARE-LIVER) centre, Birmingham, United Kingdom*
Email: s.p.davies.1@bham.ac.uk

Background and aims: Primary biliary cholangitis (PBC) is an autoimmune cholestatic disease with unmet clinical need. In relation, the mechanism which drives PBC pathogenesis is not fully understood. We recently demonstrated an enrichment of $CD8^+$ T cells in PBC patients that express E-cadherin$^+$, which drives their invasion into cholangiocytes through avesicular entosis (AVentosis). However, it is unclear how E-cadherin expression by $CD8^+$ T cells is regulated. Additionally, it is difficult to identify E-cadherin expression on T cells in association with cholangiocytes by tissue staining due to their own expression of E-cadherin. In epithelial cells, surface expression of E-cadherin is stabilized by p120 catenin (catenin delta-1; p120ctn). Is unclear if $CD8^+$ T cells employ the same mechanism.
Method: Fluorescence immunohistochemistry (IHC-F) was used to identify p120ctn-expressing $CD8^+$ T cells in formalin fixed paraffin embedded (FFPE) human liver tissue sections. This strategy was used to stain sections of explant livers from patients with PBC, autoimmune hepatitis (AIH) and non-cirrhotic donor livers. Semi-quantitative analysis was performed on these tissues to assess the frequency of cells in different localizations within the liver. Expression of p120ctn in primary human $CD8^+$ T cells that internalize into human cholangiocytes was assessed using immunocytochemistry (ICC).
Results: Expression of p120ctn was identified within $CD8^+$ T cells in all tissues stained. p120ct$^+$ $CD8^+$ T cells were observed both attached to the biliary epithelial surface and within cholangiocytes. Attached cells were more frequent in diseased liver tissues compared to non-cirrhotic controls. As previously observed, PBC cases exhibited the highest frequency of internalized $CD8^+$ T cells. This was mirrored with p120ct$^+$ $CD8^+$ T cells, as the majority of internalized T cells expressed p120ctn (85% minimum). p120ctn expression was documented within E-cadherin$^+$ $CD8^+$ T cells that were actively invading cholangiocytes *in vitro*.
Conclusion: $CD8^+$ T cell expression of p120ctn coincides with expression of E-cadherin and their ability to internalize into cholangiocytes. This marks a first step in understanding how E-cadherin expression by $CD8^+$ T cell is regulated. It also provides a method of identifying these cells in PBC liver tissues and provides new avenues for understanding PBC pathology that can be manipulated for therapy.

FRI-075-YI
Differential granzyme-mediated immune responses in CXCR6 +PD-1+ CD8 T cells in acute versus chronic ALT flares

Roni Souleiman[1,2,3,4,5], Erich Freyer[1,2,3,4,5], Suparna Dey[1], Christine Falk[3,5,6], Benjamin Maasoumy[1,3,5], Heiner Wedemeyer[1,3,5], Anke R.M. Email: souleiman.roni@mh-hannover.de

Background and aims: Previously, we showed that circulating CXCR6$^+$PD-1$^+$ CD8 T cells correlate with liver injury and are regulated by a T cell-stimulating cytokine milieu in patients with ALT flares (EASL 2024). A better understanding of the phenotypic and transcriptional characteristics of (CXCR6$^+$PD-1$^+$) CD8 T cells may clarify their role in liver inflammation pathogenesis.
Method: We analyzed blood CD8 T cells in 63 patients with ALT levels ≥5× ULN, including 24 with acute viral hepatitis (16 HBV), 16 with chronic viral hepatitis (15 HBV), and 23 non-viral cases (mainly autoimmune hepatitis) using high-resolution spectral flow cytometry. Public single-cell RNA sequencing data (blood and liver CD8+ T cells, Zhang et al., Gut 2023) from HBV-infected patients were reanalyzed to investigate transcriptional patterns.
Results: Circulating CXCR6$^+$PD-1$^+$ CD8 T cells are characterized by different granzyme expression patterns. In acute hepatitis, the expression of GZMB is predominant, whereas resolving acute and chronic hepatitis is characterized by higher levels of GZMK. UMAP analysis of transcriptome data shows that intrahepatic CD8 T cells mainly express GZMK, whereas circulating CD8 T cells mainly express GZMB. A subset of circulating cells characterized by high CXCR6, HLA-DRA and PDCD1 transcription shares the same transcriptional properties as intrahepatic cells. This subgroup also shows high expression of immunomodulatory and checkpoint genes, activation markers, CREM, and GZMK. Trajectory analysis suggests that CXCR6$^+$ CD8 T cells transition between liver and blood, characterized by a shift in granzyme expression from GZMB to GZMK.
Conclusion: During ALT flares in acute and chronic hepatitis, shifts in granzyme profiles of CXCR6$^+$PD-1$^+$ CD8 T cells are evident. The initial inflammatory response appears to be dominated by GZMB expression, followed by a shift towards GZMK, potentially reflecting evolving intrahepatic immune dynamics and adaption processes. Therefore, GZMK patterns may serve as potential biomarkers to differentiate ALT flares.

FRI-076

Exploiting the ChIP-Seq to validate the role of histone modifiers KDM and HDAC in seroconversion of hepatitis B reactivation patients

Nirupma Trehanpati[1], Jayesh Kumar Sevak[1], Gayantika Verma[1], Mojahidul Islam[1], Gayatri Ramakrishna[1], Shiv Kumar Sarin[1]. [1]*Institute of Liver and Biliary Sciences, Delhi, India*
Email: trehanpati@gmail.com

Background and aims: Hepatitis B virus (HBV) infection remains a global health challenge, with functional cure being rare. Epigenetic modifications play a crucial role in driving seroconversion and achieving a functional cure. We aimed to investigate the histone modifiers in hepatitis B reactivation patients leading to seroconversion.
Method: Sixteen HBV reactivation (rHBV) patients were followed up till 24 weeks for seroconversion (HBsAg loss and anti-HBs > 10 IU/ml). Peripheral blood mononuclear cells (PBMCs) from seroconverters (SC) and non-seroconverters (NSC) were analysed for global methylation patterns and validated through chromatin immunoprecipitation sequencing (ChIP-seq) for H3K9 acetylation (H3K9ac) and methylation (H3K9me).
Results: At baseline, seroconverters showed hypomethylation of histone modifiers and transcription factors including *KDM4C, KDM2B*, *HDAC4*, *JMJD1C*, *GATA6*, *RAD51B* and *NCOR2* which was consistent through 24 weeks. Additional hypomethylation was observed in immune-related genes such as *IL17RA*, *IFNGR2*, *TLR5*, *IRF8*, *STAT5B*, and *TGF-beta*. ChIP sequencing with H3K9ac revealed increased acetylation of *KDM4C*, *KDM5B*, *JMJD1C*, *HDAC2*, *HDAC4*, *GATA6*, *NCOR2*, *RAD51B*, and *IL17RA*, as well as *IFNGR2*, *IL27*, *IL1RA*, *IL7R*, *IL15* and *IL15RA* in seroconverters at baseline and at 24 weeks. Similarly, decreased H3K9Me also leads to the activation of *G6PD, IGFR2, IL15RA, IL17B, IL2RA, DNMT3A, ATP6VOA1, ATP11C, ATP13A2* in seroconverters at baseline and 24 weeks. This enhanced acetylation and decreased methylation is associated with genes related to rapid immune metabolic activation, potentially facilitating HBsAg seroconversion. Conversely, ChIP sequencing revealed increased H3K9 acetylation of exhaustion genes including *LAG3, CTLA4*, *FOXP1*, *PDCD2L*, *PDCD10*, *TGFBR2*, *TGFBR3*, and *HIF1-alpha* in non-seroconverters. This upregulation of exhaustion related genes was observed both at baseline and 24 weeks. Similarly, increased H3K9 methylation was observed in non-seroconverters with upregulation of PDCD11 and TOX2 at baseline and 24 weeks.
Conclusion: Increased H3K9 acetylation and decreased methylation in rHBV patients at baseline and 24 weeks was associated with immune metabolic activation driving HBsAg seroconversion. However, non-seroconverters showed increased acetylation of *LAG3, CTLA4*, *FOXP1*, *PDCD2L*, *PDCD10*, *TGFBR2*, *TGFBR3*, and *HIF1-alpha* which causes immune exhaustion and viral persistence.

FRI-077-YI

T-cell receptor analysis of circulating T cells reveals non-epitope-driven clonal expansion in metabolic-associated steatotic liver disease

Xinlei Zhao[1,2], Sven Aschenbroich[3], Xiaojie Yu[1,2], Su Ir Lyu[1], Ulrike Koitzsch[1,2], Nadja Sereda[3], Karl-Peter Rheinwalt[4], Andreas Plamper[4], Nan Fang[3], Robert Schierwagen[5], Jonel Trebicka[5,6], Uta Drebber[1], Margarete Odenthal[1,2], Maximilian Joseph Brol[5].

Email: xinlei.zhao@uk-koeln.de

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) is characterized by hepatic steatosis, frequently resulting in inflammatory associated steatohepatitis (MASH), which in turn often leads to liver fibrosis or even cirrhosis. The immune system is crucial for these severe MASH alterations. In our study, we aimed to investigate the clonal expansion of circulating T cells during the progression of MASLD.
Method: From a total of 210 obese patients who underwent bariatric surgery, liver biopsies were obtained intraoperatively and the MASLD progression was classified using the Kleiner score. Immune cells were studied by quantitative immunohistology. Buffy-coats were prepared from blood taken at the time-point of bariatric surgery. Simultaneous, multiplexed library preparation on 96 buffy-coats was performed using the AccuraCode® technology, followed by ultra-deep sequencing. For T-cell receptor (TCR) analysis (identification of clonotypes, clones, gene usage, TCR-repertoires, diversity, motif, sequence studies) a bioinformatic pipeline was established.
Results: By targeting the TCR heterogeneity, clonal expansion was analyzed in 96 buffy-coats, selected according to patient´s MASLD progression: MASLD score 0–1 (n = 22), MASH score 2–4 (n = 41) and 5–7 (n = 33). Interestingly, there was no association of the number of circulating T-cell clonotypes with hepatic infiltration of various immune cell-types. However, we observed a significantly enhanced number of TCR-clonotypes along with development of severe MASH (MASH 5–7). Moreover, clonotype/clone ratios indicated a tendency towards a higher clonal expansion in patients with severe MASH. Most notably, TCR motif and sequence studies revealed that the expanded clonotypes were directed against epitopes of opportunistic or frequently common viral infections (CMC, EBV), but not to liver-specific antigens.
Conclusion: These results provide primary evidence that a general, but not epitope-directed clonal T-cell expansion occurs during MASLD progression. Further insights into clonal T-cell activation will be gained by ongoing studies on expanded cohorts, healthy non-obese controls, and patients with MASH regression.

FRI-078

Inflammation-educated macrophages drive exacerbated re-injury patterns via innate immune memory

Yuting Wang[1], Paul Horn[1], Tianjiao Zhang[1], Frank Tacke[1], Felix Heymann[1], Moritz Peiseler[1]. [1]*Department of Hepatology & Gastroenterology, Charité Universitätsmedizin Berlin, Campus Virchow Klinikum and Campus Charité Mitte, Berlin, Germany*
Email: yuting.wang@charite.de

Background and aims: Chronic liver injury leads to pronounced immune alterations, but the persistence of these changes and the impact of the immunological reprogramming on the liver's response to re-injury remains uncertain. Patients with chronic liver diseases suffer from phases of high disease activity followed by months of injury regression.
Method: Here we used a mouse model of chronic toxicity (CCl4) and regression of liver injury and simulated re-injury by administering a single dose of CCl4 after regression. Through the utilization of fate-mapping tools, intravital imaging, and multiplex flow cytometry, we tracked macrophages from different origins and analyzed the alternations in their phenotype and function.
Results: We found that while liver architecture and damage returned to normal levels during regression, rechallenge injury resulted in significantly more severe liver damage compared to long-term chronic injury and acute injury on an otherwise healthy liver. Moreover, we showed that chronic injury resulted in a significant influx of monocytes into the liver, with infiltration of monocyte-derived macrophages, which persisted into the regression phase. These monocyte-derived macrophages displayed a proinflammatory profile and engaged in frequent and prolonged interactions with circulating neutrophils. Furthermore, they were able to rapidly

secrete cytokines such as TNF-α and IL-1β upon re-stimulation, indicating an increased pro-inflammatory potential.
Conclusion: Our study reveals reprogramming of liver macrophages during the regression of chronic liver injury, resulting in a hyperirritable immune state of the liver and a heightened inflammatory response upon re-injury.

Integrated spatial transcriptomics and multi-omics analysis of sequential extrahepatic bile duct biopsies reveal key mechanisms of ischemic biliary injury during liver transplantation
Shaojun Shi[1], Guanzhi Lai[1], Michail Doukas[2], Thierry van den Bosch[2], Rongji Ye[1], Chengjun Sun[1], Xiangling Wei[1], Ming Han[1], Wuzheng Xia[1], Linwei Wu[1]. [1]*Department of Organ Transplantation, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou, China;* [2]*Department of Pathology, Erasmus MC-University Medical Center, Rotterdam, Netherlands*
Email: shaojun_shi@foxmail.com

Background and aims: Ischemic cholangiopathy (IC), a severe complication of liver transplantation caused by ischemia-reperfusion injury, primarily affects the extrahepatic and intrahepatic large bile ducts. Despite its clinical significance, the molecular mechanisms of IC remain poorly understood. Sequential EHBD sampling during transplantation offers a unique opportunity to reduce the variability of sampling and explore the spatiotemporal dynamics of IC. This study employs sequential biopsies, advanced spatial transcriptomics, and multi-omics strategies to uncover the critical mechanisms underlying IC.
Method: Sequential EHBD biopsies were obtained from donor livers during liver transplantation at three defined time points: T0 (non-ischemic control, during procurement), T1 (post-cold ischemia, during the back-table stage), and T2 (post-reperfusion injury, ~1 hour after reperfusion). Biopsies were immediately fixed, embedded, and subjected to hematoxylin and eosin staining for systematic histological assessment. Bulk RNA sequencing, proteomics, and untargeted metabolomics were performed on fresh frozen liver tissues from donors (n = 10), while spatial transcriptomics were conducted on snap-frozen samples from donors (n = 2) using Stereo-seq capture chips. Sequencing data were processed, normalized, and analyzed with the Stereo-Seq Analysis Workflow.
Results: T1 and T2 biopsies showed significant morphological damage compared to T0, including epithelial loss, periluminal and deep peribiliary gland (PBG) injury, etc. Histological scores were significantly higher for T1 and T2, with statistical differences ($p < 0.05$). Multi-omics analysis revealed that T2, compared to T1, showed significant upregulation of PPAR, Glucagon, cGMP–PKG, and cAMP signaling pathways ($p < 0.05$), and downregulation of PI3K–Akt, HIF–1, and Thyroid hormone synthesis pathways ($p < 0.05$). Spatial transcriptomics revealed region-specific injury patterns in the EHBD, with distinct programmed cell death modes (necroptosis, ferroptosis, apoptosis) observed in PBG-like progenitor cells and mature cholangiocytes at T1 and T2. Notably, PBG-like cells exhibited a higher proportion of cellular senescence at T1 compared to T2 ($p < 0.05$).
Conclusion: This study highlights the region- and phase-specific injury patterns in the EHBD during liver transplantation, characterized by distinct programmed cell death modes and cellular senescence dynamics in PBG-like progenitor cells and mature cholangiocytes. The integration of spatial transcriptomics and multi-omics approaches provides valuable insights into the molecular mechanisms underlying ischemic biliary injury, paving the way for targeted therapeutic strategies against IC.

Affinity-tuning chimeric antigen receptors could improve the therapeutic efficacy of regulatory t cells in liver transplantation
Ada Sera Kurt[1], Marwa Elgosbi[1], Emmanuelle Landmann[1], Elisavet Codela[1], Diana Marin-Correa[1], Marc Martinez-llordella[1], Alberto Sanchez-Fueyo[1]. [1]*Roger Williams Institute of Liver Studies, Faculty of Life Sciences and Medicine, King's College London, London, United Kingdom*
Email: ada_sera.kurt@kcl.ac.uk

Background and aims: Regulatory T-cells (Tregs), known for their potent immunomodulatory properties, can be genetically engineered to target donor liver antigens using chimeric antigen receptor (CAR) technology. Autologous anti-HLA-A2 CAR-Tregs are currently being evaluated in the clinic to induce allograft tolerance in HLA-A2-negative liver transplant recipients who have received an HLA-A2-positive liver. As compared to T cell receptors, CARs confer supraphysiological affinity to the target cognate antigen. Whether modifying the binding affinity of the single-chain variable fragment (scFv) of the CAR impacts the functionality of CAR-Tregs has not been investigated. In this study, we aimed to evaluate both in vitro and in vivo the functional properties of affinity-tuned anti-HLA-A2 CAR-Tregs, as a means to optimize CAR design for future applications in liver transplantation.
Method: Three second-generation anti-HLA-A2 CAR constructs expressing low-affinity (LA), moderate-affinity (MA) and high-affinity (HA) scFv antigen-binding domains were designed. Human HLA-A2 negative $CD4^+CD25^+CD127^-$ Tregs were FACS sorted and transduced using lentiviruses. The antigen-specificity and suppressive function of the affinity-tuned LA and HA CAR-Tregs in response to their cognate antigen were evaluated by performing activation and suppression assays in vitro and precision-cut human liver slices (PCLS) ex vivo. Therapeutic efficacy was evaluated in vivo by assessing their persistence within the graft and their ability to prevent $HLA\text{-}A2^+$ PBMC-mediated graft-versus-host disease (GvHD) in irradiated NSG mice. To further investigate the mechanistic basis of functional changes, the concepts of CAR target avidity, internalization and recycling were explored by tracking dextramer expression following cognate antigen engagement.
Results: Following stimulation with the HLA-A2 cognate antigen, LA CAR-Tregs exhibited a higher proportion of activated alloantigen-specific cells compared to HA CAR-Tregs. This resulted in a more suppressive cell product which demonstrated enhanced activation and infiltration in PCLS ex vivo. In vivo, infusion of LA CAR-Tregs together with $HLA\text{-}A2^+$ PBMCs resulted in delayed GvHD onset and improved CAR-Treg persistence, correlating with lower human PBMC reconstitution and prolonged recipient survival. Moreover, HA CAR-Tregs exhibited higher avidity for their target antigen. This prolonged antigen engagement resulted in reduced $dextramer^+$ expression on the cell surface when stimulated at physiological levels of HLA-A2 antigen, indicating rapid CAR internalization and surface downregulation.
Conclusion: Affinity-tuning the CAR of anti-HLA-A2 CAR-Tregs can drastically modify their function and should be considered when designing engineered Treg products for clinical applications.

SAT-510-YI

Reconstruction of native biliary networks in decellularized rat liver scaffolds with human intrahepatic cholangiocyte organoids

Álvaro Blanes-Rodríguez[1], Sandra Melitón Barbancho[1], Marta Sáinz Viartola[2], Javier Martínez-García[1,2], Pedro Baptista[1,3,4,5]. *[1]Aragón Health Research Institute (IIS Aragón), Zaragoza, Spain; [2]University of Zaragoza, Zaragoza, Spain; [3]Universidad Carlos III de Madrid, Biomedical Engineering Department, Madrid, Spain; [4]CIBER Enfermedades Hepáticas y Digestivas (CIBEREHD), Madrid, Spain; [5]Fundación ARAID, Zaragoza, Spain*
Email: pmbaptista@iisaragon.es

Background and aims: The development of functional bioengineered livers is essential to address the current critical shortage of donor organs for transplantation. One major challenge in liver bioengineering is establishing a cell source that can proliferate and differentiate into a functional biliary tree capable of bile transport and seamless integration with hepatic tissue. This study addresses this challenge by using human intrahepatic cholangiocyte organoids (ICOs), which can be expanded at scale and differentiated within a decellularized liver scaffold to form a mature, functional biliary network.
Method: Human ICOs were derived from fresh or cryopreserved human hepatocytes and expanded in large-scale cultures using spinner flasks over a 14-day period. Organoids were then dissociated into single cells and injected into decellularized rat liver scaffolds via the bile duct (BD) using a syringe pump. To ensure cover across both large and small intrahepatic bile ducts, cells were introduced at alternating and specific high and low pressures. The scaffolds were maintained in a perfusion bioreactor for 7 days with continuous perfusion provided by a peristaltic pump and media changes every 2–3 days. Pressure levels were continuously monitored, and glucose and lactate levels were measured daily to assess metabolic activity. Following this maturation period in vitro, the recellularized scaffold was analyzed for hepatic markers and gene expression to evaluate the establishment of a functional biliary network.
Results: ICOs expanded in spinner flasks successfully attached to the decellularized adult rat liver scaffold. The scaffold's microenvironment promoted the differentiation of ICOs into cholangiocyte-like cells, as shown by the loss of Ki67 expression, indicating reduced proliferation. Organoids injected at high pressure formed biliary-like structures across both large and small intrahepatic bile ducts while maintaining compartmental specificity, with no parenchymal invasion. This was confirmed by immunofluorescence of cholangiocyte-specific markers and upregulation of mature cholangiocyte genes, including CK19 and CK7.
Conclusion: This study demonstrates that ICOs can effectively repopulate the biliary network of decellularized adult rat liver scaffolds, forming structured large and small intrahepatic bile ducts via a two-step injection process using alternating high and low pressures. These findings represent a significant advancement towards creating a functional biliary tree within bioengineered livers, paving the way for using decellularized scaffolds from larger animals in liver transplantation.

SAT-511-YI

Extracellular nicotinamide adenine dinucleotide as an independent prognostic marker for long-term survival after liver transplantation

Can Kamali[1], Kaan Kamali[1], Philipp Brunnbauer[1], Al-Hussein Saqr[1], Naomi Chioma Okpala[1], Sue Easaw[1], Eriselda Keshi[1], Igor Sauer[1], Johann Pratschke[1], Felix Krenzien. *[1]Charité - Universitätsmedizin Berlin, Department of Surgery, Berlin, Germany*
Email: can.kamali@charite.de

Background and aims: Liver transplantation remains the definitive treatment for both acute and chronic end-stage liver diseases. The success of this life-saving intervention heavily relies on reliable prognostic markers, which are essential for predicting post-transplant survival rates, guiding patient selection, and optimizing postoperative care. This study explores the relationship between pre- and postoperative plasma levels of extracellular nicotinamide adenine dinucleotide (eNAD$^+$) and patient outcomes.
Method: We monitored patients undergoing liver transplantation from December 2016 to May 2023. Fasting peripheral venous blood samples were collected pre-transplantation and on postoperative days (POD) 1, 3, 7, 14, and 30, along with routine clinical parameters. eNAD$^+$ levels were quantified using a novel enzymatic two-step cycling assay developed by our group.
Results: Fifty-three patients aged 28 to 72 (mean age 53) were enrolled from December 2016 to December 2017 and monitored until May 2023. The 5-year post-transplant survival rate was 61.5%. eNAD$^+$ levels peaked significantly on the first POD (0.40 ± 0.08 μM), compared to preoperative levels ($p = 0.002$) and subsequent days (POD 7: $p = 0.0277$, POD 14: $p = 0.0397$, and POD 30: $p = 0.0085$). There was a significant difference in eNAD$^+$ levels between survivors ($n = 29$, 0.38 ± 0.07 μM) and non-survivors ($n = 18$, 0.45 ± 0.07 μM) on POD1. The threshold eNAD$^+$ level of 0.3750 μM on POD1, identified using the Youden-J statistic, showed the highest sensitivity (83.33%) and specificity (58.62%), with an area under the receiver-operator curve (AUROC) of 0.773. Kaplan-Meier analysis revealed that patients with low eNAD$^+$ (*NAD_low:* ≤0.3750 μM) had a significantly higher 5-year survival rate (85%) compared to those with high eNAD$^+$ (*NAD_high:* > 0.3750 μM) (44.4%, $p = 0.0057$). Finally, no statistically significant correlations were found between eNAD$^+$ levels and conventional parameters—including age, transaminase, bilirubin, INR, creatinine, and CRP levels—of organ donors and recipients, nor with cold and warm ischemia times or MELD scores.
Conclusion: Our research identifies significant fluctuations in eNAD$^+$ levels after liver transplantation, providing new prognostic insights. Through a longitudinal analysis of clinical data spanning seven years, we demonstrated that eNAD$^+$ concentrations could serve as a valuable *independent prognostic* marker. Crucially, measuring eNAD$^+$ levels may allow for the early identification of high-risk patients, facilitating early and targeted interventions that improve patient outcomes.

SAT-512

HepatoPredict has a good prognostic value in patients with hepatocellular carcinoma independently of biopsied nodule

Rita Andrade[1], Silvia Gomes Silva[2], Migla Miskinyte[3], Margarida Quaresma[3], Laura Frazão[3], Carolina Peixoto[3], Antonio Figueiredo[4], Maria Agusta Cipriano[5], Maria Reis[3], Daniela Proença[3], André Folgado[3], Jose Pereira-Leal[3], Rui Oliveira[5], Hugo Pinto Marques[2], José Guilherme Tralhão[6], Joana Cardoso[3]. *[1]Surgery Department, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal, Coimbra, Portugal; [2]Hepato-Biliary-Pancreatic and Transplantation Centre, Hospital Curry Cabral, Centro Hospitalar de Lisboa Central, E.P.E., Lisboa, Portugal; [3]Ophiomics – Precision Medicine, Lisboa, Portugal; [4]Pathology Service, Hospital Curry Cabral, Centro Hospitalar de Lisboa Central, E.P.E., Lisboa, Portugal; [5]Pathology Service, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal; [6]Surgery Department, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal*
Email: jvaz@ophiomics.com

Background and aims: Liver transplantation (LT) is the most effective early-stage hepatocellular carcinoma (HCC) treatment. However, current patient selection criteria poorly predict recurrence and may hinder equitable access to care. The HepatoPredict tool (HP), a machine learning-based model, was developed to address this need by combining molecular and clinical data to forecast LT outcomes and categorise patients based on the likely benefit of a LT. HP has previously outperformed existing clinical criteria. However, its reliance on needle biopsy raised concerns about the impact of sampling bias on its effectiveness. This study aimed to assess the

influence of sampling heterogeneity on HP's performance by sampling beyond the largest nodule.
Method: Tumor samples from HCC patients who underwent LT at two Portuguese centres were analysed. At least two independent tumour samples from different regions of one or more nodules per patient were collected and processed using the HP assay. Samples were classified as likely to benefit from LT or no predicted benefit. Predictions were evaluated based on clinical outcomes (relapse). Metrics included concordance (whether the algorithm produces the same HP classification in different samples from the same nodule) and prognostic accuracy in concordant cases.
Results: A total of 158 independent tumour samples from 77 nodules were collected from 46 patients. The HP tool achieved 84% accuracy overall. Among nodules, 83% were concordant, with HP correctly predicting prognosis in 91% of cases. At the patient level, 80% showed concordant classifications, with 89% correct predictions. Thus, sampling a nodule twice yielded an 80% likelihood of consistent HP classification. Focusing on the largest nodule did not reveal any significant difference in concordance (83% for the largest vs. 84% for others) or accuracy of prediction (92% for the largest vs. 89% for others).
Conclusion: HP's performance is largely unaffected by sampling heterogeneity, with single-region biopsies sufficient for reliable classification, even when taken from nodules other than the largest. These findings confirm that HP effectively captures tumour biology, supporting its role in optimising LT candidate selection, promoting equitable organ allocation, and improving outcomes through integrated molecular and clinical analyses.

SAT-515

"The feasibility of cell-free DNA for monitoring liver graft rejection: a pilot study perspective"

Joanna Raszeja-Wyszomirska[1], Monika Kolanowska[2], Jakub Franke[3], Maciej Wójcicki[4], Karolina Wronka[4], Marek Krawczyk[5], Anna Wójcicka[2]. *[1]Department of Hepatology, Transplantology and Internal Medicine, Medical University of Warsaw, Warsaw, Poland; [2]Wiedzieć Więcej Foundation, Warsaw, Poland; [3]Medical University of Warsawa, II Department of Radiology, Warsaw, Poland; [4]Medical University of Warsaw, Department of Hepatology, Transplantology and Internal Medicine, Warsaw, Poland; [5]Medical University of Warsaw, Department of General, Transplant and Liver Surgery, Warsaw, Poland*
Email: jwyszomirska@wum.edu.pl

Background and aims: Circulating cell-free DNA (cfDNA) is a promising biomarker in oncology and prenatal diagnostics. In transplant medicine, donor-derived cfDNA (dd-cfDNA) has been proposed as an early marker of graft rejection, but its reliance on sequencing or genotyping increases cost and limits accessibility. Total cfDNA, potentially elevated during graft rejection due to increased cellular turnover, could offer a simpler, cost-effective alternative. This pilot study aimed to determine if total cfDNA levels shortly after liver transplantation (LT) correlate with markers like AST, ALT, or ALP and predict rejection. A secondary objective was to explore whether total cfDNA levels vary across different etiologies of liver disease.
Method: The study included 70 LT recipients (46% male, median age 53 years, MELD 17) with liver failure from alcohol (n = 13), autoimmune diseases (n = 20), viruses (n = 9), HCC (n = 10), or other etiologies (n = 18). Patients were monitored for 18 months with bi-monthly lab tests. Peripheral blood (5 ml) collected 10 days post-LT was analyzed for total cfDNA using the Cobas® cfDNA Sample Preparation Kit (Roche) and quantified via Quantus fluorometer (Promega). Kendall's Tau tested correlations between cfDNA and AST, ALT, ALP, or tacrolimus dose. The Kruskal-Wallis test evaluated cfDNA differences among etiologies.
Results: cfDNA was successfully extracted from all samples, with a median concentration of 11 ng/ml. The highest levels (up to 70 ng/ml) were observed in HCC and autoimmune disease patients, reflecting higher cellular turnover, while the lowest (<3 ng/ml) appeared across other etiologies except HCC. A weak correlation was noted between cfDNA and ALT (Kendall's Tau = 0.46, p = 0.0105), but cfDNA did not correlate significantly with AST, ALP, or tacrolimus dose. No significant differences in cfDNA were found between etiologies. Neither cfDNA levels nor trends predicted graft rejection.
Conclusion: This study suggests total cfDNA levels are not reliable predictors of LT outcomes or graft rejection. However, elevated levels in HCC patients highlight the potential of cfDNA as a biomarker for tumor-related cellular turnover. Larger studies are needed to explore cfDNA's role in HCC and as an adjunct tool in transplant monitoring.

3D engineered endothelial cell implants protect liver explant viability ex vivo and reduce liver inflammation

Mireia Medrano-Bosch[1], Blanca Simón-Codina[1], Alazne Moreno-Lanceta[1,2], Meritxell Perramón[2,3], Manuel Morales-Ruiz[1,2,3], Elazer Edelman[4,5], Wladimiro Jiménez[1,2,3], Pedro Melgar-Lesmes[1,6,7,8,9]. *[1]Department of Biomedicine, School of Medicine, University of Barcelona, Barcelona, Spain; [2]Institut d'Investigacions Biomèdiques August Pi-Sunyer (IDIBAPS), Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Barcelona, Spain; [3]Biochemistry and Molecular Genetics Service, Hospital Clínic, Barcelona, Spain; [4]Institute for Medical Engineering and Science, Massachusetts Institute of Technology, Cambridge, MA, United States; [5]Cardiovascular Division, Brigham and Women's Hospital, Harvard Medical School, Boston, Massachusetts, United States; [6]Fundació de Recerca Clínic Barcelona-Institut d'Investigacions Biomèdiques August Pi-Sunyer (IDIBAPS), Barcelona, Spain; [7]Biochemistry and Molecular Genetics Service, Hospital Clínic of Barcelona, Barcelona, Spain; [8]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Barcelona, Spain; [9]Institute for Medical Engineering and Science, Massachusetts Institute of Technology, Cambridge, Massachusetts, United States*
Email: mmedranobosch@ub.edu

Background and aims: Endothelial cells play critical protective roles that contribute to tissue homeostasis. Indeed, retention or restoration of ECs healthy phenotype is important to reverse chronic liver disease and enhance liver graft viability during transplantation. Embedding healthy ECs in a 3D collagen-based matrix scaffold (MEECs) shields their immunogenicity and maximizes their protective roles. Here, we explore the beneficial effects of MEECs on tissue preservation and liver inflammation *ex vivo*.
Method: Precision-cut liver slices (PCLS) from fibrotic or healthy mice were cultured in direct contact with acellular matrices (AM) or MEECs for 24 hours. Liver fibrosis was induced in Balb/c mice by i.p. injection of CCl_4 for 8 weeks. To assess tissue viability, the ATP levels and the expression of CYP2B9 and HGF were analyzed in PCLS, and the amount of AST released into the medium was measured. The expression of a panel of genes related to liver inflammation (NOS2, TNF-α, ARG1, MRC1, ICAM-1, VCAM-1) was quantified using Real-time PCR. To investigate the protective role of MEECs secretome, healthy mouse PCLS were stimulated with LPS and treated with MEECs.
Results: PCLS from fibrotic (FB) and healthy (CT) mice treated with MEECs exhibited greater viability than slices exposed to AM as evidenced by an increase in ATP levels (FB: 5.3 vs 7.1 pmol/μg, $p < 0.05$; CT: 9.9 vs 12.9 pmol/μg, $p < 0.01$), and the hepatic expression of CYP2B9 (FB: 1.5 vs 3.1 fold change (fc), $p < 0.05$; CT: 1.2 vs 2.2 fc, $p < 0.05$) and HGF (FB: 1.0 vs 1.3 fc, $p < 0.05$; CT: 1.0 vs 1.5 fc, $p < 0.05$). This increase was accompanied by a decrease in the release of AST into the culture medium (FB: 139.5 vs 127.8 U/L, $p < 0.05$; CT: 143.6 vs 123 U/L, $p < 0.05$). Treatment with MEECs promoted the mitigation of liver inflammation, evidenced by a reduction in the expression of pro-inflammatory genes (NOS2 and TNF-α) and an increase in the expression of anti-inflammatory genes (ARG1 and MRC1) in both fibrotic and healthy mice PCLS. Treatment with MEECs also led to a reduction in the gene expression of the adhesion molecules ICAM-1 and VCAM-1 in fibrotic mice PCLS, indicating an improvement in the

endothelial inflammatory phenotype. These changes were not observed in healthy mice PCLS. MEECs expressed higher amounts of HGF compared to ECs grown in 2D. MEECs improved cell viability of healthy PCLS stimulated with LPS. Healthy PCLS stimulated with LPS and treated with MEECs showed higher ATP levels than those treated with AM. This beneficial effect was blocked when antibodies against HGF were added to the culture medium.
Conclusion: MEECs improve hepatic viability and exhibit anti-inflammatory properties in mouse liver explants. The protective role of MEECs on explant viability may be partly attributed to the secretion of HGF. This study demonstrates the potential of MEECs for the treatment of chronic liver disease and the *ex situ* preservation of healthy liver grafts.

SAT-517
Three-dimensional cell cultures for biliary disease therapies
Mattia Pasqua[1], Giandomenico Amico[1], Maria Giovanna Francipane[1].
[1]*Ri.MED Foundation, Palermo, Italy*
Email: mgfrancipane@fondazionerimed.com

Background and aims: Cholangiocytes exhibit cellular plasticity and can repair various regions of the biliary tree in ex vivo models. Cholangiocyte cultures, particularly those in the form of three-dimensional (3D) organoids, therefore hold great potential for advancing bile duct repair and reconstruction in various clinical settings. Even more promising are multi-cellular biliary organoids, where cholangiocytes are combined with other cell types typically found in the native duct. Despite their potential, however, to our knowledge, such complex cultures have not yet been described. On the other hand, injectable hydrogels are increasingly used in regenerative medicine as they facilitate cell delivery to the target sites and may also recruit resident cells, contributing to the regenerative response. Thus, our long-term goal is to develop injectable therapeutic organoids for biliary regeneration by combining bile duct cells with a biocompatible biomaterial. Here, we present preliminary efforts toward this goal, including the generation of multi-cellular biliary organoids from cholangiocyte stem cells (CSCs) and mesenchymal stromal cells (MSCs), their in vitro characterization and behavior in type I collagen.
Method: 3D mono- and co-cultures of CSCs and MSCs were generated by seeding 500,000 cells/mL in ultra-low attachment plates and culturing them under agitation (80 rpm) for 14 days. The organoids were characterized by flow cytometry (assessing cell cycle, apoptosis, and phenotype) and immunofluorescence. Organoid function was assessed by investigating the ability of cells to export the bile salt derivative Cholyl-Lys-Fluorescein (CLF). Both dissociated single cells and whole organoids were embedded in type I collagen, and cell viability, as well as rearrangement within the gel, were analyzed through histology and immunofluorescence up to Day 14.
Results: CSCs in monoculture formed aggregates by Day 5 and grew significantly between Day 7 and Day 14, doubling their diameter. Day 7 CSC organoids exhibited increased expression of mature cholangiocyte markers, such as CFTR and AQP1, compared to both Day 14 organoids and 2D cultures. They also demonstrated CLF export activity. When CSCs and MSCs were co-cultured, CSCs predominated, comprising approximately 95% of the total cell population. Interestingly, 26% of the MSCs differentiated into endothelial-like cells, as indicated by the expression of VEGFR2, while the remaining MSCs retained their original phenotype. When embedded in type I collagen, both dissociated single cells and whole organoids reorganized into a tissue structure closely resembling the native duct.
Conclusion: We have successfully obtained organoids comprising three cell types. When embedded in a natural hydrogel, these organoids may support biliary epithelium regeneration, vascular integration and immunomodulation in vivo.

SAT-518
The recovery failure of fecal microbiota diversity in patients after liver transplant is associated with a complicated postoperative course
Anna Lautz[1], Maike Rebecca Pollmanns[1], Nicole Treichel[2], Sophia Schlaak[1], Florian Vondran[3], Ulf Peter Neumann[4], Alexander Koch[1], Thomas Clavel[2], Tony Bruns[1], Christian Trautwein[1,5], Theresa Hildegard Wirtz[1]. [1]*Medical Department III, RWTH Aachen University Hospital, Aachen, Germany;* [2]*Functional Microbiome Research Group, RWTH University Hospital Aachen, Aachen, Germany;* [3]*Department of General, Visceral, Pediatric and Transplant Surgery, RWTH Aachen University Hospital, Aachen, Germany;* [4]*Department of General- Visceral- and Transplantation Surgery, University Hospital Essen, Essen, Germany;* [5]*Leibniz Research Centre for Working Environment and Human Factors at the TU Dortmund (IfADo), Dortmund, Germany*
Email: mpollmanns@ukaachen.de

Background and aims: The fecal microbiome plays a critical role in the development and progression of chronic liver diseases. Liver transplantation (LT) serves as a curative treatment for advanced liver diseases and significantly impacts the complex interplay between the gut and the liver, referred to as the gut-liver axis. This study aimed to investigate alterations in the fecal microbiota in patients before and after LT and to assess their relevance for the postoperative outcome.
Method: Between 2020 and 2023, a total of 241 fecal samples were obtained from 53 patients before and at various time points up to two years after liver transplant. Samples from 25 healthy individuals served as controls. 16S rRNA gene amplicon sequencing was conducted to examine the prognostic relevance of alpha diversity (measured as the effective species count) and relative bacterial abundance regarding post-transplant complications and mortality.
Results: During the postoperative course, the effective species count increased but did not reach the level observed in healthy controls (28.4 vs. 42.8; $p = 0.003$). The effective species count before transplantation did not correlate with length of hospital stay, occurrence of complications, or post-transplant mortality. However, patients who experienced a decrease in the effective species count (defined as the difference from pre-transplant to 2–4 weeks post-transplant) had significantly longer intensive care unit ($p = 0.02$) and overall hospital stays ($p = 0.002$). Additionally, these patients exhibited a higher incidence of post-transplant biliary complications. Taxonomic analysis revealed that patients with a reduction in *Lachnospiraceae* (30.9–0.2%) or *Ruminococcaceae* (13–0.5%) or an increase in *Enterococcaceae* (0.1–45.1%) 2–4 weeks postoperatively had increased lengths of hospital stay and more biliary complications.
Conclusion: In summary, we demonstrate that microbiota diversity in liver transplant recipients remains reduced for several weeks during the postoperative period. Reduced diversity and an increase in specific taxa are associated with a complicated postoperative course.

SAT-519
Kallikrein-Kinin system activation in hepatic ischemia/Reperfusion injury: a key driver of Edema and thrombosis
Rajni Yadav[1], Vaibhav Tiwari[1], Aishwarya Bhatnagar[1], Himanshi Himanshi[1], Tahseen Khan[1], Rajkumar Tulsawani[2], Savneet Kaur[1], Shiv Kumar Sarin[1], Dinesh Mani Tripathi[1]. [1]*Institute of Liver and Biliary Sciences, New Delhi, India;* [2]*DIPAS, DRDO, New Delhi, India*
Email: dineshmanitripathi@gmail.com

Background and aims: Ischemia/Reperfusion (I/R) injury is a critical pathological condition affects liver, leading to tissue damage, vascular dysfunction and edema. The kinetics of Liver Sinusoidal Endothelial (LSECs) is less known. We investigated LSECs mediated underlying mechanism involved in pathogenesis of I/R injury.
Method: Hepatic I/R injury was developed by clamping left lateral & median lobes for 1H, followed by 24H reperfusion. *Invivo-exvivo* hemodynamic were monitored followed by biochemical,

haematological and coagulation investigations and ELISA. I/R lobe and hyperperfused (HP) lobe (Right lateral, caudate, quadrant) of same liver. bile duct (BD), hepatic artery (HA) and portal vein (PV) were collected. Liver Wet/dry weight ratio was estimated. Primary LSECs isolated and acquired, Gene and protein was estimated. Histological analysis of both I/R and HP lobes. Sham animals as controls.

Results: Hemodynamic analysis revealed increase portal flow (+30% $p < 0.001$) and decrease MAP (−39%, $p < 0.001$) in I/R rats vs sham. elevated HA flow was positively correlated with PP ($r = 0.851$, $p > 0.001$) indicates hepatic arterial buffer response (HABR), histologically, increased number and dilated HA (>2-fold vs sham, $p < 0.01$) in portal triad, suggesting increased angiogenesis. HIF-α (+2.9X), eNOS (+4.8X), adenosine A2A receptor (+38X), ET1 (+1.3X) and VEGFR2/3 were upregulated in HA validate these findings. Microsteatosis in PV and central vein (CV) zone in I/R and HP was observed, though more pronounced macrosteatosis in CV area in HP was seen. Elevated ALT, ALP, GGT levels indicates hepatic and biliary damage. Enhanced Portal and biliary fibrosis (2-fold vs sham) accompanied by increased α-SMA + (2-fold) and PDGFR-β+ portal fibroblasts (1.5-fold vs sham) were observed. Prolonged PT, elevated INR, D-dimer and Factor-XII, vWF, ADAMTS13 levels, suggests coagulation abnormalities, endothelium damage and PV thrombosis. CD31+ LSECs peaked in I/R (45%) and HP (39%) vs sham (5.4%) confirms its activated phenotype. Mechanistically, serum Kininogen-1/2 levels and its receptors B1/B2 were increased I/R: 47%, HP: 23%, sham: 2.7% in CD31+ LSECs, further confirmed by elevated calcium levels and increased expression of calcium-binding protein calpain (2-fold), indicating activation of kallikrein-kinin system (KKS). Interestingly, low expression of junctional (Claudin, VE-Cadherin) and cytoskeleton proteins (F-Actin, MLC, RhoA, ROCK, lamin A/C, B) in both I/R and HP suggested loss of cytoskeletal and nucleoskeletal stability, this promotes loss of vascular permeability and edema as confirmed by wet/dry weight ratio (sham = 4, I/R = 6.9).

Conclusion: I/R injury induced kallikrein-kinin system activation leading to hepatic microvascular dysfunction, coagulation, loss of vascular permeability and edema. Complement and coagulation system activation and vascular damage further develops pro-thrombotic microenvironment might contribute to portal hypertension.

SAT-520

Effective in vivo transplantation of revascularized porcine liver scaffolds in pigs for extended function over one month

Sandra Melitón Barbancho[1,2], Valeria Chiluiza[1], Pablo Royo Dachary[3], Helen Almeida[3], Javier Martínez-García[1,4], Álvaro Blanes-Rodríguez[1], Maria Lourdes Bengochea Martinez[3], Cristina Pastor[4,5], Pedro Baptista[1,2,6,7]. *[1]Instituto de Investigación Sanitaria Aragón (IISA), Zaragoza, Spain; [2]Centro de investigación Biomédica en Red | Enfermedades Hepáticas y Digestivas (CIBER EHD), Zaragoza, Spain; [3]Hospital Clínico Universitario Lozano Blesa, Zaragoza, Spain; [4]Universidad de Zaragoza (UNIZAR), Zaragoza, Spain; [5]Instituto Aragonés de Ciencias de la Salud (IACS), Zaragoza, Spain; [6]Carlos III University, Madrid, Spain; [7]Fundación Agencia Aragonesa para la Investigación y el Desarrollo (ARAID Fundation), Zaragoza, Spain*
Email: pmbaptista@iisaragon.es

Background and aims: The clinical application of bioengineered livers offers a promising solution to the shortage of transplantable organs, yet challenges such as replicating organ-scale vascularization and sourcing suitable vascular cells persist. While microvasculature and large vessel networks have been achieved in small-scale in vitro models, establishing functional and patent vascular networks capable of sustaining organ perfusion and functionality post-transplantation remains a significant bottleneck in this approach. To tackle these issues in this study, we developed a revascularization strategy that mimics native vascular physiology, employing decellularized porcine liver scaffolds (pDLS) to assess in vitro and in vivo functionality over a 30-day post-transplantation period.

Method: Essential cell types critical to vascular reconstruction and physiology — porcine endothelial (pUVEC), endothelial progenitors (pOECs), smooth muscle (pA-SMCs), and mesenchymal stromal cells (pBM-MSCs) — were isolated, characterized and prepared for injection into pDLS. This was followed by a 3-day protocol, using alternating tailored injection pressures and specific cell ratios according to vessel diameter and target vessel - portal vein (PV), superior vena cava (SVC), or hepatic artery (HA). Vascular development was promoted through strategic growth factor exposure and gradual mechanical stimulation within a perfusion bioreactor. After a 14-day, the bioengineered scaffolds were transplanted in a porcine auxiliary heterotopic model, allowing for continuous blood perfusion. Perfusion were monitored in vivo via flow probes and CT angiography, with subsequent histological analysis after sacrifice to assess vascular tree reconstruction, integration, cell viability and function.

Results: Microscopic analyses post-revascularization assessed the spatial organization and cellular integration within the bioengineered vascular network. Key markers of vascular function — including nitric oxide (NO) and prostacyclin (PGI2) secretion, glucose and lactate metabolism, vessel contractility, and expression of genes linked to fluid shear stress — validated the functional viability of the bioengineered vessels. Histological examination at 32 days post-transplantation revealed well-organized perfused vascular structures within the hepatic parenchyma, facilitating comprehensive tissue-level histopathology.

Conclusion: This study represents a significant advance in liver bioengineering, particularly in overcoming the challenges of revascularization. By integrating specific cell types under tailored and calibrated seeding pressures within a controlled bioreactor environment with optimized maturation conditions. These engineered vascular networks exhibited robust functionality in vitro and sustained effective blood flow in vivo, highlighting their potential for future clinical applications in bioengineered organ transplantation and regenerative medicine.

Outcomes for patients listed for liver transplantation with low MELD-Na scores: high frequency of MELD-Na score increases, liver transplantation, death and removal from waitlist

Mary E. Rinella[1], Emaraee Cobb[1], Alan Hutchison[1], Thomas Cotter[2], Michael Charlton[1,3], Rebecca Taub[4], Erik Ness[4], Burhaneddin Sandıkcı[5]. *[1]University of Chicago, Chicago, United States; [2]University of Texas, Southwestern, Dallas, United States; [3]Madrigal Pharmaceuticals, Conshohocken, United States; [4]Madrigal Pharmaceuticals, West Conshohocken, United States; [5]Istanbul Technical University, Istanbul, Türkiye*
Email: mrinella@bsd.uchicago.edu

Background and aims: The MELD-Na score, is one of the most widely and consistently validated predictors of mortality for patients with cirrhosis. It is widely perceived that there is a threshold for MELD-Na score, e.g. 15, above which it is believed liver transplantation (LTx) confers a survival benefit at one year and referral to LTx centers is frequently deferred for patients with lower MELD-Na scores. No minimum MELD-Na score required for LTx evaluation or listing, though the threshold for referral for LTx evaluation varies widely between centers. Outcomes according to MELD-Na score at time of listing, e.g. are, however, not well described. The Scientific Registry

for Transplant Recipients (SRTR), which requires MELD-Na score updates and captures key major liver outcomes, including death, removals from LTx list, and transplantation, offers a unique resource to assess the outcomes of patients across the spectrum of MELD-Na scores at listing.
Method: We analyzed data from all adult patients listed for LTx in the United States in a five year period between Jan 2016, to Dec 2022. A total of 1,191,163 records from 88,512 patients who had at least were examined. Changes in MELD-Na score, LTx, death, removed (too sick) and removed (too well) were assessed at 1, 3, 6 and 12 months after listing.
Results: The proportion of patients with MELD-Na scores at listing 6–10, 11–15, 16–20, 21–25, 26–30, 31–35 and 36–40 was: 19.6%, 17.9%, 19.0%, 15.2%, 10.6%, 8.1% and 9.5% respectively. Overall, MELD-Na increases of ≥4 occurred in 62.6% of waitlisted patients at any point in follow up. Among patients with low MELD-Na scores at listing (6–10 and 11–15), ~10.0% had an increase in MELD-Na of ≥4 within 12 mos of waitlisting. Proportions were similar for those MELD-Na scores 6–10 and 11–15. A further 50.2% underwent LTx, were removed (too sick), or died. An increase in MELD-Na of ≥4 was strongly predictive of mortality regardless or transplantation ($p < 0.001$). Patients with MASH had significantly greater probability of waitlist mortality than patients with other indications (>50% more likely c.f. acute alcohol related liver disease).
Conclusion: In this prospective analysis of over 34,000 patients placed on LTx waitlist, with MELD-Na scores ≤15, a substantial majority either had MELD-Na increases of ≥4, died, were removed as too sick or underwent liver transplantation. Increases in MELD-Na are highly predictive of mortality, with or without LTx. This demonstrates that low-MELD patients are still at high risk of adverse outcomes and should be considered, if appropriate, for LTx evaluation and listing.

TOP-507
Quantifying liver function by cholate clearance in extracorporeal circuits with a genetically modified porcine liver and brain-dead human decedent

Abraham Shaked[1], Michael McRae[2], Leanne Lanieri[3], Alexander Sagar[4], Kathryn Stiede[3], Kirsten Swenson[3], Peter Friend[5], Greg Everson[6]. *[1]Penn Transplant Institute, University of Pennsylvania Perelman School of Medicine, Philadelphia, Pennsylvania, United States; [2]Custom DX Solutions LLC, Houston, Texas, United States; [3]eGenesis, Cambridge, Massachusetts, United States; [4]University of Oxford, Oxford, United Kingdom; [5]OrganOx, Oxford, United Kingdom; [6]HepQuant, LLC, Denver, Colorado, United States*
Email: greg.everson@hepquant.com

Background and aims: One potential application of liver xenografts is augmentation of a patient's liver function via an extracorporeal liver cross-circulation (ELC) until the native liver recovers or until a human liver transplant becomes possible. To define the augmentation and stability of liver function during ELC, we measured the hepatic filtration rate (HFR) of intravenously administered 13C-cholate isotope in brain dead research donors (BDRD) during ELC in a circuit with genetically modified porcine livers.
Method: Three brain-dead research donors (BDRD) were studied during ELC via the METRA device (OrganOx, Oxford, UK). The genetically modified porcine livers (EGEN-5784) were from cloned ESUS-1784 Yucatan minipigs. ELCs were maintained for 72–96 hours via normothermic continuous perfusion. Cholate clearances were determined pre-ELC and at 24, 48, and 72 hours during ELC; and after ELC disconnection, in BDRD3. HFR was calculated using HepQuant SHUNT V2.0 methods. For each test, 20 mg of 13C-cholate premixed with human serum albumin was injected into a peripheral vein of the BDRD and blood samples for measurement of 13C-cholate concentrations were collected at 0, 5, 20, and 60 min post. Systemic hepatic filtration rates (HFR), which are the cholate clearances adjusted for body weight, were calculated for the ELC system comprised of the BDRD and porcine livers.
Results: BDRDs included a 79-year-old male (BDRD 1), a 74-year-old female (BDRD 2), and a 57-year-old male (BDRD 3). During ELC, there was a significant increase in HFR relative to baseline, and HFR levels of the combined native human and porcine livers were substantially higher than the mean of healthy controls (n = 50, data not shown), 5.4 ± 1.0 mL/min/kg. HFR for BDRD 1 was 5.6 (pre), 9.9 (24 h), 10.0 (48 h), and 8.43 (72 h) mL/min/kg; for BDRD 2 was 3.5 (pre), 6.9 (24 h), 6.7 (48 h), and 6.7 (72 h) mL/min/kg; and for BDRD 3 was 4.4 (pre), 6.6 (24 h), 6.9 (48 h), 7.4 (72 h), and 5.4 (post) mL/min/kg. Interestingly, BDRD 3 had cirrhosis by pre-trial surgical exploration and HFR showed a 1.0 mL/min/kg improvement from baseline post-ELC.
Conclusion: HFR using 13C-cholate and the HepQuant SHUNT V2.0 method may be useful for assessing the impact of ELC on hepatic function in BDRDs, and, by extension, both allografts and patients being maintained on extracorporeal circuits.

TOP-508
Derivation and validation of a new donor risk score incorporating graft steatosis and donor diabetes mellitus

Milan J. Sonneveld[1], Sarwa Darwish Murad[2], Fatemeh Parouei[1], Caroline den Hoed[3], Jeroen de Jonge[1], Robert Porte[4], Harry L.A. Janssen[1], Marieke van Rosmalen[5], Serge Vogelaar[5], Adriaan J. van der Meer[1], Raoel Maan[1], Wojciech Polak[1], Willem Pieter Brouwer[1]. *[1]Erasmus MC, Rotterdam, Netherlands; [2]Erasmus MC, Rotterdam, Netherlands; [3]Er, Rotterdam, Netherlands; [4]Er, Rotterdam, Netherlands; [5]Eurotransplant, Leiden, Netherlands*
Email: m.j.sonneveld@erasmusmc.nl

Background and aims: Pre-transplant assessment of donor liver graft quality is an important challenge for transplant physicians. Graft steatosis is an important risk factor for adverse outcomes after transplantation, and the concomitant presence of diabetes mellitus (DM) further increases risk. Incorporation of these factors in donor risk scores is of major importance, as the prevalence of metabolic dysfunction is increasing in the donor population. We aimed to derive and validate a simple donor risk score (DRS) based on presence of DM and graft steatosis and other readily available donor factors.
Method: We analysed data from all consecutive first adult full-graft DBD liver transplantations performed in the Eurotransplant region between 2010 and 2020. Presence of steatosis was assessed based on donor imaging reports. Cases were allocated to the derivation and validation groups based on year of transplant. We used backward selection cox-regression analysis to identify donor and graft factors (available at the time of graft offering) associated with retransplantation-free survival of the recipient. Identified risk factors were used to create a point-based risk stratification tool, the performance of which was assessed in the validation dataset and across clinically relevant subgroups.
Results: A total of 12174 transplants were available for analysis, 7650 of which were allocated to the derivation dataset. In the derivation dataset, median donor age was 57 (IQR 45–68), 54% was male, 484 (10.7%) had DM and 1050 (23.2%) had signs of steatosis. In the derivation dataset, donor age >50 ($p < 0.001$), GGT > ULN ($p < 0.001$), donor DM ($p = 0.002$), presence of graft steatosis based on imaging ($p = 0.007$) and non-local graft procurement ($p < 0.001$) were independently associated with impaired re-transplantation-free survival. A point-based model was built, allocating a point for each risk factor, yielding a DRS ranging from 0–5 points. In the validation dataset (n = 4524), a higher risk score was associated with worse retransplantation-free survival. Retransplantation-free survival at 5 years was 71.6% for recipients of a low risk graft (0–1 risk factor, 22% of cohort), 62.7% for recipients of an intermediate risk graft (2–3 risk factors, 67% of cohort) and 51.1% in recipient of a high risk graft (>3 risk factors, 11% of cohort; $p < 0.001$ by log-rank test). Sensitivity

analysis showed that higher risk grafts were associated with poorer outcomes regardless of recipient age and recipient MELD score.
Conclusion: This validated risk score based on donor age, GGT, presence of donor DM, graft steatosis and non-local procurement predicts retransplantation-free survival in adult DBD liver transplantation and can be used for rapid pre-transplant assessment of graft quality in clinical practice.

FRI-455-YI
The impact of donor and recipient HSD17B13, PNPLA3 and TM6SF2 genotype on post-transplant fibrosis, steatosis and survival in liver transplant recipients

Maria Rosina Troppmair[1], Lukas Oberhuber[2], Lukas Forer[3], Sebastian Schoenherr[3], Bernhard Glodny[4], Benjamin Henninger[4], Christian Kremser[4], Herbert Tilg[1], Heinz Zoller[1], Benedikt Schaefer[1]. *[1]Department of Medicine I, Medical University of Innsbruck, Innsbruck, Austria; [2]Department of Internal Medicine, Hospital Merano, Meran, Italy; [3]Institute of Genetic Epidemiology, Medical University of Innsbruck, Innsbruck, Austria; [4]Department of Radiology, Medical University of Innsbruck, Innsbruck, Austria*
Email: m.troppmair@i-med.ac.at

Background and aims: The link between certain genetic variants and severity of metabolic dysfunction associated steatotic liver disease (MASLD) is well established. The G-allele in position rs738409 of PNPLA3 and the T-allele in position rs58542926 of TM6SF2 are known to contribute to the development of steatosis, steatohepatitis and fibrosis. The A-allele in position rs72613567 of HSD17B13 is protective. The aim of our study was to evaluate the impact of those genetic variants of recipients and their respective donors on the development of steatosis, fibrosis and survival after liver transplantation (LT).
Method: In this single-center retrospective study, adults who received a liver transplant between 2000 and 2019 and their respective donors were genotyped for PNPLA3, HSD17B13 and TM6SF2 risk variants. Steatosis after transplantation was assessed using MRI (PDFF ≥5%), Fibroscan (CAP ≥248 dB/m) and/or unenhanced computed tomography (CTLP score <42). FIB4-score was used as longitudinal surrogate marker for fibrosis risk.
Results: In our cohort of 435 liver transplant recipients, 34% developed steatosis after transplantation (median follow-up 8 years). The risk alleles of PNPLA3 and TM6SF2 were more common in liver transplant recipients compared to their respective donors (62% vs 43% for PNPLA3, $p < 0.001$; 19% vs. 10% for TM6SF2, $p < 0.001$). In contrast, the protective G-allele in position rs6834314 of HSD17B13 was more frequent in donors than in recipients (47% vs 37%, $p = 0.006$). A subgroup of 392 individuals was also genotyped for rs72613567 in HSD17B13 and we could show a strong linkage disequilibrium of both HSD17B13 variants ($D' = 0.94$, $r^2 = 0.87$, $p < 0.001$). A combined risk score composed of PNPLA3, TM6SF2 and HSD17B13 showed higher rates of post-transplant steatosis with higher scores without reaching statistical significance (27.5% with a score of 0 or 1 points, 31.7% with 2 points, 36.8% with 3 points and 39.2% with 4 to 6 points, $p = 0.470$). During long-time follow-up, FIB4-scores were sig. lower in patients homozygous for the protective variant in HSD17B13. Higher pre-transplant recipient BMI or history of ALD was sig. associated with higher rates of post-transplant steatosis. The presence of a TM6SF2 risk-allele in LT recipients was associated with a sig. shorter median survival (16 years vs 9 years, $p < 0.001$), independent of age, sex and donor TM6SF2 genotype. PNPLA3 and HSD17B13 risk genotypes were not associated with differences in post-transplant survival.
Conclusion: PNPLA3, TM6SF2 and HSD17B13 variants present specific risk alterations after liver transplantation.

FRI-456
Liver resection versus systemic therapy in patients with hepatocellular carcinoma and vascular invasion in the "Immunotherapy Era." On behalf of HE.RC.O.LE.S. and ITA.LI.CA study groups

Alessandro Vitale[1], Simone Famularo[2], Edoardo Giannini[3]. *[1]Padua University, Padova, Italy; [2]Cattolica University, Rome, Italy; [3]Genova University, Genova, Italy*
Email: alessandro.vitale@unipd.it

Background and aims: Solid evidence indicates that liver resection (LR) achieves better results than Sorafenib (SOR) in selected patients with hepatocellular carcinoma (HCC) and macroscopic vascular invasion (MVI). However, no studies have compared LR with Atezo-Beva (AB) in this setting. In the present study, we sought to compare the effectiveness of LR over ST (SOR and AB) in HCC non-metastatic patients with MVI.
Method: Only non-metastatic HCC patients with MVI treated consecutively in 2015–2024 were considered. Hence, 211 patients undergoing LR were selected from the HE.RC.O.LE.S. register (n = 5441) as the study group, whereas 342 patients were selected from the ITA.LI.CA register (n = 8166) as the control group (244 undergoing SOR and 98 AB). Since this study aimed to compare three potential treatments in advanced HCC patients, we used inverse probability weights (IPW) calculated using a machine learning technique (generalised boosted models) to decrease the selection bias among groups. To estimate the effectiveness of LR over systemic, overall survival (OS) and progression-free survival (PFS) curves were calculated using the Kaplan-Meier method and compared with the log-rank test pre- and after IPW. A LASSO Cox model was used to identify OS and PFS predictors through multivariable analyses.
Results: IPW created two well-balanced SOR and AB pseudo-populations with the LR group regarding the patient, liver function, and HCC characteristics. After IPW, the median survival times were 40 months (IQR 13–54), 12 months (IQR 7–24), and 21 months (IQR 8–43) for LR, SOR, and AB, respectively ($p < 0.001$). Systemic therapy significantly increased the risk of patient death over LR (SOR vs LR: HR 2.20, 95% CI 1.56–3.12, $p < 0.001$) and AB (AB vs LR: HR 1.66, 95% CI 1.02–2.72, $p = 0.042$). A Cox IPW-weighted multivariable regression identified the following independent survival predictors: systemic therapy, platelet count, comorbidity index, and non-VP1-2 MVI. Conversely, LR did not improve PFS over SOR and AB at multivariable analysis in weighted and unweighted populations.
Conclusion: This is the first study directly comparing LR with AB in patients with HCC and MVI without extra-hepatic metastases. Although AB has decreased the gap between surgery and ST in resectable tumours with MVI, LR should still be considered the first therapeutic option in these patients.

FRI-461
Impact of pre-transplant infection and multi-drug resistant organisms colonization on in-hospital post-transplant survival in subjects with pre-transplant liver failure

Alice Mulè[1], Marco Merli[2], Giovanni Perricone[2], Fulvio Crippa[2], Flavia Stefanini[2], Riccardo De Carlis[2], Chiara Oltolini[2], Mauro Grimaudo[2], Giovanna Travi[2], Leonardo Centonze[2], Gianpaola Monti[2], Luca Saverio Belli[2], Andrea Lauterio[3], Massimo Puoti[3]. *[1]ASST Grande Ospedale Metropolitano Niguarda, Università degli Studi di Brescia, Milano, Italy; [2]ASST Grande Ospedale Metropolitano Niguarda, Milano, Italy; [3]ASST Grande Ospedale Metropolitano Niguarda, Università degli studi di Milano Bicocca, Milano, Italy*
Email: alice.mule@outlook.it

Background and aims: Limited data are available on the impact of infections and colonization occurring before liver transplant (LT) on post-LT in-hospital mortality. We investigated the post-LT outcome in patients with pre-LT liver failure with and without pre-LT infections.

Method: A monocentric retrospective study was conducted from 01/01/2018 to 01/08/2024 including all LT recipients. Consecutive candidates with Mayo End-stage Liver Disease (MELD) score >30 and/or Acute on Chronic Liver Failure or Acute Liver Failure were enrolled. Clinical, biochemical, and microbiological data were collected in all enrolled subjects. Patients who did and did not experienced any bacterial, viral or fungal infections and/or colonization within 30 days before LT were compared.
Results: Among 751 LT recipients 99 patients were included. Median age was 57 (IQR 14) years, 73.7% were male (n = 73). Median Charlson Comorbidity Index and MELD score were 5 (IQR 5) and 32 (IQR 5) respectively. Multi-Drug-Resistant Organisms (MDROs) colonization was reported in 30.3% of patients (n = 30), while *Candida* spp. colonization in 62.6% (n = 62). Pre-LT infections were reported in 52 (52.5%) patients, with 68 infectious episodes. Bloodstream infections (n = 18; 26.5%), spontaneous bacterial peritonitis (n = 13; 19.1%) and urinary tract infections (n = 7; 10.3%) were the most common syndromes. Septic shock was reported in 10.3% of cases (n = 7). Fungal infections accounted for 5.8% of cases (n = 3). MDROs sustained 19.2% of the infections (n = 10): Extended-Spectrum Beta-Lactamase producing bacteria (n = 5; 50%), Vancomycin-Resistant Enterococci (n = 3; 30%), Carbapenem-Resistant *Enterobacterales* (CRE) (n = 2; 20%), Difficult-to-Treat Resistance *A. baumannii* (n = 2; 20%). At univariate analysis in-hospital mortality did not result significantly different between patients with and without pre-LT infection (p = 0.95). Post-LT complications were significantly more frequent in the pre-LT infection group: Acute Kidney Injury (p = 0.02), need of Continuous Renal Replacement Therapy (p = 0.03), length of hospitalization (p = 0.01), post-LT infections (p = 0.01), including infection sustained by MDROs (p = 0.03) and septic shock (p = 0.05). Kaplan-Maier analysis showed that overall in-hospital survival was similar among the two groups, while infection-free survival was lower in pre-LT infection patients (p = 0.017). At multivariate analysis higher MELD score (p = 0.006), pre-LT colonization by CRE (p = 0.025), pre-LT infections sustained by MDROs (p = 0.035), and re-transplantation (p = 0.024) predicted in-hospital mortality.
Conclusion: In our analysis pre-LT infections were associated with increased post-LT complications but not with reduced survival. Nevertheless, CRE colonization, and pre-LT infection sustained by MDROs significantly impacted post-LT mortality.

FRI-462

Benefits of calcineurin inhibitor sparing regimen in a biopsy-guided personalized immunosuppression program after liver transplantation

Alisa Kielkowski[1], Alejandro Campos-Murguia[1], Emily Bosselmann[1], Björn Hartleben[2], Sophia Heinrich[1], Jakob Hagenah[1], Friederike Dellbrügge[1], Theresa Kirchner[1], Sinan Yilmaz[1], Esma Turlak[1], Bastian Engel[1], Elmar Jaeckel[3], Richard Taubert[1].
[1]Department of Gastroenterology, Hepatology, Infectious Diseases and Endocrinology, Hannover Medical School, Hannover, Germany; [2]Institute for Pathology, Hannover Medical School, Hannover, Germany, [3]Ajmera Transplant Center, Toronto General Hospital, United Health Network, University of Toronto, Toronto, Canada
Email: taubert.richard@mh-hannover.de

Background and aims: Chronic immunosuppression (IS) including calcineurin inhibitors (CNI) although required is a source of morbimortality, including infections, malignancy risk and chronic kidney disease after liver transplantation (LT). Our personalized IS program, based on surveillance biopsies (svLbx) (Adult Liver Allograft Dysfunction Initiative (ALADIN)) demonstrated the safety of reducing CNI dose, with a short-term renal benefit. Here, we report an update on the long-term outcomes of our prospective ALADIN cohort.
Method: Single center retrospective study between (Oct/2018 – Oct/2024), of the prospective ALADIN study. All included LT recipients (LTR) had a basal svLBx. Rejection rates, graft- and kidney-function, and survival were monitored longitudinally.
Results: A total of 249 LTR were included, 171 (69%) were followed for up to three visits after the initial svLbx with median FU time of 14 months, 33 months, and 47 months (FU1, FU2, FU3). LTR with complete FU were grouped into those in whom CNI reduction was possible (n = 89) and those without CNI reduction (n = 82). At baseline svLbx, LTR who underwent CNI reduction had lower kidney function (eGFR: 63 ml/min vs 77 ml/min; p = 0.02), higher CNI IS score (p < 0.01), and a shorter time since LT (54 vs 120 months; p < 0.01) compared to those without CNI reduction. For a fair comparison of the two groups in terms of outcomes, a propensity score match was conducted, with the three afore mentioned variables included as covariates, ultimately resulting in a satisfactory balance between the groups. In those LTR with CNI reduction (n = 53), there was a 33% delta dose reduction between first and last visit, for no CNI reduction (n = 53) there was an increase delta dose of 16% (CNI IS dosis at last FU: CNI reduction vs. no CNI reduction: 0.75 vs. 1.5 p < 0.01). Kidney function was stable in LTR with reduced CNI regimen (eGFR basal-Last visit delta, 0 ml/min), whereas a decline was observed in those without CNI reduction (eGFR basal-last visit delta, –8 ml/min; p < 0.01). Including all LTR, a linear mixed model for kidney function (eGFR) adjusted for age, time after LT, diabetes, hypertension, and age, showed an independent negative influence of CNI dose (β estimate: –2.7; p = 0.01) in the eGFR. Regarding survival, an overall survival (OS) analysis was performed between patients with and without CNI reduction, matched for time after LT. We identified a survival benefit (no CNI reduction: 88% OS, CNI reduction: 95% OS, over 60 months of FU; log rank 0.05); causes of mortality included malignancy and infection. No differences were observed in fibrosis progression (median Delta Ishak F basal FU: 0 vs. 0, p = 0.5) in LTR (n = 69) who underwent FU biopsies, or in the rate of rejection (2% vs. 1.9%).
Conclusion: Whitin a personalized IS svLbx based program, CNI reduction stabilizes kidney function and improves OS without increasing graft injury.

FRI-463-YI

Effect of donor and recipient CYP3A5 genotypes on the pharmacokinetics of tacrolimus after liver transplantation

Ana Pascual-Dapena[1], Olga Millan[2], Pablo Ruiz[1], Gonzalo Crespo[1], Nerea Sainz[2], Jessica Aspas[3], Yilliam Fundora[3], Olga Morato[3], Mercè Brunet[2], Jordi Colmenero[1]. *[1]Liver Transplantation Unit, Hepatology Service, Hospital Clínic de Barcelona, Barcelona, Spain; [2]Pharmacology and Toxicology Section, Biomedical Diagnostic Center, Hospital Clínic de Barcelona, Barcelona, Spain; [3]Hepato-Pancreato-Biliary Surgery Unit, General and Digestive Surgery Service, Hospital Clínic de Barcelona, Barcelona, Spain*
Email: anapascuald@gmail.com

Background and aims: Tacrolimus, the main immunosuppressant in liver transplantation (LT), is primarily metabolized in the intestine and liver through cytochrome P450 3A5 (CYP3A5). Carrying an *1 allele variant is associated with higher expression and activity of CYP3A5, which leads to more efficient metabolism (EM) of tacrolimus and requires higher doses to achieve therapeutic levels compared to allele variants without *1 (inefficient metabolism, IM). The aim of this study was to evaluate, in real-world practice, the influence of CYP3A5 *1 allele variants in both the donor and recipient on tacrolimus doses and the concentration/dose ratio (C/D) in a cohort of LT patients. In the available literature, there is insufficient evidence to make strong recommendations on dose adjustments specifically in LT, given the particularities of donor-recipient genotype discordances.
Method: CYP3A5 genotyping was performed to identify *1 allele carriers in liver donor-recipient pairs (1/2023–9/24). Clinical and analytical variables post-LT, tacrolimus doses, trough levels, and C/D ratios were collected at the first trough level, day 7 post-initiation, day 40, 3 months, and 6 months post-LT.
Results: Data from 48 donor-recipient LT pairs were analyzed. Both groups were predominantly male (75%) with a median age of 58 years

(IQR 54–65). Fourteen (29%) recipients had the EM genotype and 34 (71%) had the IM genotype. Seven (15%) donors were carriers of the EM genotype, and the rest had the IM genotype. In total, 30 (63%) pairs were donor-recipient IM, and 18 (37%) were EM. The starting tacrolimus doses were similar between the EM and IM genotypes (0.06 mg/kg). Tacrolimus doses/kg at day 7, 3 months, and 6 months were higher in LT recipients with the EM genotype in either donor or recipient compared to those with the IM genotype (0.11 mg/kg/day vs. 0.08 mg/kg/day, p = 0.07). The C/D ratio at the first trough level and day 7 was lower in recipients with the EM genotype compared to those with IM (0.55 ± 0.27 vs. 1.19 ± 0.92 and 0.87 ± 0.35 vs. 1.15 ± 0.58; p = 0.02 and p = 0.11, respectively). The donor EM genotypes were associated with a lower C/D ratio at 3 and 6 months compared to IM (0.95 ± 0.50 vs 1.3 ± 1.04 and 1.05 ± 0.46 vs 1.9 ± 1.28; p = 0.31 and p = 0.039, respectively). The 30 donor-recipient pairs with IM maintained a C/D ratio >1 at all time points (mean 1.29), while pairs with any EM genotype maintained a C/D ratio <1 (mean 0.63, p = 0.018).

Conclusion: The presence of CYP3A5 *1 allele variants in liver transplant donors and/or recipients is associated with different tacrolimus pharmacokinetic profiles. The CYP3A5 *1 genotype of the recipient is associated with the need for higher doses and lower C/D ratios of tacrolimus during the first month post-LT, whereas the CYP3A5 *1 genotype of the donor is associated with the need for higher doses and lower C/D ratios of tacrolimus from the third month post-transplant. These findings support the use of pharmacogenomics as a tool for individualizing immunosuppression in LT, though further studies are needed.

FRI-464

How immunosuppression influences cancer survival in liver transplant recipients: insights from a tertiary care center

Carmen Alonso Martin[1], Irene Peñas Herrero[2], Carolina Almohalla Alvarez[2], Félix García Pajares[2], Gloria Sánchez Antolín[2]. *[1]Complejo Asistencial Universitario De Salamanca, Salamanca, Spain; [2]Hospital Universitario Rio Hortega, Valladolid, Spain*
Email: calonsoma@saludcastillayleon.es

Background and aims: Cancer survival in liver transplant recipients is influenced by various factors, including the immunosuppressive therapies essential for preventing graft rejection. However, these therapies may increase the risk of malignancy and adversely affect long-term survival. This study aims to evaluate the survival rates of liver transplant recipients diagnosed with post-transplant malignancies, comparing them with general population benchmarks, and emphasizing the role of immunosuppression in modulating outcomes.

Method: This retrospective study analyzed 692 liver transplant recipients from a Spanish tertiary care hospital between January 2002 and December 2022, of whom 108 developed malignancies. Data were collected for dermatological, digestive, gynecological, hematological, and otorhinolaryngological (ORL) tumors. Immunosuppressive regimens were recorded to assess their correlation with survival outcomes. Survival times were calculated as the interval between diagnosis and death or last follow-up. Comparative analysis incorporated published general population benchmarks for each tumor type. Statistical analyses included mean, median, and survival distributions.

Results: Dermatological tumors: Mean survival was 2660 days, below the general benchmark of 3650 days. mTOR inhibitors appeared to reduce associated risks. Digestive tumors (Recurrence of HCC was excluded): Mean survival surpassed benchmarks (3110 days vs. 1825 days), suggesting better management or earlier detection despite immunosuppression. Gynecological/ Prostate tumors: Mean survival was lower than expected (1728 days vs. 2190 days/3000 days vs. 3650 days). Calcineurin inhibitors at high doses were linked to reduced survival. Hematological tumors: Median survival was 1825 days, compared to the benchmark of 3377 days. Mixed effects were observed with mycophenolate mofetil. ORL tumors: Patients showed significantly lower survival (median: 1460 days vs. 3211 days), with stronger associations observed in patients receiving prolonged high-dose corticosteroids. For most tumor types, survival in transplant recipients was inferior to population benchmarks, with the exception of digestive malignancies, which exhibited superior outcomes, potentially reflecting optimized immunosuppressive management and early detection strategies.

Conclusion: The findings highlight the intricate interplay between immunosuppressive therapy and post-transplant oncology outcomes. While indispensable for graft survival, immunosuppressive regimens may elevate cancer risk and influence survival trajectories. Enhanced screening protocols, personalized immunosuppressive strategies, and early interventions are essential to mitigate risks, particularly in hematological and ORL malignancies. Conversely, the superior outcomes observed in digestive tumors underscore the importance of tailored immunosuppressive approaches, which could serve as a model for other tumor types.

Sexual health after liver transplantation is significantly impacted and varies by gender

Chanattha Thimphitthaya[1], Alvaro Noriega Ramirez[2], Dyanna Gregory[2], Arjmand Mufti[2], Shannan Tujios[2], Lisa VanWagner[2], Amit Singal[2], Sarah Lieber[2]. *[1]Department of Internal Medicine, University of Texas Southwestern Medical Center, Dallas, United States; [2]Department of Internal Medicine, Division of Digestive and Liver Diseases, University of Texas Southwestern Medical Center, Dallas, United States*
Email: chanattha.thimphitthaya@utsouthwestern.edu

Background and aims: Liver disease affects sexual health (SH) through factors such as hormone metabolism, autonomic or neurologic dysfunction, medication effects, and relationship dynamics. However, little is known about the impact of liver transplantation (LT) on SH and health-related quality of life (HRQoL), especially among different genders.

Method: We performed a cross-sectional study of adult LT recipients at least 1-year post-LT being followed at a large US transplant center. An electronic survey assessed: 1) sexual satisfaction and interest, 2) symptoms, and 3) HRQoL (physical and mental) using questions from Patient-Reported Outcomes Measurement Information System (PROMIS) reported as T scores (50 reflects a mean score among patients with cancer and chronic diseases with a standard deviation (SD) of 10). Additionally, we investigated patient preferences for sharing concerns about SH with LT providers, importance of sexuality on a Likert scale from 1 to 10 (low to high importance), and relationship dynamics.

Results: A total of 113 patients completed the survey; 68 (60.2%) were male with median age of 57 years and a median time of 4 (IQR 1.95–6.57) years post-LT. Median score for importance of sexuality was 6.5 (IQR 5.0–8.0). Among all-comers, 83.6% of males and 73.2% of females reported being sexually active since LT; the median time to resuming sexual activity was 4–6 months post-LT. The primary reason for sexual inactivity in the last 30 days was lack of interest for females (60.0%) and difficulty having an erection among males (64.0%). Females reported lower interest in sex compared to males with mean (SD) scores of 39.9 (11.6) and 49.2 (10.5) respectively (p-value <0.01). Mean sexual satisfaction scores were comparable at 47.9 (SD 8.1) for females and 48.1 (SD 7.8) for males (p = 0.90). Mean (SD) physical HRQoL scores were also similar: 45.3 (10.3) for females and 47.8 (8.3) for males (p = 0.16); whereas mental HRQoL T-scores were 47.7 (11.4) in females and 49.7 (10.7) in males (p = 0.36). Factors affecting sexual satisfaction included fatigue (56.9%), medication side effects (40.9%) and surgical scar (16.4%). Regarding relationships with partners,

36.4% reported no change in their physical relationship while 44.4% noted a positive impact on their emotional relationship. Although 82.1% of respondents considered SH as important, only 20.8% were asked about it during clinic visits in the past six months. While 78.2% expressed comfort discussing their SH with a LT provider,41.3% of female and 21.3% of male respondents preferred same-gender providers for these discussions.
Conclusion: SH and relationships are greatly impacted after LT and differentially affect women and men. Further research is needed to identify factors associated with better or worse SH by gender so that patients can receive better support and education while navigating this life-changing recovery.

FRI-466
Effects of sodium-linked glucose transporter 2 inhibitors in liver transplant recipients with impaired renal function
Christiana Graf[1], Alina Bauschen[2], Nicholas Zeuzem[3], Julian Allgeier[3], Nikola Mareljic[4], Mona-May Langer[4], Sabine Weber[4], Gerald Denk[4], Markus Guba[4], Julia Mayerle[4], Christian M. Lange[4]. *[1]LMU University Hospital, Department of Internal Medicine II, München, Germany; [2]LMU, München, Germany; [3]LMU University Hospital, Department of Internal Medicine II, Munich, Germany; [4]LMU University Hospital Munich, Department of Internal Medicine II, Munich, Germany*
Email: christiana.graf@med.uni-muenchen.de

Background and aims: Sodium-glucose co-transporter 2 inhibitors (SGLT2i) have gained significant attention in clinical research due to its diverse therapeutic effects. The aim of the following retrospective study was to analyze the nephroprotective effects of SGLT2i in patients experiencing renal insufficiency following liver transplantation.
Method: Patients with renal insufficiency following liver transplantation with and without being treated with SLGT2i inhibitors between 2021 and 2024 at the LMU University Hospital Munich were included in the study. We analyzed changes in eGFR, creatinine levels, liver parameters and the safety profile.
Results: A total of 42 patients with SGLT2i treatment and 42 controls without treatment were included. Main characteristics such as age ($p = 0.08$), gender ($p = 0.34$), baseline kidney and liver parameters were observed to be similar in both study cohorts. Median observation period was 12 (range; 1–24) and 18 months (range, 2–32) in patients with and without treatment of SGLT2i. A significant improvement in creatinine ($p = 0.02$) and eGFR ($p = 0.04$) levels was observed during treatment with SGLT2i, while renal function (creatinine, $p = 0.01$; eGFR, $p = 0.009$) significantly deteriorated in the relating control cohort. Improvement in renal function under treatment with SGLT2i was also observed to be significant in a subcohort of patients with a baseline GFR < 30 ml/min ($n = 10$; creatinine, $p = 0.02$). In contrast, no change in liver parameters could be detected over time in both cohorts. Regarding the safety profile of SGLT2i in this specific population, no adverse events could be detected.
Conclusion: SGLT2i seem to be safe and effective in patients with renal insufficiency following liver transplantation.

FRI-467
Incidence and risk factors for incisional hernias following liver transplantation: a retrospective single-centre european study
Callum Riley[1], Anna Hong[1], Sanchit Sharma[1], Rebecca Mladenovic[1], Junaid Qayyum[1], Ahmed Al-Naqshabandy[2], James Serbrock[2], Alexandra Williams[2], Jasveen Kaur[2], Akshat Sinha[2], Adam Lashen[2], Samagra Agarwal[3], David Bartlett[1,4], Neil Rajoriya[1,4]. *[1]Queen Elizabeth Hospital, Birmingham, United Kingdom; [2]University of Birmingham Medical School, Birmingham, United Kingdom; [3]All India Institute of Medical Sciences, Department of Gastroenterology, New Delhi, India; [4]University of Birmingham, Department of Immunology and Immunotherapy, Birmingham, United Kingdom*
Email: CJJRiley@gmail.com

Background and aims: Patients who develop incisional hernias after liver transplantation (LT) experience reduced quality of life. Retrospective studies from outside of the UK show varying incidences (between 4.6% and 43%) and risk factors for these hernias. This study aims to report the experience of post-LT incisional hernias in a large volume LT centre, identifying risk factors and time to development.
Method: A retrospective analysis of LTs from the Birmingham LT Unit (January 2013–May 2023) with at least 6 months of follow-up was conducted. Risk factors, including age, sex, BMI, refractory ascites, hypertension, diabetes, UKELD and MELD scores were recorded at time of listing. Data were analysed using the Mann-Whitney U test for continuous variables and Chi-squared test for binary variables. A multivariable analysis was also conducted.
Results: 1026 patients (63% male, mean age 52.80 (SD ± 13.5) years) were identified, with 129 (12.6%) developing post-LT incisional hernias (median follow up was 1326 (IQR 574.75–1930.30) days). The median dry BMI pre-listing was 27.47 (23.70–31.00) kg/m^2. At listing, 367 (35.8%) of patients had ascites, 199 (19.4%) hypertension, 244 (23.8%) diabetes, and 44 (4.3%) had a transplant during the follow-up period. Median UKELD score was 56 (52–59), and MELD 16 (12–20). Univariable analysis identified BMI > 25 kg/m^2 ($p = 0.0047$), refractory ascites ($p < 0.0001$), and re-transplantation during follow up ($p = 0.038$) as risk factors. None were significant in multivariable analysis. Any combination of one, two or three of the risk factors identified on univariable analysis increased the risk of incisional hernia formation. Median time to hernia development after LT was 454 (249–977) days.
Conclusion: This study of post-LT incisional hernias shows an incidence of 12.6% for incisional hernias post LT. Having a BMI > 25 kg/m^2 at listing, refractory ascites pre-LT, along with having a re-graft are risk factors for incisional hernia development on univariable analysis.

FRI-468
Chronic rejection outcomes in pediatric post liver transplantation-single center experience-King Faisal specialist hospital & research center,Riyadh, Saudi Arabia
Dalal Albogami[1], Alexandra Aldana[1], Kishwer Kumar[1], Ali Akhtar[1], Dieter Clemens Broering[1], Mohammad Shagrani[1]. *[1]King Faisal Specialist Hospital & Research Center, Riyadh, Saudi Arabia, Riyadh, Saudi Arabia*
Email: mshagrani@kfshrc.edu.sa

Background and aims: Chronic rejection (CR) of the donor organ after liver transplantation is an ongoing immunological injury that commonly leads to permanent dysfunction and ultimately to graft loss. The incidence of chronic rejection in pediatrics has decreased from 12% to 5.3% in previous reported rates (1, 2).
Method: We retrospectively studied 837 children who undergone liver transplantation between October 2010 to November 2024 in our center. We determined the incidence of CR, risk factors and its outcomes (remission, progression to a chronic allograft failure) In this cohort study, the children were divided into two groups those with (a remission, successful outcome) and those with (progressive, unfortunate outcome). We compared patient and graft characteristics that were associated with CR, remission and progression to chronic allograft failure.
Results: We identified 30 patients with CR (30/837,3.6%). Six of the 30 patients (20%) achieved a stable remission by immunosuppressive adjustment or adding rescue therapies such as Everolimus or single dose of basliximab. None of these 6 patients had ductopenia in the liver biopsies. In 24 out 30 patients (80%) CR followed a progressive course, despite changing immunosuppression, ultimately leading to chronic allograft failure and to retransplantation (19/24, 79%) or death (5/24, 21%). All patients in the latter group had shown interlobular bile duct loss and ductopenia in liver histology.
Conclusion: Our data indicate that ductopenia in liver histology predicts a very low chance of reversal of CR upon adaptation of the

immunosuppressive regimen. Ductopenia should therefore lead to consider early retransplantation given the increased risk of sepsis and death during intensification of immunosuppression.

Sodium and lactate levels during hypothermic oxygenated machine perfusion as predictive biomarkers for early allograft dysfunction in liver transplantation

David Pereyra[1,2], Jule Dingfelder[1,2], Moriz Riha[1], Julian Müller[1], Laurin Rauter[1], Nikolaus Becker[1], Gabriela Berlakovich[1], Georg Gyoeri[1]. [1]*Medical University of Vienna, Department of General Surgery, Division of Transplantation, Vienna, Austria;* [2]*Medical University of Vienna, Department of General Surgery, Division of Visceral Surgery, Vienna, Austria*
Email: david.pereyra@meduniwien.ac.at

Background and aims: Hypothermic oxygenated machine perfusion (HOPE) improves liver transplantation (LTx) outcomes, yet there is a critical need for simple and accessible biomarkers to assess graft viability during perfusion. Currently, no standardized parameters are broadly available for monitoring HOPE effectiveness.
Method: This retrospective study analyzed 158 patients who underwent LTx with HOPE-perfused liver grafts at the Medical University of Vienna (2018–2023). HOPE followed standardized protocols using University of Wisconsin machine perfusion solution. Blood gas analysis of perfusate was conducted at 30-minute intervals up to 120 minutes. Hospitalization data were prospectively documented. Early allograft dysfunction (EAD) was defined using Olthoff criteria. Receiver operating characteristic (ROC) curves were used to identify predictive biomarkers for EAD.
Results: Of the 158 patients, 44 (27.8%) developed EAD. Grafts with EAD had significantly lower sodium levels and higher lactate levels during HOPE, particularly at 90 minutes. Sodium (<85 mmol/L) and lactate (>4.3 mmol/L) at 90 minutes demonstrated predictive potential for EAD, with ROC areas of 0.741 and 0.633, respectively. Stratification by these cut-offs identified distinct risk cohorts with a low-risk cohort (high sodium, low lactate) with an EAD incidence of 17.6%, while the high-risk cohort (low sodium, high lactate) displayed an incidence of EAD at 69.2% ($p < 0.001$). Importantly, both sodium and lactate remained as significant parameters in a multivariable model next to cold ischemia time and donation after circulatory death as donor type.
Conclusion: Monitoring perfusate sodium and lactate levels at 90 minutes during HOPE offers a simple and effective method for assessing liver graft viability. This approach enables the identification of high-risk grafts before transplantation, paving the way for improved patient outcomes through personalized graft utilization strategies. The findings support integrating routine blood gas analysis into HOPE protocols to enhance decision-making in liver transplantation.

Retrospective study on simultaneous liver kidney transplantation: renal outcome and prevalence of acute cellular rejection

Dorien Pint[1,2], Abid Suddle[2], Sapna Shah[3]. [1]*University Hospital Antwerp, Edegem, Belgium;* [2]*Institute of Liver Studies, King's College Hospital, London, United Kingdom;* [3]*King's College Hospital London, London, United Kingdom*
Email: dorien.pint@uza.be

Background and aims: There has been a long-standing hypothesis that SLK has an immune protective effect for the transplanted kidney from the hepatic allograft. This hypothesis was challenged when recent data showed increased rejection rates for both liver and kidney grafts in patients with pre-existing DSA, particularly against class II HLA with mean fluorescence intensity (MFI) of >10000. In 2014 the immunosuppression protocol in our unit was changed following a case of antibody-mediated rejection (ABMR) and renal graft loss after SLK related to DSA to class II HLA. This study aims to evaluate liver, kidney, and overall survival outcomes in SLK recipients over a 5-year follow-up period following the protocol change. Additionally, the study assesses the incidence of acute and chronic rejection episodes in kidney grafts within the first 5 years post-SLK.
Method: We retrospectively collected clinical, biochemical, and outcome data on patients receiving SLK from 2014 to 2019 in King's College Hospital Londen.
Results: After a follow-up of 5 years, 18 patients (50%) achieved an estimated glomerular filtration rate (eGFR) greater than 45 mL/min/1.73 m². Only one patient (2.9%) needed renal replacement therapy (RRT) after 5 years, two patients (5.3%) were deceased. Additionally, renal allograft outcomes were analysed based on the presence or absence of acute rejection within the first year. The mean eGFR was compared between these patient groups. At 1 month post-transplant, the mean eGFR was significantly higher in the non-AR group (52 mL/min/1.73 m²) compared to the AR group (33 mL/min/1.73 m²; $p = 0.022$). However, the mean eGFR at the 5-year benchmark in the non-AR group was 50 mL/min/1.73 m² compared to 40 mL/min/1.73 m² in the AR group and was not statistically significant anymore ($p = 0.081$) and one patient in the non-AR group required RRT. AR of the kidney transplant was observed in 9 patients (22%), while no episodes of chronic rejection were recorded during the follow-up period. Both acute TCMR and ABMR occurred in 5 out of 36 patients (13.9%), with one patient with both TCMR and ABMR. The length of stay was longer in the AR group, with a mean of 36 days compared to 26 days in the non-AR group ($p = 0.027$). The presence of pre-transplant anti-HLA antibodies was analysed. Of the nine patients with an AR episode, two patients (22%) had class I anti-HLA antibodies, four patients (44%) had both class I and II anti-HLA antibodies, and three patients had no preformed DSA.
Conclusion: Our findings show that SLK is a viable and effective treatment option for patients with concurrent liver and kidney diseases. Patients who are deemed high risk for ABMR due to the presence of preformed DSA class II HLA antibodies should receive the enhanced immunosuppression protocol and close monitoring of their DSAs after transplant. Our study showed that despite the occurrence of an AR episode, renal outcome does not differ significantly after a 5-year follow-up period when managed properly.

FRI-471

Comparison of the effects of tenofovir alafenamide and entecavir on renal function and serum lipids in liver transplant recipients: a retrospective observational study

Hüseyin Döngelli[1], Nilay Danış[2], Tarkan Ünek[3], Tufan Egeli[3], Cihan Ağalar[3], Mücahit Özbilgin[3], Hülya Ellidokuz[4], Mesut Akarsu[2]. [1]*Department of Internal Medicine, Dokuz Eylul University Hospital, Izmir, Türkiye;* [2]*Department of Gastroenterology, Dokuz Eylul University Hospital, Izmir, Türkiye;* [3]*Department of General Surgery, Dokuz Eylul University Hospital, Izmir, Türkiye;* [4]*Institute of Oncology, Dokuz Eylul University Hospital, Izmir, Türkiye*
Email: drhuseyindongelli@gmail.com

Background and aims: Antiviral treatments can impact serum lipids as well as kidney function. We conducted a retrospective observational study with a 48-month follow-up period, involving liver transplant recipients receiving either entecavir or tenofovir

alafenamide, to assess the effects of these antiviral medications on lipid profiles and renal function.
Method: The study was conducted with 47 patients at the Gastroenterology Department of Izmir Dokuz Eylül University Hospital. Research data were retrospectively collected. Serum creatinine and lipid levels were measured at least once per year for each patient. The Friedman test was applied to compare glomerular filtration rate and serum lipids.
Results: During the 48-month observation period, a mean decrease in glomerular filtration rate of 10 mL/min/1.73 m² was observed in the tenofovir alafenamide treatment group ($p < 0.001$), while a decrease of 8 mL/min/1.73 m² occurred in the entecavir group ($p < 0.001$). However, there was no statistically significant difference in the glomerular filtration rate decrease between the two groups ($p = 0.990$). Additionally, no patient required renal replacement therapy, and no hepatitis reactivation was noted. Although entecavir showed more favorable effects on total cholesterol compared to tenofovir alafenamide at the 12th and 24th months ($p = 0.025$ and $p = 0.023$, respectively), neither treatment demonstrated a lipid-lowering effect by the end of the 48-month observation period.
Conclusion: We found no significant difference in renal safety between tenofovir alafenamide and entecavir. Switching from tenofovir disoproxil to either tenofovir alafenamide or entecavir did not improve kidney function in the short or long term. Entecavir demonstrated fewer dyslipidemic effects compared to tenofovir alafenamide, with lipid-lowering effects observed during the first two years of treatment. Overall, both entecavir and tenofovir alafenamide have similar impacts on serum lipids and renal function, making them safe and effective treatment options for liver transplant recipients.

Email: chloe.valentin@outlook.fr

Background and aims: Portal hypertension (PH) after liver transplantation (LT) may warrant the use of transjugular intrahepatic portosystemic shunt (TIPS), but data on TIPS outcomes in this setting are limited. The aim of this study was to evaluate the impact of TIPS on 5-year retransplantation-free survival (reLT-FS).
Method: We retrospectively analyzed a cohort of 82 LT patients from 15 French teaching hospitals who underwent post-LT TIPS between 1999 and 2023 (65% male, median age 56 years). The primary endpoint was reLT-FS at 5 years. Secondary endpoints included reLT-FS at 1 year, overall survival (OS) at 1 and 5 years, and clinical and hemodynamic efficacy of TIPS as measured by hepatic venous pressure gradient (HVPG). Complications following TIPS were also analyzed. Multivariate analyses were performed using an age-adjusted Cox model.
Results: Of the patients, 79% received TIPS after 2010. All had symptomatic PH, primarily refractory ascites (74%) and hydrothorax (28%), with a median HVPG of 14.5 mmHg. Causes of PH included cirrhosis (n = 34), vascular disease (VD, n = 36), and unknown or unreported causes (n = 12). The median time from LT to TIPS was 42 months, longer in cirrhosis cases than in VD cases (70 vs. 15 months; $p = 0.016$). After TIPS, HVPG remained ≥10 mmHg in 17.9% of patients, although this did not predict clinical efficacy, which was achieved in 36.2% of cases. Clinical efficacy correlated with age <60 years (46.0% vs. 11.8%; $p = 0.011$) and end-to-end inferior vena cava anastomosis (100% vs. 33.3%; $p = 0.017$). Complications occurred in 36 patients within 7 days of TIPS. Twenty patients required reLT (median time 8.5 months post-TIPS). OS and reLT-FS were 73.9% and 62.0% at 1 year and 59.6% and 40.7% at 5 years, respectively. At 1 year, reLT-FS was lower in cases with cirrhosis (55.2% vs. 77.9%; $p = 0.037$) and early post-TIPS complications (48.3% vs. 79.2%; $p = 0.004$), where 7 reLTs and 16 deaths occurred. Notably, reLT following early post-TIPS complications was associated with a high mortality rate (43% at one year). At 5 years, reLT-FS was higher with clinical TIPS efficacy (64.9% vs. 27.7%; $p = 0.001$) and VD vs. cirrhosis (51.1% vs. 35.2%; $p = 0.048$). On multivariate analysis, early post-TIPS complications were the only predictors of OS (HR = 0.21; $p < 0.01$) and 1-year reLT-FS (HR = 0.28; $p < 0.001$). Clinical efficacy was the only factor influencing 5-year reLT-FS (HR = 3.96; $p = 0.002$).
Conclusion: In post-LT PH, TIPS may reduce the need for reLT at 5 years if clinical improvement is achieved. An end-to-end inferior vena cava anastomosis predicts TIPS efficacy, while early complications are common and worsen prognosis, even despite reLT. Identification of risk factors for these complications is essential for selection of appropriate TIPS or reLT candidates. A study comparing TIPS with reLT in this population is ongoing.

FRI-475-YI

The effect of dual hypothermic oxygenated machine perfusion on the incidence of post-transplant diabetes mellitus in recipients of livers donated after circulatory death

Efrayim H. Küçükerbil[1], Femke De Goeij[1], Caroline den Hoed[1], Milan J. Sonneveld[1], Wojciech Polak[1], Robert Porte[1], Jeroen de Jonge[1], Sarwa Darwish Murad[1]. *[1]Erasmus University Medical Center, Rotterdam, Netherlands*
Email: e.kucukerbil@erasmusmc.nl

Background and aims: New onset post-transplantation diabetes mellitus (PTDM) is a significant metabolic complication that effects 2.5–25% of liver transplant recipients, and results in poorer graft and patient survival, as well as an increased risk of cardiovascular events. A combination of modifiable and non-modifiable donor and recipient risk factors contribute to PTDM development. Especially, transplantation with a liver from a donor after circulatory death (DCD) has been associated with a significantly increased risk of PTDM, thought to be due to the deleterious effect of ischemia-reperfusion injury on insulin resistance of the graft. Dual hypothermic oxygenated machine perfusion (DHOPE) mitigates ischemia-reperfusion injury by improving mitochondrial function during preservation. We therefore hypothesized that DHOPE treatment of DCD livers reduces the risk of PTDM development.

Method: This is an post-hoc analysis of the recently published DHOPE-DCD Trial, in which DCD livers were randomized between DHOPE versus conventional static cold storage (SCS). All trial patients from our center were included in this study, except those with pre-transplant DM. The primary outcome was frequency and 1-year cumulative incidence of PTDM, defined as the need for diabetics to control sustained hyperglycemic blood levels. Transient PTDM (T-PTDM) was defined as PTDM that resolved within 6 months. Immunosuppressive protocols (tacrolimus monotherapy or reduced-dose tacrolimus + mycophenolate, and fixed 4-month steroid taper) were similar in both groups.
Results: A total of 41 DM-naïve patients were included, n = 18 in the DHOPE and n = 23 in the SCS group. None (0%) of the DHOPE patients developed T-PTDM, vs 4/23 (17%) of the SCS arm (p = 0.118). The 1-year cumulative incidence of PTDM was 11% (2/18) in the DHOPE and 41% (9/23) in the SCS group (p = 0.049) after a median of 36 (range 27–44) and 34 (10–166) days, respectively. All PTDM patients used anti-diabetics, with 55% being insulin dependent. Two SCS patients had tacrolimus monotherapy, while the other nine (82%) had reduced-dose tacrolimus + mycophenolate at the time of diagnosis.
Conclusion: The cumulative incidence of PTDM was significantly lower in recipients of a DHOPE preserved DCD liver, compared to SCS, and none developed T-PTDM, despite similar exposure to steroids and tacrolimus. All cases of PTDM occurred within 6 months post liver transplantation. Albeit small in sample size, these results are promising and warrant further research into the metabolic effects of DHOPE preservation on liver allografts.

FRI-476

Current status of endoscopic treatment for anastomotic biliary stricture after living donor liver transplantation at our institution

EIsuke Ozawa[1], Akane Shimakura[1], Naohiro Komatsu[2], Mizuki Kitagawa[1], Yasuhiko Nakao, Kousuke Takahashi[1], Ryu Sasaki[1], Masafumi Haraguchi, Masanori Fukushima[1], Satoshi Miuma[1], Hisamitsu Miyaaki[1]. *[1]Nagasaki University Hospital, Nagasaki, Japan; [2]Nagasaki Minato Medical Center, Nagasaki, Japan*
Email: a.shimakura@nagasaki-u.ac.jp

Background and aims: Anastomotic Biliary stricture (ABS) at the biliary-biliary anastomosis occurs in 15–30% of cases after living donor liver transplantation (LDLT) and is often challenging to treat. This report examines the endoscopic treatment outcomes for ABS following LDLT at our institution.
Method: The study included 46 cases of ABS among 190 adult patients who underwent LDLT with biliary-biliary anastomosis at our institution between 2009 and December 2021. Endoscopic treatment involved the placement of either plastic stents (PS) or fully covered self-expandable metal stents (FCSEMS). The BONASTENT M-intraductal stent was used for 16 weeks, ensuring no blockage of bile ducts, and subsequently removed. Technical success was defined as successful stent placement at the stricture site, and clinical success was defined as confirmed improvement of the biliary stricture on cholangiography at the time of stent removal. Treatment outcomes for the above cases were analyzed. Cost comparison was performed over a two-year period between cases treated with FCSEMS and a random selection of cases treated with PS.
Results: The median age of the patients was 58 years (range 38–70 years), with 27 males and 19 females. The graft type was right lobe in 20 cases and left lobe in 26 cases. The median time to ABS onset was 4 months (range 0–42 months). Among the 46 cases, FCSEMS placement was attempted in 20 cases, with successful placement achieved in all cases. Of the 17 cases where the stent was removed, 16 showed resolution of the stricture. The technical success rate of FCSEMS was 100%, and the clinical success rate was 94.1%. Cumulative re-stricture rates among clinically successful patients were 6.25% at 6 months, 12.5% at 1 year, and 12.5% at 3 years, with a median follow-up period of 52 months (range 0–79 months). Complications associated with FCSEMS included transient cholangitis in 5 cases, obstructive cholangitis caused by FCSEMS in 1 case, and stent migration in 1 case. There were no cases of post-ERCP pancreatitis, bleeding, or perforation. Regarding costs, the median number of hospital admissions was 2 for FCSEMS cases and 3 for PS cases, with median total hospital stays of 27 days and 24 days, respectively. The median total medical fee were 3,050,840 yen for FCSEMS and 3,673,210 yen for PS, with no significant differences observed.
Conclusion: FCSEMS demonstrated high stent free rates in LDLT patients with ABS and showed comparable cost performance to PS. These findings suggest that FCSEMS may contribute to improved quality of life for these patients.

FRI-477-YI

Recurrence of primary sclerosing cholangitis after liver transplantation: a single centre experience

Emil Bik[1], Anna Stadnik[2], Maciej Wójcicki[1], Pawel Piluch[1], Joanna Raszeja-Wyszomirska[1], Piotr Milkiewicz[3]. *[1]Department of Hepatology, Transplantology and Internal Medicine, Medical University of Warsaw, Warsaw, Poland; [2]Department of Radiology, Medical University of Warsaw, Warsaw, Poland; [3]Department of Hepatology, Transplantology and Internal Medicine, Medical University of Warsaw, Warsaw, Poland, Translational Medicine Group, Pomeranian Medical University, Szczecin, Poland, Warsaw, Szczecin, Poland*
Email: emilbbik@gmail.com

Background and aims: Primary sclerosing cholangitis (PSC) is a progressive cholestatic condition which may lead to liver transplantation (LTx). Recurrence of PSC (rPSC) after grafting is estimated to occur in 25% of patients (Dyson, 2018) and may pose a significant challenge including graft loss and impaired survival. In this study we evaluated the incidence, risk factors, and post-transplant outcomes associated with rPSC.
Method: We analyzed a group of 69 patients who had their LTx done between July 2015 and January 2022 and followed our protocol of regular magnetic resonance cholangiopancreatography (MRCP) procedures after LTx. All of them had their first MRCP done within a median time of 14 months and 48 of them had following MRCP with median time of 35 months. Median follow-up period was 58 months. Clinical and laboratory data from pre- and post-transplant periods were analysed. Radiological features of rPSC were assessed with criteria proposed by Graziadei (1999). Chi-square test was used for categorical variables, and the Mann–Whitney U test was used for the comparison of quantitative variables.
Results: Analyzed group comprised 44 males and 25 females with median age 35 years. Forty-five of them had inflammatory bowel disease (1 had colectomy before due to advanced colitis). Seven had cholangiocarcinoma (CCa) not detected before LTx and 2 were transplanted after neoadjuvant radiochemotherapy following Mayo protocol. Radiological features of rPSC were diagnosed in 26/69 patients (38%) during their first MRCP. A second MRCP showed features of rPSC in 31/48 (65%) patients. Four patients lost their grafts due to rPSC and required retransplantation (reLTx) within a median time of 61 months. Overall survival of the analyzed group during the follow-up period was 91%. Four patients died due to recurrent CCa and 2 due to complications following retransplantation. There were no significant associations between rPSC and age, gender, concurrent inflammatory bowel disease, liver biochemistry or MELD score at the time of LTx in univariate analysis. Among patients diagnosed with radiological rPSC at their first MRCP, 9/26 (35%) had normal cholestatic enzyme activity. During the second MRCP 15/31 patients (48%) with features of rPSC also presented with normal cholestatic enzyme levels.
Conclusion: The recurrence rate of PSC following liver transplantation, as assessed with routine MRCP imaging, is higher than previously reported. No pretransplant risk factors for rPSC were identified. Our findings highlight the need for close and prolonged monitoring of LTx recipients with PSC, as radiological recurrence can occur even in patients with normal cholestatic enzyme levels.

FRI-478

Outcome and predictors of major adverse cardiovascular events after liver transplantation: a single center experience

Eugenia Vittoria Pesatori[1], Luisa Pasulo[1], Mauro Viganò[1,2], Leonardi Filippo[1], Stefania Camagni[3], Flavia Neri[3], Alessandro Loglio[1], Domenico Pinelli[3], Stefano Fagiuoli[1,2]. *[1]Gastroenterology and Transplant Hepatology, ASST Papa Giovanni XXIII, Bergamo, Italy; [2]Department of Medicine and Surgery, University of Milano Bicocca, Milan, Italy; [3]Department of Surgery, ASST Papa Giovanni XXIII, Bergamo, Italy*
Email: eugenia.pesatori@gmail.com

Background and aims: Liver transplantation (LT) is the only life-saving treatment option for end-stage liver disease. However, major adverse cardiovascular events (MACE) are a leading cause of morbidity and mortality after LT, accounting for over 40% of early deaths (<30 days) after surgery. The present study aimed to assess the incidence, predictors and outcome of post-LT MACE.
Method: All consecutive adult patients who underwent LT from January 2018 to February 2023 in our Center were retrospectively evaluated. Each patient was represented only once in the cohort. MACE were defined as: congestive heart failure, acute coronary syndrome, arrhythmia, ischemic stroke, peripheral artery disease. Continuous variables were shown as median (IQR) while categorical variables were shown as percentages. Logistic regression was used to evaluate association between variables and outcomes.
Results: A total of 235 patients were included in the analysis. The median age was 58 years and 69% were male. The most common indications for LT were HCV (23%) and alcoholic cirrhosis (24%). Arterial hypertension, diabetes and obesity were present, respectively, in 29%, 26% and 14% of patients. During a mean follow up of 33 months (range 1–60), 36 (15%) LT recipients experienced a MACE. The early mortality rate (<30 days from OLT) for cardiovascular events was 33% (4/12). 20% of MACE occurred during LT or less than 48 hours after surgery, reaching 80.5% within 30 days from OLT and 86% at 1 year post-LT. The most frequent event was arrythmia (56%), followed by acute coronary syndrome (22%) and congestive heart failure (19%). Previous history of arrhythmia (OR = 7.86, 95% CI 1.98–33.3, p = 0.003) and obesity (OR = 2.55, 95% CI 1.03–5.96, p = 0.035) were significantly associated with MACE occurrence both at univariate and multivariate analysis. The concomitant presence of more than one cardiovascular risk factor (diabetes + hypertension + age >60 years) was way more frequent in MACE cohort compared to no-MACE cohort (16% vs 5%, p = 0.02).
Conclusion: Despite the accurate patient's selection pre-LT, 15% of patients developed an early post-LT MACE, being arrythmias the most frequent event. Previous history of arryhtmia and obesity were strongly associated with MACE.

FRI-479

AI-driven prediction of fibrosis progression in liver transplant recipients using a temporal deep learning framework

Xiang Xuan Eunice Tan[1], Yingji Sun[2], Jennifer Lee[2], Camille Gener[2], Alyssa Apilan[2], Divya Sharma[3], Mamatha Bhat[2]. *[1]National University Hospital, Singapore, Singapore; [2]Ajmera Transplant Centre, Toronto, Canada; [3]York University, Toronto, Canada*
Email: eunice_tan@nus.edu.sg

Background and aims: Improvements in surgical techniques and perioperative care in liver transplant (LT) recipients have resulted in improved short-term survival. With increasing graft survival, older recipient age, and increasing proportion of patients with steatohepatitis being transplanted, LT recipients today are at increased risk of allograft fibrosis. Given the lack of clinical decision tools, we aimed to develop a machine learning (ML) tool to identify patients at highest risk of progressive fibrosis over time.
Method: We included all patients with index liver transplants performed at the Ajmera Transplant Centre from 1 Feb 1985 to 31 Dec 2023 who had subsequent paired fibrosis measurements by liver biopsy or transient elastography (TE). Due to the superior accuracy of TE findings at the extremes of cut-offs, we only included fibrosis stages F0 and F4 and excluded measurements in the intermediate range. Clinical demographic, anthropometric, and serial biochemistry data such as liver enzymes, bilirubin, and creatinine were extracted from the year preceding the fibrosis measurement. Fibrosis stage was classified semi-quantitatively based on biopsy report or TE. We utilized deep ML methods such as recurrent neural network (RNN), long short-term memory model (LSTM) and our proposed Temporal attenuation Gated Recurrent Unit (GRU) model to assess accuracy in prediction of rate of fibrosis progression/regression. Assessment of each method was conducted using mean squared error (MSE) and Pearson's r.
Results: 1318 patients had paired fibrosis measurements post-LT: 2408 and 337 were from liver biopsies and TE respectively. Using longitudinal data from one year before fibrosis measurements, we compared our proposed deep learning-based Temporal attenuation GRU method with other temporal ML techniques to predict fibrosis progression/regression stage. The RNN and LSTM model had MSE 0.87 ± 0.03 and 0.83 ± 0.05, and Pearson's $r = 0.74 \pm 0.01$ and 0.81 ± 0.01 respectively. Using the Temporal attenuation GRU method, the MSE improved to 0.61 ± 0.03, $r = 0.84 \pm 0.01$. When a weighted MSE loss function was applied to allow more importance in the longitudinal data points closest to the fibrosis measurement, the temporal attenuation GRU MSE improved to 0.28 ± 0.01, $r = 0.92 \pm 0.01$. The top five variables identified as being associated with rate of progression were current fibrosis stage, time from LT, donor gender, pre-LT diabetes and leukocyte count.
Conclusion: Advanced ML techniques today can aid in non-invasive prediction of allograft fibrosis progression reliably. This can help select patients for whom biopsies are required for assessment of fibrosis progression/regression. While TE is also useful, it is not easily accessible in some. Our study demonstrates that using longitudinal clinical variables used in routine assessment can reliably predict post LT allograft fibrosis progression.

FRI-480-YI

Changes in sarcopenia and adipose tissue alterations do not predict post-transplant outcomes in patients with cirrhosis and hepatocellular carcinoma undergoing liver transplantation

Francesca D'Arcangelo[1], Margherita Marchiori[1], Jacopo Lanari[2], Alberto Ferrarese[1], Martina Gambato[1], Salvatore Piano, Giacomo Germani[1], Francesco Paolo Russo[1], Marco Senzolo[1], Paolo Angeli[3], Umberto Cillo[2], Patrizia Burra[1], Alberto Zanetto[1]. *[1]Gastroenterology/Multivisceral Transplant Unit, Department of Surgery, Oncology and Gastroenterology, Padua University Hospital, Italy, Padua, Italy; [2]Hepatobiliary Surgery and Liver Transplantation Unit, Department of Surgery, Oncology and Gastroenterology, Padua University Hospital, Padua, Italy; [3]Unit of Internal Medicine and Hepatology, Department of Medicine, University and Hospital of Padova, Padova, Italy, Padua, Italy*
Email: francesca.darcangelo02@gmail.com

Background and aims: Sarcopenia and adipose tissue alterations may predict liver decompensation and reduced survival during the waiting period and after liver transplant (LT). However, the evolution of body composition from pre- to post-transplant and its association with patient outcomes are poorly understood. Therefore, we aimed to assess the evolution of sarcopenia and adipose tissue alterations from pre- to post-LT and their potential impact on patient outcomes.
Method: Adult patients with hepatocellular carcinoma (HCC) who underwent LT at Padua University Hospital between January 2015 and March 2022 were retrospectively included. Body composition was assessed via CT scans within six months pre-LT and at 3-, 6-, and 12-months post-LT. The Skeletal Muscle Index (SMI), Visceral Adipose Tissue Index (VATI), and Subcutaneous Adipose Tissue Index (SATI) were calculated. Uni and multivariate Cox regression analysis was used to evaluate the association with clinical outcomes.

Results: 164 patients (85.3% male, median age 62 years) were included. HCV infection was the most common aetiology of liver disease, followed by alcohol-related liver disease (20%); indication to LT was HCC in 69% of patients. Prevalence of sarcopenia was 45% (median SMI of 50 cm^2/m^2; IQR 56.43–45.03), while VAT and SAT alterations were observed in 22.4% and 49.4% of patients, respectively. Sarcopenia prevalence slightly increased from 45.1% pre-LT to 56.1% at 12 months. VAT alterations increased consistently, from 40.6% pre-LT to 60% at 12 months post-LT, whereas SAT alterations remained largely stable. Pre-transplant body composition alterations were not associated with decreased survival at 1, 3, or 5 years (sarcopenia: p = 0.21; VATI alteration: p = 0.20; SATI alteration: p = 0.28). No association was found between changes in body composition and survival (sarcopenia: p = 0.43; VATI alteration: p = 0.50; SATI alteration: p = 0.43). In multivariate analysis, COPD (OR: 0.9; 95% CI 0.7–9.1; p = 0.042) and CKD (OR: 1.7; 95% CI 1.8–17.9; p = 0.003) were the only independent predictors of survival. In patients with HCC, no association was found between body mass composition or its evolution and the risk of HCC recurrence.
Conclusion: Sarcopenia and alterations of adipose tissue are highly prevalent in patients with cirrhosis and HCC undergoing transplantation; however, they are not linked to post-LT outcomes. Significant body composition changes occur within one-year post-LT but are not associated with post-transplant complications or survival. These findings would not support the assessment of body composition for LT evaluation nor early post-LT risk stratification in compensated cirrhosis with HCC.

Email: giuliana.amaddeo@aphp.fr

Background and aims: Immunotherapy (IT) is an attractive strategy for downstaging and bridging hepatocellular carcinoma (HCC) to liver transplantation (LT). This multicenter study reports the feasibility and effectiveness of LT post-IT in HCC patients.
Method: The study cohort was identified in ten French liver transplant centers in the GRef2 research network. All patients were treated with IT between February 2019 and June 2023 and had their livers transplanted between May 2020 and March 2024. Clinical, biological, and radiological data were collected for each patient at the beginning of IT, the end of IT, and before LT. The primary endpoint was the tolerance and effectiveness of LT.
Results: Twenty-one patients [17 men/4 females; median age 62 years (57–64)] who underwent LT for HCC after IT were included. Fourteen/21 patients (66.7%) were BCLC-B at baseline, followed by 4 BCLC-A (19%), 2 BCLC-0 (9.5%), and 1 BCLC-C (4.8%). HCC was multinodular in 17/21 (81%) cases, with a median size of the largest nodule of 36 mm (21–60). Thirteen patients had an AFP score >2 (downstaging group) and 8 of ≤2 (bridging group). Patients in the downstaging group were beyond Milan criteria, and 3 in the bridging group (p = 0.006). Sixteen patients (76.2%) received Atezolizumab/Bevacizumab, and five (23.8%) other immune checkpoint inhibitors (ICs) alone or in combination with tyrosine kinase inhibitors during 8.5 cycles (4.7–14). At the end of IT, four patients had a CR (19%), eight PR (38.1%), six SD (28.6%), and three PD (14.3%) according to the mRECIST criteria. Most patients shifted to an early/intermediate BCLC stage (p = 0.001) and reached Milan criteria (57.1%, p = 0.023). Nineteen patients (90.5%) achieved an AFP score of ≤2, while 2 (9.5%) remained >2 (p = 0.003). The median interval between the last IT cycle and LT was 5.1 (2.7–9.3) months. All patients except 3 received standard immunosuppressive treatment (tacrolimus, mycophenolate mofetil, corticosteroids). Two cases (10%) of rejection occurred, resolved after increasing immunosuppression. Early serious adverse events occurred in 6 patients (28.5%), four of which were fatal (23.8%) and in the first 3 months post-LT. Four patients (19%) had late complications, and five (27%) died. Factors associated with lower overall survival were the onset of early complications (p = 0.00026), Child-Pugh B (p = 0.014), no treatment before ICIs (p = 0.012), and less than five cycles of IT (p = 0.037). Only one patient (5.2%) had an HCC recurrence post-LT. On explant pathology, 15 patients (71.4%) had viable tumors, and necrosis ≥50% was detected in 9 cases (42.8%). According to the R3-AFP score, 5 patients (27.8%) were at very low, 3 at low (33.3%), and 10 at high (47.6%) recurrence risk.
Conclusion: LT following IT is feasible in selected patients with HCC and has an acceptable risk of rejection. However, the high immediate mortality observed requires further exploration in prospective studies.

FRI-482

Coronary atherosclerosis progression in patients with cirrhosis: effect of liver transplantation and association with early post-LT kidney dysfunction

Giulia Pagano[1], Judit Mestres[1], Cautar El Maimouni[1], Clara Viñals[1], Susanna Prat[1], Pablo Ruiz[1], Jordi Colmenero[1], Emilio Ortega[1], Gonzalo Crespo[1]. *[1]Hospital Clínic, Barcelona, Spain*
Email: gcrespo@clinic.cat

Background and aims: Cardiovascular (CV) diseases are the second leading cause of long-term mortality in liver transplant (LT) recipients. Coronary artery calcium score (CACS) in computed tomography (CT) evaluates atherosclerotic burden and predicts CV events and mortality, and progression of CACS further identifies a subgroup of patients at higher risk of CV morbidity and mortality in the general population. Data on the progression of CACS in LT patients or patients with cirrhosis are scarce.
Method: Cohort study that included LT recipients and patients with cirrhosis that underwent LT evaluation but were eventually discarded from LT (non-LT). All subjects had a baseline (at LT evaluation) CACS ($CACS_{bl}$) and underwent a follow-up CACS ($CACS_{fu}$) 5 years thereafter. Progression of CACS was defined using the annualized difference between CACS and compared between the groups. In LT recipients, CV risk factors, renal function and immunosuppression including cumulative exposure to tacrolimus (CET) and steroids, all evaluated 12 months after LT, were studied as potential predictors of CACS progression by linear regression.

Results: Seventy-five LT recipients and 20 non-LT patients were included. $CACS_{fu}$ was performed 5.2 (IQR 4.7–6.2) years after $CACS_{bl}$. At baseline, there were no significant differences between the groups regarding the etiology of liver disease or CV risk factors. $CACS_{bl}$ and $CACS_{fu}$ were, respectively, 42 (0.5–333) and 208 (28–841) in LT recipients and 107 (1–290) and 371 (45–570) in non-LT (p = 0.801 for $CACS_{bl}$ and p = 0.887 for $CACS_{fu}$). Annualized progression of CACS was 23/year (2–86) in LT recipients and 30/year (4–57) in non-LT (p = 0.833). Twelve months after LT, LDL-cholesterol was 109 (88–121) mg/dL, eGFR was 61 (47–75) ml/min, and 87% and 73% of LT recipients had, respectively, HbA1c and blood pressure within range. Twelve-months CET corresponded to high exposure to tacrolimus only in 20% of patients. Age, $CACS_{bl}$, diabetes and eGFR 12 months after LT were significantly associated with the annualized progression of CACS on univariate analysis, while only $CACS_{bl}$ and 12 months eGFR persisted as independent predictive factors in multivariate analysis.
Conclusion: Over a 5 years period, CACS progression was not faster in a cohort of LT recipients with optimized control of CV risk factors and standard/low exposure to tacrolimus than in patients with cirrhosis. Pre-LT CACS and kidney dysfunction at 12 months after LT predict progression of CACS in LT recipients. Interventions aiming at preserving kidney function after LT may slow down the progression of atherosclerosis in this population.

FRI-483

Adherence to the mediterranean diet and physical activity levels among liver transplant recipients in Greece: relationship to the metabolic syndrome

Kleoniki Chatzistavridou[1], Achilleas Triantafyllou[1], Styliani Vasileiadou[2], Athanasios Kofinas[2], Daphne Mavropoulou[2], Olga Giouleme[3], Ioannis Goulis[1], Anna-Bettina Haidich[4], Georgios Tsoulfas[2], Emmanouil Sinakos[1]. *[1]4th Department of Internal Medicine, Aristotle University of Thessaloniki, Hippokration General Hospital, Thessaloniki, Greece; [2]Department of Transplantation and Surgery, Aristotle University of Thessaloniki, Hippokration General Hospital, Thessaloniki, Greece; [3]2nd Propaedeutic Department of Internal Medicine, Aristotle University of Thessaloniki, Hippokration General Hospital, Thessaloniki, Greece; [4]Laboratory of Hygiene, Social and Preventive Medicine, and Medical Statistics, School of Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece*
Email: hatzkleo@hotmail.com

Background and aims: Liver transplant (LT) recipients have an increased cardiovascular risk due –among other factors– to the presence of Metabolic Syndrome (MS) in approximately half of them. One of the first-line therapeutic interventions for the MS is the adoption of a healthy dietary pattern, such as the Mediterranean Diet (MD), which has been widely recognized for its beneficial effects on metabolic profile, overall morbidity, and mortality. The aim of the present study is to evaluate the degree of adherence to the MD and the physical activity (PA) among LT recipients in Greece and to investigate its potential association with the development of MS components.
Method: The study comprises 135 clinically stable patients who underwent LT at least one year prior to their evaluation and are being followed at the outpatient clinic of our hospital. Adherence to the MD was assessed using the MEDAS questionnaire, which provides a scoring range from 0 to 14, with higher scores indicating greater compliance. Physical activity (PA) was evaluated through the IPAQ-short form questionnaire, categorizing activity levels into low, moderate, or high. Data analysis and dependency testing were performed using linear and logistic regression models, both univariate and multivariate.
Results: 93 of the participants were males, (69%), with a median age of 61 years (IQR 18) and a median time from transplantation of 11 years (IQR 10.5). The most frequent underlying etiology for LT was viral hepatitis (46%), with 20% of cases involving coexistent hepatocellular carcinoma, ethanol abuse, or a combination of these. Regarding viral hepatitis, hepatitis B virus was present in 53 of 61 patients (87%). Concerning PA levels, the majority of participants demonstrated moderate activity (82 patients, 61%), while only 1 exhibited high activity levels. The degree of adherence to the MD was moderate (median score: 8, IQR 2). Overall, 64% of the participants presented at least one new (de novo) MS parameter after LT. Specifically, 45 patients developed Arterial Hypertension, 58 Dyslipidemia, 38 Diabetes Mellitus, and 5 Coronary Artery Disease (3.7%). Older age was associated with higher MD compliance in the multivariate linear regression model. No statistically significant association was identified between the degree of MD adherence and the newly developed MS components.
Conclusion: Adherence to the MD and PA levels among LT recipients are moderate, potentially leading to beneficial effects on metabolic profile, and thus overall mortality. The lack of association between MD compliance and the development of MS components suggests the involvement of additional contributing factors, emphasizing the necessity for more comprehensive investigations in LT recipients.

FRI-484

Machine learning in predicting 3-month mortality for liver transplant candidates with HCC: a paradigm shift

Abdelghani Halimi[1], Ilias Kounis[2], Audrey Coilly[2], Clement Cormi[3], Eric Vibert[2], Sonia Garcia-Salicetti[4], Nesma Houmani[4]. *[1]SAMOVAR, Télécom SudParis, Institut Polytechnique de Paris, Chaire BOPA, Rue de la Chapelle de l'Hôpital, Palaiseau, France; [2]AP-HP Hôpital Paul-Brousse, Centre Hépato-Biliaire, Inserm, Université Paris-Saclay, UMR-S 1193, Université Paris-Saclay, Inserm, Physiopathogénèse et traitement des maladies du Foie, FHU Hepatinov, Villejuif, France; [3]Chaire BOPA, Rue de la Chapelle de l'Hôpital, Villejuif, France; [4]SAMOVAR, Télécom SudParis, Institut Polytechnique de Paris, Palaiseau, France*
Email: abdelghani.halimi@telecom-sudparis.eu

Background and aims: Predicting waitlist mortality in liver transplant (LT) candidates with hepatocellular carcinoma (HCC) is both critical and challenging. Traditional scores, like MELD scores, assess liver disease but ignore tumor risks, while HCC-specific models such as AFP model focus on tumors but overlook liver failure. This creates an unmet clinical need for an approach that evaluates both risks to optimize prioritization for transplantation. We address this gap using machine learning (ML) to predict 3-month mortality by combining liver dysfunction and tumor progression features.
Method: We used the OPTN/UNOS data registry to compare ML models with traditional scores to predict 3-month mortality in LT candidates with HCC. Inclusion criteria were adult patients listed for LT who (i) either died or were delisted due to clinical deterioration within 3 months, or (ii) survived beyond 3 months. Patients listed for multi-organ transplants were excluded. The cohort included 25 clinical, laboratory, and disease-related variables, with an additional 6 dynamic variables derived from changes in laboratory values, leading to 31 variables. Logistic Regression and Random Forest (RF) models were assessed using both feature sets. To address class imbalance, a down-sampling strategy was applied, and performance was assessed using 3-fold cross-validation.
Results: 11,641 patients were included, of whom 448 died or were removed from the waitlist within 3 months (mean: age 60, raw MELD 22) and 11,193 surviving on the waiting list beyond 3 months (mean: age 60, raw MELD 14). The AFP model performed the worst (AUC: 0.601). ALBI outperformed the Child-Pugh score (AUC: 0.710 vs. 0.699), while MELD scores demonstrated superior performance: MELD 3.0 achieved the highest AUC (0.752) compared to MELD (0.736) and MELD-Na (0.745). However, all traditional scores showed imbalance between sensitivity and specificity. ML models using 25

variables outperformed traditional scores, with RF achieving an AUC of 0.800. Incorporating 31 dynamic variables further improved performance, with RF achieving an AUC of 0.825 and balanced sensitivity (76.06%) and specificity (76.21%). Gini importance analysis identified new key predictors beyond MELD components, including largest tumor size, alpha-fetoprotein dynamics, BMI, and ascites severity.
Conclusion: RF outperformed traditional scores in predicting 3-month waitlist mortality for LT candidates with HCC, by integrating both liver dysfunction and tumor progression risks. This approach, pending validation, could enhance organ allocation.

FRI-485
Development of an explainable machine learning model for predicting waitlist mortality in liver transplant candidates
Abdelghani Halimi[1], Ilias Kounis[2], Audrey Coilly[2], Clement Cormi[3], Eric Vibert[2], Sonia Garcia-Salicetti[4], Nesma Houmani[4]. *[1]SAMOVAR, Télécom SudParis, Institut Polytechnique de Paris, Chaire BOPA, Rue de la Chapelle de l'Hôpital, Palaiseau, France; [2]AP-HP Hôpital Paul-Brousse, Centre Hépato-Biliaire; Inserm, Université Paris-Saclay, UMR-S 1193, Université Paris-Saclay, Inserm, Physiopathogénèse et traitement des maladies du Foie, FHU Hepatinov, Villejuif, France; [3]Chaire BOPA, Rue de la Chapelle de l'Hôpital, Villejuif, France; [4]SAMOVAR, Télécom SudParis, Institut Polytechnique de Paris, Palaiseau, France*
Email: abdelghani.halimi@telecom-sudparis.eu

Background and aims: Predicting waitlist mortality for liver transplant (LT) candidates remains a critical challenge due to the complexity of patient profiles and competing risks. Traditional models such as MELD, MELD-Na, and MELD 3.0, while effective in assessing liver dysfunction, lack the precision needed to capture dynamic, patient-specific factors. This study aims to evaluate the performance of an explainable ML model over traditional Model for End-Stage Liver Disease (MELD) scores in predicting 3-month mortality among adult LT candidates. By integrating Light Gradient Boosting Machine (LightGBM) with SHapley Additive exPlanations (SHAP), we sought to identify and analyze the most significant predictive variables, thereby proposing new factors for enhancing liver transplant allocation systems.
Method: We conducted a retrospective cohort analysis using data from the Organ Procurement and Transplantation Network/United Network for Organ Sharing registry, covering patients listed for liver transplantation (LT) from February 27, 2002, to September 30, 2023. Employing LightGBM, we compared its performance against MELD, MELD-Na and MELD 3.0 scores in predicting waitlist mortality. SHAP was used to improve model explainability and to identify critical predictive factors.
Results: Among 94,891 patients, 11,466 died or were delisted within 3 months (mean age 55, raw MELD 31) and 83,425 surviving on the waiting list (mean age 53, raw MELD 16). MELD, MELD-Na and MELD 3.0 achieved AUCs of 0.881 (95% CI: [0.880, 0.882]), 0.888 (95% CI: [0.887, 0.889]) and 0.884 (95% CI: [0.882, 0.885]), respectively. LightGBM demonstrated superior predictive performance over MELD scores, with an AUC of 0.934 (95% CI: [0.933, 0.935]). This corresponded to a sensitivity of 85.51% (95% CI: [85.23, 85.79]) and specificity of 85.77% (95% CI: [85.44, 86.09]). SHAP analysis revealed new key predictors of mortality, beyond traditional MELD components, including patient's functional state, age at registration, degree of ascites, and bilirubin changes over time.
Conclusion: Our explainable machine learning model outperforms traditional MELD-based scores in predicting 3-month waitlist mortality for liver transplant candidates. By integrating dynamic and static factors such as bilirubin changes, functional state, and degree of ascites, this model provides a comprehensive and personalized risk assessment. It represents a promising tool to refine organ allocation strategies and improve patient outcomes, pending prospective validation.

FRI-486
NT-proBNP predicts the development of acute-on-chronic liver failure and mortality in patients with cirrhosis listed for liver transplantation
Juan Manuel Diaz, Rocio Blanco[1], Lorena Savluk[2], Maria Nelly Gutierrez Acevedo[3], Agustina Martinez Garmendia[3], Carlos de la Peña Ramirez[4], Sebastián Marciano[3], Juan Carlos Spina[2], Igancio Bluro[1], Adrian Gadano[3], Diego Giunta[5], Joan Claria[4,6], Javier Fernández[4,6], Ezequiel Mauro[3,6]. *[1]Echocardiography Department, Cardiology Division, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, CABA, Argentina; [2]Radiology Department, Hospital Italiano de Buenos Aires, Buenos Aires, CABA, Argentina; [3]Liver Unit & Liver Transplant Unit, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, CABA, Argentina; [4]European Foundation for the Study of Chronic Liver Failure (EF Clif), Barcelona, Spain, Barcelona, Spain; [5]Instituto Universitario Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, CABA, Argentina; [6]Hospital Clinic, IDIBAPS, University of Barcelona and CIBERehd, Barcelona, Spain, Barcelona, Spain*
Email: juanmanuel.diaz@efclif.com

Background and aims: Acute-on-chronic liver failure (ACLF) is a severe complication of cirrhosis characterized by high mortality and limited access to liver transplantation (LT). NT-proBNP has been proposed as a biomarker, but its ability to predict ACLF development and waiting list (WL) mortality has not been studied.
Method: This observational study included 277 patients with cirrhosis on the WL between 2014 and 2020. Clinical data, such as sarcopenia, cystatin C (CysC), and NT-proBNP were collected at listing. A competing risk analysis was performed, considering LT and death as risks for ACLF development and LT as a competing risk for WL mortality. The NT-proBNP threshold was set at ≥125 pg/mL based on prior studies.
Results: Over a median follow-up of 9 months, 89 (32%) patients developed ACLF, 58 (30.8%) underwent LT without ACLF, and 10 (3.6%) died or were delisted. Patients with elevated NT-proBNP levels exhibited worse liver function (higher MELD-Na and Child-Pugh scores) and increased sarcopenia. NT-proBNP showed a modest correlation with kidney markers, such as creatinine and CysC (r^2 = 0.47 and 0.45; $p < 0.001$), as well as with MELD-Na ($r^2 = 0.58$, $p < 0.001$) and CLIF-C AD ($r^2 = 0.52$, $p < 0.001$). In contrast, no correlation was observed with systemic inflammatory markers, such as WBC count. Higher NT-proBNP levels were associated with ACLF [81 (42–163) pg/mL vs. 300 (141–600) pg/mL; $p < 0.001$] and death on the WL [108.5 pg/mL (49–204) vs. 300 pg/mL (142–600), $p < 0.001$]. NT-proBNP levels also increased with ACLF severity and organ failure. NT-proBNP ≥125 pg/mL was associated with higher ACLF incidence at 3 and 12 months (28.5% and 49.2% vs. 3.6% and 6.1%, respectively; $p < 0.001$) and higher 1-year mortality (22.3% vs. 4%; $p < 0.001$). Multivariate analysis revealed that NT-proBNP ≥125 pg/mL independently predicted ACLF development (sHR 4.00; 95% CI: 1.76–9.10; $p = 0.001$), after adjusting for clinically relevant variables such as MELD-Na (sHR 1.16; 95% CI: 1.11–1.21; $p < 0.001$) and CysC (sHR 2.72; 95% CI: 1.43–5.14; $p = 0.002$). Similarly, NT-proBNP ≥125 pg/mL predicted WL mortality (sHR 3.89; 95% CI: 1.28–11.79; $p = 0.016$), adjusted for MELD-Na (sHR 1.00; 95% CI: 0.94–1.05; $p = 0.992$) and CysC (sHR 5.89; 95% CI: 2.17–15.99; $p < 0.001$). The combination of NT-proBNP with MELD-Na and CysC demonstrated a predictive accuracy for 3-month mortality on the WL, with an AUC of 0.82 (95% CI: 0.73–0.91, $p = 0.045$).
Conclusion: NT-proBNP level ≥125 pg/mL is an independent predictor of ACLF development and WL mortality. Its use may facilitate preventive interventions and improve WL prioritization.

FRI-487

Treatment of grafts not meeting criteria for transplantation with nor-ursodeoxycholic acid during normothermic machine perfusion reduces apoptosis and biliary injury markers

Jule Dingfelder[1], Laurin Rauter[2], David Pereyra[1], Moriz Riha[2], Nikolaus Becker[2], Andreas Salat[2], Gerd Silberhumer[3], Thomas Soliman[2], Gabriela Berlakovich[2], Dagmar Kollmann[3], Georg Gyoeri[2]. *[1]Medical University of Vienna, Department of General Surgery, Division of Transplantation, Medical University of Vienna, Department of General Surgery, Division of Visceral Surgery, Vienna, Austria; [2]Medical University of Vienna, Department of General Surgery, Division of Transplantation, Vienna, Austria; [3]Medical University of Vienna, Department of General Surgery, Division of Visceral Surgery, Vienna, Austria*
Email: jule.dingfelder@meduniwien.ac.at

Background and aims: Normothermic machine perfusion (NMP) allows for viability assessment in livers at risk for higher post-operative morbidity and provides a platform for ex vivo therapeutic intervention. Nor-ursodeoxycholic acid (norUDCA) is an agent with anti-inflammatory and antifibrotic properties that was used in phase II trials in patients with primary sclerosing cholangitis and metabolic dysfunction-associated steatohepatitis. We aimed to investigate the effects of norUDCA during NMP on livers that did not meet the criteria for transplantation during viability assessment.
Method: We evaluated apoptosis markers in perfusate and bile composition in samples of 18 normothermic perfused grafts that did not meet criteria for transplantation. Nine livers received treatment of 1500 mg of norUDCA after two hours, perfusion duration was 12 hours. Apoptosis markers (active caspase-3, Bcl-2, cleaved PARP, Cytochrome c, p53) were measured on the Luminex platform. To account for donor heterogeneity, the relative dynamic of apoptosis markers was determined for individual grafts after application of norUDCA. Blood gas analysis of perfusate and bile, as well as additional measurements including alanine-aminotransferase (ALT) and aspartate-aminotransferase (AST) were performed every two hours.
Results: NorUDCA treatment after two hours lead to a significant reduction of apoptosis markers cleaved PARP (6 h: p = 0.0142) and p53 (6 h: p = 0.0106; 12 h p = 0.0400), additionally to a significant reduction in delta 2 h–6 h values compared to control livers: active caspase-3 (p = 0.0188), Bcl-2 (p = 0.0400), cleaved PARP (p = 0.0244) and Cytochrome c (p = 0.0304). Of note is the overall dynamic reduction of apoptosis markers in the treatment group, whereas the control group increased or remained constant. Further, treated grafts presented with improved biliary viability and reduced biliary injury markers, evident in higher bile bicarbonate concentration (3 h: 0.026; 4 h: p = 0.016; 5 h p = 0.030), as well as lower bile transaminases AST (8 h: p = 0.017) and ALT (8 h: p = 0.004; 12 h: p = 0.026).
Conclusion: The present data suggests an anti-apoptotic effect as well as an improvement in bile compostition after treatment of extended criteria donor grafts with norUDCA during NMP. NorUDCA might be able to ameliorate the detrimental effects of bile toxicity on the ischemia-injured biliary tree. Therefore, therapeutic application of norUDCA prior to transplantation seems promising, especially for liver grafts at risk for biliary complications.

FRI-488

Concomitant sarcopenia and myosteatosis in patients with cirrhosis is associated with longer recovery and mortality after liver transplantation

Ellina Lytvyak[1], Devika Shreekumar[2], Shagani Thisairajah[2], Maryam Motamedrad[2], Narmeen Umar[2], Glenda Meeberg[3], Norberto Sanchez-Fernandez[3], Alessandro Parente[3,4], Norman Kneteman[3], Khaled Dajani[3], Blaire Anderson[3], David Bigam[3], James Shapiro[3], Aldo J. Montano-Loza[5]. *[1]Division of Preventive Medicine, University of Alberta, Edmonton, Canada; [2]Division of Gastroenterology and Liver Unit, University of Alberta, Edmonton, Canada; [3]Division of Transplantation Surgery, Department of Surgery, University of Alberta, Edmonton, Canada; [4]Institute of Liver Studies, King's College Hospital NHS Foundation Trust, London, United Kingdom; [5]Division of Gastroenterology and Liver Unit, University of Alberta, Edmonton, Edmonton, Canada*
Email: montanol@ualberta.ca

Background and aims: Skeletal muscle abnormalities, such as sarcopenia (low muscle mass) and myosteatosis (pathological fat accumulation in muscle) are well-established predictors of worse outcomes in patients with cirrhosis. Still, their impact on the post-liver transplantation (LT) course is unknown. We aimed to assess the association between sarcopenia and myosteatosis and recovery time and negative clinical outcomes in patients who underwent LT.
Method: In this cohort study, we evaluated patients with cirrhosis who underwent LT and had computed tomography (CT) imaging performed within three months before LT. Body composition analysis was assessed using Slice-O-Matic software (V4.2; Tomovision) to measure the skeletal muscle index (SMI) in cm^2/m^2 and muscle radiodensity in Hounsfield Units (HU). Sarcopenia was defined as SMI <39 cm^2/m^2 in females and <50 cm^2/m^2 in males. Myosteatosis was defined as mean skeletal muscle radiodensity <28 HU for females and <33 HU in males. Cox regression models were built to estimate and measure associations between skeletal muscle abnormalities and post-LT clinical outcomes.
Results: We evaluated 302 patients, 67.9% (n = 205) were males with a mean age at LT of 51.6 ± 11.6 years, and a MELD score at LT of 21.2 ± 9.7. The main indications for LT were alcohol-associated liver disease (38.4%, n = 116), hepatitis C (28.1%, n = 85), autoimmune liver diseases (19.2%, n = 58), and metabolically-associated steatotic liver disease (7.6%, n = 23). Hepatocellular carcinoma was present in 27.2% (n = 82) patients. Sarcopenia was identified in 51.3% (n = 155) and myosteatosis in 41.1% (n = 124). Concomitant sarcopenia-myosteatosis were present in 26.2% (n = 79). After LT, patients with concurrent sarcopenia and myosteatosis tended to have longer post-LT ICU median length of stay (LOS) (4 [IQR 8] vs 3 [IQR 5] days; p = 0.082) and substantially longer post-LT hospital LOS (28 [IQR 33] vs 20 [IQR 21] days; p = 0.017). Patients with concurrent sarcopenia-myosteatosis had worse 1- and 5-year post-LT survival (83.5% and 68.3% vs. 89.7% and 83.0%, log-rank p = 0.005). The 5-year post-LT survival was only 56.9% in patients with concomitant sarcopenia-myosteatosis and older than 60 years. In addition, concomitant sarcopenia-myosteatosis was associated with higher post-LT mortality (HR 1.86, 95%CI 1.19–2.87, p = 0.006) and was more pronounced in those older than 60 years (HR 2.61, 95%CI 1.06–6.43, p = 0.038). The association between concurrent sarcopenia-myosteatosis and overall mortality remained significant after adjusting for age, sex and MELD score at LT (HR 4.82, 95%CI 1.10–21.09, p = 0.037).
Conclusion: Concurrent sarcopenia-myosteatosis is present in over a quarter of cirrhotic patients who received LT and is linked to prolonged recovery times and reduced post-LT survival, particularly among older patients. Integrating this objective assessment into clinical practice could serve as a valuable criterion for evaluating the futility of LT.

FRI-489-YI

Coronary angiography in the preoperative work-up for liver transplantation (LT): a multicenter italian cohort study

Background and aims: Evaluating coronary artery disease (CAD) is critical in liver transplant (LT) candidates due to increasing age and comorbidities. Coronary angiography (CATH) is the gold standard for CAD diagnosis but is not feasible for routine screening due to cost and invasiveness. Data on CATH in European LT cohorts are limited. We aimed to assess the role of CATH in a multicenter pre-LT cohort.
Method: 18/21 adult LT centers in our Country participated, enrolling adult cirrhotic patients (pts) who underwent CATH during cardiac work-up between 2018–2022. We evaluated: indications for CATH, rate of significant coronary stenosis (SCS: ≥50% major vessels or ≥70% moderate branches), post-LT major cardiovascular events (MACEs) and survival.
Results: Between 2018–2022, the 18 centers performed 5336 LT from deceased donors. 305 pts underwent pre-LT CATH and constituted our study cohort. Median age 62 years (y); 85% male; BMI 27 kg/m²; 68% smokers; 57% diabetes; 55% arterial hypertension; 13% CAD history, 9% peripheral artery disease, 26% CAD family history. Liver disease etiology was 34% viral, 27% alcohol, 15% MASLD, 12% alcohol+MASLD, MELD score 13 (IQR 9–18), 61% HCC. Indications for CATH were: 31% positive coronary CT (CCTA), 25% ≥3 cardiovascular risk factors, 12% cardiac consultation, 11% positive myocardial scintigraphy, 9% positive stress echocardiography (Echo), 8% CAD history, 4% resting echocardiographic abnormalities. CATH complications occurred in 16 pts (5%) (6 anaemia, 4 pseudoaneurysms, 1 acute kidney injury, 1 allergic reaction, 2 wound bleeds, 1 arrhythmia, 1 coronary spasm). SCS was detected in 120 pts (39%), 65 (54%) underwent revascularization. At univariate analysis, SCS was associated with male (OR = 2.02, CI: 1.00–4.09, p = 0.049) and smoking history (OR: 1.92, CI: 1.07–3.47, p = 0.029). At multivariable analysis, active smoking (OR 2.02, CI: 1.07–3.88, p = 0.037) and MASLD (OR 1.89, CI: 1.02–3.55, p = 0.044) were independent predictors of SCS. Positive predictive value (PPV) of CCTA and Echo was 57% and 35%, respectively. After CATH, 46/305 pts were excluded from LT list, 259/305 pts placed on LT waiting list. By June 2023, 230 underwent LT [49 (21%) after pre-LT revascularization]. 28 (12%) MACEs occurred within 2 y after LT (12 heart failure, 9 ischemic, 7arrhythmia), with 3 related deaths. Among 9 ischemic events, all had pre-LT SCS, and 67% (6/9) underwent pre-LT revascularization. 1- and 2-y cumulative survival rates were 92% and 90%, respectively.
Conclusion: Cardiac work-up varies across our 18 LT centers. CCTA showed a PPV of 57%. 39% of pts selected for CATH had SCS, 54% requiring revascularization. Smoking and MASLD were independent predictors of SCS. Post-LT MACEs occurred in 12% of selected patients, with cardiac-related mortality rate of 9%. National efforts should be made to share a unified cardiac work-up protocol tailored for our LT recipients.

FRI-490

Reintegration into working life for liver transplant recipients: cross-disciplinary evaluation of risk factors for unemployment

Margherita Saracco[1,2], Alessandro Godono[2], Massimo Maci[2], Astrid Cecilia Surra[2], Giuliano Curoso[2], Fllippo Angelino[2], Cristiana Arnone[2], Silvia Strona[1], Bruno Papaleo[3], Sara Sottile[4], Maria Vittoria Picciaiola[4], Paolo Boffetta[4], Cinzia Frascheri[5], Enrico Pira[2], Antonio Ottobrelli[1], Donatella Cocchis[6], Giorgio Maria Saracco[1], Renato Romagnoli[6], Silvia Martini[1].

Email: margherita.saracco@gmail.com

Background and aims: The return to work of liver transplant (LT) recipients is essential, yet specific guidelines for this process are lacking. The BRIC-2022-ID25 project investigates the impact of liver disease and transplantation on work ability by examining correlations among clinical, social, and occupational factors before and after LT, with the aim of enhancing professional reintegration.
Method: In collaboration with the occupational medicine department, we enrolled patients who underwent LT in our Centre between 2018 and 2023, aged 18 to 68 years, who were not retired prior to LT. Participants completed the WHODAS 2.0 (World Health Organization Disability Assessment Schedule) and Work Ability Index (WAI) questionnaires, and results were merged with clinical and occupational data from both pre-LT and post-LT follow-ups. We performed interim analyses on patients interviewed from January to June 2024.
Results: A total of 140 recipients participated; 76% had liver cirrhosis (49% with hepatocellular carcinoma - HCC), and 19% were diagnosed with hepatic/hepato-renal polycystosis. The mean age was 55 years (range 24–69), with 64% males and an average interval of 42 months between LT and the interview. Notably, 50% had a middle-school education. Post-LT, 49% were unemployed, with 62% indicating that health issues hindered their job search. Significant correlations were identified between unemployment and factors such as pre-LT alcohol abuse (p = 0.005), age over 60 at LT (p = 0.02), having a caregiver outside the household (p = 0.004), working before LT (p < 0.001) and a greater number of post-LT hospitalizations (p = 0.05). A low self-assessment of work capacity (WAS) correlated with being over 50 years old (p = 0.02), lower education levels (p = 0.04), pre-OLT HCC (p = 0.02), and a MELD score <14 at LT (p = 0.04). Total WAI score was lower in non-Italian patients (p = 0.001). Poorer disability scores (WHODAS) were associated with female gender (p = 0.02), having a caregiver outside the family (p = 0.04), and non-Italian nationality (p = 0.002).
Conclusion: Interim analyses reveal a 49% of unemployment rates following LT, with health status affecting 62% of cases. Factors such as caregiving responsibilities, education level, nationality, and gender, along with age, pre-LT HCC, and complications, significantly impact work ability. Enhanced efforts are needed to ensure equitable employment opportunities for transplant recipients.

FRI-491

Outcomes of ABO-incompatible deceased donor liver transplantation in adults with acute liver failure: a study from a Costa Rican hospital

Maria Lynch-Mejia[1], Pablo Coste[1], Sheila Araya-Chavarría[1], Vanessa Lopez Jara[1], Irene Mora-Quesada[1], Michelle Muñoz-Hermann-Legueu[1], Alejandra Ochoa[1], Rolando Paez-Saenz[1]. [1]*Rafael Angel Calderon Guardia Hospital, San Jose, Costa Rica*
Email: mariaflynch@hotmail.com

Background and aims: The acceptance of ABO-incompatible organs (ABOi) has increased with the development of desensitization strategies, which have shown complication rates similar to those of ABO-compatible (ABOc) deceased donor liver transplantation (DDLT). This approach is particularly relevant in countries with low organ donation rates and limited resources, such as in Latin America (LATAM), although no outcome reports from the region are currently available. The aim of this study is to analyze the medical outcomes of ABOi DDLT at a Costa Rican hospital.
Method: A retrospective, comparative analysis was conducted on the clinical characteristics and outcomes of a cohort of patients >12 years with acute liver failure who were received ABOi or ABOc DDLT at the Liver Unit of Calderon Guardia Hospital from 2009 to 2024.
Results: 8 DDLT (3 ABOi and 5 ABOc) were performed for Wilson disease (n = 6) or drug induced liver injury (n = 2), with a median age of 22.5 years. 87.5% of the recipients were female. The median MELD-Na score was 37 (range: 34–40) in the ABOi group and 27 (range: 21–40) in the ABOc group (p = 0.11). ABOi pre-LT desensitization strategies consisted of plasmapheresis (PP) (n = 3) and rituximab (n = 2); and immunosuppression (IS) on basiliximab (n = 3), tacrolimus (n = 3), mycophenolate (n = 2) and steroids (n = 3). Quantification of isoagglutinin was performed in 2 ABOi cases (pre-LT titers 1:64 and 1:16), and post-LT titers peaking at 1:128 within 3 weeks in both cases, no PP was performed to lower these titers. The second patient had histological evidence of antibody mediated rejection (AMR) within 10 days post LT, leading to PP and immunoglobulin treatment, reducing titers to <1:16. In the 1-year follow up, the patient had 2 more episodes of AMR resulting in adjustment of IS. The incidence of cytomegalovirus and bacterial pneumonia was similar among groups, while fungal infections arose only in two ABOc DDLT cases, both with Aspergillosis, one of which also had Candidemia. Anastomotic biliary stenosis occurred in 3 ABOi and 2 ABOc patients, with earlier onset in ABOi DDLT (median time 4 vs 20 months, respectively). Protocolized endoscopic management was performed in all cases; however, stenosis complete resolution at 1 year was documented in only 2 patients, one from each group. No vascular complications occurred in the ABOi group. Regarding patient and graft survival rate, the 1-year survival rate for the 8 patients (3 ABOi, 5 ABOc) was 100%. At 3 years, all 5 transplanted patients (1 ABOi, 4 ABOc) had a 100% survival rates. At 5 years of the 4 transplanted patients (1 ABOi, 3 ABOc) the survival rate for ABOi was 100% vs 66.6% for ABOc.
Conclusion: Despite the use of heterogeneous desensitization strategies, ABOi DDLT was associated with 1-year patient and graft survival comparable to ABOc DDLT, with no significant differences in complication rates. These findings emphasize the importance of protocolized therapeutic approaches for ABOi DDLT, especially in regions with low donation rates and restricted resources, such as LATAM.

FRI-492

Torque Teno virus as a biomarker of immune status and attenuated immune response to vaccination in liver transplant recipients

Nicolas Ducasa[1], Paula Benencio[1], Maria Margarita Anders[2], Bianca Mazzitelli[1], Lucía Bleichmar[1], Manuel Barbero[3], Fernando Cairo[3], Natalia Sobenko, Patricia Etcheves[4], Giampaolo Scarton[4], Chiara Zecchin[5], Manuel Mendizabal[5], Florencia Quiroga[1], Mirna Biglione[1], Ezequiel Mauro[6]. Email: mauro@recerca.clinic.cat

Background and aims: Liver transplant recipients (LTRs) are at higher risk for SARS-CoV-2 infections and often exhibit suboptimal responses to vaccination. Our aim was to characterize the immune status of LTRs, focusing on Torque Teno Virus (TTV) as a biomarker, and to evaluate humoral and cellular responses after the primary vaccination series (1st and 2nd doses) and the booster dose (3rd dose) against SARS-CoV-2, compared to healthy controls (HC).
Method: This multicenter, prospective study included 122 LTRs from August 2021 to March 2022. Humoral response was assessed by anti-Spike (anti-S) and neutralizing antibodies (anti-N) against SARS-CoV-2 variants (Wuhan, Delta, and Omicron). Cellular response was evaluated using an ELISPOT assay to measure IFN-γ-producing cells after stimulation with SARS-CoV-2 Wuhan and Omicron peptides. Additionally, the frequency of T and B cell populations was analyzed, and TTV viral load was quantified by qPCR as a surrogate marker of immune status.
Results: Following both the primary vaccination series and booster dose, LTRs showed a lower proportion of anti-S positivity compared to HC (1st and 2nd doses: 57.4% vs. 81.5%, p = 0.019; 3rd dose: 75% vs. 100%, p = 0.003). Anti-S levels were significantly lower in LTRs compared to HC after the 1st and 2nd doses (62.60 IU/mL vs. 619.2 IU/mL, p < 0.001), and the booster dose (406.6 IU/mL vs. 1350 IU/mL, p = 0.007). Similarly, anti-N levels were markedly lower in LTRs. Cellular responses, measured by IFN-γ-producing cells, were diminished in LTRs after the 3rd dose (Wuhan: 29.2% vs. 83.3%, p = 0.017; Omicron: 39.6% vs. 83.3%, p = 0.078). LTRs exhibited an altered CD4/CD8 ratio (2 vs. 2.8, p = 0.02), a lower percentage of naïve CD4+ (59.40% vs. 71.05%, p = 0.003) and CD8+ (20.75% vs. 42.45%, p = 0.01) cells, but a higher proportion of CD4+ and CD8+ effector memory (16% vs. 4.96%, p < 0.001; 12.40% vs. 9.52%, p = 0.228) and terminal effector cells (2.09% vs. 0.66%, p = 0.01; 46.65% vs. 23.25%, p = 0.002). TTV viral load (log10 copies/mL) was higher in LTRs compared to HC (5.45 vs. 4.10, p < 0.001), in non-responders after the primary vaccination series (5.94 vs. 4.90, p < 0.001), and after the booster dose (6.26 vs. 5.30, p = 0.005). Multivariate analysis identified the use of mycophenolate [OR: 0.16 (0.03–0.70), p = 0.022] and TTV [OR: 0.17 (0.05–0.43), p = 0.001] as independent predictors of humoral response to the 3rd dose in LTRs.
Conclusion: LTRs exhibit significantly reduced humoral and cellular responses to SARS-CoV-2 vaccination. Our findings highlight an immunosenescent state in LTRs, with a diminished ability to effectively respond to novel antigens. Emerging biomarkers, such as TTV, could provide valuable insights into the immune status of LTRs and support the development of individualized vaccination strategies.

FRI-493

Conversion from standard-release to prolonged-release tacrolimus mitigates calcineurin-induced nephrotoxicity in patients after liver transplantation

Maximilian Joseph Brol[1], Isabella Munske[1], Iyad Kabar[1], Frank Erhard Uschner[1], Michael Praktiknjo[1], Martin Schulz[1], Kai-Henrik Peiffer[1], Florian Rennebaum[1], Philipp Houben[2], Andreas Pascher[2], Hartmut Schmidt[1,3], Jonel Trebicka[1,4], Tina Schomacher[1], Anna Hüsing-Kabar[1]. [1]*Department of Internal Medicine B, University Hospital Münster, Münster, Germany;* [2]*Department of General, Visceral and Transplant Surgery, University Hospital Münster, Münster, Germany;* [3]*Department of Hepatology,*

Gastroenterology and Transplantation Medicine, University Hospital Essen, Essen, Germany; [4]European Foundation for the Study of Chronic Liver Failure-EF Clif, Barcelona, Spain
Email: maximilian.brol@ukmuenster.de

Background and aims: Chronic calcineurin inhibitor (CNI)-induced nephrotoxicity is a major complication in the management of patients after liver transplantation (LT) since it is associated with an increased risk of both morbidity and mortality. While conventionally released tacrolimus (standard-release Tac) is mostly used in post-LT management, tacrolimus can further be administered with a modified galenic using MeltDose® technology (LCPT) leading to an extended drug release. In this context, the tacrolimus concentration-dose ratio (C/D ratio) is of particular value for investigating nephrotoxicity-related renal outcomes since an increased C/D ratio might prevent renal dysfunction by improved drug bioavailability. The aim of the study was to investigate the effects of switching from standard-release Tac to LCPT on the C/D ratio and renal function.
Method: This monocentric, retrospective observational study included adult LT recipients from the University Hospital Münster (August 2010–March 2022) who underwent at least 2 years of Tac-based therapy. Patients who were switched from standard-release Tac to LCPT formed the LCPT group (n = 63), while the control group (n = 107) continued to receive standard-release Tac. The day of the conversion was considered to be the baseline (t0). Clinical data were collected at three-month intervals over a total of 24 months. Statistical analysis included binary logistic regression to determine predictive factors for improvement of estimated glomerular filtration rate (eGFR).
Results: At t0, comparable median C/D ratios were observed in both groups (p = 0.553). After conversion, significantly higher median C/D ratios were observed on average in the LCPT group for both the first (p = 0.003) and second (p = 0.004) year of the study. At the same time, an increase in mean eGFR compared to t0 was found in the LCPT group over the entire study period, although this increase of 2.9 ml/min/1.73 m² was no longer significant 24 months after t0. In contrast, the control group showed a significant decrease in the mean eGFR compared to t0 at each measurement time point over the observation period; after 24 months, the mean decrease was −5.4 ml/min/1.73 m² (p < 0.001). In multivariable binary logistic regression, only eGFR at t0 (OR 0.985, 95%CI 0.972–0.997, p = 0.018) and use of LCPT (OR 3.334 95%CI 1.717–6.475) formulation were predictive factors of eGFR increase. Median serum bilirubin and GOT levels were all statistically significant lower in the LCPT group, while there were no significant differences for GPT and INR at all visits.
Conclusion: In comparison to standard-release Tac, LCPT appears to stabilize renal function in liver transplant recipients over a two-year period, potentially offering long-term nephroprotective benefits without compromising graft function.

FRI-494
Graft rejection and biliary complications affect liver stiffness measurements in the first year after liver transplantation

Michele Sagasta[1], Clara Dibenedetto[1], Enrico Sguazzini[1], Lucio Caccamo[2], Barbara Antonelli[2], Maria Francesca Donato[1], Pietro Lampertico[1,3]. *[1]Division of Gastroenterology and Hepatology, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]Division of General Surgery, Liver Transplant Center, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [3]CRC "A. M. and A. Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy*
Email: michele.sagasta@policlinico.mi.it

Background and aims: Liver stiffness measurement (LSM) is an easy and non-invasive tool to assess graft function in the long-term management after liver transplantation (LT). The early period post-LT is characterized by well-known complications that could also affect LSM, however this relationship has not been established. The aim of this study is to evaluate the association between early post LT complications (≤12 months) and LSM changes.
Method: This single centre study retrospectively enrolled all consecutive patients undergoing LT between 2015 and 2023. Exclusion criteria were death within 6 months post-LT, re-LT and lack of LSM at 6 or 12 months (namely T1 and T2). LSM was performed at T1 and T2 by vibration-controlled transient elastography (Fibroscan, Echosens, Paris). We investigated the association between the occurrence of early post-LT complications and LSM >8 kPa, defining presumed graft damage. All graft rejection episodes were biopsy-proven. Chi-square and T-test were used to analyse categorical and continuous variables, respectively.
Results: 326 LT recipients were enrolled, median age 58 (18–72) years, 73% males. Liver diseases pre-LT were viral hepatitis (54%), Met-ALD (29%), immune-mediated (10%) and others (7%). 179 LT-recipients were transplanted for HCC (55%), 125 for decompensated cirrhosis (38%). The immunosuppressive regimen was CNI-based in all LT recipients. Median LSM was 6.6 (2.5–30.5) kPa at T1 and 6.1 (2.5–24.1) kPa at T2 (p = 0.02). LSM was > 8 kPa in 87 patients (27%) at T1 and 65 patients (20%) at T2. Graft rejection was reported in 22% of LT recipients at T1 and 3% at T2, biliary complications in 17% at T1 and 9% at T2, vascular complications in 12% at T1 and 1% at T2. CMV reactivation occurred exclusively within the first 6 months post-LT (27%). Arterial hypertension (AH) was the most frequent comorbidity (67%), followed by steroid-induced diabetes (32%) and chronic kidney disease (CKD; > grade 3; 15%), both at T1 and T2. By univariate analysis, among all early complications/comorbidities analysed (biliary, graft rejection, vascular, CMV reactivation, steroid-induced diabetes, AH and CKD) only graft rejection was significantly associated with LSM > 8 kPa at T1 (37% in LSM > 8 *vs* 17% in LSM ≤8, p < 0.01), whereas biliary complication (15% in LSM > 8 *vs* 7% in LSM ≤8, p = 0.03) and CKD (25% LSM > 8 *vs* 13% in LSM ≤8, p = 0.02) were significant at T2.
Conclusion: Our results demonstrate that LSM increase observed in the first 6 months post-LT is mostly associated with graft rejection, while in the second semester correlates with biliary complications and CKD. These results support the integration of LSM monitoring in the work-up of early post-LT complications.

FRI-495-YI
Hypothermic oxygenated machine perfusion (HOPE) treatment prior to organ transplant alters key immune modulators in patients receiving liver transplantation

Maike Rebecca Pollmanns[1], Johanna Reißing[1], Josua Johnsen[1], Johan Hohenschwert[1], Dominik Krautgartner[1], Felix Oldhafer[2], Ulf Peter Neumann[3], Florian Vondran[2], Alexander Koch[1], Tony Bruns[1], Theresa Hildegard Wirtz[1]. *[1]Medical Department III, RWTH Aachen University Hospital, Aachen, Germany; [2]Department of General, Visceral, Pediatric and Transplant Surgery, RWTH Aachen University Hospital, Aachen, Germany; [3]Department of General- Visceral- and Transplantation Surgery, University Hospital Essen, Essen, Germany*
Email: mpollmanns@ukaachen.de

Background and aims: Hypothermic oxygenated machine perfusion (HOPE) is recognized as a powerful strategy to protect allografts from ischemia-reperfusion injury. While its benefits on early graft function have been demonstrated in several trials, its specific impact on immune regulation post-transplant remains unexplored. This study aimed to investigate how HOPE influences key immune modulators in patients undergoing liver transplantation.
Method: A single-center study of 100 patients receiving liver transplantation at the University Hospital RWTH Aachen between 2019 and 2024 was conducted. Of these, 38 received HOPE-treated donor livers, while 62 received livers with standard preservation treatment. Soluble immune markers, including T-cell immunoglobulin mucin domain-containing protein 3 (sTIM-3), sCD163 and programmed death ligand 1 (sPD-L1), were measured in patients`

serum before surgery (baseline), within 24 hours post-surgery (POD1) and one week after surgery (POD7).
Results: Patients who received HOPE-treated livers experienced significantly fewer postoperative complications (p = 0.04). Post-surgery, these patients exhibited significantly lower sTIM-3 concentrations, a marker involved in T-cell activation, suggesting reduced immune activation (p = 0.04). The macrophage activation marker sCD163 was also significantly reduced in the HOPE group (p = 0.005). Conversely, sPD-L1, known to inhibit T-cell activation and to promote immune tolerance, was elevated in the HOPE-treated patients, potentially contributing to improved graft tolerance (p = 0.004).
Conclusion: Our findings demonstrate that HOPE treatment has an immediate impact on the host immune response in patients following liver transplantation. The observed changes in sTIM-3, sCD163, and sPD-L1 provide early insights in immunomodulatory effects of HOPE and its potential to improve post-transplant outcomes by influencing key immune pathways.

FRI-496
Impact of donor-recipient age disparity on survival and recurrence in liver transplantation for hepatocellular carcinoma
Nada El-domiaty[1,2], Audrey Coilly[1], Alina Pascal[1], Rodolphe Sobesky[1], Wafaa Ibrahim[3], Philippe Ichai[4], Gabriella Pittau[1], Lea Duhaut[1], Oriana Ciacio[1], Salloum Chady[1], Eleonora De Martin[1], Marc Antoine Allard[1], Jean-Charles Duclos-Vallée[1], Nicolas Golse[1], Antonio Sa Cunha[1], Daniel Azoulay[1], Eric Vibert[1], René Adam[1], Olivier Rosemorduc[1], Didier Samuel[1], Daniel Cherqui[1], Faouzi Saliba[1].

Email: nadadomty@hotmail.com

Background and aims: The age disparity between liver transplantation (LT) recipients and donors may influence long-term outcomes, including survival and recurrence of hepatocellular carcinoma (HCC). This study evaluates the impact of donor-recipient age combinations on post-transplant outcomes in HCC patients.
Method: A cohort of 586 HCC patients who underwent LT between 2000 and 2022 was classified into four groups based on recipient and donor age: Group 1 (recipient ≤65 years, donor ≤65 years; n = 319), Group 2 (recipient ≤65 years, donor >65 years; n = 130), Group 3 (recipient > 65 years, donor ≤65 years; n = 87), and Group 4 (recipient > 65 years, donor > 65 years; n = 50). Survival and recurrence rates were compared using Kaplan-Meier analysis and log-rank tests.
Results: During mean follow-up periods of 89 ± 68 months, the cohort has 82.4% males and 17.6% females with a mean age of 58.9 ± 8.7years.The main aetiologies of underlying cirrhosis were alcoholic-associated liver disease (29.2%), HCV (28.3%), MASH (15.5%) and HBV (13%).
The mean MELD score at time of LT was 13.6 ± 7.4. 79.9% of the patients were within Milan criteria at time of LT. 42.7% of donors were females. The mean age of donors at time of LT was 54 ± 20 years. At time of LT, tumours among 4 groups were within Milan criteria (78%, 81.7%, 77.1% & 85.4%, respectively, P = 0.765). MVI (p = 0.853) and tumour differentiation (p = 0.26) could not differ between the 4 groups. Recurrence incidence was significantly different among 4 groups (21.4%, 20%,16.1% and 26%, respectively, p = 0.037). Group 4 had the highest cumulative HCC recurrence rates at 1, 3, 5 and 10 (13.1%, 23.4%, 26.5% and 37.0%, respectively), while Groups 1 and 3 had the lowest recurrence rates (log-rank p = 0.033). Group 1 demonstrated the best long-term survival rates at 1, 3, 5 and 10 years (93.7%, 82.1%, 73.2% and 59.6%, respectively), while Group 4 showed significantly lower survival at all time points (78.0%, 61.8%, 31.5% and 21.0%, respectively; log-rank p = 0.020).
Conclusion: Donor-recipient age disparity significantly impacts long-term survival and recurrence in HCC patients undergoing liver transplantation. Younger recipients (≤65 years) paired with younger donors (≤65 years) demonstrate superior outcomes, while older recipients (> 65 years) paired with older donors (>65 years) exhibit the poorest outcomes. These findings highlight the importance of considering age compatibility during donor selection to optimize post-transplant outcomes in HCC patients.

FRI-497
Steatotic liver disease is associated with frailty, but this does not influence transplant listing outcomes: a retrospective study
Niall Burke[1], Alexandra Frolkis[1], Victoria Kronsten[1], Dhaarica Jeyanesan[1], Kosh Agarwal[1], Varuna Aluvihare[1], William Bernal[1], Maria Guerra Veloz[1], Michael Heneghan[1], Deepak Joshi[1], Abid Suddle[1], Claire Kelly[1]. *[1]Kings College Hospital, London, United Kingdom*
Email: niall.burke@nhs.net

Background and aims: Steatotic liver disease (SLD) has emerged as a primary driver for liver transplant assessment. Frailty is increasingly recognised as critical in the assessment and management of patients with chronic liver disease. Our aim was to identify whether frailty was more prevalent in SLD and whether this influenced transplant listing outcomes.
Method: We identified all adults >18 years assessed for liver transplantation between September 2023 and September 2024 at King's College Hospital. SLD was defined as MASLD, alcohol, or MetALD. All other aetiologies (viral, autoimmune, vascular, genetic, cryptogenic) were combined as non-SLD. Those with HCC, variant indications, or re-do liver transplantations were excluded. Age, sex, liver frailty index (LFI), UKELD, hepatic encephalopathy, ascites, diabetes, BMI, and transplant listing outcome were identified for all patients. Chi-squared and t-tests assessed associations between SLD and clinical characteristics.
Results: 197 individuals with CLD were assessed for liver transplantation, of whom 110 (55%) had SLD. Median age at assessment was 55 years (Q1 46, Q3 62) with 40% female. Median UKELD was 54 with no significant difference between SLD and non-SLD (p = 0.7). Fifty (57%) of those in the non-SLD group and 38 (34%) of those with SLD were listed. Patients with SLD were more likely to have a prohibitive comorbidity profile (n = 26; 37%) than non-SLD (n = 7; 21%) but also more likely to lack a clinical indication for transplant (n = 24; 34% v n = 6; 18%). Psychosocial contraindications were similar in SLD (n = 7; 10%) to non-SLD (n = 3; 9%). Obesity (BMI > 30) was more common in SLD (38% v 22%; p < 0.05) as was ascites (60% v 31% p < 0.01) but rates of encephalopathy were not statistically different between the two cohorts. Within the SLD cohort, for those not listed, there was no difference in LFI based on reason for not listing (36% frailty for those not listed due to comorbidities vs 38% for those not listed due to lack of indication p = 0.41). Frailty was significantly associated with SLD (odds ratio [OR] 4.2; 95% confidence interval 1.4–12.1). However, frailty was not significantly associated with transplant listing (p > 0.4).
Conclusion: SLD is the leading cause for transplant referral but not transplant listing. The prevalence of frailty is higher in SLD as compared to other aetiologies of chronic liver disease. Predictably, SLD patients are more likely to have ascites, diabetes, and elevated BMI. The prevalence of frailty was equivalent in SLD patients declined for comorbidities and those declined for lack of indication. This suggests that frailty is prevalent in SLD and not a driver for listing. This further supports the need for intervention to improve frailty in the SLD population and to seek greater clarification on the role of frailty assessment in the transplant process. Future studies will explore how frailty differentially impacts transplant waiting list and post operative outcomes in SLD.

FRI-498

Prognostic impact of multi-resistant bacteria gut colonization in patients undergoing liver transplantation

Marina Orti-Cuerva[1,2], María Prieto de la Torre[1,2], Miryam Barrera Romero[1,2], Paloma Elma Alañón-Martínez[1,2], Marta Guerrero-Misas[1,2,3], Pilar Barrera Baena[1,2,3], Guadalupe Costán[1,2,3], Jorge Rodríguez Gómez[2,4], Antonio Poyato González[1,2,3], Jose Luis Montero[1,2,3], Manuel De La Mata Garcia[1,2,3], Manuel Rodríguez-Perálvarez[1,2,3]. *[1]Department of Hepatology and Liver Transplantation, Hospital Universitario Reina Sofía, Córdoba, Spain; [2]Instituto Maimónides de investigación biomédica de Córdoba (IMIBIC), Córdoba, Spain; [3]Centro de investigación biomédica en red de enfermedades hepáticas y digestivas (CIBERehd), Madrid, Spain; [4]Intensive Care Unit, Hospital Universitario Reina Sofía, Córdoba, Spain*
Email: ropeml@hotmail.com

Background and aims: Patients with decompensated cirrhosis are prone to gut colonization by multi-resistant bacteria (MRB). Whether MRB gut colonization could impact post-transplant outcomes is yet to be ascertained.
Method: Retrospective observational study including a consecutive cohort of adult patients undergoing liver transplantation in a single center between January 2019 and October 2024. Patients with human immunodeficiency virus infection, retransplantation, or combined organ transplantation were excluded. A rectal swab was obtained from all patients immediately before liver transplantation to determine BMR colonization. We studied the impact of BMR colonization on the risk of infections, length of hospital stay, and mortality. Logistic regression, Kaplan Meier curves and Cox regression were used as appropriate.
Results: We included 272 patients undergoing liver transplantation among whom the prevalence of BMR colonization was 9.2% (n = 25). The most frequent microbiological agents were extended-spectrum beta-lactamases (ESBL) producing E. coli (n = 12) and carbapenemase-producing Klebsiella pneumoniae (n = 6). Sex, alcohol, tobacco use, and liver function (MELD) showed no association with the risk of colonization. MRB-colonized patients had received systemic antibiotic therapy more frequently in the months prior to transplantation (48% vs. 27%; p = 0.028), and had a more frequent history of spontaneous bacterial peritonitis (20% vs. 4.5%; p = 0.010). Patients receiving a liver transplantation due to non-tumoral MELD exceptions, particularly refractory ascites, had doubled prevalence of MRB gut colonization (16.9% vs. 5.8%; p = 0.004). Having two or more hospital admissions within the previous year was a risk factor for BMR colonization (23.1% vs. 7.7%; p = 0.021). After liver transplantation, MRB-colonized patients were at increased risk of bacterial infections during admission (36% vs. 15.4%; p = 0.022) and had a trend towards higher cytomegalovirus reactivation (16% vs. 6.1%; p = 0.083). Patients with and without BMR colonization had comparable length of hospital stay (19.3 days in colonized vs. 17.9 days in non-colonized; p = 0.63). Overall survival at 1 and 5 years was 89.6% and 80.7%, respectively in non-colonized patients, compared to 73.9% and 65.7%, respectively, in the BMR-colonized group (log rank p = 0.038).
Conclusion: Pre-transplant gut MRB colonization in liver transplant candidates increases the risk of infections early after liver transplantation and negatively impacts survival. These patients should benefit from minimized immunosuppression and individualized protocols of antimicrobial prophylaxis. Funding: "Instituto de Salud Carlos III" (grant reference PI22/00312) and European Union.

FRI-499

Hepatic artery atherosclerosis is a risk factor for biliary strictures after liver transplantation

Paloma Elma Alañón-Martínez[1,2], Marina Orti-Cuerva[1,2], Ana Luque-López[1,2], Jose Luis Montero[1,2,3], Marina E. Sánchez-Frias[2,4], Ruben Ciria[2,5], Pilar Barrera Baena[1,2,3], Antonio Poyato González[1,2,3], Manuel De La Mata Garcia[1,2,3], Javier Briceño[2,5], Manuel Rodríguez-Perálvarez[1,2,3]. *[1]Department of Hepatology and Liver Transplantation, Hospital universitario Reina Sofía, Córdoba, Spain; [2]Instituto Maimónides de investigación biomédica de Córdoba (IMIBIC), Córdoba, Spain; [3]Centro de investigación biomédica en red de enfermedades hepáticas y digestivas (CIBERehd), Madrid, Spain; [4]Department of Pathology, Hospital universitario Reina Sofía, Córdoba, Spain; [5]Department of HPB Surgery and Liver Transplantation, Hospital universitario Reina Sofía, Córdoba, Spain*
Email: ropeml@hotmail.com

Background and aims: The aging of liver donors and transplant candidates, along with the growing prevalence of metabolic comorbidities, may increase the prevalence of hepatic artery (HA) atherosclerosis. Since the biliary epithelium relies exclusively on hepatic arterial flow, HA atherosclerosis could increase the risk of biliary complications after liver transplantation (LT).
Method: Retrospective observational study including all adult patients undergoing LT in a single institution between 2012 and 2023 who had a blinded pathological evaluation of the donor and recipient hepatic arteries. Patients receiving a retransplantation, combined organ transplantation, or showing hepatic artery thrombosis after transplantation were excluded. Risk factors for biliary complications were analyzed using univariate and multivariate Cox's regression, censoring events at 24 months post-transplantation.
Results: Among 322 included patients, 63 (19.6%) developed biliary complications after a median follow-up of 44 months (IQR 17–22 months). The incidence of biliary strictures was 11.8% (n = 38) at 12 months and 14.3% (n = 46) at 24 months. Neither age nor LT indication modified the risk of biliary complications (p = 0.88 and p = 0.38, respectively). There was a non-significant trend toward higher risk of biliary complications in male patients (16.7% vs. 8.5%, p = 0.057). Cardiovascular risk factors were comparable between patients with and without biliary complications at 24 months: hypertension (34.8% vs. 33%, p = 0.81), diabetes (28.3% vs. 28.6%, p = 0.96), and dyslipidemia (15.2% vs. 21.4%, p = 0.34). Liver grafts from donation after circulatory death were associated with higher risk of developing biliary strictures at 24 months compared to grafts from brainstem-death donors (23.6% vs. 12.4%, p = 0.03).
Histological analysis of intraoperative artery biopsy samples revealed atherosclerosis in 54% of donors and in 5.6% of recipients. Patients with atherosclerosis either in the donor or the recipient hepatic arteries (58.4%) showed a higher risk of biliary complications (17.6 vs 9.7%, p = 0.047). After controlling for age, sex, transplantation indication (hepatocellular carcinoma), donor steatosis, and cardiovascular comorbidities in the multivariate Cox's regression analysis, hepatic artery atherosclerosis (HR = 2.18 [95%CI 1.12–4.21; p = 0.021]) and donation after circulatory death (HR = 2.43 [95%CI 1.25–4,76; p = 0.009) were the only independent predictors of biliary complications after LT.
Conclusion: Donor or recipient hepatic artery atherosclerosis is associated with an increased risk of biliary strictures after liver transplantation. In such patients, the use of antiplatelet therapy could be considered to reduce the risk of biliary complications. Funding: "Instituto de Salud Carlos III" (grant reference PI22/00312) and European Union.

FRI-500

Association between pre-transplant body mass index and survival after liver transplantation in an adult recipient cohort from Johannesburg, South Africa

Preyanka Pillay[1], Adam Mahomed[2], June Fabian[3]. *[1]Wits Donald Gordon Medical Centre, Department of Internal Medicine, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa; [2]Charlotte Maxeke Johannesburg Academic Hospital, Department of Internal Medicine, Faculty of Health Sciences, University of the Witwatersrand, Wits Donald Gordon Medical Centre, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa; [3]Wits Donald Gordon Medical Centre, Faculty of Health Sciences,*

University of the Witwatersrand, Johannesburg, South Africa
Email: preyankapillay@yahoo.com

Background and aims: There is uncertainty regarding associations between recipient pre-transplant body mass index (BMI) and survival after liver transplantation, particularly whether obesity is associated with increased mortality. There are no studies investigating associations in Africa which has limited liver transplant services. Currently, there are two liver transplant units in South Africa. The study aimed to determine the association between recipient pre-transplant BMI and survival after liver transplantation amongst adults in Johannesburg, South Africa.
Method: Adults 18 years or older, who received an index liver transplant for chronic liver disease from August 2004 to January 2024 at Wits Donald Gordon Medical Centre, Johannesburg, South Africa were included in this cohort study. Secondary data analysis was performed using an institutional review board approved database. Multivariable Cox regression determined adjusted hazard ratios (HRs) and 95% confidence intervals (CIs) for the associations of recipient pre-transplant BMI at listing and all-cause post-liver transplant mortality. Survival at 1- and 5 years post-transplantation was also assessed. BMI (kg/m^2) was categorised using the World Health Organisation classification: underweight (<18.5), normal (18.5–24.9), overweight (25–29.9), obese: class I (30.0–34.9); class II (35.0–39.9); class III (> = 40). Potential confounders adjusted for were age, sex, self-reported ethnicity, aetiology of cirrhosis, Model for End-Stage Liver Disease (MELD) score, ascites, diabetes, waitlist duration, and postoperative complications. Effect modification by age, sex, self-reported ethnicity, and MELD were assessed.
Results: Among 489 adults, the median (IQR) age was 53 (43–60) years, 290 (59.3%) were male, 8 (1.6%) Asian, 89 (18.4%) Black, 35 (7.2%) Indian, 15 (3.1%) Mixed, and 338 (69.7%) White ethnicity. Of these, 21 (4.3%) were underweight, 168 (34.4%) normal, 169 (34.6%) overweight, 93 (19.0%) class I, 32 (6.5%) class II, and 6 (1.2%) class III obesity. After a median (IQR) of 5.3 (1.3–8.9) years follow-up, there were 187 (38.2%) deaths post-liver transplantation. After adjusting for potential confounders, compared to adults with normal BMI, only class III obesity was positively associated with post-liver transplant mortality (HR, 3.95; 95% CI, 1.49–10.47). BMI categories were not significantly associated with mortality at 1- and 5 years post-transplantation. There was no effect modification.
Conclusion: Overall, among adults receiving an index liver transplant for chronic liver disease in Johannesburg, South Africa, there was no significant association across BMI categories except for class III obesity which was positively associated with post-liver transplant mortality. Due to limited participants with class III obesity, larger studies are needed to reliably evaluate associations at extremes of BMI.

FRI-501
Extensive portal vein thrombosis in patients with cirrhosis undergoing liver transplantation : results of a national multicenter retrospective study

Romain Barusseau[1], Baptiste Giguet[2], Yasmina Chouik[3], Ilias Kounis[4], Magdalena Meszaros[5], Sébastien Dharancy[6], Claire Francoz[7], Filomena Conti[8], Hélène Larrue[9], Marie-Noëlle Hilleret[10], Camille Besch[11], Thierry Artzner[11], Delphine Weil-Verhoeven[12], Christophe Bureau[9], Francois Durand[7], Georges-Philippe Pageaux[5], Audrey Coilly[4], Jérôme Dumortier[3], Pauline Houssel-Debry[2], Boris Guiu[5], Petru Bucur[13], Valentin Rolle[1], Christine Silvain[1], Laure Elkrief[13]. *[1]Poitiers University Hospital, Poitiers, France; [2]Rennes University Hospital, Rennes, France; [3]Lyon University Hospital, Lyon, France; [4]AP-HP Hospital Paul Brousse, Paris, France; [5]Montpellier University Hospital, Montpellier, France; [6]Lille University Hospital, Lille, France; [7]AP-HP Hospital Beaujon, Paris, France; [8]AP-HP Hospital Pitié-Salpétrière, Paris, France; [9]Toulouse University Hospital, Toulouse, France; [10]Grenoble University Hospital, Grenoble, France; [11]Strasbourg University Hospital, Strasbourg, France; [12]Besançon University Hospital, Besançon, France; [13]Tours University Hospital, Tours, France*
Email: r.barusseau@gmail.com

Background and aims: Portal vein thrombosis (PVT) significantly impacts patient outcomes during liver transplantation (LT) and post-transplant survival, with an even greater impact in cases of extensive PVT. Portal vein (PV) recanalization using transjugular intrahepatic portosystemic shunt (TIPS) has been proposed in patients with PVT awaiting LT to facilitate LT and, consequently, improve post-transplant outcome. However, specific studies focusing on patients with extensive PVT are lacking. Aims: to evaluate the outcome of patients with extensive PVT undergoing LT, identify pre-transplant prognostic factors, taking into account patients management.
Method: Retrospective study performed in 12 French LT centers. All patients with cirrhosis and extensive non tumoral PVT (defined as either Yerdel grade ≥III or cavernoma of the main PV) listed for LT from 2010 to 2023 were included. All CT scans were retrospectively reviewed. Evolution of PVT from listing to LT was assessed using the VALDIG-PVT criteria. Primary endpoint was transplantation-free survival (ReLT-FS) at 1 year after LT.
Results: Among 1308 patients with cirrhosis and PVT on the waiting list, 131 had an extensive PVT (75% men, median age 57 years). 74% of the patients had a chronic PVT (known for ≥6 months). PVT was classified Yerdel grade I, II and ≥III in 6%, 50% and 43% of the patients, respectively. A cavernoma was present in 81% and calcifications of the main PV were present in 47% of the patients. 61% of the patients were treated with anticoagulation (AC) before LT. 88 out of 131 patients received a LT. From listing to LT, improvement of PVT, PVT stability and progression of PVT occurred in 13%, 73%, and 15% patients, respectively. 17 (14%) patients had received a TIPS before LT, while 26% could have been considered as potential candidates for TIPS placement (i.e progression of PVT under anticoagulation and MELD < 18, no hepatic encephalopathy nor hepatocellular carcinoma) Porto or mesenterico-portal (PPA), reno-portal (RPA), gastro-portal (LGA) and cavoportal (CPA) anastomoses were performed in 75%, 14%, 6%, and 5% of the patients, respectively. 34% of the patients received AC after LT. At one year after LT, 18% were dead, 6 had had undergone re-transplantation. Overall, one-year ReLT-FS after LT was 76% (95% CI: 67.1–84.9). One-year ReLT-FS was 78% (95% CI 67.8–88.2), 67% (95% CI 40.4–93.6), 100%, and 25% (95% CI 0–67.4) in patients who had a PPA, RPA, LGA and CPA, respectively. By multivariable analysis, the only factor associated with ReLT-FS at one year after LT was a Yerdel grade III PVT (p = 0.02). Neither TIPS performed before LT (p = 0.28), nor the type of anastomosis (p = 0.18), nor pre (p = 0.56) nor post LT AC (p = 0.78) were associated with ReLT-FS at one year.
Conclusion: Extensive PVT remains associated with a high short-term mortality after LT. Even when it is potentially feasible, TIPS is performed in a small proportion of the patients. Whether TIPS in patients with extensive PVT improves post-LT will deserve further, prospective evaluation.

FRI-502
An audit to assess adherence to local guidelines for prophylaxis and monitoring of herpes simplex virus (HSV) in patients following orthotopic liver transplant in a tertiary transplant centre

Rachel McGaw[1], Khalisha Mahmood[1], Tanzina Haque[1], Fatema Jessa[1]. *[1]Royal Free Hospital, London, United Kingdom*
Email: rachel.mcgaw@nhs.net

Background and aims: Herpes simplex virus (HSV) can cause severe clinical manifestations in immunocompromised patients post liver transplant (OLT) leading to significant morbidity and mortality. OLT patients at high risk (HRPs) of developing primary HSV (P-HSV) following transplant, i.e. HSV seropositive or unknown HSV serostatus allografts transplanted to a HSV seronegative recipient, are given HSV prophylaxis (HSVPx) with antiviral medication for 1 month post OLT to reduce the risk of P-HSV. This audit aimed to review if all HRPs were given HSVPx and monitored by weekly HSV DNA testing in

blood as per local protocol (LP). All patients post OLT were reviewed for development of HSV within 30 days of OLT.
Method: A retrospective review of patients who had OLT between November 2021 and December 2023 at a single liver transplant centre was completed and HRPs were identified. Treatment and monitoring of HRPs was evaluated using electronic prescribing records. HRPs were reviewed for the development of P-HSV, while non-HRPs were reviewed for HSV reactivation i.e. HSV PCR positive blood test or high clinical suspicion for HSV. Patients who developed HSV were audited for appropriate management as per LP. Data from only the most recent OLT was collected for patients retransplanted within 30 days.
Results: 210 patients underwent OLT over the study period, 35/210 (17%) were HRPs. 32/35 (91%) HRPs were prescribed HSVPx as per LP. 1/35 (3%) did not receive HSVPx and had detectable HSV DNA 4 days following OLT (P-HSV). The donor allograft had detectable HSV DNA. 1/35 (3%) HRP was prescribed HSVPx via the wrong route for 4 doses before switching to the correct formulation for the remainder of the prophylactic course. This patient did not develop P-HSV. 1/35 (3%) did not complete the 1-month course due to developing pancytopenia on HSVPx. A clinical decision was made to discontinue the HSVPx and monitor the patient. The patient did not develop P-HSV. 1/35 (3%) had HSV DNA monitoring as per LP. 12/35 (34%) had no HSV DNA testing within the 30 days post OLT, the remaining 22/35 (63%) had HSV DNA monitored less than outlined in LP. 17/35 (49%) of HRPs had HSV DNA tested on day 30 post OLT. Available data may have been limited to lack of access to testing that may have been carried out at other centres. No HRPs receiving HSVPx who were monitored developed P-HSV. Overall, 9/210 (4%) OLT recipients developed HSV in the 30 days following OLT and all were treated as per LP. 1/9 (11%) was a HRP who developed P-HSV. 8/9 (89%) were non-HRPs who developed HSV reactivation. 1/8 (13%) reactivations tested positive for CMV DNA and so was treated as per the local CMV protocol.
Conclusion: This audit identifies that 17% of the population studied were at risk of developing P-HSV. With 91% of HRPs given HSVPx and despite limited monitoring, rates of P-HSV were low. The single case of P-HSV was donor derived. The remaining HSV cases were reactivations, underscoring the importance of HSV monitoring in the post OLT cohort.

FRI-503-YI
Pre-transplant hepatorenal syndrome as a predictor of recurrent post-transplant cirrhosis and portal hypertension-related complications
Abhinav Rao[1], Ahmed Ibrahim[1], Don Rockey[1]. [1]*Medical University of South Carolina, Charleston, United States*
Email: raoab@musc.edu

Background and aims: HRS is a devastating complication in cirrhosis patients with severe portal hypertension. Here, we have hypothesized that patients who develop HRS prior to transplant and recurrent cirrhosis after transplant may experience worse portal hypertension complications post-transplant.
Method: Using the TriNetX database, which includes 115,676,318 patients from 66 US healthcare organizations, we examined patients aged ≥18 years with cirrhosis who underwent liver transplantation and developed HRS within a year prior to transplantation, from January 2010 to October 2024. New diagnoses of recurrent post-transplant cirrhosis, ascites, SBP, HE, variceal bleeding, and liver transplant rejection were captured. We propensity matched cirrhosis patients with pre-transplant HRS to those without pre-transplant HRS using age, sex, essential hypertension, and type II diabetes mellitus (T2DM) as matching variables. Diagnoses were identified using ICD-9 and ICD-10 codes and data were analyzed using built-in functions of the TriNetX Analytics Platform (R, version 4.0).
Results: 71,460 patients underwent liver transplantation, including 7,821 (11%) with HRS within one year of transplantation. The average age was 54 years (SD: 12), with the majority being male (62%) and Caucasian (69%); the mean pre-transplant MELD was 36 (SD: 8). In cirrhosis patients without HRS, demographics were similar, but the mean MELD was 25 (SD: 8). Essential hypertension and T2DM were equally common in both groups (hypertension: 54%; T2DM: 37%). Patients with pre-transplant HRS had a higher risk of developing recurrent post-transplant cirrhosis than those without HRS (30% vs. 14%; OR 2.2, $p < 0.001$). Of the common complications of portal hypertension, ascites after transplant was the most strongly associated with pre-transplant HRS (OR: 2.5, CI 2.2–2.9, $p < 0.001$), but SBP (OR: 1.9, CI 1.5–2.3, $p < 0.001$), HE (OR: 1.7, CI 1.2–2.0, $p < 0.001$), and variceal bleeding (OR: 1.2, CI 1.1–1.3, $p < 0.05$), were also associated with pre-transplant HRS. Pre-transplant HRS was also strongly associated with acute or chronic rejection after liver transplantation (OR: 1.7, CI: 1.6–1.9, $p < 0.001$). Over a median follow-up period of 5 years following liver transplantation, patients with HRS pre-transplant had a higher risk of mortality than patients without pre-transplant HRS (OR: 1.2, CI 1.1–1.2, $p < 0.001$).
Conclusion: Cirrhosis patients with HRS prior to liver transplantation have an increased risk of recurrent post-transplant cirrhosis and portal hypertension complications following transplant and greater post-transplant mortality rates. These data raise the possibility that severe portal hypertension persists in some patients even after transplantation, and contributes to the development of cirrhosis.

FRI-504
Nephrocheck as a predicitve tool for post-operative acute kidney injury following liver transplant for chronic liver disease
Rosemary Worrall[1], Gladson Thomas[1], Manan Bajaj[1], Neil Rajoriya[1], Abhishek Chauhan[1], Jaimin Patel[1], Mansoor Bangash[1]. [1]*University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom*
Email: rosie.worrall@gmail.com

Background and aims: Post-operative AKI (po-AKI) occurs within 7 days of an index procedure and is associated with adverse outcomes. Due to the physiological changes of advanced liver diseases and the surgical stress response, substantial injury may occur prior to detection by Kidney Disease Improving Global Outcomes (KDIGO) criteria in these cohorts. The cell-cycle arrest proteins TIMP-2 and IGFBP-7, have been proposed as early renal injury biomarkers that may detect patients at high-risk of po-AKI prior to rises in creatinine (Kashani, 2013). Nephrocheck, already validated for the detection of AKI in the critically ill, is a urinary point of care test based on these biomarkers (Hoste, 2014). The aim of this study was to identify the incidence of po-AKI following LT in our unit and the utility of Nephrocheck in this setting compared to conventional criteria.
Method: A prospective pilot observational study was performed in 45 patients undergoing liver transplant (LT) for chronic liver disease at the Liver Unit, Birmingham UK between August 2019-January 2020. Exclusion criteria: pre-existing AKI, stage 5 chronic kidney disease, previous renal transplant, pre-planned use of renal replacement therapy (RRT), acute liver failure and multi-visceral transplantation. Patient characteristics, biochemical parameters, donor details, daily serum creatinine and use of renal replacement therapy were collected from the electronic patient record. Standard definitions were used for defining po-AKI occurrence. Nephrocheck was performed on urine samples collected within 24 hours of the LT and po-AKI risk defined when a value > 0.3 (ng.ml-2).1000–1 was obtained.
Results: 40% (18/45) developed po-AKI following LT and had significantly longer Intensive Care Unit stays than those who didn't ($p = 0.004$). 89% (16/18) developed po-AKI within the first 48 hours, and 11% (2/18) developed a later po-AKI after four or more days. 5/18 (27.8%) required RRT within seven days of their LT. The median Nephrocheck score in those with po-AKI was higher than those without po-AKI ($p < 0.001$). Those with higher severity po-AKI also had a significantly higher Nephrocheck score ($p < 0.001$). In total 29/45 (%) patients met the pre-defined cut-off identifying them as "at-

risk" of po-AKI. This included all 18 patients (%) who developed KDIGO po-AKI ($p < 0.0001$). Sensitivity was calculated at 1.0 and specificity 0.6; AUC-ROC 0.88 (95% confidence interval 0.78–0.91).
Conclusion: Our results suggest that using the Nephrocheck acute kidney injury cut-off of 0.3 (ng.ml-2).1000–1 can predict po-AKI in patients undergoing LT for chronic liver disease without pre-existing renal injury. The benefits of this include instigation of reno-protective strategies in at risk patients and earlier detection of renal insults, potentially preventing progression to higher grade renal injury.

FRI-509
Assessing the safety and efficacy of advanced therapies to treat inflammatory bowel disease in patients with a liver transplant
Samantha Campbell[1], Andrzej Rak[2], Alexandra Frolkis[1], Chandni Radia[2], Mehul Patel[2], Polychronis Pavlidis[2], Miriam Cortes Cerisuelo[3], Abdul Hakeem[3], Jeremy Nayagam[1], Alexandra Kent[2], Deepak Joshi[1]. *[1]King's College Hospital, Institute of Liver Studies, London, United Kingdom; [2]King's College Hospital, Gastroenterology, London, United Kingdom; [3]King's College Hospital, Liver Transplant Surgery, London, United Kingdom*
Email: samantha.campbell8@nhs.net

Background and aims: Primary sclerosing cholangitis (PSC) is associated with inflammatory bowel disease (IBD). Up to 80% of patients with PSC have IBD. The only life extending intervention for end-stage PSC is liver transplant (LT). Poorly controlled IBD post-LT increases the risk of recurrent PSC, highlighting the importance of adequate IBD control. IBD with LT presents a complex dilemma between disease control versus risks of immunosuppression. The proliferation of advanced therapies (AT; biologic or small molecule) for IBD have unknown efficacy and safety in the setting of LT. We describe our experience of IBD patients with a LT, requiring AT.
Method: Patients with IBD, who underwent LT at King's College Hospital were included. Retrospective data was collated, including demographics, IBD, AT and LT details.
Results: 81 patients with IBD and a LT were identified, and 39 (48.1%) required AT. Of the 39 patients, 30 patients were initiated post LT. Aetiology of liver disease was PSC (50/81), PSC/AIH (22/81) and other (9/81). IBD subtypes were ulcerative colitis (UC;89.7%), Crohn's disease (7.7%), and IBD-U (2.6%). Median age at first LT was 30 years (IQR 21–39), and second LT was 41 (IQR 30–45). Anti-rejection medications were tacrolimus and steroids. There was no significant difference in immunosuppression regimens in those who developed IBD post-LT ($p = 0.70$). There were 17 patients (43.6%) that received one AT, 22 patients received 2 or more. In the majority of patients with PSC, treatment with AT was first initiated post LT: 16/18 with PSC/IBD and 12/18 with PSC/AIH/IBD. First-line AT initiated post-LT was Vedolizumab in the majority (48.2%). Pre-LT, 15% of patients required AT; mean time between starting AT and LT was 48 months with an anti-TNF being initiated in 77.7%, and Vedolizumab in 11.1%. Acute cellular rejection (ACR) occurred in 16 patients on AT within the first 12 months after first LT, but only one had initiated AT within this time frame. IBD subtype did not influence incidence of ACR. In patients requiring AT (39/81); 36.8% of patients developed cholangitis post-LT. 50% were on an AT at the time of cholangitis (unable to extrapolate data in 28.5% of patients).
Conclusion: In our cohort of post LT patients with IBD, 37% of patients required initiation of an AT post LT, and over half of patients requiring AT required escalation of therapy beyond first line treatment. It is unclear whether this reflects the natural course of IBD, or influence of LT. Almost 40% of patients developed cholangitis post-LT, of whom 50% were on AT at the time of cholangitis. As the incidence of IBD and AT use increases, multi-centre experience will be invaluable, to collate larger numbers to assess the safety and efficacy of patients with IBD with LT, on AT. In conclusion, AT is initiated in a large proportion of patients with IBD after LT, and this cohort of patients require close monitoring for development of cholangitis.

FRI-510-YI
Acute pancreatitis in emergency liver transplantation for acute liver failure: prevalence, predictors and consequences
Samuel Tribich[1], Pauline Kane[2], Dylan Lewis[2], Miriam Cortes Cerisuelo[3], William Bernal[1,4]. *[1]Liver Intensive Therapy Unit, King's College Hospital, London, United Kingdom; [2]Department of Radiology, King's College Hospital, London, United Kingdom; [3]Department of Adult and Paediatric Liver Transplant Surgery, King's College Hospital, London, United Kingdom; [4]Institute of Liver Studies, King's College London, London, United Kingdom*
Email: samuel.tribich@nhs.net

Background and aims: Acute pancreatitis (AP) may contraindicate emergency liver transplantation (ELT), but biochemical and radiological biomarkers for AP perform variably in patients with acute liver failure (ALF) and the consequences for those who proceed to ELT are not well-defined. We aimed to describe AP prevalence, the relationship between biomarkers and intra-operative findings and the consequences for those who undergo ELT.
Method: Consecutive patients admitted for ALF to a specialist critical care unit who did (1/2013–12/2023) or did not (1/2018–1/2022) undergo ELT were studied. In ELT recipients, those with an intra-operative diagnosis of AP were matched by age, sex and disease aetiology to those without (1:2 ratio). Pre-ELT CT imaging was re-reviewed by 2 HPB radiologists unaware of the operative findings.
Results: 227 patients with ALF were identified (120 transplanted, 107 non-transplanted). Median age was 37 years; 65% were female. Aetiologies included paracetamol (37%), seronegative hepatitis (16%) and drug-induced liver injury (13%). Serum amylase above 100 IU/L was present in 49% (92/189) and above 300 IU/L in 15% (28/189). Radiological evidence of AP was contemporaneously reported on CT in 5% of ALF admissions (10/191). Serum amylase was significantly higher in those with radiological AP (median 261 (IQR 139–571) IU/L versus 73 (45–153) IU/L, $p < 0.001$), but was under 300 IU/L in 60% (6/10). AP was found intra-operatively in 8% of those transplanted (9/120); its presence was not associated with age, ALF aetiology or clinical presentation. Serum amylase alone was a poor discriminant test for intra-operative AP (AUROC 0.62); a level above 300 IU/L was specific (89%) but poorly sensitive (22%). Comparing intra-operative AP cases to matched controls, cases had increased organ dysfunction (SOFA score 19 (IQR 17–21) vs 15 (8–16), $p = 0.001$) and lower platelets at time of ELT (44 (IQR 38–86) vs 96 (49–136), $p = 0.02$). On re-review of imaging, pancreatic abnormalities were common in both case and control groups (78% vs 65%, $p = 0.5$). Pleural effusions were more common in those with intra-operative AP (89% vs 47%, $p = 0.05$) with no other radiological associations. AP patients had longer post-ELT on mechanical ventilation ($p = 0.008$) and renal replacement therapy ($p = 0.003$), increased rates of tracheostomy ($p = 0.037$), longer ITU and hospital lengths of stay ($p < 0.001$) and increased ITU readmission rates ($p = 0.003$). However, there was no significant difference in survival to discharge from ITU or from hospital and no significant difference in 1-year patient and graft survival.
Conclusion: Identification of AP in ALF is difficult. Hyperamylasaemia is common in patients with ALF, but biochemical and radiological diagnostic tests correlate poorly with presence of intra-operative AP, confounding ELT wait-listing decisions. Marked increases in morbidity follow an unexpected diagnosis of AP in patients transplanted for ALF, but without significant impact on mortality or graft survival.

FRI-511
QEL-001 LIBERATE study expansion cohort, CAR (Chimeric Antigen Receptor) T regulatory (Treg) cells engraftment and expansion following rATG (rabbit anti-thymocyte globulin) conditioning in post liver transplantation
Alberto Sanchez-Fueyo[1], Alison Taylor[2], Marc Martinez-llordella[3], Jie Wang-Jairaj[3], Rupert Kenefeck[3], Kourosh Saeb-Parsy[4], Jacques Pirenne[5], Jake Demetris[6], Andrew Lesniak[6],

Nathalie Belmonte[3], Aaron Vernon[7], Peter Cooper[3], John Tonkyn[3], Gareth Wright[3], Annie Woodburne[3], Laurie Baylor Curtis[3], Luke Devey[3]. [1]*Academic Head of the Institute of Liver Studies at King's College London, King's College Hospital, London, United Kingdom;* [2]*King's College Hospital, London, United Kingdom;* [3]*Quell Therapeutics, London, United Kingdom;* [4]*Addenbrooke's Hospital, Cambridge, University of Cambridge, Cambridge, United Kingdom;* [5]*University Hospitals, Leuven, Leuven, United Kingdom;* [6]*Department of Pathology, University of Pittsburgh, Pittsburgh, United States;* [7]*Quell Therapeutics, Boston, United States*
Email: sanchez_fueyo@kcl.ac.uk

Background and aims: LIBERATE (NCT05234190) is an ongoing phase I/IIa, single-arm, open-label study to investigate the potential of QEL- 001, an autologous Chimeric Antigen Receptor (CAR) T regulatory (Treg) cell therapy to potentially induce allograft tolerance and allow the complete discontinuation of immunosuppression (IS) in post liver transplantation. QEL- 001 expresses an HLA -A2 specific CAR, a FOXP3 phenotype lock and an inducible safety switch. The Safety Cohort of the study has been completed (N = 3) and shown QEL - 001 was well tolerated, trafficked to and engrafted in the transplanted livers.
Method: The Expansion Cohort is being conducted in the UK and EU. Eligible subjects were aged 18–75 years and underwent liver transplantation 1–5 years prior to enrolment. Low dose rATG (rabbit anti-thymocyte globulin) was administered no less than 4 weeks before QEL- 001 infusion. A Data Safety Monitoring Board (DSMB) performed an independent review of the data.
Results: Eligible subjects received low dose rATG (2.5 mg/kg, up to 200 mg in total) at least 4 weeks prior to QEL - 001 infusion. Mild to moderate AEs were reported, such as fever, headache and infusion site swelling, attributable to ATG administration, which resolved within a few days with minimum or no intervention. ATG mediated a significant reduction in CD4 and CD8 T-cell frequencies. Other immune populations appear to be mostly unaffected. Active ATG was cleared from circulation approximately 3 weeks post ATG administration. QEL- 001 CAR-Treg engraftment was observed and remained detectable in circulation for at least 2 months after cell infusion, significantly longer than those observed in the Safety Cohort without ATG conditioning. CAR-Tregs can be detected by digital polymerase chain reaction (dPCR) in the post QEL- 001 infusion liver biopsy tissue. Clinical batches produced for all subjects were within the pre-defined product specifications, and without CD8 impurities. QEL- 001 CAR Treg maintained phenotypic stability, and consistently across batches in vivo, post-infusion.
Conclusion: QEL- 001 infusion after rATG conditioning was well tolerated in patients treated to date. Specific T-cell lymphodepletion was apparent one week post ATG which subsequently enhanced QEL-001 engraftment and durability in circulation compared with previous data in the safety cohort. Additional clinical and mechanistic data will be presented at the Congress.

FRI-512
TAVI in liver transplant candidates: a retrospective analysis from a high-volume transplant center

Marta Sánchez-Ric[1], Giulia Pagano[1], Ander Regueiro[1], Marc Giménez-Milà[1], Annabel Blasi[1], Pablo Ruiz[1], Jordi Colmenero[1], Gonzalo Crespo[1]. [1]*Hospital Clínic, Barcelona, Spain*
Email: gcrespo@clinic.cat

Background and aims: Percutaneous treatment (transcatheter aortic valve implantation, TAVI) is less aggressive than surgical valve replacement (SVR) for severe aortic valve disease (AVD) and enables treatment for high surgical risk patients. In patients with cirrhosis that may be potential candidates for liver transplantation (LT) but have severe aortic valve disease that contraindicates LT, and in whom SVR is not feasible due to liver disease, TAVI could fix the valve condition and enable access to LT.
Method: Retrospective single-center study. We reviewed all patients evaluated for LT between July 2015 and December 2022 and identified those who underwent TAVI as part of pre-LT assessment. Patient characteristics, procedure details, complications, and final outcomes were analyzed.
Results: In the study period, 912 LT evaluations were conducted at our center. Among them, severe AVD requiring TAVI was identified in 4 (0.4%) patients: 3 men and 1 woman aged 59–69 years. Three TAVIs were performed for stenosis and one for post-endocarditis valve insufficiency. The indication for LT in all four cases was decompensated cirrhosis, with a combined liver-kidney transplant required in two of these cases. Pre-TAVI MELD-Na scores ranged from 14–29 and platelet count ranged from 35.000–130.000/microliter. All patients were prescribed aspirin for one month following the procedure. Two patients experienced gastrointestinal bleeding (one due to portal hypertension gastropathy and the other one from a gastric polyp), both cases resolved without complications, although they required blood transfusions. Arrhythmic events occurred in all four patients; three of them self-limiting without associated heart failure, and one of them persistent until death. This latter patient underwent TAVI as an emergency procedure due to acute pulmonary edema and passed away 10 days later while awaiting LT. Of the remaining three, two successfully underwent LT without perioperative complications 2 and 4 months after TAVI and remain asymptomatic with functioning TAVIs after 2 and 6 years of follow-up. In the fourth patient, LT was contraindicated despite a well-functioning TAVI, due to severe secondary pulmonary hypertension.
Conclusion: The need for TAVI in LT candidates is rare at out center. This procedure can help facilitate and give access to LT in patients with severe aortic valve disease, leading to excellent post-LT outcomes, although it carries risks, especially in emergency settings. Our data may serve as a basis to expand sample size through a multicenter study.

FRI-513
Clinical factors associated with non-tumoral portal vein thrombosis in liver transplant candidates and its impact on pre-transplant outcomes

Simona Parisse[1], Maria Carlucci[1], Fabio Melandro[2], Mario Corona[3], Flaminia Ferri[1], Adriano De Santis[1], Pierleone Lucatelli[3], Gianluca Mennini[2], Massimo Rossi[2], Stefano Ginanni Corradini[1]. [1]*Department of Translational and Precision Medicine, Sapienza University of Rome, Rome, Italy;* [2]*General Surgery and Organ Transplantation Unit, Department of General and Specialty Surgery, Sapienza University of Rome, Rome, Italy;* [3]*Interventional Radiology Unit, Department of Diagnostic Medicine and Radiology, Sapienza University of Rome, Rome, Italy*
Email: simona.parisse@gmail.com

Background and aims: Portal vein thrombosis (PVT) can occur in liver transplant (LT) candidates, often associated with advanced cirrhosis. When severe, PVT may be a contraindication to LT. Features of metabolic syndrome (MS) are increasingly common in LT candidates and should be carefully considered during the evaluation process. Data on the possible association between MS features and PVT are controversial. This study aims to investigate clinical factors associated with the presence of PVT in LT candidates and its impact on access to the LT waiting list (WL) and to LT.
Method: 726 consecutive patients evaluated for LT were retrospectively enrolled (2008–2020). Data on the presence and extent of PVT, classified according to Yerdel, as well as clinical variables, were collected. Reasons for exclusion from listing and WL drop-out were also recorded. Multivariate binary logistic regression models were performed using the backward selection and bootstrap methods, considering presence of PVT, access to the WL, and LT as dependent variables, and clinically significant as covariates.
Results: PVT was identified in 11.4% of evaluated patients (n = 83), with advanced PVT (Yerdel stages 3–4) observed in 22% of PVT cases.

Two-hundred-eighty patients (38.6%) were listed and 161 transplanted (22.2%). Obesity was the sole independent factor associated with presence of PVT (p = 0.00028, OR 2.689, 95% CI 1.575–4.580) after adjusting for age, sex, MELD-Na, hepatocellular carcinoma, diabetes, dyslipidemia, and arterial hypertension. Among listed patients, those with PVT were more frequently excluded due to clinical contraindications compared to non-PVT patients in the univariate analysis (26% vs 14%, p = 0.042). However, multivariate binary logistic regression revealed no independent association between PVT and access to the WL. Similarly, among transplanted patients, PVT was not independently associated to LT. No significant differences were observed in the causes of WL drop-out. Nevertheless, advanced PVT was more prevalent among PVT non-transplanted patients compared to PVT transplanted patients in the univariate analysis (40% vs 20%, p = 0.04). No significant differences were observed in the causes of WL drop-out.

Conclusion: Among LT candidates, obesity is strongly associated with the presence of PVT, likely due to pro-inflammatory and pro-thrombotic stimuli from the gut-liver axis. However, PVT does not seem to be significantly independently associated with pre-transplant outcomes.

FRI-514

Dynamic changes of spleen stiffness in liver transplanted patients:preliminary findings from a single-center study

Sofia Ridolfo[1,2], Clara Dibenedetto[1], Valentina Cardone[1,2], Michele Sagasta[1], Enrico Sguazzini[1], Barbara Antonelli[3], Lucio Caccamo[3], Mirella Fraquelli[4], Maria Francesca Donato[5], Pietro Lampertico[1,6]. *[1]Division of Gastroenterology and Hepatology, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]University of Milan, Milan, Italy; [3]General and Liver Transplant Surgery Unit, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [4]Division of Gastroenterology and Endoscopy Unit, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [5]Division of Gastroenterology and Hepatology, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [6]CRC "A. M. and A. Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy*
Email: sofia.ridolfo@unimi.it

Background and aims: Vibration controlled transient elastography (VCTE; Fibroscan®) is a non-invasive method to assess liver stiffness measurement (LSM) and evaluate liver fibrosis. VCTE has also been widely used in post-liver transplantation (LT) setting to identify graft damage. Spleen stiffness measurement (SSM) is known to improve non-invasive diagnosis of clinically significant portal hypertension (CSPH) but data in the post-LT setting is limited. The aim of this study is to evaluate changes in SSM, spleen size and liver stiffness following LT.

Method: From January 2022 to July 2024, all consecutive LT recipients transplanted at our centre with available SSM pre-LT were enrolled. Patients with re-LT, splenectomy or without SSM pre-LT were excluded. SSM was measured by VCTE Fibroscan® (Echosens, Paris) before LT and at 3–6–12 months after surgery when available, while LSM was assessed only after LT at the same time points. Ultrasonographic and biochemical data were also collected.

Results: Twenty-two recipients (median age 61.5 years, 55% males, 45% viral-etiology, 32% with HCC; 4 DCD grafts; donor age 58 years, 100% on CNI-based immunosuppression) were studied. Median SSM significantly decreased from 59 kPa pre-LT to 27, 22, 27 kPa at 3, 6, 12 months post-LT, respectively (p < 0.05), with 44% with >50% decrease already at month 3. Spleen diameter has reduced from 15 cm pre-LT to 14, 13, 11 cm at 3, 6, 12 months post-LT (p < 0.05), likewise platelet count significantly improved over time (65,000, 153,000, 148,000, 157,000/mm^3, p < 0.05). In the first year post-LT, LSM did not significantly change over time (~6–7 kPa at all post-LT time points, p = ns). A weak correlation was observed between spleen SSM values and spleen diameter at 3; the correlation progressively improves at 6 and 12 months (Spearman correlation 0.058, 0.262, 0.340 at 3, 6 and 12 months respectively, p = ns). No statistically significant correlation was found between the decrease in spleen stiffness and the increase in platelet count across the time points (Spearman correlation 0.360, 0.090, −0.205 at 3, 6 and 12 months respectively, p = ns).

Conclusion: Our study demonstrates a significant reduction of SSM and spleen diameter occurring within three months and remaining stable during the first year after LT. These results are consistent with the early reversal of CSPH after LT. The weak correlations found between SSM, diameter spleen and platelet count may be due to sample size. However, SSM could be a useful innovative tool to monitor liver transplanted patients.

FRI-515

Evolving trends and the role of mitigating performance status decline on the liver transplant waitlist

Tomohiro Tanaka[1], Jonathan Platt[1], Emily Roberts[1], David Axelrod[2]. *[1]University of Iowa, Iowa City, United States; [2]University Hospitals, Cleveland, United States*
Email: tomohiro-tanaka@uiowa.edu

Background and aims: Liver transplant (LT) candidates with low performance status (PS) face higher risks of mortality. Most studies on impaired PS and post-LT outcomes focus on static assessments measured at the time of LT, overlooking changes in PS during the waitlist period and potential selection bias.

Method: We conducted a nationwide retrospective cohort study using data from the Organ Procurement and Transplantation Network (OPTN), including adult LT candidates (age ≥18) listed between January 2015 and December 2023. Trends in the proportion of low Karnofsky Performance Status (KPS) listed for LT were assessed with logistic regression models. The impact of declining KPS before LT on post-LT survival was estimated with Cox proportional hazards models. Inverse probability censoring weighting (IPCW) was employed to mitigate selection bias resulting from death and drop-out while on the waitlist.

Results: A total of 57,917 candidates were listed for LT, of whom 39.5% had a low KPS (10–40%) at listing. While the likelihood of low KPS at waitlisting did not significantly change, fewer patients had a low KPS at the time of LT (p < 0.001). Each additional recent month of waitlisting was associated with a 0.4% increase in ΔKPS (change in KPS between waitlisting and LT), compared to the previous month (p < 0.001). A ten-percent increase in ΔKPS reduced the posttransplant hazard of death by 4% (HR 0.96, 95% CI 0.94–0.98). Absence of a decline in ΔKPS was associated with a 12% lower posttransplant hazard of death (0.88, 0.83–0.94). The sensitivity analysis confirmed robustness by testing different criteria for waitlist time (≤90 days), baseline functional status (only for those with the lowest KPS at listing), and the redefined binary category of ΔKPS.

Conclusion: The significant improvement in KPS at LT and the increasing ΔKPS over time may reflect more effective interventions during the waitlist period in the recent era. Our weighted survival model suggests that preventing and mitigating low KPS before transplantation could optimize post-LT outcomes, demonstrating the importance of focused efforts to improve overall functional status among LT candidates.

FRI-516

Impact of comorbidities on liver transplant outcomes: assessing sex-specific differences by using machine learning analysis

Email: tserrano.aullo@gmail.com

Background and aims: Comorbidity plays a critical role in mortality of patients on both the waiting list for liver transplantation (LT), as well as in post-LT mortality. The aim of this study was to analyze the impact of comorbidities on survival through an intention-to-treat analysis.
Method: This prospective multicenter study included 1,504 consecutive patients on the LT waiting list across 18 Spanish hospitals. To classify patients based on comorbidities, unsupervised agglomerative clustering algorithms were applied using machine learning techniques. All analyses were stratified by sex.
Results: Comorbidities were more prevalent in males than in females ($p < 0.001$), with differing patterns between the sexes. The most frequent comorbidities and risk factors were smoking habit, arterial hypertension, obesity, and diabetes. Significant sex-based differences were observed for diabetes, renal insufficiency, cardiovascular disease, smoking habit, obesity, COPD, OSHAS, atrial fibrillation, and connective tissue disease. Patients were grouped into clusters based on differential comorbidities in both sexes. We identified clusters characterized by varying compositions of comorbidities, resulting in different overall survival outcomes. Kaplan-Meier curves of overall survival for clustering groups showed differences between the groups in both males ($p = 0.045$) and females ($p = 0.027$). Indexes derived from clustering were able to predict mortality for both sexes ($p < 0.001$, $p = 0.003$).
Conclusion: This study highlights the importance of comorbidities in LT outcomes and identifies clusters characterized by varying compositions of comorbidities that may affect overall survival. In addition, the findings underscore the need for sex-disaggregated analyses in patients with end-stage liver disease.

FRI-518-YI

Depression is highly prevalent amongst patients listed for liver transplant and unrelated to liver disease severity

Victoria Kronsten[1], Alexandra Frolkis[1], Alison Taylor[1], Jemma Day[2], Paul McKie[1], Catherine Polling[3], Racquel Beckford[1], Niloufar Safinia[1], Maria Guerra Veloz[1], Deepak Joshi[1], Michael Heneghan[1], Abid Suddle[1], Kosh Agarwal, Varuna Aluvihare[1], Debbie L. Shawcross[1], Claire Kelly[1]. *[1]Roger Williams Institute of Liver Studies, King's College Hospital, London, United Kingdom; [2]Children's Psychological Services, King's College Hospital, London, United Kingdom; [3]Mental Health Liaison Team, King's College Hospital, London, United Kingdom*
Email: victoria.kronsten@nhs.net

Background and aims: The prevalence of anxiety and depression is higher amongst patients with chronic liver disease (CLD) than the general population. Depression increases liver transplant (LT) wait-list mortality and negatively impacts post-LT survival. Patients on the LT wait-list are also under an immense psychological burden and experience increased illness uncertainty. We aimed to identify the prevalence of anxiety and depression amongst our diverse LT wait-list patient cohort and compare this to patients with CLD not on the wait-list.
Method: The Hospital Anxiety and Depression Scale (HADS) questionnaire was distributed to a sequential unselected cohort of patients attending the LT wait-list clinic and to non-wait listed patients with CLD attending hepatology clinics at King's College Hospital. An anxiety and/or depression sub-score (HADS-A, HADS-D) ≥8 was consistent with a probable diagnosis of current anxiety and/or depression.
Results: 30 patients on the LT wait-list (median time listed 297 days (interquartile range (IQR) 84–611) and 24 patients with CLD not wait-listed were assessed. Patients on the wait-list were younger (median age 45 years (IQR 34–58) than those in the CLD cohort (median age 56 years (IQR 50–62) ($p < 0.05$). There was no significant difference in Model for End-Stage Liver Disease-Sodium (MELD-Na) between the wait-list (median MELD 10.5 (IQR: 8–12)) and CLD cohorts (median MELD 9.5 (IQR: 7–12)) ($p = 0.6$). 47% of the wait-list cohort had a pre-existing mental illness diagnosis, compared to 50% of the CLD cohort ($p = 0.8$). More patients in the CLD cohort (33%) were on anti-depressants compared to the wait-list cohort (10%) ($p < 0.05$). 57% of the wait-list cohort screened positive for current depression compared to 25% of the CLD cohort ($p < 0.05$). Median HADS-D score was significantly higher in the wait-list cohort (8 (IQR 5–10)) than the CLD cohort (5 (IQR 1–8) ($p < 0.05$). Prevalence of probable anxiety was similar in the wait-list and CLD cohorts (47% vs. 50% respectively, $p = 0.8$), with no significant difference in median HADS-A ($p = 0.3$). Interestingly, 53% of the cases of probable depression in the wait-list cohort were not previously diagnosed, suggesting this may in part represent an adjustment disorder, whilst all cases in the CLD cohort who screened positive for depression had a pre-existing diagnosis of depression ($p < 0.05$). There was no correlation between HADS-D and MELD-Na scores.
Conclusion: The prevalence of anxiety and depression is high in CLD. The prevalence of depression is higher still in patients listed for LT. Depression in patients listed for LT is underdiagnosed and under-treated. A holistic approach is needed in the management of this patient cohort, including active screening for anxiety and depression, appropriate treatment and support where needed, and integration of

a dedicated psychologist into the multidisciplinary team pre- and post-transplant.

FRI-519

The post-operative recurrence rate is significantly higher in patients with HBV-HCC compared to those with HCV-HCC

Tsung-Han Wu[1], Yen-Chun Liu[2], Rachel Wen-Juei Jeng[2], Chung-Wei Su[2], Po-Ting Lin[2], Wei Teng[2], Chien-Hao Huang[2], Chun-Yen Lin[2]. *[1]Division of Liver and Transplantation Surgery, Department of Surgery, Linkou Chang-Gung Memorial Hospital, Taoyuan, Taiwan; [2]Department of Gastroenterology and Hepatology, Linkou Medical Center, Chang Gung Memorial Hospital, Taoyuan, Taiwan*
Email: chunyenlin@gmail.com

Background and aims: The survival outcome of HBV and HCV-related HCC (hepatocellular carcinoma) patients who received curative hepatectomy showed variable results in previous studies. However, most of the studies were conducted before introducing DAA (direct-acting antiviral) therapy for HCV patients. With the application of DAA for HCV patients, it remains unclear about the outcome of HBV and HCV-related HCC patients after curative hepatectomy.
Method: This prospective study enrolled HCC patients with positive HBsAg and anti-HCV who received curative hepatectomy from July 2015 to September 2024. Cox regression analysis was applied for independent predictors of HCC recurrence. The Kaplan-Meier method with the log-rank test was used to compare cumulative incidences of HCC recurrence and overall survival between HBV and HCV patients. A propensity score matching(PSM) at a 1:1 ratio was applied to adjust confounders between HBV and HCV patients such as age, sex, cirrhotic status, preoperative ALT levels and TNM clinical stage at first curative operation.
Results: There were 122 HBV patients and 55 HCV patients enrolling into the study with mean age of 63 years, 79% of male, 35% of cirrhosis, 85% of ALBI grade I, 60% of TNM stage I, and 57% having microvascular invasion. Among HBV patients, 95% were HBeAg negative, median HBV DNA level at operative date was 2.78 $\log_{10}$ IU/mL, and 43% received nucleos(t)ide analogue (Nuc) before curative surgery. While for HCV patients, 93% had undetectable HCV RNA and 62% had received DAA therapy before curative surgery. During the median follow-up of 3.4 years, a total of 58 patients (45 HBV, 13 HCV) had HCC recurrence. Multivariate Cox regression identified TNM stage ≥II (adjusted hazard ratio (aHR):2.648 (95% CI: 1.571–4.463), $p < 0.001$) was the only independent predictor of HCC occurrence. Of note, HCV patient was less likely to encounter HCC recurrence compared to HBV patients but the statistical difference did not reach significance (crude hazard ratio: 0.681 (0.367–1.264), $p = 0.223$) Before PSM, HBV-HCC patients had a higher 4-yr recurrent rate compared to HCV-HCC patients. (41% vs. 24%, $p = 0.073$). The 4-yr overall survival (OS) was similar (91% vs 87%, $p = 0.294$). After PSM (55 HBV and 55 HCV patients), the HBV-HCC patients still had a higher 4-yr recurrence rate than HCV-HCC patients(51% vs 24%, $p = 0.012$). Similarily, the 4-yr OS was still comparable in both groups. (90% vs 87%, $p = 0.473$).
Conclusion: Despite propensity score matching to adjust clinical and tumor factors between HBV and HCV-HCC patients, HBV-HCC still shows higher recurrence rates after curative resection. However, the OS remains comparable in both groups. These findings emphasize the distinct recurrence risk in HBV-HCC patients, suggesting the need for tailored management strategies in this population.

Rising global burden of liver transplants attributable to metabolic-associated steatotic hepatitis: trends from 68 countries (2009–2023)

Zobair Younossi[1,2], James M. Paik[1,2], Vincent Wai-Sun Wong[1,3], Giacomo Germani[4,5], Patrizia Burra[1,5], Annette Paik[1,2], Ariana Nader[2], Maria Stepanova[2,6], Saleh Alqahtani[7,8,9,10]. *[1]The Global NASH/MASH Council, Washington, District of Columbia, United States; [2]Beatty Liver and Obesity Research Program, Inova Health System, Falls Church, VA, United States; [3]Division of Gastroenterology and Hepatology, Stanford University School of Medicine, Palo Alto, California, United States; [4]The Global NASH/MASH Council, Washington, DC, United States, [5]Department of Surgery, Oncology and Gastroenterology, University of Padova, Padova, Italy; [6]The Global NASH Council, Washington, District of Columbia, United States; [7]The Global NASH/MASH Council, Washington, United States; [8]Division of Gastroenterology & Hepatology, Weill Cornell Medicine, New York, Washington, United States; [9]Liver, Digestive, and Lifestyle Research Section, and Organ Transplant Center of Excellence, King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia; [10]Center for Outcomes Research in Liver Disease, Washington, United States*
Email: zobair.younossi@cldq.org

Background and aims: The global burden of metabolic-associated steatotic hepatitis (MASH) as a leading indication for liver transplantation (LT) outside the United States (U.S.) remains poorly characterized. Our aim was to use the Global Observatory on Donation and Transplantation (GODT) and other datasets to better understand the contribution of MASH as an indication for LT in different regions of the world.
Method: Data on the total number of LT from 68 countries (2009–2023) were obtained from GODT. The number of LT attributable to MASH [cirrhosis or hepatocellular carcinoma (HCC)] was calculated by using the estimated proportion of LT due to MASH for each country and for each year using mixed-effects models. These models included national data on LT-MASH from sources (when available) such as the U.S. Scientific Registry of Transplant Recipients and relevant literature. Country-specific factors, including etiological data for HCC and cirrhosis, as well as the Healthcare Access and Quality Index, were sourced from the Global Burden of Disease (GBD) 2021 dataset. Additional data about age, sex, income, and the prevalence of obesity and type 2 diabetes (T2D) were obtained from WHO, NCD-RisC, and the International Diabetes Federation (IDF). Forecasts for the etiology of HCC and cirrhosis for 2022–2023 were generated using Auto-Regressive Integrated Moving Average (ARIMA) models. Confidence intervals for the estimates were derived using the delta method. Temporal trends were analyzed using Joinpoint regression to calculate annual percentage changes (APC).
Results: In 2022, 37,436 LTs were performed in 68 countries, increasing to 41,024 in 2023. LT-MASH increased by +8.63% [from 5,152 (95% CI: 3,996–6,308) in 2022 to 5,598 (95% CI: 4,306–6,888) in 2023]. The median proportion of LT-MASH across countries was 12.07%, ranging from 6.67% to 20.6%. U.S. reported the highest number of LT-MASH in 2023 (1,945; 95% CI: 1,688–2,202), followed by China, India, Brazil, and Türkiye. The highest LT-MASH rate was also observed in U.S. (5.72 per 1,000,000 population). Other countries with rates ≥2.0 per 1,000,000 included Croatia, Türkiye, Canada, Belgium, Republic of Korea, Saudi Arabia, Mongolia, Sweden, Portugal, Spain, and France. Among the 57 countries with at least 10 years of data, 35 exhibited significant increases in MASH-LTs from 2009 to 2023. India, Saudi Arabia, Türkiye, China, and Brazil showed the highest APC in LT-MASH (APC > 5%). In the United States, the number of LT-MASH transplants increased annually by 3.82%, rising from 1,119 (95% CI: 1,002–1,236) in 2009 to 1,945 (95% CI: 1,688–2,202) in 2023.
Conclusion: The burden of liver transplants due to MASH has been rising steadily across different regions of the world. These findings highlight the growing public health impact of MASH and underscore the urgency of implementing targeted prevention strategies and interventions across the globe.

Development and external validation of preoperative prediction model for early recurrence of intrahepatic cholangiocarcinoma

Sang Hyun Choi[1], Dong Hwan Kim[1], Sehee Kim[1], Seung Soo Lee[2].
[1]*Asan Medical Center, Seoul, Korea, Rep. of South;* [2]*asa, Seoul, Korea, Rep. of South*
Email: edwardchoi83@gmail.com

Background and aims: Early recurrence (ER) of intrahepatic cholangiocarcinoma (ICCA) following surgical resection is clinically significant. This study aimed to develop and validate a preoperative risk scoring system to predict ER of ICCA after surgical resection, utilizing clinical and computed tomography (CT) features.
Method: This multicenter retrospective study included 365 patients who underwent curative-intent surgical resection for ICCA at six institutions between 2009 and 2016. Of these, 264 patients from one institution constituted the development cohort, while 101 patients from the other institutions constituted the external validation cohort. Logistic regression models were constructed to predict ER based on preoperative variables and were subsequently translated into a risk-scoring system. The discrimination performance of the risk-scoring system was validated using external data and compared to the American Joint Committee on Cancer (AJCC) TNM staging system.
Results: Among the 365 patients (mean age, 62 ± 10 years, 229 men), 153 had ER. A preoperative risk scoring system that incorporated both clinical and CT features demonstrated superior discriminatory performance compared to the postoperative AJCC TNM staging system in both the development (area under the curve [AUC], 0.78 vs. 0.68; $p = 0.002$) and validation cohorts (AUC, 0.69 vs. 0.66; $p = 0.641$). The preoperative risk scoring system effectively stratified patients based on their risk for ER: the 1-year recurrence-free survival rates for the low, intermediate, and high-risk groups were 85.5%, 56.6%, and 15.6%, respectively ($p < 0.001$) in the development cohort, and 87.5%, 58.5%, and 25.0%, respectively ($p < 0.001$) in the validation cohort.
Conclusion: A preoperative risk scoring system that incorporates clinical and CT imaging features was valuable in identifying high-risk patients with ICCA for ER following resection.

Background and aims: Intensive Care Unit (ICU) admission is usually denied in patients with advanced hepatocellular carcinoma (HCC) due to the perceived poor prognosis. However, immunotherapy based on immune-checkpoint inhibitors (ICI) has transformed the treatment landscape of these patients. With the increasing use of ICI-based therapies, the role of critical care is becoming more relevant in managing severe adverse events related to this therapy. The outcome of HCC patients requiring critical care requires to be revisited. Our aim is to assess the outcome of patients with advanced HCC treated with IT admitted to ICU.
Method: We evaluated patients treated with ICI combinations across 20 medical centers globally between November 2012 and April 2024. Demographic data, IT types, main causes of admission, organ support, and mortality in the short and medium term were recorded.
Results: Of 1,065 patients, 47 (4.4%) were admitted to the ICU. Most were male (76.6%) with cirrhosis (93.6%), and 59.7% received IT as first-line therapy. The primary reasons for ICU admission were immune-related adverse events (irAE) in 46.8% and variceal bleeding in 29.8%. Median time to ICU admission was 115 days after initiation of IT [38–202], with 51 days [31–137] for irAEs. Half of the patients required organ support, with a median SOFA score of 4 (2–8). ICU

mortality was 25.5%. Two thirds of the patients (66%) were alive 28 days post-ICU discharge, with 3- and 6-month survival rates of 83% and 69%. The 61.3% of survivors were rechallenged with IT or started new HCC therapy.
Conclusion: Immune-related adverse events are the main cause of ICU admission in patients with advanced HCC receiving IT. Despite the severity, 66% were discharged, and nearly half resumed the same cancer therapies. These findings highlight the vital role of ICU care in managing HCC patients, challenging the notion of excluding them from intensive care, and emphasizing the need to identify factors that improve prognosis.

Email: pierre.nahon@aphp.fr

Background and aims: New tools for HCC early detection are only cost-effective for patients with a high annual incidence exceeding 2%. The aim of this study was to develop Machine Learning (ML) models for risk stratification of HCC in prospective cohorts of patients with compensated cirrhosis and to compare their performance to traditional scoring systems.
Method: Data were collected from the HCC 2000 trial, the ANRS CO12 CirVir and CO22 Hepather cohorts, and CIRRAL cohort. All patients underwent semiannual ultrasound surveillance. The population was divided into a training group (two-thirds) and a validation group (one-third). The cumulative incidence of HCC was estimated within a competitive risk framework. A Fine-Gray regression model was constructed as a reference for comparison with the ML models, alongside the published FASTRAK and aMAP scores. A Single Tree (ST) model was developed using conditional decision tree methodology. Prognostic algorithms were derived using a Random Forest (RF) approach. The discrimination performance of the models was assessed in the validation set using the C-Index, and calibration curves were generated.
Results: 3,671 patients had either non-viral cirrhosis or cirrhosis related to resolved HCV or controlled HBV. After a median follow-up of 37.1 months in the training group, 182 patients (7.5%) developed HCC (1-yr incidence: 2.2%). 75 HCC cases occurred in the validation group (1-yr incidence: 2.4%). Non-viral causes of cirrhosis (alcohol and/or metabolic) were associated with a lower risk of HCC. The ST approach identified six main predictors, generating eight groups based on various combinations of these predictors, each with contrasting HCC risks. The most predictive factor at the root of the tree was age, which divided patients into two main subpopulations. Among younger patients, one group with slightly impaired liver function (despite a compensated status) showed moderate to high risks of HCC, while an extreme phenotype of young patients with resolved HCV infection and elevated GGT levels presented a particularly high risk despite normal liver function. RF models were constructed by aggregating 1,000 decision trees, confirming the results of the single tree analysis and identifying advanced age, GGT levels, thrombocytopenia, and elevated bilirubin as strong predictors of HCC. Comparisons of C-indexes indicated no significant advantage for the ML models over traditional short-term scores, although there appeared to be an improvement in long-term prediction (5-year C-index of 0.76 for RF versus 0.75 for all others). Calibration levels were similar between ML approaches and traditional models in the validation population.
Conclusion: ML algorithms highlight interactions between variables, aid in identifying patient clusters defined by varying risk levels, and highlight "extreme phenotypes" of patients with particularly high risks of HCC.

Email: fabio.piscaglia@unibo.it

Background and aims: Clinically significant portal hypertension (CSPH) is an independent predictor for hepatocellular carcinoma (HCC) development and a key prognostic factor, influencing patient access to oncological treatments. This study aims to evaluate the prevalence of CSPH and its impact across different HCC stages according to the Barcelona Clinic Liver Cancer (BCLC) staging system.

Method: A retrospective analysis was conducted on HCC patients registered in the Italian Liver Cancer (ITA.LI.CA) database between January 1987 and December 2022. Patients with HCC in BCLC stage D or stage C without extrahepatic metastasis or macrovascular invasion and those with Child-Pugh score > B7, were excluded. The presence of CSPH in the remaining patients was assessed based on esophageal or gastric varices, tense ascites, or liver stiffness > 25 kPa on elastography.
Results: Of 10,907 total patients, 7,069 were included, with 2,652 diagnosed with CSPH. The prevalence of CSPH was highest in alcoholic etiology and BCLC stage C (44.7%), followed by stages A (39.1%), B (33.9%), and 0 (19.6%). CSPH was associated with reduced survival in the overall population. In univariate analysis, CSPH was linked to worse survival in BCLC stages A, B, and C, but not in stage 0. Multivariate analysis confirmed this association for stages A and B, but not for stage C. Only 9.7% of patients with CSPH were on non-selective beta-blockers (NSBB), and while NSBB use was associated with improved survival in univariate analysis, this effect was not seen in multivariate analysis.
Conclusion: Our study demonstrates that CSPH significantly impacts survival in the early and intermediate stages of HCC, but not in very early or advanced stages. These results may be explained by the milder underlying liver disease (or more frequent access to liver transplantation) in very early stages, or by a greater oncological burden in advanced stages, which may have a largely dominant impact on survival. Our study also shows that CSPH is particularly common in advanced HCC patients, who often require anti-angiogenic therapies that necessitate special precautions precisely due to the presence of CSPH. A further analysis considering subgrouping of BCLC-C according to presence or absence of venous invasion is underway.

Email: abelina.kreuter@meduniwien.ac.at

Background and aims: While the Child-Turcotte-Pugh (CTP) as well as the albumin-bilirubin (ALBI) score represent important clinical tools for risk stratification in patients with cirrhosis and hepatocellular carcinoma (HCC), their prognostic abilities in patients with non-cirrhotic HCC is unclear.
Method: We included two cohorts of patients with HCC. Cohort I (Viennese HCC database) included non-surgical patients with BCLC stage A-C (non-cirrhotic: n = 132, cirrhotic: n = 773), and cohort II included patients with advanced HCC treated with atezolizumab/bevacizumab or durvalumab/tremelimumab from two large international databases (AB-/DT-Real: non-cirrhotic: n = 259, cirrhotic: n = 841). We evaluated the prognostic value of CTP/ALBI for overall survival (OS) by calculating Cox regression analyses as well as time-dependent AUROCs.
Results: Mean age in cohort I was 69 ± 12 in non-cirrhotic and 66 ± 11 years in cirrhotic HCC patients. Further baseline characteristics in the non-cirrhotic/cirrhotic cohorts were as follows: 83%/82% were male, 12%/46% as well as 39%/64% had CTP stage B and ALBI grade II. Most patients were classified as BCLC C (67%/46%). Patients received A/B (89%/89%) and D/T (11%/11%) in cohort II. Mean age was 66 ± 13/66 ± 11 years, 80%/82% were male. While 7%/23% had CTP stage B, 53%/57% had ALBI grade II and 3%/6% grade III. Median OS in cohort I in non-cirrhotic/cirrhotic patients was 19.0 (95%CI, 15.1–24.9)/22.4 (95%CI,

20.6–26.8) months in CTP-A, and 11.5 (95%CI, 3.4-NA)/10.2 (95%CI, 8.0–12.1) months in CTP-B. For ALBI grade I vs. II, median OS in non-cirrhotic/cirrhotic patients was 22.6 (95%CI, 14.6–29.3)/26.2 (95%CI, 21.5–30.7) months vs. 15.3 (95%CI, 11.6–24.7)/12.8 (95%CI, 11.1–14.7). While median OS in cohort II in non-cirrhotic/cirrhotic patients was 14.6 (95%CI, 11.7–19.2)/17.0 (95%CI, 15.6–19.6) months in CTP-A, it was 4.1 (95%CI, 1.8-NA)/7.7 (95%CI, 6.5–9.7) months in CTP-B. For ALBI grade I vs. II, median OS in non-cirrhotic/cirrhotic patients was 20.6 (95%CI, 15.0–23.1)/20.8 (95%CI, 17.8–26.3) months vs. 10.9 (95%CI, 8.9–14.5)/11.1 (95%CI, 9.7–12.6) months. In multivariable Cox regression analyses in non-cirrhotic HCC, CTP-B (cohort I: aHR, 2.65 [95%CI, 1.26–5.57], p = 0.010, cohort II: aHR, 3.24 [95%CI, 1.73–6.08], p < 0.001) and ALBI score (cohort I: aHR, 1.89 [95%CI, 1.11–3.21], p = 0.020, cohort II: aHR, 2.45 [95%CI, 1.71–3.52], p < 0.001) were independently associated with OS. Time-dependent AUROCs in non-cirrhotic vs. cirrhotic patients for CTP at 6 months (cohort I: 0.573 vs. 0.659 & cohort II: 0.679 vs. 0.672) and 12 months (cohort I: 0.538 vs. 0.630 & cohort II: 0.639 vs. 0.692) and ALBI at 6 months (cohort I: 0.598 vs. 0.671 & cohort II: 0.739 vs. 0.692) and 12 months (cohort I: 0.584 vs. 0.659 & cohort II: 0.635 vs. 0.720) were comparable.

Conclusion: CTP and ALBI scores can be used as clinical risk stratification tools in patients with non-cirrhotic HCC, and their prognostic power in non-cirrhotic HCC is comparable to that in patients with HCC and cirrhosis.

WED-084

Added-value of PET imaging to AFP score in predicting HCC recurrence after liver transplantation

Alina Pascale[1,2], Aimee Bambara Sanon[3], Cyril Cosse[4], Rodolphe Sobesky[2,3], Eleonora De Martin[2,3], Ilias Kounis[2,3], Lea Duhaut[3], Alina Lutu[3], Bruno Roche[3], Faouzi Saliba[2,3], Philippe Ichaï[3], Gabriella Pittau[3], Oriana Ciacio[3], Daniel Pietrasz[2,3], Marc Antoine Allard[2,3], René Adam[2,3], Daniel Azoulay[2,3], Antonio Sa Cunha[2,3], Daniel Cherqui[2,3], Eric Vibert[2,3], Audrey Coilly[2,3], Olivier Rosmorduc[2,3], Florent Besson[5], Nicolas Golse[2,3]. *[1]Hepato-Biliary Center, CHU Paul Brousse, APHP, Paris-Saclay University, INSERM UMRS 1193, Villejuif, France; [2]Paris-Saclay University, INSERM UMRS 1193, Villejuif, France; [3]Hepato-Biliary Center, CHU Paul Brousse, APHP, Villejuif, France; [4]Sorbonne University, Paris, France; [5]CHU Bicêtre, APHP, Kremlin-Bicêtre, France*
Email: nicolas.golse@aphp.fr

Background and aims: Despite the increasing use of positron emission tomography (PET) imaging in hepatocellular carcinoma (HCC) context, its utility in predicting recurrence post-liver transplantation (LT) is not clear, and PET is not considered among the selection criteria in LT for HCC. We investigated the correlation between HCC recurrence after LT and PET imaging characteristics before LT.

Method: We retrospectively analyzed 346 patients consecutively transplanted for HCC in Hepato-Biliary Center, Paul Brousse Hospital, between January 2017 and December 2023. Among them, 99 patients had available data before LT on 18F-fluorodeoxyglucose PET (FDG PET) and/or choline PET imaging and were included in the study. We collected pre-LT demographic data, characteristics of liver cirrhosis, HCC and PET imaging and post-LT data. At listing, all patients had an alpha-fetoprotein (AFP) score ≤ 2, according to French selection criteria for LT in HCC. Statistical analyses were performed using STATA 15.1 software and SPSS.

Results: The median age of patients was 63 years and 83 were males (83.8%). The main causes of liver cirrhosis were: viral hepatitis (41.4%), alcohol consumption (39.4%), and metabolic (14.1%). The median MELD (Model for End-Stage Liver Disease) score was 12. Most patients (89.9%) had a bridging treatment while waiting for LT. The median waiting time on waiting list was 5.1 months. The median follow-up post LT was of 36 months. 20 patients (20.8%) experienced HCC recurrence post-LT, with a median time to recurrence of 11.6 months post-LT. The 5-year disease-free survival (DFS) was of 57%, and the 5-year overall survival of 66%. Among the 99 patients with available PET imaging data, 44 patients underwent PET imaging before and after bridging therapy. 102 FDG-PET and 78 choline-PET were analysed, of which 27% of FDG-PET and 35% of choline-PET were positive (intrahepatic only), respectively. In these patients, the complete metabolic response to bridging treatment was associated with a better recurrence-free survival post LT (p = 0.047). Net reclassement index, based on AFP score and PET imaging at listing, was of 0.51, p = 0.02. We created a nomogram predicting HCC recurrence risk at listing, including PET features.

Conclusion: In our cohort, the recurrence-free survival after LT in HCC patients is better predicted when adding the PET imaging data to AFP score. We need to validate these data in external cohorts, but this could be an indication of a potential role for PET imaging in better selecting the best HCC candidates for LT.

WED-085

Bone mineral density predicts survival in patients with hepatocellular carcinoma and portal vein tumor thrombosis

Roman Klöckner[1], Lukas Müller[2,3], Lorena Heim[2], Felix Hahn[2], Fabian Stöhr[2], Tilman Emrich[2], Dirk Graafen[2], Jan-Peter Grunz[3,4], Daniel Pinto dos Santos[5,6], Arndt Weinmann[2], Friedrich Foerster[2], Jens Mittler[2], Jens U. Marquardt[1], Tobias Bäuerle[2], Aline Mähringer-Kunz[2]. *[1]University Hospital of Schleswig-Holstein - Campus Lübeck, Lübeck, Germany; [2]University Medical Center Mainz, Mainz, Germany; [3]University of Wisconsin, Madison, United States; [4]University Hospital Würzburg, Würzburg, Germany; [5]University Hospital of Cologne, Cologne, Germany; [6]University Hospital of Frankfurt, Frankfurt, Germany*
Email: aline.maehringer.kunz@gmail.com

Background and aims: Low bone mineral density (BMD) has emerged as a risk factor in hepatocellular carcinoma (HCC). This study explores the potential of BMD as a prognostic indicator in patients with HCC complicated by portal vein tumor thrombosis (PVTT), which is characterized by an exceptionally poor prognosis.

Method: This retrospective study included 462 patients with HCC and PVTT at our tertiary care center between January 2005 and December 2020. BMD was ascertained by measuring the CT attenuation at the midvertebral core of the first lumbar vertebra using the established cut-off of 160 HU. Analyses were performed at initial HCC diagnosis and PVTT onset. We analyzed the impact of BMD on median overall survival (OS) and conducted multivariate analyses with established survival predictors.

Results: The median BMD was 136 HU (interquartile range [IQR], 113–160 HU) at HCC diagnosis and 134 HU (IQR, 109–159 HU) at PVTT diagnosis. At initial HCC diagnosis, the median OS was 10.4 months in patients with BMD ≥ 160 HU and 5.5 months in those with BMD < 160 HU (P < 0.001). Similarly, at PVTT diagnosis, the median OS was 8.5 months in individuals with higher BMD and 4.7 months in patients with lower BMD (P < 0.001). In multivariate analysis, BMD remained an independent prognostic factor alongside growth type and ALBI grade.

Conclusion: BMD is an independent prognostic marker of survival in patients with HCC and PVTT. Incorporating BMD into existing classification and scoring systems could enhance the accuracy of survival predictions and inform clinical decision-making processes.

WED-086

Clinical evaluation of multimarker algorithmic scores for detection of early stage hepatocellular carcinoma in high-risk liver patients

Hidenori Toyoda[1], Aliya Sarmanova[2], Konstantin Kroeniger[3], Takashi Kumada[4], Ashish Sharma[2]. *[1]Ogaki Municipal Hospital, Ogaki, Japan; [2]Roche Diagnostics International AG, Rotkreuz, Switzerland; [3]Roche Diagnostics GmbH, Penzberg, Germany; [4]Gifu Kyoritsu University, Ogaki, Japan*
Email: hmtoyoda@spice.ocn.ne.jp

Background and aims: Hepatocellular carcinoma (HCC) is a leading cause of cancer-related death. Biannual ultrasound surveillance with or without a-fetoprotein (AFP) testing is recommended for at-risk patients, but its sensitivity for early stage HCC, for which potentially curative treatments exist, is suboptimal. We compared the clinical performance of GALAD (sex, age, AFP-L3, AFP and Protein induced by vitamin K absence-II (PIVKA-II)) and GAAD (sex, age, AFP and PIVKA-II) [Piratvisuth T, 2022, doi: 10.1002/hep4.1847] algorithms for differentiating early-stage HCC and benign chronic liver disease (CLD) in Japan.
Method: Adult patients ≥20 y.o. were retrospectively enrolled in a single-center, case-control cohort at Ogaki Municipal Hospital from January 1, 2010, to March 31, 2022. Eligible HCC cases had first-time HCC diagnosis confirmed by ultrasound or pathology as per the EASL guidelines. CLD controls had no HCC confirmed by imaging within 6 months. The recruitment we aimed for has a 4:1 ratio of cirrhotic to non-cirrhotic patients, equally representing viral and non-viral etiologies. Cirrhosis was defined as a FIB-4 index⩾3.25. Serum PIVKA-II, AFP and AFP-L3 levels were measured using Elecsys® assays on cobas® e 601. Same samples were also measured for AFP, AFP-L3, and PIVKA-II using the WAKO μTASWako i30 Immunoanalyzer. Established HCC detection cut-offs were 2.47 for GALAD and 2.57 for GAAD scores (range 0–10 for both Cobas algorithms) and –0.63 for μTASWako GALAD.
Results: A total of 902 patients (191 HCC; 711 CLD) were included: mean age 65.09 years, 547 males (61%), 901 of Japanese ethnicity, 704 (38.83%) had cirrhosis. Among HCC patients, 127 (66.5%) had early-stage HCC (BCLC 0/A). GAAD and GALAD algorithms showed similar performance for distinguishing HCC from CLD (area under the curve [AUC] both 85% for early, 96% for late and 89% for all stage HCC). At 90% specificity GAAD, GALAD (both Cobas) and μTASWako GALAD had comparable sensitivity for identifying all-stage HCC (71%(95%CI 0.64–0.77), 71%(0.64–0.77) vs 70%(0.63–0.76)). For early-stage HCC, AUCs were similar across cirrhotic viral 85.1%(78.5–91.7), 85.2%(78.6–91.7) vs 86.3%(80.5–92.2)) and non-viral (80.3%(70.4–90.1), 79.6% (69.7–89.5) vs 87.6%(80–95.3)) as well as non-cirrhotic viral (91.3% (83.7–98.8), 91.3%(83.9–98.7) vs 85.4%(75–95.9)) and non-viral (87.5%(67–100), 87.2%(67.3–100) vs 88.1%(67.5–100)) etiologies.
Conclusion: In a Japanese cohort, GALAD and GAAD showed similar performance in differentiating HCC and CLD controls, irrespective of etiology, presence of cirrhosis and tumor stages. The Elecsys AFP-L3 assay may have negligible impact within the GALAD algorithm. GAAD in vitro diagnostics tool offers a reliable and accurate way to aid the diagnosis of early-stage HCC, and may represent a more convenient alternative to GALAD by using only 2 assays while maintaining the diagnostic performance.

WED-087
Prognosis after resection or ablation of hepatocellular carcinoma: a danish population-based multi-state cohort study

Andreas Halgreen Eiset[1], Gerda Elisabeth Villadsen[1], Simona Conte[2], Clara Stenderup[1], Peter Jepsen[1,3]. *[1]Department of Hepatology and Gastroenterology, Aarhus University Hospital, Aarhus, Denmark; [2]AstraZeneca Nordics, Stockholm, Sweden; [3]Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark*
Email: aneise@rm.dk

Background and aims: Hepatocellular carcinoma (HCC) has a high risk of recurrence, highlighting the need for adjuvant therapies to reduce this risk. We aimed to provide a comprehensive multi-state description of the prognosis after curative-intent treatments.
Method: Aarhus University Hospital is one of Denmark's three centers caring for patients with HCC. We offer all treatment modalities available and manage all HCC patients within a population of 1.9 million following EASL guidelines. The data was collected from our electronic patient records. We included all patients diagnosed with HCC between 1 January 2013 and 30 April 2023, and whose initial treatment was resection or ablation with curative intent, possibly in combination with transarterial chemoembolization (TACE). We followed patients from their initial treatment to death or censoring on 31 December 2023. To describe their prognosis, we used a multi-state model consisting of six states: index treatment, recurrence, locoregional (i.e., any non-systemic treatment) treatment post-recurrence, systemic treatment post-recurrence, death without recurrence, and death after recurrence. We used the Aalen-Johansen method to compute cumulative risks and state occupation probabilities, and we used Cox regression to identify prognostic factors.
Results: We included 296 patients (79% men, median age 69 years), of whom 115 were treated with resection and 181 with ablation. The largest tumor treated with ablation alone was 40 mm, and 29 tumors (median size 45 mm, maximum 78 mm) had been treated with ablation + TACE. Overall, the 2-year risk of recurrence was 55%, and the 5-year risk was 70%. Following the first recurrence, 76% received locoregional treatment,12% systemic treatment, and 12% did not receive either treatment. At 5 years after the initial treatment, 10% were alive and recurrence-free; 17% were alive and had experienced a recurrence treated with locoregional but not systemic treatment; 6% were alive and had experienced a recurrence treated with systemic treatment; 19% had died without a recurrence, and 47% had died following recurrence. At 5 years after the first recurrence, 18% were alive and had received locoregional but not systemic treatment; 7% were alive and had received systemic treatment; and 75% were dead. The 1-year mortality after initiation of systemic treatment was 43%. The prognosis was virtually identical for patients treated with resection or ablation: hazard ratio for recurrence for resection vs. ablation = 0.9 (95% CI 0.6 to 1.2) adjusted for sex, age, and presence of cirrhosis.
Conclusion: This population-based study showed that the risk of recurrence is very high after curative-intent treatments, and patients have a markedly higher mortality after a recurrence. Thus, interventions to reduce the risk of recurrence have great potential to reduce mortality.

WED-088
Prognostic influence of clinically significant portal hypertension in patients with compensated cirrhosis and hepatocellular carcinoma receiving systemic therapy: The HIPERIA study

Antonio Guerrero[1,2], Miguel Ramírez Verdyguer[1,2], Sergio Muñoz Martínez[2,3], Marta Campos[2,4], Miguel Sogbe[5], Jose Luis Herrera Fajes[6], Sonia Pascual[7], Berta Cuyàs[8], Beatriz Minguez[2,9], Sara Lamas-Álvarez[10], Jose Fortea[11], María Paz Valer Lopez-Fando[12], María del Mar Lozano[13], Mariano Gómez-Rubio[14], Christie Perelló[15], Maria Luisa Gutiérrez[16], Marta Romero-Gutiérrez[17], Antonio Mancebo[18], Jose María Moreno Planas[18], Luis Téllez[1,2], José Luis Calleja Panero[15], Gemma De la Poza[12], Belen Piqueras[12], Angela Puente[11], Maria Varela[10], Joan Genesca[2,9], Edilmar Alvarado-Tapias[8], Delia D'Avola[2,5], Ana Matilla[2,6], Bruno Sangro[2,5,19], María Reig[2,4], José Luis Lledó[1,2], Agustín Albillos[1,2]. *[1]Department of Gastroenterology and Hepatology, Ramón y Cajal University Hospital, University of Alcalá, Ramón y Cajal Institute for Health Research (IRYCIS), Madrid, Spain; [2]Centro de Investigación Biomédica en Red en Enfermedades Hepáticas y Digestivas (CIBEREHD), Carlos III Health Institute, Madrid, Spain; [3]Liver Cancer Unit, ICMDiM, Hospital Clínic. Email: antonio.guerrero90@hotmail.com

Background and aims: hepatocellular carcinoma (HCC) typically occurs in patients with cirrhosis, and its prognosis is influenced by both tumour stage and liver disease severity. Clinically significant portal hypertension (CSPH) represents a critical milestone in compensated cirrhosis, being associated with an increased decompensation risk and reduced survival following surgery for HCC. However, its prognostic significance in HCC patients on systemic therapy has not been established. This study investigates the impact of CSPH on overall survival and the systemic treatment window in patients with compensated cirrhosis and HCC.
Method: Multicentre retrospective study of patients with HCC and compensated cirrhosis receiving systemic therapy. The primary objective was overall survival and the secondary one: systemic treatment window, defined as the duration of treatment until symptomatic progression or death. Symptomatic progression was defined as severe hepatic decompensation and/or ECOG PS 3–4, warranting treatment discontinuation at the treating physician's discretion. CSPH was defined based on Baveno VII criteria. Mortality and the treatment window were analysed as time-to-event variables with adjusted hazard ratios (aHR) derived from Cox regression, accounting for prognostic variables (age, etiology of cirrhosis, MELD, ALBI, BCLC stage, and type of systemic treatment). Survival was analysed using Kaplan-Meier curves.
Results: Between January 2015 and January 2023, 663 patients were included (86.6% male, median age 66 years). Main cirrhosis etiologies were HCV (49%) and alcohol (40%). All patients were Child-Pugh A, with a median MELD score of 8, and ALBI grades 1 and 2 in 39% and 61%, respectively. Most patients were BCLC stages was B (39%) and C (56%). Systemic treatments included sorafenib (86.9%), atezolizumab-bevacizumab (7.6%), lenvatinib (3.9%), and nivolumab (1.7%). CSPH was present in 411 patients (62%), and esophageal varices in 280 (42%). The presence of CSPH was independently associated with decreased overall survival [median:13.0 (95%CI: 11.1–14.7) vs. 21.7 (18.8–25.9) months,] with aHR of 1.37 (95%CI: 1.07–1.77, $p = 0.014$). Additionally, CSPH was linked to a shorter treatment duration [median: 10.21 (95% CI: 8.70–11.76) vs. 18.82 (15.89–21.02) months], with aHR of 1.37 (95% CI: 1.05–1.79, $p = 0.02$).
Conclusion: The presence of CSPH stratifies the prognosis of patients with compensated cirrhosis and HCC undergoing systemic treatment. CSPH identifies a population of patients with compensated cirrhosis with poorer survival and a shorter therapeutic opportunity window across the different tumour stages.

WED-089-YI
Development and validation of PSU's AI-assisted ultrasound (AI-US) algorithm for focal liver lesion detection
Janthakan Wongsuwan[1], Teeravut Tubtawee[1], Nattaphon Wansom[2], Sitang Nirattisaikul[1], Sitthichok Chaichulee[1], Apichat Kaewdech[1].
[1]Prince of Songkla University, Hatyai, Thailand; [2]Siriraj Hospital, Mahidol University, Bangkok, Thailand
Email: apichat.ka@psu.ac.th

Background and aims: Ultrasound (US) is recommended as the primary imaging modality for hepatocellular carcinoma (HCC) surveillance, particularly in patients at high risk due to chronic liver disease (CLD). Current guidelines advocate biannual US surveillance, often combined with serum alpha-fetoprotein (AFP) measurement. However, US has limitations, including inadequate image quality in 20% of cases, operator dependence, and reliance on radiologist expertise, especially in patients with MASLD. AI-assisted US systems are emerging as a promising solution to improve the detection of focal liver lesions (FLLs), including HCC. This study aimed to develop an AI system to identify FLLs in patients with CLD.
Method: We used the YOLOv8 supervised deep learning algorithm. US images were collected from CLD patients, pre-processed by cropping and removing labels, and annotated by two blinded expert radiologists. Radiologists independently classified the images into five groups: normal, cysts, focal fatty sparing (FFS), focal fatty infiltration (FFI), and nodules/masses. Task 1 classified liver-specific images using a YOLOv8m-cls model. Task 2 detected fields of view with a YOLOv8m detection model, ensuring that only relevant areas were cropped for analysis. Task 3 performed multi-label classification of distinct liver lesions using YOLOv8m-cls. The model's sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and area under the receiver operating characteristic curve (AUROC) were evaluated.
Results: The algorithm was trained and tested on B-mode US images from 360 patients (mean age 58.9 ± 13.8 years, 37.1% male, cirrhosis 27.7%, fatty liver 24.2%). Of 3,798 images, 263 were classified as cysts, 308 as FFS, 56 as FFI, and 673 as nodules/masses. The model demonstrated strong performance, achieving an AUROC of 0.9046 for cyst detection, with a sensitivity of 27.59%, specificity of 99.23%, PPV of 53.31%, and NPV of 97.71%. For FFS, the AUROC was 0.8478, with a sensitivity of 55.88%, specificity of 88.89%, PPV of 15.97%, and NPV of 98.16%. For nodules/masses, the AUROC was 0.8355, with a sensitivity of 52.17%, specificity of 94.77%, PPV of 52.17%, and NPV of 94.77%. Normal classification yielded an AUROC of 0.8656. The confusion matrix showed true positive rates of 80% for cysts, 91% for FFS, 66% for nodules/masses, and 95% for normal findings, with minimal misclassification.
Conclusion: The results of this study highlight the potential of deep learning algorithms to assist radiologists in the accurate and efficient diagnosis of FLLs from US images. Incorporating clinical data enhances the performance of the algorithm, making it a valuable tool for improving diagnostic accuracy.

WED-090-YI
The mind and monitoring: The psychological impact of hepatocellular carcinoma surveillance
Azzra Maricar[1], Maria Qurashi[2], Madhumitha Pandiaraja[2], Karolina Rzeniewicz[2], Shuell de Souza[2], Rohini Sharma[2]. *[1]Imperial College London, London, United Kingdom; [2]Department of Surgery and Cancer, Imperial College London, London, United Kingdom*
Email: azzra.maricar@kcl.ac.uk

Background and aims: Hepatocellular carcinoma (HCC) is the third leading cause of cancer-related death worldwide. HCC surveillance benefits patients with cirrhosis via early cancer detection, resulting in improved survival. There is a paucity of data on the potential harms of surveillance, particularly psychological implications. Baseline rates of anxiety (31.6%) and depression(28.9%) in the HCC surveillance population are nearly fivefold and eightfold higher than the UK population, likely due to comorbidities and pre-existing mental health diagnoses. This study aimed to explore the prevalence of psychological harms associated with HCC surveillance utilising the Hospital Anxiety and Depression Score (HADS), and to determine any potential change in psychological state of patients prior to and on receipt of surveillance.
Method: Administration was at two timepoints: (1) between surveillance episodes and (2) on the day of surveillance scan. We

compared HADS scores and the proportion of patients reaching thresholds for anxiety, depression, and psychological distress between timepoints. Sociodemographic data (sex, age, ethnicity, socio-economic status, aetiology of liver disease, prior mental health status) were obtained from electronic patient records.
Results: Patient demographics were as follows: the majority were male (60%); white (50%); most common aetiology Alcohol Related Liver Disease (44%); median age 61 years. Prior mental health diagnosis was identified in 17 (34%) patients, with the most common diagnosis being mixed mental and behavioural disorders (12%). Participants were asked to complete the HADS twice: firstly, on the day of surveillance ultrasound scan and secondly, at another time point in between surveillance episodes. 50 participants completed the surveillance HADS. 38 participants returned for baseline questionnaire(n = 12 lost to follow up). The prevalence of anxiety, depression and total psychological distress at baseline was 31.6%, 28.9% and 31.6%, respectively. Higher socioeconomic status was associated with prevalence of anxiety at baseline(OR 5.88; 95% CI = 1.30–26.51; p = 0.02). There was no statistical significance in the prevalence of anxiety and depression between timepoints (p = 1.00). Updated results will be presented at meeting.
Conclusion: There was no increase in anxiety or depression on receipt of HCC surveillance. There is a high baseline prevalence of anxiety and depression amongst patients undergoing HCC surveillance. However, this does not appear to be associated with receipt of HCC surveillance itself.

WED-091
Delta hepatitis versus HBV monoinfection associated hepatocellular carcinoma: spot the difference
Mirela Chitul[1,2], Razvan Cerban[1,2], Speranta Iacob[1,2], Daria Gheorghe[2], Diana Stan[2], Liana Gheorghe[1,2]. [1]*Fundeni Clinical Institute, Bucharest, Romania;* [2]*Carol Davila University of Medicine and Pharmacy, Bucharest, Romania*
Email: mirela_onica@yahoo.com

Background and aims: Hepatitis delta virus (HDV) was recently proved to be directly carcinogenic on the hepatocytes, via different mechanisms compared to hepatitis B virus monoinfection (HBV), leading to a different hepatocellular carcinoma (HCC) pattern. Hence, our aim was to describe the prevalence of HCC in HDV infection versus HBV alone and to highlight the differences between HCC behaviour in both groups.
Method: A retrospective study was conducted in a Hepatology Tertiary Care Centre. All HBsAg positive adult patients admitted from 1st of January 2021 to 31st of December 2023 were included. Statistics was performed using IBM SPSS 29.0. Patients were split in study group: HBV+HDV+HCC and control group: HBV+HCC.
Results: A total of 679 patients were included. The estimated prevalence of HCC in HDV infected population was 20.8% versus 9.1% in the control group, p = 0.000, with OR = 2.263, CI 1.536–3.333, p = 0.001. Younger patients were found to develop HCC in delta hepatitis (mean ± stdev, 59 ± 8.727 years vs 63 ± 11.28 years, p = 0.027). Patients in the study group have smaller tumors (maximum diameter: 32.66 ± 23.181 mm vs 56.75 ± 38.09 mm, p = 0.002), but with no difference in AFP values (177.24 ± 364.8 ng/ml vs 183.07 ± 336.77 ng/ml, p = 0.941) compared to the control group at HCC diagnosis. BCLC classification (p = 0.001) and AFP Duvoux score (p = 0.001) showed more advanced HCC in HBV monoinfection. Hence, treatment in the study group was predominantly loco-regional whereas in the control group was mainly systemic (p < 0.000). The presence of HCC in HDV infected patients was strongly correlated with advanced liver disease (measured by MELD, MELD Na and MELD 3.0, p = 0.001), higher HBsAg titre (p = 0.001) and lower HBV DNA viral load (p = 0.001).
Conclusion: HCC is more frequent in HDV infected patients, leading to a different HCC pattern, with smaller tumours, less advanced neoplasia and access to curative treatment, compared to HBV monoinfection associated HCC. HDV associated HCC occurs in patients with advanced liver disease, higher HBs Ag titre and lower HBV DNA viral load.

WED-092-YI
Lower allele frequency of the TERT-rs2242652 in sub-saharan african than american populations and hepatocellular carcinoma risk

Background and aims: Hepatocellular carcinoma (HCC) is the third leading cause of cancer-related deaths worldwide. The single nucleotide polymorphism (SNP) rs2242652 in the telomerase reverse transcriptase (*TERT*) gene has been linked to a lower risk of HCC in individuals of European descent and Chinese Han populations. In sub-Saharan Africa, the earlier onset of HCC and higher incidence of this cancer suggest a potential role for inherited genetic predisposition or the absence of protective germline factors. In this study, we evaluated for the first time whether *TERT*-rs2242652 is associated with HCC in sub-Saharan African populations from Ghana, Nigeria, and Cameroon, and we compare the finding with a European descent-predominant population from the United States (U.S.).
Method: A total of 537 patients with pathology- or radiology-confirmed diagnosis of HCC were included, comprising individuals from the U.S. (n = 348), Ghana (n = 79), Nigeria (n = 43), and Cameroon (n = 67). The control group consisted of 2,872 cancer-free individuals from the same populations: U.S. (n = 2,399), Ghana (n = 323), Nigeria (n = 85), and Cameroon (n = 65). Whole-exome sequencing (Exome+, Helix, Inc.) was conducted using germline DNA from participants, and data for the *TERT*-rs2242652 were extracted for analysis. Unconditional logistic regression was used to calculate odds

ratios (ORs) and 95% confidence intervals (CIs). Protective allele frequencies (PAF) were assessed with chi-square tests.
Results: In the U.S. cohort, *TERT*-rs2242652 was significantly associated with a lower risk of HCC (OR = 0.75 for AG/AA vs. GG; 95% CI: 0.58–0.96; p = 0.021), with an overall PAF of 18.8% (15.4% in HCC cases vs. 19.3% in controls). In the combined sub-Saharan African population, no significant association was observed; however, a trend towards a decreased risk of HCC was noted (OR = 0.80; 95% CI: 0.53–1.22; p = 0.29), with an overall PAF of 12.2% (10.6% in HCC cases vs. 12.9% in controls). Separate analyses of the Ghanaian, Nigerian, and Cameroonian populations yielded similar non-significant trends with the protective allele and HCC risk. Overall, the PAF of the combined African populations was lower than the U.S. cohort (p < 0.0001 ; PAF = 12.2% in Africans vs. 18.8% in European Americans).
Conclusion: This study is the first to evaluate *TERT*-rs2242652 in sub-Saharan African populations, revealing lower PAF compared to European Americans. The reduced frequency of this protective allele might contribute to the younger HCC onset and higher mortality in sub-Saharan Africa. These findings highlight the importance of conducting diverse, multi-ethnic genetic studies to address disparities in the clinical application of genetic discoveries for HCC prevention, risk stratification, and treatment.

Prognostic significance of tumor-associated endothelial B7-H3 expression in hepatocellular carcinoma
Yunmi Ko[1], Yun Bin Lee[1], Eun Ju Cho[1], Jeong-Hoon Lee[1], Yoon Jun Kim[1], Jung-Hwan Yoon[1], Su Jong Yu[1]. [1]*Seoul National University College of Medicine, Seoul, Korea, Rep. of South*
Email: ydoctor2@snu.ac.kr

Background and aims: B7-H3 (CD276), a newly identified member of the B7 family, is overexpressed in various solid tumors and acts as a T cell inhibitor that promotes tumor aggressiveness and proliferation. This study evaluated whether tumor or endothelial B7-H3 expression was associated with tumor behavior and prognosis in hepatocellular carcinoma (HCC) following surgical resection.
Method: We included consecutive patients with HCC who had undergone surgical resection (n = 624) or liver transplantation (n = 100) at two tertiary hospitals between 2009 and 2013. Tissue microarray (TMA) was used to assess B7-H3 expression in tumor and adjacent tissues. The primary outcome was overall survival (OS), and the secondary outcome was recurrence-free survival (RFS), analyzed according to B7-H3 expression levels.
Results: Among the 624 patients in the surgical resection cohort, moderate-to-strong B7-H3 expression was observed in 20.7% (129/624) of tumors and 54.8% (342/624) of endothelial tissues. The median follow-up duration was 6.8 (interquartile range [IQR] = 3.3–9.8) years. After balancing baseline characteristics using inverse probability of treatment weighting (IPTW), patients with the moderate-to-strong endothelial B7-H3 expression had significantly worse OS (adjusted hazard ratio [aHR] = 1.58, 95% confidence interval [CI] = 1.17–2.12, *P* = 0.003) and RFS (aHR = 1.33, 95% CI = 1.07–1.64, *P* = 0.009) compared to those with the none-to-weak expression. Similar findings were reproduced in the liver transplantation cohort, where higher endothelial B7-H3 group was indicative of unfavorable outcomes.
Conclusion: High endothelial B7-H3 expression in HCC was associated with aggressive tumor features and poor survival outcomes. Our findings suggest that B7-H3 could serve as a potential therapeutic target in HCC.

Diagnostic accuracy of novel serum biomarkers in predicting recurrence of hepatocellular carcinoma: a systematic review and diagnostic test accuracy meta-analysis
Sean Loke[1], Benedict Ong[1], Joanna Ng[1], Eleanor Lee[1], Ryan Chiew[2], Adam Cheng[1], Jia Hao Law[1,3], Alfred Kow[1,3]. [1]*National University of Singapore, Singapore, Singapore;* [2]*National University of Singapore, Singaore, Singapore;* [3]*National University Hospital, Singapore, Singapore*
Email: e0905173@u.nus.edu

Background and aims: High recurrence rates of hepatocellular carcinoma (HCC) remain a pressing issue, with early detection crucial for timely intervention. Alpha-fetoprotein (AFP) remains the standard biomarker to monitor patients post curative treatment – however, with poor sensitivity, other novel biomarkers have been trialed with varying efficacies. This meta-analysis aims to revisit the diagnostic accuracy of AFP and evaluate the efficacy of other biomarkers including AFP-L3, Protein Induced Vitamin K Absence or Antagonist-II (PIVKA-II) and circulating tumor cells (CTCs) in detecting recurrent HCC.
Method: We conducted a PRISMA-DTA adherent meta-analysis. PubMed, Embase and Cochrane databases were searched from inception to 1 November 2024 for relevant articles. Data on test accuracies of AFP, AFP-L3, PIVKA-II and CTCs were extracted. Prespecified cutoff values for AFP were determined at 0–10 ng/mL, 10–20 ng/mL, 20–50 ng/mL 50–200 ng/mL and 200–1000 ng/mL. For AFP-L3, at 15%. For PIVKA-II, at 40 mAU/ml. For CTCs, at 15 cells. Data at each cutoff were used to calculate the number of true positives, true negatives, false positives, and false negatives. A bivariate model was used to construct summary receiver operating characteristic curves and compute area under curves (AUC), sensitivities and specificities. Meta-regression was performed to explore the influence of patient and tumor factors on pooled sensitivities and specificities.
Results: 36 studies with 6104 patients were included. Sensitivities/specificities of AFP at varying cutoffs were 62.1%/78.1% (0–10 ng/mL), 52%/80.1% (10–20 ng/mL), 65.6%/74.9% (20–50 ng/mL), 50.8%/91.5% (50–200 ng/mL) and 38.6%/83.4% (200–1000 ng/mL). The highest diagnostic accuracy was observed at 50–200 ng/mL (AUC = 0.854). For PIVKA-II, sensitivities/specificities at varying cutoffs were 63.2%/89.1% (< 40 mAU/mL) and 58.5%/82.3% (> 40 mAU/mL). The highest diagnostic accuracy was observed at <40 mAU/mL (AUC = 0.848). For AFP-L3, sensitivity/specificity were 61.6%/89% at cutoff of < 15%. For CTCs, sensitivity/specificity were 67%/79.1% at cutoff of 15 cells. Meta-regression did not reveal any significant interactions between patient and disease factors, and the results.
Conclusion: The sensitivities of biomarkers for predicting HCC recurrence remain suboptimal, with PIVKA-II emerging as a promising non-conventional biomarker. Our results should be used to guide future studies in evaluating the effectiveness of combination of biomarkers. Further studies are necessary to validate these results and develop robust clinical algorithms.

WED-097
Identification of diagnostic markers based on spectral infrared fingerprints of bile samples from endoscopic drainage of patients with biliary stenosis due to extrahepatic cholangiocarcinoma or pancreatic adenocarcinoma
Solene Adam[1], Valérie Untereiner[1], Roselyne Garnotel[1], Gerard Thiefin[1], Ganesh Sockalingum[1], Elia Gigante[1,2]. [1]*BioSpectroscopie Translationnelle (BIOSPECT) - UR 7506 - Université de Reims Champagne-Ardenne (URCA), Reims, France;* [2]*CHU Reims, Service d'Hépato-gastroenterologie et cancerologie digestive, Hôpital Robert Debré, Reims, France*
Email: egigante@chu-reims.fr

Background and aims: Bile duct strictures present a diagnostic challenge in distinguishing between benign and malignant etiologies. Malignant strictures are primarily caused by extrahepatic cholangiocarcinoma (CCK) and pancreatic cancer (PK). Histopathology and cytology of bile samples are commonly used diagnostic tools in clinical practice but suffer from low sensitivity despite high specificity. This study aimed to determine whether infrared spectral fingerprints of bile samples could effectively differentiate between malignant and benign biliary obstructions.

Method: The study analyzed 198 bile samples from patients with biliary obstruction, including 39 CCK cases, 53 PK cases, and 106 benign cases. Bile samples were obtained during therapeutic endoscopic retrograde cholangiopacreatography (ERCP). High-throughput infrared spectroscopy (FTIR) was used to analyze the samples, with eight deposits per patient on silicon plates. After spectral acquisition, aberrant spectra were excluded, and the average spectrum for each sample was computed, baseline-corrected, second-derivative transformed, and normalized. Principal Component Analysis (PCA) and Hierarchical Cluster Analysis (HCA) were employed as exploratory chemometric methods to analyze the spectral data.
Results: PCA and HCA analyses identified three distinct spectral groups: A group predominantly comprising malignant cases (20 CCK, 32 PK, and 11 benign). A group predominantly comprising benign cases (4 CCK, 0 PK, and 44 benign). An undifferentiated group (15 CCK, 21 PK, and 51 benign). Separate analyses of CCK and PK cases revealed two subgroups: one clearly distinct from benign cases and another undifferentiated. This segmentation may be attributed to cancer severity, intensity and duration of cholestasis affecting bile biochemical composition, and clinico-biological differences between CCK and PK cases.
Conclusion: This study demonstrates the potential of FTIR spectral analysis of bile samples to differentiate between benign and malignant biliary obstructions. However, advanced chemometric analyses are required to enhance diagnostic performance and facilitate the implementation of this method in clinical practice.

WED-098
Predictive microRNA panel of hepatocellular carcinoma occurrence in patients with chronic hepatitis C achieving sustained virological response after direct-acting antiviral therapy

Emanuela De Santis[1], Elisa Biliotti[2], Raffaella Lionetti[2], Alessandro Caioli[1], Fabiola Ciccosanti[3], Claudia Montaldo[3], Giulio Bontempi[1], Francesco Amadio[3], Martina Genco[1], Daniele Pietrucci[4], Giovanni Chillemi[5], Mauro Piacentini[5], Raffaele Strippoli[1], Giampiero D'Offizi[3]. *[1]Sapienza, University of Rome, Rome, Italy; [2]Division of Infectious Diseases-Hepatology, IRCCS L Spallanzani, Rome, Italy; [3]National Institute for Infectious Diseases IRCCS L. Spallanzani, Rome, Italy; [4]University of Tuscia, Viterbo, Italy; [5]University of Rome Tor Vergata, Rome, Italy*
Email: emanuela.desantis@uniroma1.it

Background and aims: Direct-acting antiviral (DAA) therapy for chronic hepatitis C virus (HCV) infection results in a sustained viral response (SVR) in over 95% of patients. However, hepatocellular carcinoma (HCC), occurs in 5–7% of cirrhotic patients who achieved SVR during the post-treatment follow-up period and predictive biomarkers have not been completely identified.
Aim of this study is to define a proteomic and microRNA (miRNA) transcriptomic profile to identify cirrhotic subjects after DAA therapy having a higher risk of developing HCC.
Method: Plasma samples were obtained from 8 cirrhotic subjects with sustained virological response (SVR) after direct-acting antiviral (DAA) treatment for HCV infection who developed HCC 1), and who did not develop HCC after therapy 2). Samples were obtained before starting DAA therapy (T0), at the end of the therapy (EOT), and three months after the end of the therapy (TF). Patients were matched for age, gender, and length of follow-up. MiRNA-sequencing and subsequent bioinformatic analysis were performed from total RNA extracted from plasma samples, while, for what concerns the proteomics analysis, LC-MS was precede by depletion and fractionation workflows to account for the large dynamic range f plasma proteins.
Results: among 794 miRNAs isolated, miR-3908 and let7-5f-5p were tendentially modulated at T0, miR-326, miR-484 and miR-98-5p were significantly modulated at EOT (p: 0,039), whereas miR-106b-5p and miR130b-3p were significantly modulated at TF (p:0,045). A survey on existing literature of gene targets from HCC patients' tumor tissues and HCC cell lines revealed that some of the identified miRNAs are potentially correlated to HCC progression. The proteomics results are currently undergoing bioinformatics analysis.
Conclusion The observation of significantly modulated miRNAs at the end of therapy and at follow-up deserves further analysis for a basic understanding of mechanisms of HCC progression as well as prognostic biomarkers.

WED-099
Insights into the GALAD Score: a new optimal cut-off for hepatocellular carcinoma

Endrit Shahini[1], Rossella Donghia[2], Sergio Coletta[2], Nicola Carella[2], Palma Aurelia Iacovazzi[2], Dolores Stabile[2], Anna Ancona[2], Caterina Bonfiglio[2], Francesca Pavone[2], Raffaele Cozzolongo[1], Erica Villa[3], Patrizia Pontisso[4], Gianluigi Giannelli[2]. *[1]Gastroenterology Unit, National Institute of Gastroenterology-IRCCS "Saverio de Bellis", 70013, Castellana Grotte (Bari), Italy; [2]National Institute of Gastroenterology-IRCCS "Saverio de Bellis", 70013, Castellana Grotte (Bari), Italy; [3]Gastroenterology Unit, CHIMOMO Department, University of Modena & Reggio Emilia, Via del Pozzo 71, 41121, Modena, Italy; [4]Department of Medicine, University of Padova; 35123, Padova, Italy*
Email: endrit.shahini@irccsdebellis.it

Background and aims: Hepatocellular carcinoma (HCC) affects 70–95% of people with chronic liver disease (CLD). Men aged 40 to 60 in Western countries, are more likely to develop HCC. Abdominal ultrasonography (US) is recommended as a semiannual screening method for patients at higher risk of HCC by various international guidelines, whereas serum alpha-fetoprotein (AFP) is inconsistently recommended. HCC surveillance could be improved by combining AFP, AFP-L3, and des-gammacarboxy prothrombin (DCP). These biomarkers, along with age and gender, were combined into an algorithm to create a GALAD score, which has a higher overall accuracy for early detection of HCC than the sum of its component biomarkers. However, no studies have established a standardized GALAD cut-off due to a lack of biomarker value comparisons between healthy people and those with cirrhosis or HCC.
Method: In this cross-sectional and multicenter Italian study with a prospective design, we examined four cohorts (n = 1411) and divided them into steadily (at two different long-term times) healthy individuals (n = 706), compensated liver cirrhosis of any aetiology (n = 511), and HCC (n = 194). These participants were drawn from an Italian historical cohort that included patients from the IRCCS "S. de Bellis" Gastroenterology Department, the University of Modena and Reggio Emilia Gastroenterology Department, and Padua University Hospital.
Results: Healthy subjects were significantly younger (50.79 ± 13.70 years) than those with cirrhosis or HCC (60.16 ± 12.03 and 67.11 ± 9.86 years, respectively). GALAD scores differed significantly between groups, with the healthy group having a lower level of −4.60 ± 1.66 compared to the values of the cirrhosis and HCC groups (−2.03 ± 2.33 and 1.06 ± 4.30, respectively). A GALAD score cut-off of −1.96 was determined, with sensitivity and specificity of 80.41% and 95.18%, respectively. Individuals with GALAD values >−1.96 have a moderate or high risk (approximately 90%) for developing HCC.
Conclusion: GALAD was the most effective score for discriminating HCC among patients with advanced CLD without HCC at a new optimal cut-off implemented for the first time in a large and "steadily healthy" population. We strongly recommend incorporating this cut-off into clinical national/international guidelines for high-risk patients undergoing HCC screening and surveillance.

WED-100

Prognostic value of a composite biomarker score for predicting overall survival in HCC patients

Francesco Damone[1], Gian Paolo Caviglia[2], Piero Colombatto[1], Filippo Oliveri, Gabriele Ricco[1], Marta Guariglia[2], Silvia Gaia[3], Veronica Romagnoli[1], Daniela Cavallone[1], Emanuela Rolle[3], Patrizia Carucci[3], Ferruccio Bonino[4], Maurizia Brunetto[1,4,5].
[1]Hepatology Unit, Pisa University Hospital, Pisa, Italy; [2]Department of Medical Sciences, University of Turin, Turin, Italy; [3]Unit of Gastroenterology, Città della Salute e della Scienza - Molinette Hospital, Turin, Italy; [4]Institute of Biostructure and Bioimagin, National Research Council, Naples, Italy; [5]Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy
Email: maurizia.brunetto@unipi.it

Background and aims: Despite advances in diagnosis and treatment of Hepatocellular Carcinoma (HCC), its management remains challanging. Tumor stage and liver function, that impact overall survival (OS), currently guide treatment algorithms. Lacking histology in most cases, serum biomarkers might provide additional insights to characterize tumor biology. Alpha-fetoprotein (AFP), Prothrombin induced by vitamin K absence-II (PIVKA-II), and glypican-3 (GPC-3) have been separately used for diagnosis and monitoring, whether their measure can better stratify survival is unknown.
Method: In this retrospective cohort 275 patients admitted at the Hepatology Unit of the Pisa University Hospital and at the Gastroenterology Unit of the Molinette Hospital, Turin with a first diagnosis of HCC had AFP, PIVKA-II, and GPC-3 measured before treatment initiation. Setting pathological cut-offs (AFP > 10 ng/mL, PIVKA-II > 200 mAU/mL, GPC-3 > 100 pg/mL) each patient received a "bio-score" based on the number of elevated biomarkers (0–3). Kaplan-Meier and Cox regression analyses were used to evaluate the relationship between the bio-score and OS.
Results: The bio-score demonstrated a significant association with OS ($p < 0.001$), with higher scores correlating with worse outcomes. Patients with a bio-score of 3 had the poorest survival, while lower scores were associated with progressively better survival rates ($p < 0.001$). We performed a multivariate analysis including bio-score and the main HCC clinical-pathological features: the bio-score emerged as an independent predictor of OS ($p = 0.027$, HR = 5.316 for score of 3), surpassing the predictive power of individual biomarkers. The other independent variables associated with OS at multivariate analysis were the BCLC stage ($p < 0.001$), the presence of ascites ($p = 0.003$), ALBI grade ($p = 0.007$) and the number of lesions ($p = 0.036$).
Conclusion: The combined use of AFP, PIVKA-II, and GPC-3 as a composite biomarker score provides superior predictive accuracy for OS in HCC patients compared to individual biomarkers. This multi-biomarker approach could offer a valuable, noninvasive prognostic tool, allowing for more personalized management of HCC patients based on survival probability. Further studies are recommended to validate this model in larger cohorts.

Email: faisalsanai@hotmail.com

Background and aims: To examine disease patterns and trends of hepatocellular carcinoma (HCC) from the MENA region, we analyzed an unselected patient (pt) population in the Middle East and North Africa (MENA) region.
Method: This retrospective, non-interventional cohort reports HCC (n = 2736) patterns in pts from Egypt, Oman, Saudi Arabia (KSA), and Turkiye from the period between Jan 2016–Dec 2023. We evaluated disease characteristics, treatment interventions, and median overall survival (mOS) assessed by Kaplan Meir analysis with survival defined as the time from diagnosis to death or last follow-up.
Results: The mean age was 66 ± 12 years, 74.7% were male, 99% were cirrhotic and 70.2% had viral etiology. HCC etiology differed across the region, with hepatitis C virus the commonest in Egypt (76%), whereas hepatitis B virus was more common in Oman (83%), Turkiye (53.9%) and KSA (26.4%). The majority presented with either advanced (BCLC 'C', 32.8%) or end-stage disease (BCLC 'D', 34.7%) or had Child-Pugh B/C (50.5%). Most frequent treatment decisions were transarterial chemo- (TACE) /radio-embolization (TARE) therapies (33.1%), followed by best supportive care (20.8%), ablative therapies (15.1%), systemic therapy (10.6%), resection (8.2%), combined therapies (6.8%) and liver transplantation (LT, 6.1%). Advanced stage (BCLC B/C) presentation was more frequent in KSA (46.6%), followed by Oman (35.6%), Egypt (33.3%), and Turkiye (27.6%), while Child-Pugh C disease was similar across the 4 countries (12.7%, 9.2%, 10.9% and 9.6%, respectively). Curative interventions (LT/resection/ablation) were most frequently undertaken in Oman (59%), followed by Turkiye (38.2%), Egypt (34.2%) and least in KSA (15.7%; $p < 0.001$), while embolization therapies (bland/TACE/TARE) were similar across the countries (34.1%, 33.3%, 33.7%, respectively; $p = 0.314$). Survival differed significantly across the countries, with the shortest mOS in KSA of 25 m (95% CI:18–32), followed by Turkiye 31 m (95% CI:27–

36), Egypt 69 m (95% CI:33–84) and Oman (not estimable; Hazard ratio 5.33 [95% CI:4.54 to 6.27] p < 0.0001).
Conclusion: Presentation of HCC differed significantly across the 4 countries of the MENA region in terms of disease etiology and characteristics, with the majority presenting in advanced stages and decompensated disease. Curative interventions were more common in Oman resulting in improved survival, while advanced stage presentation was common in KSA. Strategies to improve early diagnosis of HCC in routine care are needed across the MENA region to improve disease outcomes.

Background and aims: Patients with biliary tract cancers (BTC) often require antibiotic therapy before starting systemic treatment that includes an immune checkpoint inhibitor. This study aims to evaluate the prognostic impact of antibiotic therapy administered in the 15 days prior to the start of chemoimmunotherapy in patients with BTC.
Method: The study population included patients with metastatic or locally advanced BTC from western and eastern populations treated with first-line chemoimmunotherapy. The aim of the study is to evaluate the impact of antibiotic therapy in the 15 days prior to starting oncological treatment (AT population) compared to patients who did not receive antibiotic therapy (NAT). Univariate and multivariate analyses were used to evaluate predictive factors for overall survival (OS) and progression free survival (PFS) while prognostic factors were analyzed by univariate and multivariate analysis using Cox regression model.
Results: 666 patients were enrolled in the study: 93 (14%) in AT cohort and 573 (86%) in NAT cohort. In the AT population, the incidence of cholangitis (p = 0.0017), ALT elevation (p = 0.0009), fever (p = 0.0021), decreased appetite (p = 0.0007), itching (p = 0.0081), and rash (p = 0.012) was significantly higher compared to the NAT. The median OS was 15.9 months (95% CI 13.8–18.3) in NAT cohort vs 10.1 months (95% CI 7.9–12.4) in AT cohort (NAT vs AT, HR 0.43,95% CI 0.27–0.70–15.6 p = 0.0006) while median PFS was 8.5 months in NAT cohort vs 5.4 months in AT cohort (NAT vs AT, HR 0.49,95% CI 0.34–0.71 p = 0.0001). Multivariate analysis confirmed the prognostic role of antibiotic for OS and PFS. Finally, NAT cohort showed better overall response rate compared with AT cohort (31.4% vs 20.4%, p = 0.03).
Conclusion: The use of antibiotic therapy in the 15 days prior to starting chemoimmunotherapy is an independent unfavorable prognostic factor for survival in our cohort of patients with advanced BTC treated with cisplatin, gemcitabine and durvalumab.

WED-103
Impact of statin therapy on survival in hepatocellular carcinoma: a single-center study

Konstantinos Papantoniou[1], Efthymios Tsounis[1], Evangelia Bourdalou[1], Nikitas Kimiskidis[1], Georgios Geramoutsos[1], Ploutarchos Pastras[1], Ioanna Aggeletopoulou[1], Odysseas Ampazis[1], Georgia Diamantopoulou[1], Tryphon Spyridonidis[2], Konstantinos Katsanos[3], Konstantinos Thomopoulos[1], Christos Triantos[1]. *[1]Division of Gastroenterology, Department of Internal Medicine, Patras General University Hospital, Patras, Greece; [2]Clinical Laboratory of Nuclear Medicine, Patras General University Hospital, Patras, Greece; [3]Department of Interventional Radiology, School of Medicine, Patras University Hospital, Patras, Greece*
Email: g.papanton@yahoo.gr

Background and aims: Hepatocellular carcinoma (HCC) is the most common liver cancer. HCC incidence and mortality rates continue to rise worldwide. Statins are medications commonly used to reduce cardiovascular events. However, their anti-inflammatory effects have made them a possible option in the treatment of many diseases. The aim of this study was to assess whether statin therapy prior to HCC diagnosis had a positive impact on disease progression and patient survival.
Method: We retrospectively analyzed data regarding patients diagnosed with HCC at our center. Survival outcomes were analyzed using the Kaplan-Meier analysis, log-rank testing, and Cox proportional hazards models.
Results: A total of 136 patients (91.9% male; 36.8% active smokers) were included in our study. Patients had a median age of 67 years (IQR:59–75), BMI:26.1 kg/m² (IQR:23.7–28.7), AFP:203 ng/mL (IQR:66–1003), Child-Pugh score: 6 (IQR:5–7), and MELD-Na score:10 (IQR: 7–13). Statin treatment was prescribed to 23.5% of the patients prior to diagnosis due to elevated cardiovascular risk. At baseline, 70.6% of the patients had cirrhosis, and 25.7% had decompensated disease. Most patients had intermediate (stage B) or advanced-stage (stage C or D) HCC according to the Barcelona Clinic Liver Cancer (BCLC) staging system (stage 0: 6%, stage A: 22.4%, stage B: 45.7%, stage C: 18.1%, stage D: 7.8%). Treatment approaches included surgical hepatectomy (25.7%) transarterial chemoembolization (TACE, 47.1%), radioembolization (36%), and immunotherapy (44.5%). The median follow-up period was 24 months (IQR:8–54), with 66.2% of patients experiencing death. Kaplan-Meier analysis revealed that statin use was associated with improved survival (log-rank p = 0.041). Patients receiving statins had a median survival of 51 months (IQR: 23–124), compared to 31 months (IQR: 10–74) for those not receiving statins. In univariate Cox regression analysis, a higher BCLC stage (p < 0.001) and a higher Child-Pugh score (p = 0.002) were significantly associated with an increased risk of death, while statin use (p = 0.047) and the presence of viral hepatitis (p = 0.018) were associated with improved survival. In multivariate analysis, an advanced BCLC stage (aHR = 1.67, 95%CI:1.21–2.33, p = 0.002) and a higher Child-Pugh score (aHR = 1.24, 95%CI:1.02–1.52, p = 0.034) were independently associated with increased risk of death, whereas statin use was independently associated with improved survival (aHR = 0.37, 95%CI:0.14–0.95, p = 0.04).
Conclusion: Statin treatment prior to HCC diagnosis had a positive effect in overall patient survival. Further research is needed to determine whether statin therapy can prevent tumor progression in HCC patients, and its potential role in preventing the development of advanced chronic liver disease.

WED-104
Surrogate survival endpoint in hepatocellular carcinoma patients on first-line Atezolizumab-Bevacizumab: RECIST 1.1 vs modified RECIST

Hyo Jung Park[1,2], Won-Mook Choi[1,2], Sang Hyun Choi[1,2], So Yeon Kim[1,2]. *[1]Asan Medical Center, Seoul, Korea, Rep. of South; [2]University of Ulsan College of Medicine, Seoul, Korea, Rep. of South*
Email: happyeahj@gmail.com

Background and aims: Although modified RECIST (mRECIST) criteria have been recommended for evaluating response in hepatocellular carcinoma (HCC) patients receiving systemic therapy, the superiority of mRECIST to RECIST 1.1 is unclear. We aimed to compare the correlation of RECIST 1.1 and mRECIST with overall survival (OS) in HCC patients receiving first-line atezolizumab and bevacizumab (Atezo/Bev).
Method: This retrospective study analyzed HCC patients with at least one liver target lesion who received first-line Atezo/Bev between June 2020 and December 2022 at a tertiary center. Two radiologists evaluated responses using RECIST 1.1 and mRECIST, including best overall and target lesion responses. OS was compared by Kaplan-Meier analysis and log-rank tests. Subgroup analysis was performed for patients with liver-only target lesions.
Results: The study included 207 patients (171 men; median age, 63 years). Median OS was 10.7 months, with 152 deaths. mRECIST identified a higher overall response rate than RECIST 1.1 in all patients (44.0% vs. 16.9%) and in the 144 patients with liver-only target lesion (47.2% vs. 16.0%). Both RECIST 1.1 and mRECIST could stratify OS in all patients and in the liver-only target lesion subgroup. Multivariable analysis of this subgroup, however, found that, RECIST 1.1-based overall and target responses were independently associated with OS, while those of mRECIST were not. mRECIST-target responders

classified as RECIST 1.1-target progressors showed similar OS to target non-responders by both methods (8.1 vs. 9.1 months; p = 0.86) in the liver-only target lesion subgroup.
Conclusion: Both RECIST 1.1 and mRECIST can stratify OS in HCC patients receiving Atezo/Bev, but RECIST 1.1 is more reliable and correlates better with survival than mRECIST in patients with liver-only target lesions.

WED-106

Impact of metformin on the prevention of hepatocarcinoma in chronic hepatitis C with advanced fibrosis after sustained virologic response

Henar Calvo Sánchez[1,2,3], Lorena Jara[4], Irene Villarino[1], Ruben Alvarado[4], Marta Quiñones[4], Vanessa Díaz[5], Maria Luisa Gutiérrez, Joaquín Míquel[1,2], Miguel Torralba[2,3,6], Sonia Albertos Rubio[7], Myriam Catalá[8], José Gómez[8], Oscar Barquero-Pérez[9], Conrado Fernández- Rodríguez[4,10], Juan Ramón Larrubia[1,2,3]. *[1]Department of Gastroenterology. Rey Juan Carlos University., Alcorcón, Spain; [10]Department of Public Health and Medical Specialties. Rey Juan Carlos University., Alcorcón, Spain*
Email: juan.larrubia@uah.es

Background and aims: Metformin could show protective effects on the development of hepatocellular carcinoma (HCC) in chronic hepatitis C with advanced fibrosis after sustained virologic response (SVR) by enhancing immune response and modifying tumor metabolism. Using a Random Forest-based machine learning model, we evaluate the protective role of metformin in HCC adjusted for other HCC-associated risk factors.
Method: A Random Forest model was used for the prediction of HCC in chronic hepatitis C with advanced fibrosis after SVR. This method, based on an aggregation of binary decision trees, allows handling complex data and detecting nonlinear patterns. To interpret the importance of each variable in risk prediction, SHAP (SHapley Additive exPlanations) values were used to decompose the impact of each factor in the model. The database had 365 patients (FIB4 index > 3.25) in whom information was collected on demographic, clinical and biochemical factors, such as age, sex, smoking, alcohol consumption, clinically significant portal hypertension (CSPHT), type 2 diabetes mellitus, aspartate aminotransferase, alanine aminotransferase and platelet levels, international normalized ratio (INR), FIB4 index and metformin use. Results were compared for all patients, and subsets of patients with and without CSPHT (192 and 173 patients).
Results: The Random Forest model achieved an area under the curve of 0.72 for all patients. SHAP values revealed that factors such as increased FIB4, decreased platelet count, smoking, male sex and age have a significant impact on the development of HCC. Metformin treatment is associated with a reduced likelihood of developing HCC in patients with CSPHT. This finding suggests a possible protective effect of metformin in chronic hepatitis C with advanced fibrosis after SVR. For patients with CSPHT, the reduction in risk attributable to metformin is 8% with an OR 0.67 [0.65–0.68], while for the entire data set the attributable risk is 11% with OR 0.71 [0.70,0.73] and has little impact in those without CSPHT with attributable risk 2% and an OR 0.89 [0.88–0.90].
Conclusion: Using Random Forest, it is possible to generate predictive models of HCC development in patients with advanced fibrosis after SVR. The application of SHAP values provides a valuable tool for the clinical interpretation of complex predictive models. The results suggest that metformin could have a protective effect in those patients with FIB4 > 3.25 and CSPHT, which may be relevant for risk stratification and the development of preventive strategies. These findings may contribute to the development of personalized interventions in patients at risk of developing HCC.

Use of a cGPT 4.0, a large language model in grading the Barcelona clinic liver cancer (BCLC) prognosis for patients referred for hepatocellular carcinoma management

Jonas Ho[1], Rajit Soni[1], Chun En Yau[2], Qihuang Xie[3], Xinyan Zhou[2], Chun Yi Yau[4], Dawn Lee[5], Elaine Guan[2], Yu Bin Tan[1], Samuel Jun Ming Lim[1], Daniel Lim[1]. *[1]Department of Gastroenterology and Hepatology, Singapore General Hospital, Singapore, Singapore; [2]Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore; [3]Department of Pharmacy, National University of Singapore, Singapore, Singapore; [4]Yauchunyi5@gmail.com, S, Singapore; [5]School of Medicine, Dentistry and Nursing, University of Glasgow, Glasgow, United Kingdom, Glasgow, United Kingdom*
Email: hojonasho@gmail.com

Background and aims: Large Language Models (LLMs) such as chatGPT (cGPT) are advanced artificial intelligence models. They were developed for natural language processing and have been helpful in classifying information for medical professionals. The Barcelona Clinic Liver Cancer (BCLC) staging system is a classification system for hepatocellular carcinoma (HCC) that stratifies the prognosis for patients to guide treatment decisions; they are used frequently in multi-disciplinary meetings. We aimed to determine the feasibility of using cGPT to determine the BCLC prognostic score for patients referred to an oncology clinic for hepatocellular carcinoma management.
Method: We evaluated 98 Oncology outpatient clinic visit notes in a tertiary centre where patients were referred for Hepatocellular carcinoma. Utilising redacted clinic notes from the visit, cGPT 4.0 was used to iterate through the dataset to extract pre-determined parameters relevant to the BCLC score. A rule-based algorithm was used to summarise the results with the suggested BCLC grading. The results generated by cGPT were studied qualitatively to assess for usefulness, validity and potential limitations.
Results: Out of 98 cases, 92 cases had valid results. 80% of the patients had preserved hepatic function. Majority of the patients (68%) had been classified as BCLC C, mainly due to vascular invasion. Qualitatively, the cases were summarised succinctly with headers for tumour characteristics, hepatic function and functional performance status relevant to decision making. Limitations included a "best guess" approach taken by cGPT. Notably, only 3 out of 98 cases in the data set contained the word "encephalopathy", while preserved hepatic function was often assumed based on serology and imaging results.
Conclusion: This serves as a proof-of-concept study in utilising cGPT in guiding BCLC grading, where concise summaries aid clinical decision making. While LLMs may work as tools to assist clinicians, we must be aware of potential pitfalls relating to the interpretation of results.

WED-112

Tumor burden score as a surrogate prediction marker in patients with hepatocellular carcinoma: prognostic role of performance status

Hung-Ting Tseng[1], Shu Yein Ho[2], Teh-Ia Huo[1]. *[1]Taipei Veterans General Hospital, Taipei, Taiwan; [2]Min-Sheng General Hospital, Taoyuan, Taiwan*
Email: httseng@vghtpe.gov.tw

Background and aims: Size and number are major determinants of tumor burden in hepatocellular carcinoma (HCC). Recently, tumor burden score (TBS) was proposed to evaluate the extent of tumor involvement. On the other hand, the Eastern Cooperative Oncology Group (ECOG) performance status plays an important role in HCC treatment. However, the relationship between TBS and different performance status has not been evaluated in HCC. This study aimed to assess the role of HCC patients with different TBS and performance status.
Method: A total of 4185 treatment-naïve HCC patients were retrospectively analyzed. Multivariate Cox proportional hazards model was used to determine independent prognostic predictors.
Results: Tumor burden score tended to increase in poor performance status in study patients. There was significant survival difference between low, median and high tumor burden score in difference performance status groups (all P value< 0.001). In Cox model analyze, elderly, serum albumin <3.5 g/dL, serum bilirubin >1.1 mg/dL, serum creatinine ≥ 1.0 mg/dL, serum α-fetoprotein (AFP) level > 20 ng/mL, presence of ascites, presence of vascular invasion, performance status 1 to 2, performance status = 3 to 4, medium TBS and high TBS, were independently associated increased mortality in these patients. All P value < 0.001. In subgroup analyze of different performance status, higher tumor burden score is independently associated increased mortality in patient with ECOG = 0 and ECOG = 1–2.
Conclusion: Tumor burden score is a feasible new prognostic surrogate marker of tumor burden in HCC and can well discriminate survival in patients with different performance status.

WED-113
Targeted immunotherapy combined with TACE for conversion therapy of unresectable hepatocellular carcinoma: metabolomic biomarker insights
Yuhai Hu[1], Wenshi Ou[1], Yihao Lin[1], Tianbin Chen[1]. [1]*the First Affiliated Hospital, Fujian Medical University, Fuzhou, China*
Email:

Background and aims: Hepatocellular carcinoma (HCC), accounting for most liver cancer cases, presents significant treatment challenges when unresectable. Conversion therapy has emerged as a promising approach to downstage tumors, allowing for subsequent surgical resection. This study investigates metabolic biomarkers associated with the response to a combination therapy involving targeted immunotherapy and transcatheter arterial chemoembolization (TACE) for unresectable HCC, aiming to enhance precision in predicting therapeutic outcomes.
Method: Using untargeted metabolomics based on liquid chromatography-tandem mass spectrometry (LC-MS/MS), we analyzed serum samples from HCC patients undergoing combination therapy. We applied untargeted metabolomics analyses to identify significantly changed metabolites (SCMs). Receiver operating characteristic (ROC) analysis was conducted to evaluate the potential of key metabolites as non-invasive biomarkers for treatment response.
Results: A total of 44 significantly changed metabolites (SCMs) were identified, with 6 upregulated and 38 downregulated in patients who responded favorably to conversion therapy. The identified metabolic pathways with significant involvement include lipid metabolism, porphyrin metabolism, and arachidonic acid metabolism. ROC analysis highlighted several metabolites with high discriminatory power for predicting therapeutic responses in HCC. Among the upregulated metabolites were PC(16:0/20:4(5Z,8Z,11Z,14Z)), MG (18:1/0:0/0:0), Protoporphyrinogen, and Lys-Tyr-Ile-Glu. Downregulated metabolites included 9-OXO-11α,15S-DIHYDROXY-PROSTA-5Z,13E-DIEN-1-OIC ACID, (4-ACETYLAMINO) PHENYL ESTER, and Phe-Tyr-Gln-Lys.
Conclusion: This study identifies crucial metabolic pathways, particularly involving lipid and porphyrin metabolism, associated with the efficacy of combination therapy in downstaging HCC. The findings offer valuable insights into metabolic markers that may facilitate personalized treatment approaches and enhance conversion therapy outcomes in unresectable HCC.

WED-114
Outcome in patients with liver cirrhosis and hepatocellular carcinoma : comparing MRI and ultrasound for HCC surveillance
Jasper van Leengoed[1], Laura Boer[1], Job van der Palen[2], Donald Bouman[3], Maureen Guichelaar[1]. [1]*Department of Gastroenterology and Hepatology, Medisch Spectrum Twente, Enschede, Netherlands;* [2]*Department of Epidemiology, Medisch Spectrum Twente, Enschede, Netherlands;* [3]*Department of Radiology, Medisch Spectrum Twente, Enschede, Netherlands*
Email: maureenguichelaar@yahoo.com

Background and aims: Hepatocellular carcinoma (HCC) represents the fifth most prevalent malignancy globally, predominantly affecting patients with liver cirrhosis. International guidelines recommend bi-annual screening by ultrasound (US), although MRI has shown better sensitivity to detect small HCC lesions (< 2 cm). In 2018, HCC surveillance protocol changed at the study institution from a bi-annual US screening to annual MRI-based HCC surveillance protocol. The aim of this retrospective study was to compare patient outcomes in patients with HCC who underwent either MRI or US screening.
Method: Consecutive patients with liver cirrhosis who developed HCC between 2009 and 2023 at a single institution (MST) in the Netherlands were selected for analyses. All radiologic reports were evaluated, in addition to demographic and disease-specific data, and treatment and survival outcomes. The MRI surveillance protocol included T1 in and out of phase, T2, diffusion weighted and contrast enhanced imaging (abbreviated MRI protocol). In case of dysplastic noduli (LIRADS L3 and L4), MRI surveillance changed from an annual to a bi-annual screening module.
Results: Sixty-one patients with liver cirrhosis who subsequently developed HCC were included in this study; 29 (48%) patients underwent US screening (US-HCC) and 32 (52%) MRI screening (MRI-HCC). There were no significant differences at baseline between US-HCC and MRI-HCC patients, including MELD score (mean ± SD: 9.8 ± 3.6), child-pugh score (6.2 ± 1.3) and decompensation events (in 25 (41%) patients). The mean radiologic surveillance period was 3.83 ± 2.95 years before HCC. Annual screening frequencies were 2.28 ± 1.40 MRI/yr in MRI-HCC patients and 1.82 ± 0.64 US/yr in US-HCC patients (NS). MRI screening led to increased detection of dysplastic noduli ($p < 0.01$) as seen in 24 (75%) of 32 MRI-HCC patients. At time of HCC diagnosis, MRI-HCC patients had smaller HCC lesions than US-HCC patients (20.3 ± 10.5 mm versus (26.0 ± 12.7 mm, $p < 0.01$) and lower AFP values (8.27 ± 10.93 μg/l, versus 33.14 ± 67.96 μg/l, $p < 0.01$). A greater number of curative treatment options were observed in the MRI-HCC patients (MRI-HCC: 22 (69%), versus US-HCC: 15 (52%), $p = 0.88$). Overall, the benefits of MRI screening resulted in improved patient survival in MRI-HCC patients when compared to US-HCC patients after HCC diagnosis (i.e. at 1 year; 91% versus 68%, and at 5 year 62% versus 12%, $p < 0.001$).
Conclusion: Our study findings suggest clear clinical benefit of MRI screening when compared to US screening for HCC detection in cirrhotic patients, reflected by smaller HCC lesions at diagnosis, improved treatment options and prolonged patient survival. These study findings warrant further investigation to facilitate MRI screening as a routine diagnostic tool for patients with liver cirrhosis.

Differential gene expression in hepatocellular carcinoma: a bioinformatic approach to correlate with HIF1A
Jennifer Martínez-Geijo[1], Tania Payo-Serafín[1], Carolina Méndez-Blanco[1], Beatriz San-Miguel[1], Andrés García-Palomo[2], Juan José Ortiz-de-Urbina[3], José Luis Mauriz[1]. [1]*Institute of biomedicine (IBIOMED), Universidad de León, León, Spain;* [2]*Institute of biomedicine (IBIOMED), Universidad de León, Service of Medical Oncology, Complejo Asistencial Universitario de León (CAULE),*

Hospital of León, León, Spain; [3]Institute of biomedicine (IBIOMED), Universidad de León, Pharmacy service, Complejo Asistencial Universitario de León (CAULE), Hospital of León, León, Spain
Email: jemag@unileon.es

Background and aims: Hepatocellular carcinoma (HCC) is the most common primary liver cancer and has one of the highest mortality rates worldwide. The hypoxic microenvironment contributes to treatment resistance and a more aggressive tumor phenotype. The cellular response to hypoxia is primarily regulated by hypoxia-inducible factor 1 alpha (HIF-1 alpha), which plays a crucial role in diverse tumoral processes. We aimed to identify differentially expressed genes (DEGs) in human HCC samples, examine their association to these tumor-related processes, and assess their potential correlation with HIF1A and the survival outcomes of HCC patients.
Method: We identified key tumor processes involving HIF1A, comparing its expression in HCC samples and analyzing its impact on overall survival (OS) in HCC patients. A screening of gene expression profiles from tissue samples of HCC patients in the National Center for Biotechnology Information (NCBI) Gene Expression Omnibus (GEO) database resulted in 149 datasets. Thus, 54 provided general data on HCC samples, and after screening by gene expression data, 37 datasets were selected. Despite that 17 of them focused on tumor vs. non-tumor HCC samples, only 13 included gene symbols and were analyzed with GEO2R tool. Three datasets with the highest number of DEGs were selected for their functional analysis using GeneCards database and a Venn diagram, followed by research of the relationship between DEGs and HIF1A by TNMplot, and their association with the OS of HCC patients through Kaplan-Meier plotter.
Results: TNMplot database showed a significant increase in HIF1A expression in tumor vs. non-tumor HCC samples. Kaplan-Meier plotter database revealed a significant association between HIF1A overexpression and reduced OS in HCC patients, linked to angiogenesis, energy metabolism, and immune evasion. Analysis of the three gene expression profiles selected indicated that 10, 160 and 38 DEGs in HCC samples were respectively involved in the above processes, where the correlation with HIF1A was particularly strong. Finally, Kaplan-Meier OS analysis demonstrated that overexpression of 5 DEGs most correlated with HIF1A was associated with HCC prognosis, according to their positive or negative connection with HIF1A.
Conclusion: HIF-1 alpha is related to a worse prognosis in HCC patients. Its functional importance in angiogenesis, energy metabolism and immune evasion makes this factor a crucial therapeutic target for future treatments.

WED-116

Statin and its effects on hepatocellular carcinoma risk and liver fibrosis in chronic liver disease

Jonggi Choi[1,2], Vy Nguyen[3], Eric Przybyszewski[2], Jiunn Song[2], Allison Carroll[2], Megan Michta[2], Erik Almazan[4], Tracey Simon[2], Raymond Chung[2]. *[1]Asan Medical Center, Seoul, Korea, Rep. of South; [2]Massachusetts General Hospital, Boston, United States; [3]Harvard Medical School, Boston, United States; [4]Brigham and Women's Hospital, Boston, United States*
Email: chung.raymond@mgh.harvard.edu

Background and aims: Hepatocellular carcinoma (HCC) incidence is rising globally, driven by metabolic and alcohol-related liver diseases. Statins may mitigate liver fibrosis progression, a key precursor to HCC, through anti-inflammatory and antifibrotic mechanisms. This study evaluated the association between statin use and risks of HCC and hepatic decompensation, with an emphasis on liver fibrosis progression.
Method: A historical cohort study was conducted using the Research Patient Data Registry (2000–2023), including 15,525 adults aged ≥40 years with chronic liver disease (CLD) and baseline FIB-4 scores ≥1.45. The cohort comprised 3,146 statin users and 12,379 nonusers. Statin use was defined as ≥30 cumulative defined daily doses (cDDDs). Outcomes included 10-year cumulative incidence of HCC and hepatic decompensation, as well as liver fibrosis progression, defined as a ≥25% sustained increase in FIB-4 score from baseline. Inverse probability treatment weighting method was applied for covariate adjustment, and competing risks were addressed using subhazard ratios (aSHRs) for comparison of the HCC risk between statin users and nonusers.
Results: Statin users had significantly lower 10-year cumulative incidence of HCC (4.8% vs. 9.3%; risk difference [RD], −4.5%; 95% CI, −5.7 to −3.2) and hepatic decompensation (12.9% vs. 23.1%; RD, −9.9%; 95% CI, −11.8 to −8.0). Statin use was associated with a 42% reduction in HCC risk (aSHR, 0.58; 95% CI, 0.40–0.83) and a 28% reduction in hepatic decompensation risk (aSHR, 0.72; 95% CI, 0.62–0.84). Among 9,403 patients with serial FIB-4 data, statin users showed significantly lower fibrosis progression rates (59.9% vs. 64.6%, $p < 0.001$) and stable FIB-4 scores, while nonusers exhibited significant increases. These effects were more pronounced among patients with advanced fibrosis. Lipophilic statins demonstrated greater reductions in HCC risk compared to hydrophilic statins.
Conclusion: Statin use, particularly lipophilic statins and longer durations of therapy, is associated with reduced risks of HCC and hepatic decompensation in patients with CLD. These benefits are likely mediated by attenuation of fibrosis progression, suggesting a potential role for statins as chemopreventive agents in liver disease.

WED-117

Challenges and adherence to hepatocellular carcinoma screening program in patients with advanced chronic liver disease

Email: luismiguelnevessilva@gmail.com

Background and aims: Hepatocellular carcinoma (HCC) is a major global health issue among patients with Advanced Chronic Liver Disease (ACLD). International guidelines recommend biannual ultrasound (US) screening for HCC in cirrhotic patients classified as Child-Pugh (CP) A and B, as well as those listed for transplant with CP C. However, global adherence to screening programs remains low. This study aims to assess adherence to HCC screening among patients with ACLD, identify factors contributing to non-adherence, quantify the diagnostic yield of HCC screening, and evaluate the impact of adherence on early detection of HCC.

Method: This retrospective observational cohort study included adult patients with ACLD consulted during the year of 2022 at a tertiary hospital's Liver Unit in Portugal. Patients with an ECOG performance status of ≥ 3, CP C patients not eligible for liver transplant, patients with a previous diagnosis of liver cancer or metastatic liver disease, and those under personalized surveillance for previously identified liver nodules were excluded. Adherence to screening was defined as having two imaging tests within an interval of 150 to 210 days. Adherence rates, reasons for non-adherence, and the incidence of HCC during one year of screening were analyzed.
Results: A total of 621 patients were included for analysis after applying the inclusion and exclusion criteria. The global adherence rate to HCC screening was 54.8%, with a median interval between screening events of 189 days among adherent patients. In the remaining sample, hospital-related factors (41.6%), patient-related factors (29.9%), and hepatologist-related factors (28.5%) were identified as primary barriers to adherence. Lack of social/family support significantly increased the likelihood of non-adherence. However, the adherence rate among hepatologists was 87.1%. During US screening, 77 patients were identified with liver nodules, of which 20.8% (n = 16) were confirmed as HCC. Most HCC cases (10 out of 16) were confirmed after computed tomography (CT) scan, although 25 out of 60 patients who underwent CT required additional tests for clarification (22 magnetic resonance imaging; 3 biopsy). Despite higher odds for earlier BCLC stages at diagnosis among adherent cases, statistical significance was not achieved.
Conclusion: This study underscores the challenges in achieving optimal adherence to HCC screening among patients with ACLD. Factors related to the hospital, hepatologist, and the patient contribute to non-adherence. Addressing these barriers by improving hospital administrative processes, implementing alerts for attending hepatologists, providing patient reminders, and educating patients for the benefits of screening, is crucial. The overall adherence rate and the high adherence from the attending hepatologists in our study highlight the benefits of follow-up in dedicated liver units.

WED-118-YI
Shifting etiologies and emerging metabolic factors of hepatocellular carcinoma from 2005 to 2020: a german nationwide population-based study

Josune Cabello Calleja[1], Wenyi Gu[1,2,3], Robert Schierwagen[1], Maximilian Joseph Brol[1], Frank Erhard Uschner[1], Florian Rennebaum[1], Sara Noemi Reinartz Groba[1], Michael Praktiknjo[1], Jonel Trebicka[1,4,5]. *[1]Department of Internal Medicine B, University Hospital Muenster, Muenster, Germany; [2]Department of Gastroenterology, Ren Ji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China; [3]Department of Internal Medicine I, University Hospital Frankfurt, Goethe University Frankfurt, Frankfurt, Germany; [4]European Foundation for Study of Chronic Liver Failure, Bercelona, Spain; [5]Department of Gastroenterology and Hepatology, Odense University Hospital, Odense, Denmark*
Email: josune.cabello@ukmuenster.de

Background and aims: Hepatocellular carcinoma (HCC) is the most frequent primary malignant liver disease and it is associated with complications that ultimately lead to a high mortality rate. Liver cirrhosis represents the main risk factor for HCC development. However, the underlying etiologies of liver cirrhosis have shifted in the last decade. Therefore, in this German population-based study, we aimed to assess the effects of the changing etiological trends on HCC.
Method: 393,230 admissions of patients with HCC from 2005 until 2020 were included using the diagnosis-related-groups (DRG) system based on ICD and OPS codes. We focused concretely on the investigation of underlying etiologies and cardiometabolic risk factors associated with HCC development, as well as the all-cause in-hospital mortality rate of these patients. Trends were analyzed using linear regressions or Mann-Whitney U-tests.
Results: The number of recorded admissions of patients with HCC increased significantly during the last 16 years, rising by 21.8% from 19,594 in 2005 to 23,861 in 2020. However, the overall in-hospital mortality rate of these patients decreased notably from 13.4% in 2005 to 10.5% in 2020.
The most common underlying etiology in admissions with HCC was alcohol-related liver disease (ALD), accounting for 55.5% from HCC etiologies. Among non-alcoholic etiologies, viral hepatitis was the most prevalent (32.3%), followed by metabolic dysfunction-associated steatohepatitis and steatotic liver disease (MASH/MASLD), which represented 4.5% of etiologies. Notably, during the observed period patients with MASH/MASLD exhibited an increase of 3.7-fold in hospital admissions, the strongest growth among all etiologies. Additionally, admissions of patients with ALD raised by 22.8%, from 4,008 in 2005 to 4,921 in 2020, while their in-hospital mortality rate was reduced by 23.0%. In contrast, viral hepatitis showed a significant decrease in admissions, from 3,532 in 2005 to 1,580 in 2020, along with a 7.3% reduction in in-hospital mortality rate. Throughout the observational period, all cardiometabolic risk factors showed a significant increase in patients with HCC ($p < 0.001$). Remarkably, arterial hypertension, cardiac insufficiency, and dyslipidemia appeared to be significantly more associated with a higher risk of HCC diagnosis in non-cirrhotic admissions. Furthermore, HCC patients exhibited a greater burden of metabolic comorbidities compared to those with other malignancies.
Conclusion: This nationwide study highlights the increasing prevalence of ALD, MASLD and metabolic risk factors in patients admitted with HCC. Especially, metabolic risk factors seem to play a significant role as drivers of HCC development, even in absence of cirrhosis, emphasizing the need to specifically address these factors in future investigations.

Increasing prevalence of hepatocellular carcinoma in the Netherlands: changing etiologies, tumor characteristics and survival rates

Koen van Son[1], Kirsi van Eekhout[1], Judith de Vos-Geelen[2], E.T.T.L. Tjwa[3], Joep de Bruijne[4], Dave Sprengers[5], Minneke Coenraad[6], Frederike van Vilsteren[7], Joost PH Drenth[1], Otto van Delden[1], A.G. (Onno) Holleboom[1], Maarten Tushuizen[6], Lydia van der Geest[8], R. Bart Takkenberg[1]. *[1]Amsterdam UMC, Amsterdam, Netherlands; [2]Maastricht UMC, Maastricht, Netherlands; [3]Radboudumc, Nijmegen, Netherlands; [4]UMC Utrecht, Utrecht, Netherlands; [5]Erasmus MC, Rotterdam, Netherlands; [6]LUMC, Leiden, Netherlands; [7]UMCG, Groningen, Netherlands; [8]IKNL, Utrecht, Netherlands*
Email: k.c.vanson@amsterdamumc.nl

Background and aims: Hepatocellular carcinoma (HCC) represents a major health problem with its causes shifting from viral to non-viral, particularly metabolic dysfunction-associated steatotic liver disease (MASLD). This study aimed to 1) investigate the etiology, tumor characteristics and survival rate of HCC in the Netherlands, and 2) study the association of screening and tumor characteristics and survival rates.
Method: Consecutive patients registered with a newly diagnosed HCC from 2014–2021 in the Netherlands Cancer Registry (NCR) were included. Data was gathered by trained registration clerks approximately nine months after diagnosis. Data on screening was available from January 2017 onward.
Results: Between 2014 and 2021 (n = 5,821), HCC diagnoses in the Netherlands increased 1.5-fold, with MASLD-related HCC increasing 2.43-fold. Cirrhosis was absent in 24.3% of patients overall and 14.8% of patients with MASLD-related HCC. Cirrhosis status was unregistered in many cases (27.8 and 14.8%, respectively). Overall median survival duration was 304 (IQR: 71–844) days. Multivariable Cox regression analysis showed better survival for patients with MASLD-related HCC compared to alcoholic liver disease (ALD)-related (HR: 0.70, 95% CI: 0.62–0.79) and for patients without cirrhosis compared

to with cirrhosis (HR: 0.81, 95% CI: 0.73–0.90). Between 2017 and 2021, 14.1% was diagnosed through screening. Screened patients had smaller tumor diameters (28 (IQR: 20–43) vs. 74 (IQR: 40–116) mm) and better survival probability (HR: 0.60, 95% CI: 0.52–0.69) than those presenting with disease complaints.
Conclusion: The prevalence of HCC is increasing in the Netherlands, partly driven by MASLD. Overall survival is poor but patients with MASLD-related HCC and those without cirrhosis have better survival probability. Patients diagnosed through screening had smaller tumors and better survival probability.

WED-120-YI
Machine learning-based survival analysis and risk stratification for patients with cholangiocarcinoma
Chun-Ting Ho[1], Tzu-Han Ma[2], Yu-Jen Chen[3], Ming-Huang Chen[4], Yi-Hsiang Huang[3], Ming-Chih Hou[3], Jaw-Ching Wu[5], Chien-Wei Su[1]. *[1]Division of General Medicine, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan; [2]School of Medicine, College of Medicine, National Yang Ming Chiao Tung University, Taipei, Taiwan; [3]Division of Gastroenterology and Hepatology, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan; [4]Department of Oncology, Taipei Veterans General Hospital, Taipei, Taiwan; [5]Institute of Clinical Medicine, School of Medicine, National Yang Ming Chiao Tung University, Taipei, Taiwan*
Email: cwsu2@vghtpe.gov.tw

Background and aims: To identify prognostic factors for patients with cholangiocarcinoma (CCA) and assess the performance of novel machine learning (ML)-based survival analysis models in predicting outcomes and stratifying risk.
Method: A total of 693 treatment-naïve CCA patients diagnosed at Taipei Veterans General Hospital from 2014 to 2022 were retrospectively analyzed. Patients were randomly divided into a training cohort (n = 485) and a validating cohort (n = 208). The primary endpoint was overall survival (OS). Non-invasive biomarkers and image features obtained at diagnosis were analyzed using a Cox proportional hazards model to identify independent prognostic factors. Prognostic models were developed in the training cohort using Extreme Gradient Boosting (XGBoost), Random Survival Forest (RSF), Decision Tree (DT), and Logistic Regression (LR). Model performance was validated in the validation cohort and compared based on predictive parameters (accuracy, precision, recall and F1-score) and AUROC. Shapley Additive Explanations (SHAP) were used to identify key predictors in the ML-based models. Kaplan-Meier (KM) survival analysis was performed to validate the ability of the models to stratify patient risk groups.
Results: After a median follow-up of 33.0 months (interquartile range 29.6–36.4 months), 480 patients had died, with a 5-year OS rate was 12.0%. Independent risk factors for OS included advanced tumor stage, intrahepatic CCA, lack of treatment, non-surgical modalities, prothrombin time international normalized ratio (PT INR), serum cancer antigen 19–9 (CA 19–9) levels, serum gamma-glutamyl transpeptidase (GGT) levels, albumin-bilirubin (ALBI) grade, and fibrosis-4 (FIB-4) grade. Among the models, RSF demonstrated the best performance in predicting OS (AUROC 0.791, 95% CI: 0.717–0.865), outperforming XGBoost, DT, and LR. SHAP analysis highlighted surgery, advanced tumor stage, absence of treatment, serum GGT, and CA 19–9 levels as the top five predictors in the RSF model. KM survival analysis confirmed the RSF model's robust ability to stratify patients into distinct risk groups ($p < 0.001$).
Conclusion: Machine learning-based survival analysis, particularly the Random Survival Forest, provided accurate prognostic predictions and risk stratification for CCA patients. These tools could support individualized treatment planning and optimize disease management strategies.

WED-121
Comparison of clinical characteristics, risk factors and prognosis of HCC patients with lean and non-lean MASLD undergoing surgical resection
Chun-Ting Ho[1], Hao-Jan Lei[2], Gar-Yang Chau[2], Chia Jung Ho[1], Yi-Chen Lin[1], Yi-Hsiang Huang[3], Ming-Chih Hou[4], Jaw-Ching Wu[5], Chien-Wei Su[1]. *[1]Division of General Medicine, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan; [2]Division of General Surgery, Department of Surgery, Taipei Veterans General Hospital, Taipei, Taiwan; [3]Healthcare and Service Center, Taipei Veterans General Hospital, Taipei, Taiwan; [4]Division of Gastroenterology and Hepatology, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan; [5]Institute of Clinical Medicine, School of Medicine, National Yang Ming Chiao Tung University, Taipei, Taiwan*
Email: cwsu2@vghtpe.gov.tw

Background and aims: Lean and non-lean metabolic dysfunction-associated steatotic liver disease (MASLD) exhibit distinct pathophysiological mechanisms and clinical characteristics, potentially affecting the prognosis of patients with concurrent hepatocellular carcinoma (HCC) differently. This study aimed to evaluate and compare outcomes and risk factors associated with overall survival (OS) and recurrence-free survival (RFS) in HCC patients with lean and non-lean MASLD undergoing surgical resection.
Method: This retrospective study included 410 HCC patients with MASLD who underwent surgical resection at Taipei Veterans General Hospital between 2016 and 2022. Patients were classified into lean MASLD and non-lean MASLD groups based on a BMI cutoff of 23 kg/m². Baseline demographics, serum biochemistry, imaging features at diagnosis, and pathological data from hepatectomy specimens were analyzed. Cox proportional hazards models were used to identify prognostic factors for OS and RFS. Kaplan-Meier survival analyses were performed to compare outcomes of the two cohorts.
Results: Lean MASLD patients exhibited smaller tumor sizes, lower serum albumin levels, higher fibrosis-4 (FIB-4) scores, and less fatty change in the non-tumorous liver compared to non-lean MASLD patients. After a median follow-up of 60.4 months, 79 patients had died, and 168 patients had HCC recurrence. The 5-year OS rates were 66.9% for lean MASLD and 79.4% for non-lean MASLD ($p = 0.150$), with no significant difference in RFS between groups ($p = 0.809$). Independent risk factors for poor OS in the lean MASLD group included lower serum albumin levels and larger tumor size. In the non-lean MASLD group, additional factors such as FIB-4, histological grade, and the presence of steatohepatitis significantly impacted OS. For RFS, prothrombin time international normalized ratio (PT INR), serum aspartate aminotransferase (AST), alpha-fetoprotein (AFP) levels, and microscopic small vessel invasion were significant prognostic factors in the lean MASLD group, while alanine aminotransferase (ALT), tumor number, Ishak modified histology activity index (HAI) score, and microscopic small vessel invasion were significant in the non-lean MASLD group.
Conclusion: HCC patients with lean and non-lean MASLD who underwent surgical resection demonstrated distinct clinical and pathological features, with different prognostic factors for poor OS and RFS. Despite these differences, the long-term outcomes in terms of OS and RFS were comparable between the two groups.

WED-123
Prognostic significance of neutrophil-to-lymphocyte and platelet-to-lymphocyte ratios in hepatocellular carcinoma: a retrospective multicentre study on overall survival following hepatectomy or orthotopic liver transplantation
Konstantinos Arvanitakis[1], Spyridon Pantzios[2], Chrysanthos Christou[3], Vasileios Papadopoulos[4], Orestis Sidiropoulos[2], Georgios Katsanos[3], Ioannis Elefsiniotis[2], Georgios Tsoulfas[3], Georgios Germanidis[1]. *[1]Division of Gastroenterology and Hepatology, First Department of Internal Medicine, AHEPA University Hospital, Aristotle University of*

Thessaloniki, Thessaloniki, Greece; [2]Academic Department of Internal Medicine-Hepatogastroenterology Unit, General Oncology Hospital of Kifissia, National and Kapodistrian University of Athens, Athens, Greece; [3]Department of Transplantation Surgery, Hippokration General Hospital, School of Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece; [4]Laboratory of Anatomy, Medical School, Democritus University of Thrace, Alexandroupolis, Greece
Email: geogerm@auth.gr

Background and aims: Local and systemic inflammation are recognized as hallmarks of cancer, playing a critical role in the pathogenesis and progression of hepatocellular carcinoma (HCC). Inflammatory markers such as the neutrophil-to-lymphocyte ratio (NLR) and platelet-to-lymphocyte ratio (PLR) have emerged as potential prognostic indicators in HCC patients undergoing hepatectomy or liver transplantation. This study aimed to evaluate the prognostic significance of NLR and PLR in predicting overall survival (OS) among patients with HCC treated with either hepatectomy or orthotopic liver transplantation (OLT).
Method: We conducted a multicentre retrospective cohort study involving 74 individuals diagnosed with HCC (64 males; 86.5%). The mean age at diagnosis was 62.3 ± 10.2 years, with a mean MELD-Na score of 9.3 ± 15.9. A viral etiology was identified in 42 HCC patients (56.8%). Of the participants, 48 (64.9%) underwent hepatectomy, and 26 (35.1%) met the Milan criteria and received OLT. Baseline and longitudinal parameters were evaluated as potential prognosticators of overall survival (OS) using Cox proportional-hazards regression, both unadjusted and adjusted for surgical procedures (hepatectomy and transplantation), and BCLC stages (0/A vs. B/C). The performance of binary classifiers was analyzed using ROC curves. Repeated-measures ANOVA was applied to compare longitudinal data. Statistical analyses were conducted with SPSS 26.0.
Results: The most prominent predisposing factor for HCC development was chronic HBV infection, affecting 33 patients (44.6%), followed by MASH-related HCC (N = 21, 28.4%). At diagnosis, most patients had a very early (BCLC stage 0) or early stage (BCLC stage A) HCC (48 cases; 64.9%). The overall 30-day mortality rate was 8.1%. The pre-surgery PLR was a significant prognosticator for Clavien-Dindo classification ≥ 3 complications (AUROC: 0.667; 95% CI: 0.516–0.817; p = 0.030). Unlike NLR (p = 0.182), the PLR demonstrated significant variability over the first 12 months after surgery (p < 0.001). The NLR was a significant prognostic factor for OS after adjustment for surgical procedure and BCLC stage when measured 3 (HR: 1.294; 95% CI: 1.041–1.608; p = 0.020), 6 (HR: 1.410; 95% CI: 1.108–1.794; p = 0.005), and 12 (HR: 1.612; 95% CI: 1.205–2.158; p = 0.001) months post-surgery. The PLR measured 12 months post-surgery was also a significant prognostic factor for OS after adjustment for surgical procedure and BCLC stage (HR: 1.008; 95% CI: 1.002–1.005; p = 0.012).
Conclusion: Higher 3-, 6-, and 12-months post-surgery NLR and 12 months post-surgery PLR were independently associated with a substantially increased risk of shorter OS. These findings underscore the potential use of NLR and PLR in clinical decision-making as biomarkers for risk stratification and outcome prediction in HCC management, warranting further investigation in prospective studies.

WED-124
National burden of MASH-related liver cancer in the United States 1990–2021: a systematic analysis for trends and patterns of geographic variations of the global burden of disease study

Seung Up Kim[1], Beom Kyung Kim[1], Jae Seung Lee[1], Hye Won Lee[1], Mi Na Kim[1], Jun Yong Park[1], Do Young Kim[1], Sang Hoon Ahn[1]. *[1]Yonsei University, Seoul, Korea, Rep. of South*
Email: ksukorea@yuhs.ac

Background and aims: The epidemiology of metabolic dysfunction associated steatohepatitis (MASH)-related liver cancer has changed remarkably in recent past decades. We systematically reported temporal trends of disease burden from MASH-related liver cancer in the United States (U.S.) from 1990 to 2021.
Method: By the Global Burden of Disease (GBD) 2021 Study Database, we examined the incidence, mortality rate, and the disability-adjusted life-years (DALYs) of MASH-related liver cancer at a national and state level and age- and sex-specific disease burden.
Results: In the U.S., the incidence of MASH-related liver cancer showed a significant rise from 1990 to 2021; in 2021, there were 3,381 cases, representing a 371.6% increase since 1990, with an age-standardized incidence rate of 0.58 per 100,000 population. DALYs from MASH-related liver cancer rose by 324% to 59,666 in 2021, and deaths increased by 324.1% to 2,799. Geographically, Hawaii had the highest age-standardized incidence, DALY, and mortality rates, while Texas had the lowest. Oklahoma showed the largest increase in these rates since 1990. The age-standardized incidence of MASH-related liver cancer was higher in males than in females, with the highest incidence in individuals aged 85–89, DALYs peaking in those aged 75–79, and highest mortality in those aged 90–94 for both sexes. High fasting plasma glucose was a significant risk factor, contributing to 35.6% of DALYs in males and 32.5% in females, with smoking also contributing 11.8% in males and 8.9% in females.
Conclusion: The disease burden of MASH-related liver cancer has significantly increased so far, necessitating vigorous intervention for at-risk patients.

WED-125
The Liver Frailty Index predicts survival in hepatocellular carcinoma: an australian multicentre prospective cohort study (APriCa study)

Leo Ye[1], Karen Waller[2], Martin Weltman[3], Simone Strasser[4], Ken Liu[4], Geoff McCaughan[5], Cameron Gofton[5], Miriam Levy[6], Jacob George[7], Mark Danta[1,8]. *[1]School of Clinical Medicine, St Vincent's Healthcare Clinical Campus, Faculty of Medicine and Health, UNSW Sydney, Darlinghurst, Sydney, Australia; [2]Concord Hospital, Concord, Sydney, Australia; [3]Nepean Hospital, Nepean, Sydney, Australia; [4]Royal Prince Alfred Hospital, Camperdown, Sydney, Australia; [5]Royal North Shore Hospital, St Leonards, Sydney, Australia; [6]Liverpool Hospital, Liverpool, Sydney, Australia; [7]Westmead Hospital, Westmead, Sydney, Australia; [8]St Vincent's Hospital, Darlinghurst, Sydney, Australia*
Email: leo.ye@student.unsw.edu.au

Background and aims: Frailty assessments have demonstrated promise in stratification of prognosis in cirrhosis, however prospective studies in hepatocellular carcinoma (HCC) are limited. We aimed to determine frailty characteristics of individuals with newly diagnosed HCC using the Liver Frailty Index (LFI).
Method: A multicentre prospective observational cohort study was conducted across seven hospitals in Sydney. LFI testing using hand grip strength, time to perform five chair stands and three position balance (side by side, semi-tandem, tandem) was performed, generating a continuous score and also classifying participants as robust (LFI < 3.2), pre-frail (LFI 3.2–4.4) or frail (LFI ≥ 4.5). The relationship between frailty, overall survival (OS) and Barcelona Clinic Liver Cancer (BCLC) parameters were compared.
Results: Among 93 individuals (82% male; median age 71.0 years (interquartile range (IQR) 65.0–76.0), LFI class identified n = 24 (26%) as frail, n = 64 (69%) as pre-frail and n = 5 (5%) as robust. The median follow-up was 7.0 months (IQR: 5.0–13.5). Frailty was associated with older age, metabolic dysfunction-associated steatotic liver disease and allocation to management with palliative intent. Poorer Eastern Cooperative Oncology Group score was weakly correlated with LFI score (Kendall rank correlation coefficient = 0.21, p = 0.013). LFI score was independently associated with death (adjusted hazard ratio (aHR) = 2.38, (95% CI: 1.15–4.91, p = 0.019) when adjusted for BCLC stage and alpha-fetoprotein (AFP) level. Likewise, LFI class was a significant predictor of death on multivariable analysis when adjusted for BCLC stage and AFP level including in subgroup analysis of frail vs pre-frail individuals (aHR = 3.73, 95%CI: 1.38–10.10, p =

0.034). The 6-month mortality rates for robust, pre-frail and frail individuals were 0%, 19% and 38% respectively. LFI score was a fair predictor of 6-month survival (area under the curve = 0.67, 95%CI: 0.53–0.81, p = 0.045). The maximum value of Youden's index was utilised to evaluate the optimal LFI cut-off, calculated to be LFI = 3.91 (sensitivity = 88%, specificity = 57%). At this cut-off 43 individuals (64%) were more frail with a 6-month survival of 67% compared to the 24 individuals (36%) less frail whom had a 6-month survival of 92%. The log-rank test showed individuals more frail than this cut-off displayed significantly poorer 6-month survival (p = 0.036). The model of BCLC stage and AFP level had a Harrell's C concordance statistic of 0.73 in predicting survival compared to the model with BCLC stage, AFP level and LFI score with a concordance statistic of 0.79. The likelihood ratio test highlighted a significant difference between these models (p = 0.005).

Conclusion: Frailty is prevalent in this cohort. The LFI is an independent predictor of death in HCC. The addition of the LFI to current BCLC staging may improve the prediction of survival.

WED-126-YI

Treatment of hepatocellular carcinoma according to multiparametric therapeutic hierarchy approach: a prospective multicenter validation study

Massimo Iavarone[1,2], Lorenzo Canova[1,3], Eleonora Alimenti[1], Anna Maria Ierardi[4], Pierpaolo Buondetti[4], Barbara Antonelli[5], Mariangela Bruccoleri[1], Angelo Sangiovanni[1], Pietro Lampertico[1,2]. *[1]Division of Gastroenterology and Hepatology, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]CRC 'A. M. and A. Migliavacca' Center for Liver Disease, Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy; [3]Università degli Studi di Milano, Milan, Italy; [4]Radiology Department, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [5]General and Liver Transplant Surgery Unit, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy*
Email: lorenzo.canova27@gmail.com

Background and aims: Treatment strategy of hepatocellular carcinoma (HCC) is a complex decision-making process that considers several variables in clinical practice. A "multiparametric therapeutic approach" has been proposed (*Lancet Oncol* 2023): the feasibility of all treatments is evaluated systematically in a hierarchical order, to match each patient with the optimal therapy. The aim of the study is to validate the reliability of the new multiparametric decisional framework (MPDF) and the impact of the several variables on the final treatment decision in clinical practice.

Method: This is a prospective ongoing study. Primary endpoints are: 1) adherence to MPDF for treatment allocation, 2) identification of the relative weight of variables involved in this MPDF for treatment decision, while secondary endpoints are overall survival and radiological response after treatment. The study includes all consecutive patients with HCC managed in our center from September 1st, 2023. The disease is staged according to Barcelona Clinic Liver Cancer (BCLC) classification, while patient's characterization is conducted by Charlson Comorbidity Index (CCI), Liver Frailty Index (LFI), skeletal muscle mass index by CT, Child-Pugh (CPT) and ALBI and MELD. Each patient is allocated to treatment according to MPDF, BCLC 2022 as the benchmark.

Results: As September 1st, 2024, 131 patients were recruited into the study [median age 69 (39–92) years, 74% male, 36% HCV, 37% first treatment for HCC]. Twenty-four (18%) patients were classified BCLC 0, 48 (36%) A, 21 (16%) B, 31 (23.6%) C and 7 (5.3%) D. The median CCI was 8 (4–15), the median LFI was 3.92 (2–5.95). One hundred and seven (81.6%) patients were in CPT class A, 17 (13%) in B and 4 (3%) in C, while 90 (68.7%) were classified ALBI grade 1 and 38 (29%) ALBI grade 2. The median MELD score was 8 (6–22). According to the MPDF, 15 (11.5%) patients were allocated to liver transplant, 6 (4.6%) to laparoscopic surgical resection, 33 (25.2%) to microwave thermal ablation (MWTA), 26 (19.8%) to transarterial treatments (17 TACE and 9 TARE), 6 (4.6%) to other locoregional therapies (5 MWTA+TACE and 1 electrochemotherapy), 32 (24.4%) to systemic treatment and 6 (4.6%) to palliative care only. In 6 cases, the MDT decided for reassessment at 3 months. Treatment allocation was coherent to the BCLC 2022 recommendations in 83% BCLC 0, 77% BCLC A, 90% BCLC B, 80% BCLC C and 71% BCLC D.

Conclusion: Preliminary data of our ongoing prospective study suggest that personalized approach for HCC treatment by MPDF is feasible in clinical practice and might help ensuring a customized approach in a standardized framework. Updated data will be presented at the meeting.

WED-131

Low FIB-4 in multinational hepatocellular carcinoma cohort

Zhenning Yu[1], Margaret Teng[2], Cheng Han Ng[3], Anand Kulkarnl[4], Ken Liu[5], Karn Wijarnpreecha[6,7], Beom Kyung Kim[8,9], Mark Muthiah[3,10], Sung Won Lee[11], Gang Chen[12], Takumi Kawaguchi[13], Hirokazu Takahashi[14], Daniel Huang[3,10]. *[1]Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore; [2]National University Health System, Singapore, Singapore; [3]National University Hospital, Singapore, Singapore; [4]Asian Institute of Gastroenterology, Hyderabad, India; [5]Royal Prince Alfred Hospital, Sydney, Australia; [6]Banner University Medical Center, Arizona, United States; [7]University of Arizona College of Medicine, Arizona, United States; [8]Yonsei University College of Medicine, Seoul, Korea, Rep. of South; [9]Yonsei Liver Center, Severance Hospital, Seoul, Korea, Rep. of South; [10]National University of Singapore, Singapore, Singapore; [11]Catholic University of Korea, Seoul, Korea, Rep. of South; [12]The First Affiliated Hospital of Wenzhou Medical University, Wenzhou, China; [13]Kurume University School of Medicine, Kurume, Japan; [14]Saga University Hospital, Saga, Japan*
Email: daniel_huang@nus.edu.sg

Background and aims: The fibrosis-4 index (FIB-4) is recommended as one method to risk stratify people with chronic liver disease. However, it is unclear what proportion of people with hepatocellular carcinoma (HCC) have a low FIB-4. We aimed to assess the proportion of people with HCC of various etiologies who have a low FIB-4.

Method: This cohort study included 1,778 consecutive adults (26% female) with hepatocellular carcinoma (HCC) from seven international centers in Australia, India, Japan, South Korea, Singapore, and the United States. The primary objective was to determine the proportion of patients with a low FIB-4 for each etiology, defined as FIB-4 <1.45 for hepatitis B virus (HBV)- or hepatitis C virus (HCV)-related HCC, and FIB-4 <1.3 (<2.0 for Age >65) for metabolic dysfunction-associated steatotic liver disease (MASLD)- or alcohol-associated HCC.

Results: The median (IQR) age and body mass index were 73 (66–82) and 25.6 (22.3–28.0) kg/m^2. The median FIB-4 was 5.09 (2.60–9.96), and 952 (55%) had known cirrhosis. A total of 138 patients (8%) had a low FIB-4. 952 patients (55%) had known cirrhosis. The proportion of people with HBV-, HCV-, alcohol-, and MASLD-related HCC who had a low FIB-4 were 11%, 2%, 3%, and 11%, respectively. A low FIB-4 was associated with lower odds of receiving HCC surveillance (p = 0.002) but increased odds of receiving curative treatment (p = 0.002). After adjusting for confounders, a low FIB-4 was associated with lower mortality (adjusted HR 0.54, 95% CI 0.38–0.76).

Conclusion: The majority of people with alcohol- and HCV-related HCC have an elevated FIB-4, however, one in ten with HBV- and MASLD-related HCC have a low FIB-4.

WED-132

Serologic and immunologic biomarkers for the identification of patients with hepatocellular carcinoma with high tumour burden and poor survival

Marta Guariglia[1], Silvia Gaia[2], Francesca Saba[1], Emanuela Rolle[2], Maria Lorena Abate[1], Chiara Rosso[1], Angelo Armandi[1,3], Patrizia Carucci[2], Elisabetta Bugianesi[1,2], Gian Paolo Caviglia[1].

[1]Department of Medical Sciences, University of Torino, Turin, Italy; [2]Gastroenterology Unit, Città della Salute e della Scienza—Molinette Hospital, Turin, Italy; [3]Metabolic Liver Disease Research Program, Department of Medicine, University Medical Center Mainz, Mainz, Germany
Email: gianpaolo.caviglia@unito.it

Background and aims: The prognosis of patients with hepatocellular carcinoma (HCC) closely correlates with liver disease stage and tumour burden at diagnosis. However, no biomarker reflecting HCC behaviour and aggressiveness is currently available for patients' prognostication. Therefore, we investigated the prognostic value of selected immunologic (interleukin [IL]-6, IL-8, and IL-10) and serologic (alpha-fetoprotein [AFP], protein induced by vitamin K absence or antagonist II [PIVKA-II], and glypican-3 [GPC-3]) biomarkers in patients with HCC.
Method: A total of 285 patients (median age: 68, IQR 60–75 years; males: 231, 81.1%; HCV/MASLD: 130/155) with a new diagnosis of HCC were retrospectively enrolled. Most patients had an early-stage HCC (BCLC: 0/A, n = 184, 64.6%); patients with BCLC stage D were excluded from the analysis. Serum IL-6, IL-8, and IL-10 were measured at HCC diagnosis by multiplex immunoassays (Bio-Plex® 200, Bio-Rad, USA), AFP and PIVKA-II by CLEIA (Lumipulse® G600 II, Fujirebio, Japan), and GPC-3 by EIA (Fujirebio Diagnostics AB, Sweden). Literature cut-offs were used for biomarkers' dichotomization. The primary end-point was overall survival (OS).
Results: Patients' median OS was 32.9 (95%CI 29.0–47.7) months. At univariate analysis, all biomarkers were associated with OS. IL-6 > 4.28 pg/mL: HR = 1.97, 95%CI 1.37–2.83; IL-8 > 17.60 pg/mL: HR = 2.20, 95%CI 1.40–3.44; IL-10 < 1.00 pg/mL: HR = 1.62, 95%CI 1.08–2.43; AFP > 20 ng/mL: HR = 2.27, 95%CI 1.59–3.26; PIVKA-II > 200 mAU/mL: HR = 2.59, 95%CI 1.78–3.76; and GCP-3 > 150 pg/mL: HR = 1.61, 95%CI 1.10–2.35. Remarkably, the biomarkers' combination allowed stratifying patients into 3 risk categories with different OS: 0–2 biomarkers+ (mortality: 31/115, 27%; median OS: 58.9, 95%CI 48.9–109.5 months), 3–4 biomarkers+ (mortality: 60/125, 48%; median OS: 28.5, 95%CI 22.9–35.1 months), and 5–6 biomarkers+ (mortality: 31/45, 69%; median OS: 11.6, 95%CI 6.4–17.3) (Log-rank test: p < 0.001). This multi-parameter model was significantly associated with OS (aHR = 2.20, 95%CI 1.68–2.86) independently from BCLC stage (aHR = 1.96, 95%CI 1.59–2.42).
Conclusion: In patients with HCC, the combination of serologic and immunologic biomarkers may provide prognostic information and contribute to personalized treatment strategies. *Project PNC 0000001 D[3] 4 Health, The National Plan for Complementary Investments to the NRRP, funded by the European Union – NextGenerationEU.*

WED-133
A machine learning model to predict the treatment response of atezolizumab plus bevacizumab in patients with hepatocellular carcinoma incorporating computed tomogram-derived imaging biomarkers

Moon Haeng Hur[1], Bo Hyun Kim[2], Byeong Geun Song[3], Dong Hyun Sinn[3], Youngsu Park[2], Yuri Cho[2], Jeayeon Park[1], Yunmi Ko[1], Hyunjae Shin[1], Yun Bin Lee, Eun Ju Cho[1], Su Jong Yu[1], Yoon Jun Kim[1], Jung-Hwan Yoon[1], Jeong-Hoon Lee[1]. [1]*Seoul National University College of Medicine, Seoul, Korea, Rep. of South;* [2]*National Cancer Center Korea, Goyang, Korea, Rep. of South;* [3]*Sungkyunkwan University School of Medicine, Seoul, Korea, Rep. of South*
Email: pindra@empal.com

Background and aims: Despite the growing number of patients receiving atezolizumab plus bevacizumab (Atezo/Bev) for hepatocellular carcinoma (HCC), reliable models to predict treatment response in advance remain lacking. We aimed to develop machine learning models that can predict objective response (complete or partial response) after Atezo/Bev therapy incorporating clinical data and imaging biomarkers derived from abdominal computed tomography (CT).
Method: A total of 500 consecutive patients with HCC who received Atezo/Bev as a first-line systemic therapy between 2020 and 2023 were included from 3 referral centers in Korea. Blood test results, including alpha-fetoprotein (AFP) and protein induced by vitamin K absence-II (PIVKA-II), were collected right before initiating Atezo/Bev and at the first imaging follow-up visit, 6–9 weeks after the first therapy. In patients with available imaging biomarkers derived from baseline CT (n = 389), seven additional biomarkers were obtained using a deep learning-based CT auto-segmentation software: volume of abdominal visceral fat, muscle, liver, and spleen; total fat-to-trunk volume ratio; liver and muscle Hounsfield unit (HU). Patients were randomized 1:1 to either the training or test cohorts and gradient boosting machine algorithm was employed to develop the models.
Results: During a median follow-up of 9.6 (interquartile range [IQR] = 5.7–14.2) months, 129 patients (25.8%) achieved objective response. Model 1 was developed using eight clinical variables: MoRAL score ($2x\sqrt{AFP} + 11x\sqrt{PIVKA\text{-}II}$), ALBI score, neutrophil-to-lymphocyte ratio (NLR), and eosinophil count at the first imaging follow-up and change in these variables from baseline. This model demonstrated an area under the receiver operating characteristic curve (AUROC) of 0.748 (95% confidence interval [CI] = 0.764–0.812) in the training cohort and 0.747 (95% CI = 0.679–0.809) in the test cohort. Model 2, which incorporated seven imaging biomarkers in addition to clinical variables, showed improved predictive accuracy in both the training (0.789, 95% CI = 0.717–0.862) and test cohorts (0.769, 95% CI = 0.691–0.839).
Conclusion: Using the clinical data and CT-derived imaging biomarkers, these machine learning-based models can predict response and help determine future treatment plans in advance for HCC patients receiving Atezo/Bev therapy.

WED-134
Age differences in the association between alcohol consumption and risk of hepatocellular carcinoma: a nationwide cohort study

Mi Na Kim[1,2,3], Kyungdo Han[4], Jae Seung Lee[1,2,3], Hye Won Lee[1,2,3], Beom Kyung Kim[1,2,3], Seung Up Kim[1,2,3], Jun Yong Park[1,2,3], Do Young Kim[1,2,3], Sang Hoon Ahn[1,2,3]. [1]*Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Korea, Rep. of South;* [2]*Institute of Gastroenterology, Yonsei University College of Medicine, Seoul, Korea, Rep. of South;* [3]*Yonsei Liver Center, Severance Hospital, Seoul, Korea, Rep. of South;* [4]*Department of Statistics and Actuarial Science, Soongsil University, Seoul, Korea, Rep. of South*
Email: minakim@yuhs.ac

Background and aims: The role of age in modulating the association between alcohol consumption and the risk of HCC has not yet been cleared. Accordingly, we aimed to investigate the dose-response association between alcohol consumption and subsequent risk of HCC according to age.
Method: We included 4,234,445 individuals age ≥ 20 years who underwent a national health examination in 2009. Cox proportional hazards regression models were used to investigate the dose-response association of alcohol consumption with the risk of HCC according to age.
Results: Among 3,869,084 participants, 18,444 patients were newly diagnosed with HCC during a median follow-up period of 11.3 years. When stratified by 20-year age groups, increasing alcohol consumption was significantly associated with an increased risk of HCC in the ≥ 60 age group compared to no alcohol consumption (*P* for trend < 0.0001), whereas no significant association was found in the 20–39 and 40–59 age groups (*P* for trend = 0.725 for 20–39 age group; *P* for trend = 0.0501 for 40–59 age group). Heavy alcohol consumption was significantly associated with an increased risk of HCC in the 40–59, and ≥ 60 age groups, with this risk trend showing a progressive

increase as age advanced (aHR, 1.11; 95% CI, 1.05–1.18 for the 40–59 age group, and aHR, 1.47; 95% CI, 1.38–1.57 for ≥ age group).
Conclusion: In conclusion, our findings suggest that age is a critical factor when considering the risks of alcohol consumption on the development of HCC.

WED-135-YI
Metabolic response to locoregional treatment for hepatocellular carcinoma measured by 18F-FDGal PET/CT
Mona Kristiansen[1], Kirstine Bak-Fredslund[1,2], Stine Kramer[3], Gerda Elisabeth Villadsen[1], Michael Sørensen[1,4]. *[1]Department of Hepatology & Gastroenterology, Aarhus University Hospital, Aarhus, Denmark; [2]Department of Gastroenterology & Hepatology, Aalborg University Hospital, Aalborg, Denmark; [3]Department of Nuclear Medicine & PET Centre, Aarhus University Hospital, Aarhus, Denmark; [4]Department of Internal Medicine, Viborg Regional Hospital, Viborg, Denmark*
Email: mk.kristiansen1@gmail.com

Background and aims: Research on liver function before and after locoregional treatment for hepatocellular carcinoma (HCC), apart from surgical resection, is nearly nonexistent. This study aimed to use positron emission tomography (PET) with the liver-specific tracer [^{18}F]-fluoro-2-deoxy-D-galactose (^{18}F-FDGal) to explore the contribution of hepatocellular carcinomas to total metabolic liver function and to investigate the liver's regenerative potential to locoregional treatments for HCC.
Method: The study included 29 patients with an ^{18}F-FDGal PET/CT scan 0–40 days before locoregional treatment for HCC with surgical resection (n = 8), radiofrequency ablation (RFA) (n = 8), selective internal radiation therapy (SIRT) (n = 4), or transarterial chemoembolization (TACE) (n = 9) and an ^{18}F-FDGal PET/CT scan 31–147 days after the treatment. The total and mean metabolic activity in tumors larger than 3 cm in diameter and in liver tissue exempt from tumors larger than 3 cm in diameter were calculated before and after locoregional treatment as the percentage of the injected dose of ^{18}F-FDGal (%ID) and the percentage of the injected dose of ^{18}F-FDGal divided by the functional volume (%ID/L).
Results: In patients with tumors larger than 3 cm in diameter, the total metabolic activity of the liver was significantly higher when including the tumor compared to the surrounding liver tissue without the tumor ($p = 0.0002$). The median percent change in mean metabolic activity in the liver after locoregional treatment for patients without cirrhosis was 5.1%, compared to –6.0% for patients with cirrhosis ($p = 0.05$). After treatment, seven of the eight patients who underwent resection showed increased or stable mean metabolic liver function, while responses for those treated with RFA, SIRT, or TACE were mixed.
Conclusion: HCCs larger than 3 cm in diameter contribute substantially to the liver's galactose metabolism. The regenerative response in the liver to locoregional treatment is decreased in patients with cirrhosis, and the type of locoregional treatment seems to impact the response.

Email: mreig1@clinic.cat

Background and aims: The efficacy of immunotherapy may be influenced by the gut microbiome. Primary aim was to study the role of proton-pump inhibitors, antibiotics and gut microbiome composition on survival in patients with hepatocellular carcinoma under immunotherapy.
Method: This is an exploratory analysis of a multicenter phase I/IIa trial of patients with hepatocellular carcinoma treated with the regorafenib and nivolumab in second line. Fecal samples were collected before starting nivolumab and profiled by 16S ribosomal RNA sequencing. Main outcome was overall survival.
Results: Median age of the 40 patients analyzed was 65.4 years, 82.5% male, 60% with cirrhosis, all ECOG-PS-0 and 62.5% in BCLC-C stage. Twenty received proton-pump inhibitors before immunotherapy and 12 antibiotics within the 12 months prior to treatment start. Cox regression analysis showed that, BCLCpC2 (HR 3.0, 95%CI 1.1–8.3), AFP> 400 (HR 2.7, 95%CI 1.1–6.5), obesity (HR 3.1, 95%CI 1.2–7.8) and proton-pump inhibitors (HR 3.0, 95%CI 1.1–8.3) were associated with higher risk of death. Use of antibiotics within 12 months lowered mortality risk (HR 0.3 95%CI 0.1–0.99). After IPTW analysis and adjustment for confounders, proton-pump-inhibitors use (HR 4.4, 95%CI 1.6–12.1) was associated with higher risk of death. Multivariate analysis including microbiome profile showed that higher abundance of Streptococcaceae, Gemellaceae, Sutterellaceae and Synergistaceae families was associated with higher risk of death. Proton-pump-inhibitors use was associated with higher abundance of Streptococcaceae and lower abundance of Lachnospiraceae.

Conclusion: Use of proton-pump inhibitors and gut microbiome composition are associated with survival in hepatocellular carcinoma patients under immunotherapy. The use of this class of drug should be avoided in the absence of a mandatory indication.

WED-137-YI

Hepatocellular carcinoma after liver transplantation: development of a machine learning-based risk score for safely ruling out recurrence

Pedro Passos[1,2], José Ossian Campos Neto[2], Luiz Alberto de Freitas Júnior[2], Ryan Ribeiro[2], Paulo Garcia Costa[2,3], Clebia de Lima[2,3], Gabriel Gomes de Araújo[2], Danilo Avancini Viana[2], Rodrigo Motta[4], Arthur Menezes da Silva[2], Mateus Mendes Santos Freire[2], Angel Evangelista Barroso Magalhães[2], Elodie Hyppolito[3,5], Gustavo Rego Coelho[2,3], José Huygens Parente Garcia[2,3,6]. *[1]Centre of Research and Drug Development (NPDM), Federal University of Ceara, Fortaleza, Brazil; [2]Department of Surgery, Federal University of Ceará, Fortaleza, Brazil; [3]Walter Cantídio University Hospital, Fortaleza, Brazil; [4]Translational Gastroenterology and Liver Unit, University of Oxford, Oxford, United Kingdom; [5]Postgraduate Program in Public Health, Federal University of Ceará, Fortaleza, Brazil; [6]Postgraduate Program in Pharmacology, Federal University of Ceará, Fortaleza, Brazil*
Email: pedropassos@alu.ufc.br

Background and aims: Hepatocellular carcinoma (HCC) is one of the leading causes of cancer-related mortality, with liver transplantation (LT) being a definitive treatment for select patients. Traditional prognostic models often fail in effectively ruling out the risk of post-LT recurrence. Screening for recurrence is costly and exposes the individuals to radiation. No standardized criteria for ruling out recurrence exists. We propose a machine learning-derived risk model that aims to improve the ability to rule out this risk.
Method: We conducted a retrospective cohort study at a single reference center, including patients with HCC who underwent LT between 2004 and 2024. Missing data were addressed using multiple imputation by chained equations. The dataset was randomly divided into a training set (70%) and a testing set (30%). Using elastic net regularization, we developed a model to identify key variables and evaluate their discriminative power. Three receiver operating characteristic (ROC) curves were constructed to predict 3-, 5-, and 10-year relapse-free survival (RFS), with the area under the curve (AUC) calculated and non-zero coefficients identified. Using these coefficients, we created a risk score and categorized patients into "high risk" and "low risk", using a threshold that maximized sensitivity with acceptable specificity in the training subset. We used Kaplan-Meier estimates to yield the relapse probability at time-points. Finally, a univariate Cox proportional hazards (PH) regression analysis was performed, adjusting for the newly developed risk score.
Results: A total of 424 HCC patients which underwent LT were included. From the input variables, the elastic net model identified five predictors with non-zero coefficients: age at LT, MELD score (pre-LT), the diameter of the largest nodule (pre-LT), Barcelona Clinic Liver Cancer staging, and the presence of microvascular invasion on the explant. Using these predictors, a risk score was developed, categorizing 214 patients as "low-risk" and 210 patients as "high-risk." The AUC for 3-, 5-, and 10-year RFS on the validation cohort was 0.717 for all. Using the optimal threshold, the positive predictive value and negative predictive value of the risk score for 5-year RFS were 7.2% and 99.5% in the whole cohort, respectively, with a sensibility of 93.8%. In the low-risk group, the relapse probabilities were 0% at 3, 5, and 10 years. In the high-risk group, the relapse probabilities were 10.4% at 3 years, 14% at 5 years, and 20.8% at 10 years. Low- and high-risk groups had significantly different RFS at all assessed time-points ($p < 0.001$). In the univariate Cox PH regression, low-risk patients had a relapse hazard ratio of 0.05 (95% confidence interval: 0.01–0.35) compared to high-risk patients.
Conclusion: Our risk score exhibited outstanding performance in ruling-out HCC recurrence post-LT. This model could be used to guide post-LT monitoring and follow-up strategies, ensuring that low-risk patients benefit from less frequent monitoring.

Somatic copy number alterations in circulating cell-free DNA as a predictive biomarker for hepatocellular carcinoma: insights from a proof-of-concept study

Elisa Pinto[1], Elisabetta Lazzarini[1], Filippo Pelizzaro[1], Martina Gambato[1], Laura Santarelli[1], Sara Potente[1], Paola Zanaga[1], Teresa Zappitelli[1], Romilda Cardin[1], Patrizia Burra[1], Fabio Farinati[1], Valeria Tosello[1], Stefano Indraccolo, Francesco Paolo Russo[1].
[1]University od Padua, Padua, Italy
Email: pintoelisa93@gmail.com

Background and aims: Despite improvements in hepatocellular carcinoma (HCC) management, its prognosis remains poor. Diagnosis at advanced stages often precludes curative treatment options, and currently available biomarkers (e.g., alpha-fetoprotein (AFP)) offer limited utility in early diagnosis and prognostic stratification. Liquid biopsy has emerged as a promising tool for early HCC detection and prognostic evaluation, and the analysis of circulating cell-free DNA (ccfDNA) hold significant potential as a diagnostic tool. This proof-of-concept study aimed to investigate the potential role of tumor fraction (TF) within ccfDNA as a biomarker in HCC patients.
Method: A total of 60 patients were recruited, including 13 with chronic liver disease (CLD), 24 with cirrhosis, and 23 with HCC. Plasma samples were collected, and ccfDNA was extracted for genomic analysis. TF was calculated by focusing on somatic copy number alterations (SCNAs) within the ccfDNA.
Results: In patients with CLD and cirrhosis (n = 37), circulating tumor DNA (ctDNA) was undetectable with the exception of one cirrhotic patient, who presented a significant TF (17%) and displayed HCC shortly after. Conversely, 5 out of 22 HCC patients (21.7%) exhibited detectable ctDNA, with TF levels ranging from 3.0% to 32.6%. Patients with higher TF levels were characterized by more aggressive disease features, including elevated AFP levels, larger tumor sizes, multiple tumor nodules, and advanced-stage disease.
Conclusion: Preliminary evidence from this study suggests that the analysis of TF, specifically through the detection of SCNAs, could serve as a promising non-invasive tool for the identification and evaluation of HCC. The innovative approach has the potential to significantly enhance early diagnosis and may also improve prognostic stratification in HCC patients.

WED-139

Evaluating the performance of large language models at hepatobiliary tumor boards: a prospective study

Robert Oehring[1,2], Sharlyn S.T. Ng[1], Nikitha Shruthi Ramasetti[1], Axel Winter[1], Max Magnus Maurer[1], Johann Pratschke[1], Felix Krenzien. *[1]Department of Surgery, Campus Charité Mitte and Campus Virchow-Klinikum, Charité-Universitätsmedizin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, Berlin, Germany; [2]Department of Surgery, Harzklinikum D.C. Erxleben, Quedlinburg, Germany*
Email: robert.oehring@charite.de

Background and aims: The growing use of artificial intelligence in daily life and clinical practice raises questions about the reliability of large language models (LLMs) in medical contexts. The objective of this study is to ascertain the reliability and reproducibility of recommendations provided by different LLMs in comparison to those of a multidisciplinary team meeting (MDM) for liver tumors.
Method: A prospective study was carried out on 102 cases with hepatocellular carcinoma (HCC) and cholangiocarcinoma (CCC) who were presented to the hepatobiliary MDM at Charité – Universitätsmedizin Berlin between April and October 2024. The analysis was conducted using the LM Studio software. The following

LLMs were utilized: Phi-3-Mini-4k (Phi), Llama 3.1 8B Instruct (Llama), Mistral-7B-Instruct-v0.2 (Mistral), Qwen 1.5 (Qwen), and Gemma. The LLMs recommendations were subjected to an evaluation process in which they were compared to the MDM recommendations. The following categories were subjected to comparison: surgery (resection; liver transplantation), intervention, systemic therapy, and surveillance (follow-up; diagnostic; best supportive care).

Results: The overall concordance rates (CR) for the LLMs were as follows: 57.8% for Phi, 61.8% for Llama, 60.8% for Mistral, 55.9% for Qwen, and 32.4% for Gemma. In the case of HCC, LLM yielded the following CR: For Phi, Llama, Mistral, Qwen, and Gemma the CR were 59.1%, 52.2%, 56.8%, 38.6%, and 18.2%, respectively. The CR for CCC were as follows: For Phi, Llama, Mistral, Qwen, and Gemma 56.9%, 61.5%, 63.8%, 69%, and 27.6%, respectively. For Qwen the CR was significantly associated with tumor entity $p = 0.002$. The CR of the remaining LLMs was found to be independent of the tumor entity. Llama demonstrated the highest CR (73.3%) when surgery was recommended. The CR for intervention was lower overall, with Llama and Mistral, achieving the highest rates (57.1%). When systemic therapy was recommended, Qwen demonstrated the most favorable outcomes, with a CR of 71.9%. The CR for surveillance was notably lower, with Mistral demonstrating the greatest accuracy (63.6%). We also investigated whether LLMs recommendations differed based on timing of MDM presentation before or after therapy. Despite low agreement rates, LLMs distinguished between the two and adjusted recommendations accordingly. For example, favoring surgery pre-therapeutic and systemic therapies post-therapeutic, a pattern seen across all LLMs ($p < 0.001$).

Conclusion: The overall CR between MDM and the examined LLMs for HCC and CCC are notably low. These results were somewhat more favorable for CCC. In conclusion, the reviewed LLMs do not appear to be suitable for MDM recommendations in complex treatment decisions for HCC and CCC. It would be beneficial to conduct a review of additional models or potential optimization processes for the LLMs in question.

WED-140

Liver function and tumor stage determines adherence to tumor board recommendation in HCC

Robert Oehring[1,2], Fabian Jänick[1,3], Sharlyn S.T. Ng[1], Lena Kreidler[1], Can Kamali[1], Dominik Geisel[4], Uwe Pelzer[5], Dominik Modest[5], Matthäus Felsenstein[1], Wenzel Schöning[1], Raphael Mohr[6], Johann Pratschke[1], Ulrich Keilholz[7], Felix Krenzien. *[1]Department of Surgery, Campus Charité Mitte and Campus Virchow-Klinikum, Charité-Universitätsmedizin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, Berlin, Germany; [2]Department of Surgery, Harzklinikum D.C. Erxleben, Quedlinburg, Germany; [3]Department of Gastroenterology and Hepatology University Hospital Zurich, Zurich, Switzerland; [4]Department of Radiology, Charité-Universitätsmedizin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, Berlin, Germany; [5]Department of Hematology, Oncology and Cancer Immunology, Campus Virchow-Klinikum, Charité-Universitätsmedizin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, Berlin, Germany; [6]Department of Hepatology and Gastroenterology, Campus Charité Mitte and Campus Virchow-Klinikum, Charité-Universitätsmedizin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, Berlin, Germany; [7]Charité Comprehensive Cancer Center, Charité-Universitätsmedizin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, Berlin, Germany*
Email: robert.oehring@charite.de

Background and aims: The range of treatment options for Hepatocellular carcinoma (HCC) is extensive and requires diligent assessment during multidisciplinary tumor board meetings (MDM). It has been demonstrated that patients with HCC who are discussed in MDMs have superior outcomes. Nevertheless, a considerable number of patients do not receive the recommended therapy. The objective was to evaluate the extent to which the stage of a liver disease has influence on adherence to MDM recommendations.

Method: The analysis is a retrospective, single-center study of patients with HCC whose cases were presented to the hepatobiliary MDM at Charité - Universitätsmedizin Berlin between January 2014 and December 2018. A total of 1164 cases from 643 patients were analyzed. Adherence and the potential influence of indicators for liver disease were examined. Moreover, a survival analysis was conducted.

Results: Overall adherence rate was 82.7%. The five-year survival rate was significantly higher for the adherent group across all BCLC stages (0-A, B, C, D) than in the non-adherent group (BCLC 0-A, $p = 0.05$; BCLC B, $p = 0.04$; BCLC, C $p < 0.001$; BCLC D, $p = 0.001$). Patients with good liver function (ALBI 1 and ALBI 2a) showed no significant difference in five-year survival probability between the adherent and non-adherent groups. In contrast, for patients with poorer liver function (ALBI 2b and ALBI 3), the difference in survival probabilities was highly significant, with the adherent cohort demonstrating significantly higher five-year survival rates (both ALBI 2b and ALBI 3, $p < 0.001$). Adherence was found to be significantly influenced by Child-Pugh score $p < 0.001$. Also compliance was significantly influenced by tumor stage, measured by the following parameters: distant metastases ($p < 0.001$), BCLC stage ($p = 0.004$) and tumor size ($p = 0.02$). Poor liver function also showed a significant decrease in overall survival (OS) with Hazard Ratio (HR) 1.41 (95% CI 1.02–1.94; $p = 0.04$) for ALBI 2b and HR 2.34 for ALBI 3 (95% CI 1.48–3.68; $p < 0.001$). Also highly significant effects on OS were seen for metastasis (HR 3.06, 95% CI 1.99–4.72; $p \leq 0.001$) and portal vein invasion (HR 3.12, 95% CI 1.97–4.95; $p \leq 0.001$) as well as for higher alpha-fetoprotein levels which were also associated with shorter OS (HR 1.8, 95% CI 1.37–2.46; $p \leq 0.001$).

Conclusion: Adherence to MDM recommendations has the potential to enhance patient survival. It is noteworthy that adherence is influenced by liver function and tumor stage in patients with HCC.

WED-141

MicroRNA profiling of hepatocellular carcinoma can improve the prediction of tumor recurrence after liver resection

Robin Zenlander[1,2,3], Ghada Nouairia[1], Sonia Shtembari[4,5], Daniel Hagey[6], Olof Danielsson[4,5], Mikael Bjornstedt[4,5], Stefan Gilg[1], Gosta Eggertsen[1,2,3], Hugh Salter[4], Per Stal[1,7]. *[1]Department of Medicine, Huddinge, Karolinska Institutet, Stockholm, Sweden; [2]Division of Clinical chemistry, Department of Laboratory Medicine, Karolinska Institutet, Stockholm, Sweden; [3]Department of Clinical chemistry, Karolinska University Hospital, Stockholm, Sweden; [4]Division of Pathology, Department of Laboratory Medicine, Karolinska Institutet, Stockholm, Sweden; [5]Department of Clinical Pathology and Cancer Diagnostics, Karolinska University Hospital, Stockholm, Sweden; [6]Division of Biomolecular and Cellular Medicine, Department of Laboratory Medicine, Karolinska Institutet, Stockholm, Sweden; [7]Division of Hepatology, Department of Upper GI diseases, Karolinska University Hospital, Stockholm, Sweden*
Email: robin.zenlander@ki.se

Background and aims: Hepatocellular carcinoma (HCC) diagnosed at an early stage may undergo liver resection with curative intent.[1] However, the 2-year recurrence rate after HCC resection can be up to 34%, even under optimal conditions.[2] Currently, reliable biomarkers for accurately predicting recurrence are lacking. In this study, we evaluated whether the microRNA (miRNA) profile in HCC tissue was associated with HCC recurrence after liver resection.

Method: Patients undergoing liver resection for HCC were prospectively included. At surgery, HCC tissue samples were snap-frozen for subsequent identification and quantification of their miRNA profiles using RNA sequencing. Clinical and histopathological parameters including 2-year recurrence, circulating plasma levels of alpha-fetoprotein (AFP), tumor size, microvascular invasion, resection margin, and satellite lesions were obtained from medical records.

The miRNA expressions were compared between HCCs from patients with and without recurrence within 2 years. Differential expression analysis and Lasso regression were used to select different panels of miRNAs. Using logistic regression, the ability to predict recurrence was tested for clinical and histopathological parameters, alone and in combination with miRNAs. Results were validated in an external cohort from The Cancer Genome Atlas (TCGA).

Results: A total of 67 patients had complete data and were included in the study. Four clinical and histopathological parameters (AFP, tumor size, microvascular invasion, satellite lesions) could differentiate between recurrence and no recurrence with an AUC of 0.715. Ten miRNAs were differentially expressed in HCCs from patients with and without a 2-year recurrence. The addition of these miRNAs to the clinical and histopathological parameters significantly increased the AUC to 0.824 (p = 0.02), a result which was confirmed when the same analysis was carried out in the TCGA cohort (n = 161 cases with complete data). Lasso regression obtained a 14-miRNA panel which alone had an AUC of 0.867, however results could not be verified in TCGA.

Conclusion: The miRNA profile in HCC tissue can improve the ability of clinical and histopathological parameters to predict HCC recurrence after liver resection. However, further studies are required to identify the optimal miRNA panel.

Email: ryanlimyanzhe21@gmail.com

Background and aims: The etiologies of hepatocellular carcinoma (HCC) are changing. It is unclear if the beneficial impact of surveillance for HCC remains consistent given the changing epidemiology of HCC. We evaluated the impact of HCC surveillance on a large contemporary cohort of people with HCC.

Method: This cohort study included 1,185 participants with HCC from five international sites. Multivariable restricted mean survival time (RMST) analyses with lead time bias adjustments were conducted to assess overall survival, compared between participants who underwent any HCC surveillance compared to those who did not.

Results: RMSTs were consistently higher in participants who underwent HCC surveillance (n = 975) (RMST difference at 1 year, 0.102 years [95% CI: 0.055–0.150], p < 0.001; RMST difference at 3 years, 0.497 years [95% CI: 0.316–0.678], p < 0.001; RMST difference at 5 years, 0.960 years [95% CI: 0.635–1.286], p < 0.001) compared to participants who did not undergo surveillance (n = 210). RMSTs remained higher among participants with hepatitis B (HBV) and hepatitis C (HCV) patients who underwent surveillance, compared to no surveillance across all follow-up periods. Among participants with metabolic dysfunction-associated steatotic liver disease (MASLD) and alcohol-associated liver disease, there were no statistically significant differences in RMSTs in the first three years of follow-up between HCC surveillance and no surveillance.

Conclusion: HCC surveillance is associated with improved survival. This survival benefit is more prominent in people with HBV- and HCV-associated HCC, compared to people with MASLD- and alcohol-associated liver disease.

WED-143-YI

Ki-67 and CK19 as predictors of hepatocellular carcinoma recurrence after liver transplantation

Saur Hajiev[1], Luca Porcu[2], Adam Duckworth[3], Matthew Hoare[1]. *[1]University of Cambridge, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom; [2]Cancer Research UK Cambridge Institute, Cambridge, United Kingdom; [3]Cambridge University Hospital NHS Foundation Trust, Cambridge, United Kingdom*
Email: saur.hajiev96@gmail.com

Background and aims: Tumour recurrence after liver transplantation (LT) remains the dominant reason for poor post-transplant survival in patients transplanted for hepatocellular carcinoma (HCC). Improved risk stratification would enable targeted post-LT surveillance and treatment. Several prognostic tools based on demographics, serum markers and tumour configuration, including the recently published R3-AFP model, predict recurrence. However, none include molecular features of the explanted HCC, beyond AFP levels. Tumoral Ki-67 and CK19 expression may predict aggressive tumour biology. We examined the prognostic significance of tumoral Ki-67 and CK19 expression for HCC recurrence after LT. Secondly, we examined whether the addition of these biomarkers could refine the R3-AFP model.

Method: We conducted a retrospective analysis of sequential patients undergoing LT at Addenbrooke's Hospital, Cambridge, between January 2008 and December 2022. All patients had HCC on explant histopathology. Clinical and histopathological data was obtained retrospectively from a prospectively maintained database. Tumoral expression of Ki-67 (MIB-1) and CK19 was performed retrospectively by immunohistochemistry and scored by a specialist hepatobiliary histopathologist. Cox regression analyses were used to assess factors predicting post-LT recurrence-free and overall survival.

Results: 277 patients (238 male (85.9%); median age 59.8 years (min-max: 23.1–73.6)) underwent LT during the study period. The cumulative incidence of recurrence at 5 years post-LT was 10.5% (95% CI: 7.0–14.8%). Significant univariate predictors of HCC recurrence included viral hepatitis (HR = 2.54, p = 0.026), elevated pre-transplant AFP (HR = 1.17, p < 0.001), pre-transplant UKELD score (HR = 2.54, p = 0.026), number of lesions (HR = 1.15, p < 0.001), size of largest lesion (HR = 1.88, p < 0.001), tumour grade (p < 0.001) and microvascular invasion (p < 0.001). At univariate analysis, Ki-67 (HR = 1.38, p < 0.001) and CK19 expression were associated with HCC recurrence (HR = 3.09, p < 0.016). After multivariate adjustment

for other predictive factors neither Ki-67 (HR = 1.16, 0.98–1.38, p = 0.09) nor CK19 expression (HR = 1.66, 0.65–4.21, p = 0.29) were associated with HCC recurrence. Neither Ki-67 (HR = 1.13, 0.999–1.27, p = 0.05) nor CK19 (HR = 1.68, 0.86–3.32, p = 0.13) expression were associated with overall survival after liver transplantation. In our cohort, the R3-AFP score effectively stratified patient risk groups for recurrence, with a 5-year recurrence rate of 1.0% (95% CI: 0.1–4.8%) in very-low-risk patient and 32.6% (95% CI: 7.8–47.2%) in the very-high-risk group. Finally, Ki-67 (p = 0.077) and CK19 (p = 0.338) expression could not predict post-LT HCC recurrence independent of the R3-AFP risk score.
Conclusion: Tumoral Ki-67 and CK19 expression do not confer additional prognostic utility for recurrence-free or overall survival after LT for HCC, beyond commonly used clinicopathological variables or the R3-AFP score.

WED-144
Clinicopathological features of liver tumors in Guilin: a region with significant Aflatoxin contamination in food crops in China
Wenhua Shao[1], Mayuko Shimizu[1], Orgil Jargalsaikhan[2], Shengjun Xiao[3], Li Cai[4], Tang Shuiwen[5], Wang Shibo[5], Koichi Tsuneyama[2]. *[1]Department of Molecular Pathology, Institute of Biomedical Sciences, Tokushima University Graduate School, Tokushima, Japan; [2]Department of Pathology and Laboratory Medicine, Institute of Biomedical Sciences, Tokushima University Graduate School, Tokushima, Japan; [3]Department of Pathology, the Second Affiliated Hospital of Guilin Medical University, Guilin, China; [4]Key Laboratory of Tumor Immunology and Microenvironmental Regulation of Guangxi, Guilin Medical University, Guilin, China; [5]Key Laboratory of Tumor Immunology and Microenvironmental Regulation of Guangxi, Guilin Medical University, Guilin, Guilin, China*
Email: tsuneyama.koichi@tokushima-u.ac.jp

Background and aims: Aflatoxins, toxic metabolites produced by molds, are common contaminants of food crops. Chronic exposure to aflatoxins is strongly associated with liver diseases, including hepatocellular carcinoma (HCC). Guilin, located in southern China, has significant aflatoxin contamination in food crops. The Second Affiliated Hospital of Guilin Medical University (GMUSH) serves as a leading healthcare institution in the region. This study aimed to analyze recent liver tumor cases at GMUSH and investigate the pathological features linked to aflatoxin exposure.
Method: We analyzed 54 liver tumor cases from GMUSH that underwent surgical treatment between 2021 and 2024. Aflatoxin exposure was assessed by immunohistochemistry for aflatoxin B1 (AFB1) DNA-adducts (clone 6A10). Clinicopathological data, including tumor cell characteristics, background hepatocytes, fibrosis, and infiltrating cells, were evaluated by independent liver pathologists. Statistical analyses were performed to identify features associated with AFB1 exposure.
Results: Among the 54 cases, 38 were diagnosed with HCC, 14 with intrahepatic cholangiocarcinoma (ICC), and 2 with combined HCC-ICC. Of the 38 HCC cases, 28 (73.7%) were hepatitis B virus (HBV)-positive, while 5 of 14 ICC cases (35.7%) were HBV-positive. AFB1 DNA-adducts were found in the nucleus or cytoplasm of cells in 5 HBV-positive HCC cases. No AFB1 positivity was detected in ICC or combined HCC-ICC cases. There were no significant differences in pathological and clinical parameters between AFB1-positive and -negative cases, but the AFB1-positive group exhibited a higher incidence of glycogen deposition in both tumor cells and background hepatocytes.
Conclusion: Our immunostaining method for AFB1 detection revealed a 13% positivity rate in recent HCC cases from Guilin, with no significant clinicopathological differences between AFB1-positive and -negative cases. Detection of AFB1 DNA-adducts is a useful tool for identifying past exposure, even in the absence of aflatoxin in routine blood tests. Interestingly, the incidence of ICC in Guilin was higher than the national average, accounting for 25% of liver cancer cases. This elevated incidence may be linked to aflatoxin exposure, as animal studies have shown that aflatoxin administration can induce ICC. Furthermore, the TP53 gene mutation (R249S), a known aflatoxin signature, has been identified in ICC cases in China. We are currently conducting genetic analysis on ICC cases in parallel, and will also report these findings.

WED-145
Morphomolecular proliferative disease and microvascular invasion characterize PET-CT positive hepatocellular carcinoma cases: a single-center pilot study
Spyridon Pantzios[1], Iakovos Vlahos[2], Antonia Syriha[1], Ioanna Maria Grypari[2], Emmanouil Nychas[1], Nikolaos Ptohis[3], Despoina Myoteri[2], Dina Tiniakos[2], Ioannis Elefsiniotis[1]. *[1]Academic Department of Internal Medicine, General Oncology Hospital of Kifissia "Agioi Anargyroi", National and Kapodistrian University of Athens, Athens, Greece; [2]Dept of Pathology, Aretaieion Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece; [3]Department of Interventional Radiology, General Hospital of Athens "G. Gennimatas", Athens, Greece*
Email: spiros_pant@hotmail.com

Background and aims: Positron emission tomography (PET) – computed tomography (CT) is a helpful diagnostic tool for excluding metastatic disease in patients with hepatocellular carcinoma (HCC). However, PET-CT is rarely used for the diagnosis of intrahepatic lesions in HCC, due to its low sensitivity, which is associated with relatively elevated Standard Uptake Value (SUV) in both normal and cirrhotic liver. PET-CT positivity for primary HCC has been associated with microvascular invasion and more aggressive tumour behaviour. We aimed to study the association between the SUVmax of primary HCC in PET-CT and HCC morphomolecular classification based on liver biopsy.
Method: Twenty-eight patients (22 males, 7 with diabetes, 17 with cirrhosis, 7 of viral aetiology, 9 with varices, 15 classified as ALBI-I, BCLC stage: 7 A, 11 B, 10 C) were included in the study. All patients had primary HCC lesions and underwent ^{18}F-fluorodeoxyglucose (^{18}F-FDG) PET-CT examination and imaging-guided liver biopsy. We studied the SUVmax of all histologically proven HCCs. We divided HCCs into proliferative (pHCC, n = 14) and non-proliferative (npHCC, n = 14).
Results: Sixteen cases were PET-positive and the rest 12 PET-negative. Microvascular invasion was observed in 13 pHCC patients (92.8%) and in only 2 npHCC patients (14.3%) (p < 0.001). Baseline characteristics of the two groups were comparable for all variables studied (gender, age, diabetes, cirrhosis, etiology, varices presence, Albumin-Bilirubin/ALBI grade, α-fetoprotein serum values). Median SUVmax in pHCCs was significantly higher compared to npHCCs (8.5 vs. 4, respectively, p = 0.001). In multivariate analysis, SUVmax emerged as the only significant factor differentiating between the two groups (p = 0.033, OR = 2.5, 95% C.I. 1.077–5.940). SUVmax was strongly correlated with pHCC (Pearson r = 0.52, p = 0.005). SUVmax of 5.15 presented a sensitivity of 85.7% and specificity of 78.6% for the prediction of pHCC presence (AUROC 0.86, p = 0.001). In the subgroup of BCLC-A/B patients (n = 18), microvascular invasion was detected in 7/8 (87.5%) with PET-positive HCC compared to 2/10 (20%) with PET-negative HCC (p = 0.004). In BCLC-A/B patients with microvascular invasion, 8/9 patients (88.9%) presented with pHCCs, whereas absence of microvascular invasion presented only in patients with npHCCs (9/9, 100%) (p < 0.001).
Conclusion: Our pilot study highlights a significant relationship of SUVmax with histologically confirmed proliferative HCC, a finding requiring further investigation. PET positivity in primary HCC may be related to specific HCC histological/molecular subtypes and/or presence of microvascular invasion.

HCC detection using LI-RADS ultrasound surveillance algorithms: a comparative analysis of v2024 and v2017

Subin Heo[1], Sang Hyun Choi[1], Claude Sirlin[2]. [1]*Asan Medical Center, Seoul, Korea, Rep. of South;* [2]*UC San Diego, California, United States*
Email: edwardchoi83@gmail.com

Background and aims: The Liver Imaging Reporting and Data System (LI-RADS) Ultrasound (US) Surveillance Algorithm was updated in 2024, highlighting the need for studies to validate these changes. This study aims to compare the 2024 and 2017 versions of the LI-RADS US Surveillance Algorithms for hepatocellular carcinoma (HCC) detection in adults with cirrhosis.
Method: This retrospective analysis of a prospective clinical trial included adult patients with cirrhosis who underwent up to three rounds of semi-annual US surveillance with AFP testing; the first two rounds reviewed. Two radiologists independently assigned LI-RADS Surveillance US visualization scores (VIS-A, VIS-B, VIS-C) and categories (US-1, US-2, US-3), with any discrepancies resolved by a third reviewer. AFP positivity was assessed per LI-RADS/American Association for the Study of Liver Diseases criteria. Sensitivity and specificity in Round 1 were compared between the 2024 and 2017 versions, and univariable and multivariable logistic regression identified baseline predictors for VIS-C in Round 2.
Results: Among 407 patients (230 men; median age 56-years), 28 (7%) were diagnosed with HCC in Round 1. LI-RADS 2024 demonstrated significantly higher sensitivity for HCC detection compared to 2017 (64% vs. 39%, $p = 0.016$) but lower specificity (82% vs. 93%, $p < 0.001$). In 299 patients with negative Round 1 surveillance by LI-RADS 2024 who subsequently underwent Round 2 US, multivariable analysis indicated that baseline VIS-C (adjusted odd ratio = 22.8, [95% confidence interval, 12.0–43.3], $p < 0.001$) was the only significant predictor for VIS-C in Round 2.
Conclusion: Compared to the 2017 version, LI-RADS US Surveillance 2024 demonstrated improved sensitivity for detecting HCC, albeit with reduced specificity. Baseline VIS-C was the sole independent predictor of VIS-C in follow-up surveillance US.

WED-149

Machine learning-based decision tree model for predicting survival in patients with single-large hepatocellular carcinoma

Yi-Chen Lin[1], Chun-Ting Ho[1], Chia Jung Ho[1], Yi-Hsiang Huang[2], Ming-Chih Hou[2], Jaw-Ching Wu[3], Chien-Wei Su[1]. [1]*Division of General Medicine, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan;* [2]*Division of Gastroenterology and Hepatology, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan;* [3]*Institute of Clinical Medicine, School of Medicine, National Yang Ming Chiao Tung University, Taipei, Taiwan*
Email: cwsu2@vghtpe.gov.tw

Background and aims: Single large hepatocellular carcinoma (SLHCC) exhibits substantial heterogeneity in clinical presentations and outcomes, distinguishing it from other hepatocellular carcinoma (HCC) stages. Conventional prognostic tools and staging systems for HCC provide limited accuracy and applicability in predicting outcomes for SLHCC patients. This study aimed to develop a machine learning-based prognostic model specifically to SLHCC.
Method: This retrospective study analyzed 477 treatment-naive SLHCC patients diagnosed at Taipei Veterans General Hospital between January 2012 and January 2023. The primary study endpoint was overall survival (OS). Patients were randomly divided into a training cohort ($n = 334$) and a validation cohort ($n = 143$). In the training cohort, multivariate analysis using the Cox proportional hazards model identified independent risk factors for poor OS. These factors were incorporated into a machine learning-based decision tree model, which was then validated in the validation cohort to assess its prognostic performance.
Results: After a median follow-up of 50 months, 234 patients had died, with a 5-year OS rate of 42%. The multivariate Cox model identified larger tumor size (>10 cm), serum creatinine levels, treatment modality, albumin-bilirubin (ALBI) grade, fibrosis-4 (FIB-4) score, and serum alpha-fetoprotein (AFP) levels as independent predictors of poor OS. The machine learning-based decision tree model demonstrated robust prognostic performance, with an area under the receiver operating characteristic curve (AUROC) of 0.706 (95% CI: 0.626–0.786).
Conclusion: The machine learning-based decision tree model, incorporating non-invasive biomarkers, imaging features, and treatment modalities, provides effective prognostic insights for SLHCC patients. This tool holds potential for aiding clinicians in optimizing treatment strategies and enhancing personalized patient care.

WED-150-YI

Cost-effectiveness of ultrasound plus alpha-fetoprotein and biomarker-based strategies for hepatocellular carcinoma surveillance in patients with chronic hepatitis B

Tanat Saeoui[1], Chayanis Kositamongkol[2], Ratthanan Chantrakul[1], Pimsiri Sripongpun[1], Naichaya Chamroonkul[1], Chanon Kongkamol[1], Pochamana Phisalprapa[2], Apichat Kaewdech[1]. [1]*Prince of Songkla University, Hatyai, Thailand;* [2]*Siriraj Hospital, Mahidol University, Bangkok, Thailand*
Email: apichat.ka@psu.ac.th

Background and aims: Currently, the standard program for hepatocellular carcinoma (HCC) surveillance is the combination of ultrasound (USG) with alpha-fetoprotein (AFP) every 6 months. However, there are limitations such as accessibility, radiologist shortages, and suboptimal cost-effectiveness data. This study evaluated the cost-effectiveness of traditional HCC surveillance methods compared to biomarker-based strategies, focusing on patients with chronic hepatitis B (CHB), a population at high risk for HCC in the Asia-Pacific region.
Method: A Markov model simulated a cohort of patients with CHB to compare cost-effectiveness of surveillance strategies, including USG +AFP, GAAD score (gender, age, AFP, and des-carboxy-prothrombin), GALAD score (gender, age, AFP-L3, AFP, and des-carboxy-prothrombin), ASAP score (AFP, sex, age, and Protein induced by vitamin K absence-II), and no surveillance. Data on utilities, transition probabilities, and costs were derived from literature reviews and the Thai healthcare system. A societal perspective and a lifetime time horizon were applied for the analysis. Incremental cost-effectiveness ratios (ICERs) were calculated as costs per quality-adjusted life-year (QALY) gained. Deterministic and probabilistic sensitivity analyses were conducted to evaluate the robustness of findings.
Results: ASAP every 12 months emerged as the most cost-effective strategy, with an ICER of 62,318 THB (~1,946 USD) per QALY gained compared to no surveillance. While ASAP every 6 months provided slightly greater QALY gains, it incurred significantly higher costs, resulting in an ICER exceeding the willingness-to-pay (WTP) threshold of 160,000 THB (~5,000 USD) per QALY gained. GAAD every 6 months and GALAD every 6 months achieved similar QALY gains to ASAP strategies but were dominated due to higher costs. The strategies adopting GAAD or GALAD with 12-month surveillance intervals improved cost-effectiveness but remained inferior to ASAP every 12 months. USG+AFP every 6 months had the highest ICER of 108,294 THB (~3,382 USD) per QALY gained, significantly exceeding the ICER of other strategies. Probabilistic sensitivity analysis confirmed ASAP every 12 months as the most cost-effective strategy, falling below the WTP threshold in over 90% of simulations. Tornado diagrams highlighted that biomarker costs, utility values for HCC stages, and HCC incidence were key drivers of cost-effectiveness.
Conclusion: ASAP every 12 months is the most cost-effective surveillance strategy for patients with CHB compared to other approaches. Its combination of cost-effectiveness and feasibility makes it a practical surveillance for resource-limited settings, particularly in regions with constrained access to radiologists. Policymakers should prioritize biomarker-based surveillance

programs, in particular ASAP, to improve HCC outcomes and ensure efficient resource allocation.

WED-151-YI

Development and external validation of a weakly supervised deep learning algorithm for the diagnosis of focal liver lesions on contrast-enhanced ultrasound

Tobias Paul Seraphin[1], Adil Özsoy[1], Pompilia Radu[2], Annalisa Berzigotti[2], Tom Luedde[1], Jakob Nikolas Kather[3,4,5], Michael Kallenbach[1]. [1]*Medical Faculty and University Hospital Düsseldorf, Heinrich Heine University Düsseldorf, Dusseldorf, Germany;* [2]*Department for Visceral Surgery and Medicine, Inselspital, University of Bern, Bern, Switzerland, Bern, Switzerland;* [3]*Else Kroener Fresenius Center for Digital Health, Faculty of Medicine and University Hospital Carl Gustav Carus, TUD Dresden University of Technology, Dresden, Germany;* [4]*Department of Medicine I, Faculty of Medicine and University Hospital Carl Gustav Carus, TUD Dresden University of Technology, Dresden, Germany;* [5]*Medical Oncology, National Center for Tumor Diseases (NCT), University Hospital Heidelberg, Heidelberg, Germany*
Email: tobiaspaul.seraphin@med.uni-duesseldorf.de

Background and aims: Accurate characterization of focal liver lesions (FLL) remains a challenging task of routine clinical practice. Contrast-enhanced ultrasound (CEUS) is a reliable and comparatively inexpensive imaging modality, but its interpretation relies heavily on the expertise of the examiner. Previous studies have explored the application of AI to CEUS analysis; however, most are relying on resource-intensive preprocessing and lack external validation. This study aimed to classify FLLs applying a weakly-supervised attention-based multiple instance learning algorithm and to validate the model's performance using external cohorts.
Method: Retrospectively collected multicentric data from four FLL types were included: focal nodular hyperplasia (FNH), hemangioma, hepatocellular carcinoma (HCC), and metastasis. Deep learning features were extracted from CEUS video frames using a pretrained convolutional neural network. A class-balanced 20% test set was held out, and the remaining data was used to train a classification algorithm applying a hyperparameter grid search and five-fold cross-validation. The best hyperparameter set was selected based on the averaged area under the receiver operating characteristic curve (AUROC) across all cross-validation runs. The final model was created by ensembling the five models from the best run and then deployed on the held-out test set as well as two external cohorts from Germany (same ultrasound machine) and Switzerland (different ultrasound machine) for testing.
Results: The in-house dataset included 370 patients (FNH n = 52, hemangioma n = 149, HCC n = 67, metastasis n = 102). The final model achieved an average AUROC of 0.82 during cross-validation. On the test set, AUROCs were 0.85 for FNH, 0.87 for hemangioma, 0.92 for HCC, and 0.93 for metastasis. In external validation, AUROCs for the German cohort (39 patients) were 0.70, 0.52, 0.67, and 0.58, and for the Swiss cohort (19 patients), 0.35, 0.63, 0.49, and 0.95, for FNH, hemangioma, HCC, and metastasis, respectively. Post-hoc explainability analyses were performed to better understand the decision process of the model.
Conclusion: Weakly supervised MIL demonstrated robust performance in classifying FLL using CEUS data during cross-validation and on the held-out test set, without requiring extensive pre-processing. The performance drop in external cohorts, is likely due to small, imbalanced datasets and user- and machine-dependent artefacts. As most AI studies analyzing CEUS videos do not provide external validation of their models, further research is needed before prospective studies can confirm the clinical utility of such algorithms and their potential to assist clinicians in FLL evaluation.

WED-152

An artificial intelligence-based risk prediction model for early-onset hepatocellular carcinoma

Won Kim[1], Young Ho So[1], Saekyung Joo[1], Yong Jin Jung[1]. [1]*Seoul Metropolitan Government Seoul National University Boramae Medical Center, Seoul, Korea, Rep. of South*
Email: wonshiri@yahoo.com

Background and aims: Cancer incidence among younger populations is rising worldwide, with hepatocellular carcinoma (HCC) being the most common type of liver cancer. Despite extensive research on HCC risk prediction, little attention has been paid to early-onset HCC. We aimed to develop and validate an artificial intelligence (AI)-based prediction model of early-onset HCC.
Method: From the Korean nationwide health screening database, a total of 2,863,733 young adults aged 20–39 years who were screened between 2009 and 2010 were included and followed up until December 31, 2021. The primary outcome was HCC incidence. The cohort was randomly split into training, validation, and test sets (8:1:1) to build prediction models.
Results: During a median follow-up of 10.0 years, 1,550 HCC cases were identified. Logistic regression, random forest, multi-layer perceptron, and extreme gradient boosting (XGBoost) models were built and validated using 43 available clinical variables. In the test set, the XGBoost model showed the highest area under the curve (AUC) of 0.861, followed by logistic regression (AUC = 0.857), random forest (AUC = 0.814), and multi-layer perceptron (AUC = 0.781). The top predictive features in the XGBoost model included alanine aminotransferase, fasting serum glucose, gamma-glutamyl transferase, hepatic steatosis, age, creatinine, aspartate aminotransferase, diastolic blood pressure, liver cirrhosis, and diabetes.
Conclusion: We developed and validated an AI-based risk prediction model for early-onset HCC using the XGBoost algorithm. The model incorporated metabolic factors along with established variables like liver cirrhosis. This model may contribute to more active prevention of HCC by providing valuable insights into early-onset HCC risk.

WED-153

A patient charter for hepatocellular carcinoma: a co-created community call for action on equitable access to early diagnosis and multidisciplinary care

Yasmine HassanPharm[1], Diane Langenbacher[2], Achim Kautz[2], Jessica Hicks[3], Tim Meyer[4], Jade Chakowa[5], Cary James[3], Lili Anna Gundelach[6], TingTing Zhang[7], Manon Allaire[8], Eric BouffetMDFRCP(C)[9], Boris Baur[1]. [1]*AstraZeneca, Gaithersburg, United States;* [2]*International Liver Cancer Movement, Koln, Germany;* [3]*World Hepatitis Alliance, Geneva, Switzerland;* [4]*University College London, London, United Kingdom;* [5]*The Hepatitis Fund, Geneva, Switzerland;* [6]*Digestive Cancers Europe, Brussels, Belgium;* [7]*Hear2Care, Seattle, United States;* [8]*APHP, Paris, France;* [9]*SickKids, Toronto, Canada*
Email: yasmine.hassan@astrazeneca.com

Background and aims: Hepatocellular carcinoma (HCC) is the most prevalent form of primary liver cancer and is the sixth most common cancer worldwide. There were approximately 866,136 new cases of liver cancer and 758,725 deaths worldwide in 2022. This abstract introduces the HCC patient charter co-created by patient advocates and healthcare professionals, which outlines seven principles of quality care that people with HCC should expect to receive, wherever they live and irrespective of their socioeconomic status. To introduce the charter, we chose to highlight one of it's seven core principles: 'patients need access to a multidisciplinary team to provide comprehensive care, considering both the liver condition and cancer treatment'.
Method: The charter was developed through multidisciplinary consultations and roundtables with clinicians, patient advocacy groups (PAGS), and healthcare professionals spanning six continents.
Results: The complexity of HCC necessitates a comprehensive approach to care, which is best delivered by a multidisciplinary

team (MDT), consisting of various specialists such as epidemiologists, hepatologists/gastroenterologists, oncologists, radiologists and interventional radiologists, transplant and hepatobiliary surgeons, pathologists, radiotherapists, nurse navigators, psychologists, physiotherapists, nutrition specialists, clinical pharmacologists, palliative care providers[i] and PAGS.
MDTs provide a thorough evaluation of the individual patient's HCC, develop personalized treatment plans[ii] and have been shown to improve patient quality of life. Five year survival rates are significantly higher in the patients who were managed via MDT compared to that of the patients who were not (71.2% vs. 49.4%). Despite international guidelines, such as the Barcelona clinic liver cancer (*BCLC*), European Association for the Study of the Liver, American Association for the Study and Asia Pacific Association for the Study of Liver emphasizing the importance of the multidisciplinary approach, barriers to accessing multidisciplinary care persist. The operational details required to make MDTs effective, such as identifying groups of patients that benefit most, defining the ideal composition of the team and understanding the clinical outcomes, have not been fully established. Resource constraints and insufficient health policies mean that best practice guidelines are not adopted even where they exist, resulting in geographic and socioeconomic disparities in care.
Conclusion: The charter serves as a roadmap for stakeholders to improve the care and outcomes of HCC patients. A key component of this is the implementation of multidisciplinary care. Through implementing a holistic care pathway, healthcare providers can ensure that patients receive the highest standard of care, regardless of their location or socioeconomic status.

WED-154

Artificial intelligence foundation models for histological diagnosis of hepatocellular carcinoma based on 121,344 digitalized whole slide image patches

Yan Miao[1], Philip Yu[2], Tak-Siu Wong[3], Regina Cheuk Lam Lo[1], Ho Ming Cheng[1], Lequan Yu[1], Lung-Yi Mak[1], Man-Fung Yuen[1], Wai-Kay Seto[1]. [1]*The University of Hong Kong, Hong Kong, Hong Kong;* [2]*The Education University of Hong Kong, Hong Kong, Hong Kong;* [3]*Pamela Youde Nethersole Eastern Hospital, Hong Kong, Hong Kong*
Email: wkseto@hku.hk

Background and aims: Hepatocellular carcinoma (HCC) is known for a high mortality rate. Recent advancements in artificial intelligence, particularly in the development of general-purpose foundation models for computational pathology, enable institutions with the premier medical resources to contribute to disease diagnosis by releasing models pretrained on their private datasets as open-source. We compared the most recent versions of foundation models for the histological diagnosis of HCC.
Method: We assessed four pretrained deep learning models for diagnosing HCC using whole slide images (WSIs). Each WSI was first digitized and annotated by clinical experts. Then, squared image patches of size 1024 were extracted with a sliding-window algorithm. A patch was assigned a label based on its inclusion within a tumor annotation. We finetuned the models on the training and validation sets to incorporate the information from the HCC data. Finally, we evaluated patch-level diagnostic performance of the deep learning models on a test set. The set of models includes a ResNet (convolutional neural network (CNN) with 23.5M parameters, pretrained on 36,666 WSIs), a ViT-S (small vision transformer (ViT) with 21.7M parameters, pretrained on 36,666 WSIs), a UNI (large ViT with 303M parameters, pretrained on 100,426 WSIs), and a Virchow2 (huge ViT with 632M parameters, pretrained on 3,134,922 WSIs).
Results: With 25 patients and 158 WSIs (non-HCC = 95, HCC = 63), we obtained 84,480 training patches from 110 WSIs, 18,432 validation patches from 24 WSIs, and 18,432 test patches from 24 WSIs. On the test set, ResNet achieved an area under curve (AUC) of 0.822 (95% CI: 0.816–0.828), a sensitivity of 0.830 (0.824–0.835), a specificity of 0.868 (0.861–0.874), a positive predictive value (PPV) of 0.805 (0.796–0.814), and a negative predictive value (NPV) of 0.846 (0.839–0.853). ViT-S achieved an AUC of 0.840 (0.836–0.846), a sensitivity of 0.838 (0.833–0.843), a specificity of 0.826 (0.818–0.832), a PPV of 0.775 (0.766–0.784), and an NPV of 0.890 (0.884–0.896). UNI achieved an AUC of 0.869 (0.864–0.874), a sensitivity of 0.873 (0.868–0.878), a specificity of 0.891 (0.883–0.897), a PPV of 0.845 (0.837–0.853), and an NPV of 0.892 (0.887–0.898). Virchow2 achieved an AUC of 0.879 (0.875–0.884), a sensitivity of 0.877 (0.873–0.882), a specificity of 0.868 (0.862–0.875), a PPV of 0.826 (0.818–0.834), and an NPV of 0.918 (0.913–0.924). Virchow2 had the highest AUC, sensitivity, and NPV scores, making it ideal for resource-rich scenarios that prioritize performance. UNI had the best specificity and PPV scores, offering a balance of performance and computational cost.
Conclusion: Foundation models offer great assistance to HCC diagnosis. Larger foundation models pretrained on larger datasets are usually more generalizable, while future models should aim at classifying different tumor characteristics.

WED-155-YI

Validation of hepatocellular carcinoma risk scoring tools in patients with chronic hepatitis B virus and hepatitis C virus infection– results from a large multicentre cohort study

Email: yun.kim@uhs.nhs.uk

Background and aims: Hepatocellular carcinoma (HCC) is a recognised complication of chronic hepatitis B virus (HBV) and hepatitis C virus (HCV) infection. Identifying which patients need close surveillance for cancer is important to maximise the utility of limited resources and minimise the care burden for patients. Risk prediction scores have been developed to stratify patients in both groups, however, the effectiveness of the scores has not been well assessed in mixed ethnicity cohorts. We determined the performance of HCC risk prediction scores in a large, ethnically diverse UK cohort with HBV and HCV.
Method: We analysed the National Institute for Health and Care Research Health Informatics Collaborative (NIHR HIC) cohort derived from electronic health records from a consortium of nine hospital sites in England including 43,203 patients. aMAP (age, sex, albumin-bilirubin, platelets) and PAGE-B (platelet, age, sex) scores were applied to calculate risk of developing HCC in 3-, 5- and 10-years' time. Scores were calculated in patients with HBV or HCV mono-infection at the time of diagnosis. ICD-10 or Systematized Nomenclature of Medicine Clinical Terms (SNOMED CT) codes were used to identify HCC. Individuals with death or HCC diagnosed within 6 months of HBV or HCV diagnosis were excluded. The score performance was evaluated by Harrell's C-index and the area under the receiver operating characteristic (AUROC).
Results: 7475 HBV and 8130 HCV mono-infected patients met the inclusion criteria. At diagnosis, median (interquartile range; IQR) age was 42 (33–55) and 49 (39–58) years for HBV and HCV respectively. In the HCV cohort the majority were of White Caucasian (66%), followed by Asian (10%), Black African (2%). There was a mix of ethnicities in the HBV cohort, White Caucasian (26%), Asian (16%), Black-African (14%). A significant association was found between ethnicity and HCC, with higher rates in Asian, Black-Caribbean, and Chinese groups for HBV, and Asian and Black-African groups for HCV ($p < 0.001$). C-index [95%CI] were HBV PAGE-B 0.84 [0.83–0.87]; HBV aMAP 0.82 [0.80–0.85]; HCV aMAP 0.81 [0.80–0.83]. The performance of PAGE-B and aMAP in HBV were not significantly different. AUROC [95%CI] of predicting HCC risk at 3 years, 5 years and 10 years were HBV PAGE-B 0.847 [0.79–0.91], 0.847 [0.79–0.90], 0.832 [0.78–0.88]; HBV aMAP 0.816 [0.75–0.88], 0.793 [0.74–0.85], 0.775 [0.72–0.83]; HCV aMAP 0.811 [0.76–0.86], 0.806 [0.77–0.85], 0.786 [0.75–0.82].
Conclusion: In a multicentre UK cohort, aMAP and PAGE-B scores had comparable predictive value for HCC, supporting their use in ethnically diverse populations. New prediction tools incorporating demographic, clinical and virologic parameters in large longitudinal cohorts may improve the long-term predictive value of risk stratification for HCC in HBV and HCV.

WED-156
Evaluation of elevated tumor markers in the absence of detectable hepatocellular carcinoma during post-curative ablation follow-up

Makoto Moriyama[1], Ryosuke Tateishi[1], Yuki Matsushita[1], Tomoharu Yamada[1], Takuma Nakatsuka[1], Tatsuya Minami[1], Masaya Sato[1], Mitsuhiro Fujishiro[1], Shuichiro Shiina[2], Kazuhiko Koike[3]. *[1]Department of Gastroenterology, Tokyo University Hospital, Faculty of Medicine, The University of Tokyo, Tokyo, Japan; [2]Department of Gastroenterology, Juntendo University Hospital, Faculty of Medicine, Juntendo University, Tokyo, Japan; [3]Kanto Central Hospital, Public Schools Mutual Aid Association, Tokyo, Japan*
Email: z7m1084@gmail.com

Background and aims: Hepatocellular carcinoma (HCC) often recurs after curative treatment and requires post-treatment surveillance. While tumor markers are widely used for surveillance, some patients show elevated tumor markers without visible recurrence on imaging. This study aimed to assess the outcomes of HCC patients with persistent tumor marker elevation but no detectable recurrence on imaging following radiofrequency ablation (RFA).
Method: We analyzed 8,660 RFA treatments performed on 1,613 patients with HCC from 1999 to 2015. Among 2,294 cases that exceeded tumor marker cutoff values (alpha-fetoprotein (AFP) > 20 ng/mL for hepatitis C with sustained virological response and >200 ng/mL for others, lens culinaris agglutinin-reactive fraction of alpha-fetoprotein (AFP-L3) > 15%, des-gamma-carboxy prothrombin (DCP) > 200 mAU/mL), we identified 185 cases of recurrence diagnosed more than 180 days after tumor marker elevation following curative RFA.
Results: The mean interval between tumor marker elevation and HCC recurrence was 336.9 days. At recurrence, tumor markers were elevated as follows: AFP > 20 ng/mL in 125 cases (67.6%), AFP > 200 ng/mL in 64 cases (34.6%), AFP-L3 > 15% in 107 cases (57.8%), and DCP > 200 mAU/mL in 35 cases (18.9%). At recurrence, 124 tumors (67.0%) were less than 20 mm and 163 tumors (88.1%) were less than 30 mm. Recurrence patterns included single intrahepatic lesion in 89 cases (48.1%), 2–3 lesions in 61 cases (33.0%), 4 or more lesions in 24 cases (13.0%), vascular or bile duct invasion in 6 cases (3.2%), and distant metastasis in 5 cases (2.7%). Treatment modalities for recurrence were RFA in 153 cases (82.7%), transarterial chemoembolization in 19 cases (10.3%), resection in 7 cases (3.8%), systemic therapy in 3 cases (1.6%), and best supportive care in 3 cases (1.6%). Local cure was achieved in 138 cases (74.6%).
Conclusion: Even when HCC was not detected on imaging despite elevated tumor markers, many recurrences were subsequently detected and curative treatment was possible with appropriate surveillance. However, it should be noted that cases with multiple intrahepatic recurrences, vascular or bile duct invasion, and distant metastases were observed.

Email: thomas.baumert@unistra.fr

Background and aims: Cholangiocarcinoma (CCA) is a highly aggressive adenocarcinoma of the biliary tract system with unsatisfactory therapeutic options. Standard treatment for unresectable or metastatic CCA consisting of cisplatin and gemcitabine combined with checkpoint inhibitors targeting programmed cell death ligand 1

(PD-L1) or programmed cell death 1 (PD-1) offer only very limited objective response rates and survival. Claudin-1 (CLDN1) is a transmembrane protein overexpressed in epithelial cancer cells and a mediator of carcinogenesis, invasion and metastasis. The functional role of CLDN1 for the tumor microenvironment (TME) is largely unknown. Here, we aimed to study the functional role of CLDN1 for the TME and as a therapeutic target using CCA as a model.
Method: CLDN1 expression within the tumor and TME was analyzed by spatial transcriptomics in CCA patient tissues. A hydrodynamic tail vein injection (HDTV) model was applied to generate immunocompetent orthotopic animal models of intrahepatic CCA to study the therapeutic efficacy of anti-CLDN1 monoclonal antibodies (mAbs) as a single agent or in combination with PD-1 mAbs.
Results: CLDN1 was overexpressed in cancer cells and CLDN1 expression was associated with oncogenic signaling and reduced T cell infiltration in patient tissues. In orthotopic mouse models for CCA, CLDN1 gain-of-function studies showed enhanced tumor growth and decreased survival. Treatment with CLDN1 mAbs markedly and significantly reduced tumor burden and intratumoral fibrosis and resulted in increased intratumoral CD3+ and CD8+ T cell infiltration as well as modulation of macrophage localization. Gene expression analyses revealed down-regulation of pathways for fibrogenesis, carcinogenesis and up-regulation of pathways for T cell activation and proliferation. In contrast to PD1 mAb single agent therapy, the combination CLDN1 with PD-1 mAbs markedly and significantly improved overall survival.
Conclusion: CLDN1 plays a functional role in the TME by modulating tumor fibrosis and immune cell infiltration. Treatment with CLDN1 mAbs provides a novel perspective to improve the outcome of CCA by improving the response to CPIs.

Longitudinal analyses of Innate Lymphoid Cells in patients with HCC identifies patterns associated with disease stage and response to therapy with atezolizumab and bevacizumab

Tijana Ristic[1], Laura Kusche[1], Suparna Dey[1], Sachin Chauhan[1], Lena Becker[2], Tiago De Castro[1], Norman Woller[3], Thomas Wirth[1], Anna Saborowski[1], Arndt Vogel[1,4,5], Heiner Wedemeyer[1], Bernd Heinrich[1]. *[1]Hannover Medical School, Department of Gastroenterology, Hepatology, Infectious Diseases and Endocrinology, Carl-Neuberg-Str. 1, 30625, Hannover, Germany; [2]Hannover Medical School, Institute of Diagnostic and Interventional Radiology, Carl-Neuberg-Str. 1, 30625, Hannover, Germany; [3]Hannover Medical School, Department of Gastroenterology, Hepatology, Infectious Diseases and Endocrinology, Carl-Neuberg-Str. 1, 30657, Hannover, Germany; [4]Department of Medical Oncology and Hematology, Princess Margaret Cancer Center, University Health Network, University of Toronto, Toronto, Canada; [5]Toronto Centre for Liver Disease, Toronto General Hospital, University Health Network, University of Toronto, Toronto, Canada*
Email: heinrich.bernd@mh-hannover.de

Background and aims: Hepatocellular carcinoma (HCC) is a heterogeneous type of cancer. Patients with HCC differ in their immune cell profiles but there is no evidence this would impact treatment outcome. We investigated innate lymphoid cell (ILC)-pattern in peripheral blood mononuclear cells (PBMCs) of patients with HCC. ILCs are considered the innate counterpart of T cells. ILC composition was monitored at different stages of disease and during therapy with atezolizumab (anti-PD-L1) and bevacizumab (anti-VEGF). Frequencies of ILC1 s and natural-killer (NK) cells, ILC2 s with its subgroups of $cKIT^+$ and $cKIT^-$ILC2 s and ILC precursors (ILCPs) along with serum cytokines were measured to characterize patterns which identify response to therapy and correlate with clinical parameters of disease.
Method: PBMCs from 26 patients with advanced stage HCC and 25 patients at the stage of follow-up, who received ablative or surgical treatment and were tumor free at the time of analysis were enrolled. Patients with advanced HCC received therapy with atezolizumab and bevacizumab and were analyzed before treatment and after 3 months.
ILCs in PBMCs were analyzed using flow cytometry. Cytokines were measured in the serum. Clinical parameters were associated with immune cell profiles.
Results: ILC composition in the blood differed comparing tumor free and advanced HCC patients.
In the tumor free cohort, poor liver function and increased level of fibrosis went along with higher ILC2 frequencies. Checkpoint molecules CTLA-4 and PD-1 were increased on ILC1 s and ILC2 s and serum levels of Interleukin (IL)-1, 6, 8, 11, 12, 23, 27, Interferon alpha, TNF alpha, TSLP were lower in tumor free compared to advanced HCC patients, indicating a status of lower systemic inflammation.
Patients with advanced HCC showed lower cytotoxic NK cells but higher helper ILC1 s along with lower ILC2 s. Low ILCPs were a hallmark of advanced disease with poor liver function and high fibrosis scores. During therapy with atezolizumab and bevacizumab, ILC frequency increased with higher frequencies of ILC1 s and ILC2 s but no significant changes in cytotoxic ILC subgroups. Expression of immune checkpoints CTLA-4 and PD-1 increased on all ILCs during therapy. Reduced serum levels of cytokines IL-1 alpha, 4, 12, Interferon alpha, and TSLP but higher levels of IL-2, 6, 10 and IL-18 were measured. Response to therapy at 3 months was associated with a relative change from $CD4^+$ILC1-like cells and $cKIT^+$ILC2 s to $CD8^+$ILC1-like cells and $cKIT^-$ILC2 s.
Conclusion: The profile of ILCs differed significantly in patients with HCC based on the status of the disease. Advanced stage disease was associated with higher inflammatory cytokines, poor cytotoxic capability of ILCs and low expression of immune checkpoints on ILCs. Treatment with atezolizumab and bevacizumab resulted in no significant improvement of cytotoxic subgroups. New immunotherapy strategies need to explore whether targeting the anti-tumor properties of ILCs may improve outcome in early and advanced HCC.

TOP-127-YI

Primary cilia loss promotes neoplastic outgrowth in intrahepatic cholangiocarcinoma through suppression of neutrophilic immune surveillance

Sara Teles[1], Scott Waddell[1], Aleks Rozyczko[1], Kyle Davies[1], Kostas Gournopanos[1], Edward Jarman[1], Luke Boulter[1]. *[1]Institute of Genetics and Cancer, University of Edinburgh, Edinburgh, United Kingdom*
Email: steles@ed.ac.uk

Background and aims: Intrahepatic cholangiocarcinoma (iCCA) are epithelial neoplasms that arise from bile ducts within the liver. Cholangiocytes, which line these ducts, present protruding antennae-like primary cilia into the duct lumen. These sensory organelles regulate normal bile composition and maintain ductular homeostasis. Alterations in primary cilia number have been described in end-stage iCCA, however, whether primary cilia loss is an early event in the pathological process is unknown. As such, understanding whether primary cilia loss is involved in the early neoplastic transformation of biliary cells remains undefined. We aimed to determine: 1. Whether primary cilia are lost prior to the onset of carcinoma in iCCA and 2. How early primary cilia loss sculpts early tumorigenesis.
Method: Using patient iCCA and pre-malignant, diseased tissues we characterised the presence of primary cilia on pre-malignant and malignant biliary cells using immunofluorescence. We then combined transgenic iCCA mouse models in which we concurrently deleted the primary cilia gene *Wdr35* with iCCA-inducing mutations, to study the tumour-promoting effects of primary cilia loss. Using RNA sequencing and organoids derived from these murine models (with or without primary cilia) we characterise the neoplastic transcriptomic changes derived from primary cilia loss and

functionally interrogate how loss of this organelle affects immune cell recruitment to early cancers.
Results: Primary cilia are lost early in iCCA development. Here we show that primary cilia number is decreased in both IPNB and BilIN when compared to normal biliary cells. Experimentally controlled deletion of primary cilia-loss in mutant cells *in vivo* accelerated the formation of ductular neoplasia and significantly altered the immune landscape of these early lesions. Specifically, we found a significant reduction in neutrophil recruitment to iCCAs (across mutations) and demonstrate that this is not due to differential neutrophil priming or cell death. Rather, our data shows that primary cilia loss in mutant biliary cells disrupts their expression and secretion of neutrophil-recruiting chemokines which resulted in the significant reduction of neutrophil migration *in vitro* and a loss of neutrophilic immune infiltration in tumours *in vivo*.
Conclusion: Loss of primary cilia is an early event during the neoplastic transformation of biliary cells. By interfering with the activation of neutrophil recruitment to the liver as part of the normal innate immune response to tumour initiation, loss of primary cilia supports the survival and outgrowth of early neoplastic biliary clones, protecting them from immune clearance and demonstrating why early loss cilia loss is a critical step in cholangiocarcinogenesis.

TOP-128-YI

Efficacy of WNTinib, a novel selective therapeutic for CTNNB1-mutant tumors, in preclinical models of hepatoblastoma

Ugne Balaseviciute[1,2], Júlia Huguet-Pradell[1,2], Jordi Abril-Fornaguera[1,2], Elisa Fernández-Martínez[2], Albert Gris-Oliver[1], Roser Pinyol[1], Alex Rialdi[3], Agavni Mesropian[1,2], Gulay Ulukaya[3,4], Dan Hasson[3,4], Ieva Keraite[2], Swan N Thung[5], Ernesto Guccione[3,4,6], Josep Llovet[1,2,7]. *[1]Translational Research in Hepatic Oncology, Liver Unit, IDIBAPS, Hospital Clinic, University of Barcelona, Barcelona, Spain; [2]Liver Cancer Program, Division of Liver Diseases, Department of Medicine, Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, United States; [3]Department of Oncological Sciences, Icahn School of Medicine at Mount Sinai, New York, United States; [4]Tisch Cancer Institute Bioinformatics for Next Generation Sequencing (BiNGS) Shared Resource Facility, Icahn School of Medicine at Mount Sinai, New York, United States; [5]Department of Pathology, Icahn School of Medicine at Mount Sinai, New York, United States; [6]Center for OncoGenomics and Innovative Therapeutics (COGIT), Center for Therapeutics Discovery, Department of Oncological Sciences and Pharmacological Sciences, Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, United States; [7]Institució Catalana de Recerca i Estudis Avançats (ICREA), Barcelona, Spain*
Email: josep.llovet@mountsinai.org

Background and aims: Hepatoblastoma (HB), the most frequent pediatric form of liver cancer, is a rare disease with a rising annual incidence of 1.8 cases per million children and limited therapeutic options. Standard perioperative platin-based regimens (*e.g.* cisplatin and doxorubicin) are associated with severe and lifelong side effects. The *CTNNB1* mutation is the most prevalent alteration in HB (~90%) and represents a potential therapeutic target. This study aims to *i)* assess the efficacy of WNTinib (an effective Wnt-*CTNNB1* inhibitor in HCC) in HB, and *ii)* explore strategies to enhance WNTinib efficacy in HB.
Method: To evaluate WNTinib efficacy, we performed 3 distinct animal models, including subcutaneous implantation of patient-derived xenograft (PDX) HB-tumors (n = 6), or 5 × 10^6 immortalized (HepG2) and PDX-derived (TT001) HB cells in NSG mice (n = 14/arm). Animals were treated with WNTinib (30 mg/kg, 5 days per week) or placebo until the end of the study, with tumor growth monitored throughout. To identify strategies enhancing WNTinib performance, we performed a kinome-wide CRISPR screen in which TT001 cells were treated with WNTinib (3 uM) for 3 weeks, and subsequently exposed to 3,052 unique single-guide RNAs targeting 763 human kinase genes. Candidate genes sensitizing cells to WNTinib are being validated *in vitro*.
Results: In the PDX animal model WNTinib delayed tumor growth in 4/5 *CTNNB1* mutant PDX models and demonstrated significantly better overall survival (OS) ($p < 0.05$) when compared to the control arm. In the HepG2 and TT001 models, WNTinib significantly reduced tumor growth ($p = 0.03$ and $p = 0.032$, respectively) and extended OS (log-rank $p = 0.008$ and $p = 0.03$, respectively) compared to the placebo. The CRISPR screen identified the top significantly depleted DYRK1A, MAPK1, and TESK2, suggesting their potential role as enhancers of WNTinib's activity in HB. Interestingly, DYRK1A inhibition has been shown to modulate WNT pathway activation in other contexts. The mechanisms underlying potential crosstalk between DYRK1A inhibitors and WNTinib in HB are currently being investigated. In our preliminary data, WNTinib and Dyrk1A-IN-1 inhibitor demonstrated strong synergy at low concentrations -based on the obtained combination index of ≤0.01- in 6 different HB cell lines, highlighting their potential as a promising dual treatment strategy for HB.
Conclusion: We have demonstrated that WNTinib effectively delays tumor progression and increases the overall survival in HB experimental models and identified DYRK1A kinase as a potential target to boost the efficacy of WNTinib activity in HB.

TOP-129-YI

Perineural invasion drives hilar cholangiocarcinoma progression via epithelial-mesenchymal transition augmented by cancer-associated Schwann cell-derived nerve growth factor inducible (VGF)

Honghua Zhang[1], Linwei Guo[2], Yang Liu[1], Xiuxian Li[1], Zhixiao Song[1], Leibo Xu[1], Chao Liu[1]. *[1]Sun Yat-Sen Memorial Hospital of Sun Yat-Sen University, Guangzhou, China; [2]Fudan University Shanghai Cancer Center, Shanghai, China*
Email: zhanghh68@mail.sysu.edu.cn

Background and aims: Perineural invasion (PNI) is a frequently observed pathological feature in hilar cholangiocarcinoma (hCCA), and it is associated with poor prognosis and aggressive behavior. However, the underlying mechanisms and potential therapeutic strategies for addressing PNI remain elusive.
Method: This study retrospectively recruited 324 eligible hCCA patients to assess the prognostic significance and clinic-pathological correlation of PNI. A novel spatial proteomics approach integrating laser capture microdissection with high-resolution mass spectrometry was utilized to decipher the molecular alterations in hCCA cells and nerve fibers within PNI regions. Tumor-Schwann cell (SCs) co-culture model, patient-derived organoids, and several *in vivo* models were employed to explore the impact of the identified target on hCCA progression and to investigate potential therapeutic strategies.
Results: In this large cohort study of hCCA, PNI was detected in 59.3% (192/324) of patients and was identified as an independent risk factor associated with adverse prognosis (harzard ratio = 1.73 [1.22–2.45], $p = 0.015$), lymph node metastasis, and distant metastasis. The comparative spatial proteomics analysis of PNI regions (N = 13) versus non-PNI regions (N = 11) unveiled an up-regulation of the neurotrophic factor VGF in neural fibers as well as epithelial-mesenchymal transition (EMT) in hCCA cells. Multiplex immunofluorescence staining validated the specific overexpression of VGF in SCs within intra-tumoral nerve fibers. Further spatial distance analysis revealed an association between SC-derived VGF and EMT in hCCA cells within PNI regions. *In vitro* experiments demonstrated that both recombinant VGF protein and SCs-derived conditional media both could promote the proliferation, invasion, and EMT in hCCA cells. Furthermore, in the subcutaneous tumor implantation mouse model and sciatic nerve tumor injection mouse model, co-implantation of hCCA cells with SCs boosted the proliferation, circulating tumor cell dissemination, and nerve invasion of hCCA,

while SCs clearance, EMT inhibition, or VGF blockade could reverse the promoted progression.
Conclusion: This study establishes PNI as an independent pathological risk factor in hCCA and provides insights into the underlying molecular mechanisms, implicating SCs-derived VGF to promote EMT in hCCA cells. These findings support considering PNI as a pathological criterion and emphasize the clinical therapeutic prospects of clearing SCs, inhibiting EMT, and blocking VGF in the management of hCCA.

Engineered oncolytic vesicular stomatitis virus expressing HBsAg and IL-15 enhances immune activation and tumor killing in hepatitis B-positive hepatocellular carcinoma

Chuanjian Wu[1], Tailai Xin[1], Xiaoming Cheng[1], Yuchen Xia[1]. [1]*Wuhan University, Wuhan, China*
Email: 00032118@whu.edu.cn

Background and aims: Hepatocellular carcinoma (HCC) is one of the most prevalent and lethal cancers worldwide, with chronic hepatitis B virus (HBV) infection being a major risk factor. Despite its high incidence, effective treatment options for HBV-positive HCC remain limited. This study aims to develop a novel therapeutic strategy for HBV-positive HCC by combining oncolytic virotherapy, therapeutic vaccination, and immune modulation.
Method: We engineered a recombinant vesicular stomatitis virus (rVSVM51R) to express hepatitis B surface antigen (HBsAg) and a superagonist form of interleukin-15 (IL15) fused with the IL15Rα sushi domain (rVSVM51R-S-mIL15-Ra). The therapeutic efficacy of this multifunctional oncolytic virus was evaluated in HBV-positive subcutaneous hepatoma and primary HCC mouse models. Single-cell RNA sequencing was used to analyze tumor-infiltrating immune cells, and cell depletion experiments identified key immune cell populations contributing to tumor inhibition. The humanized version of the virus (rVSVM51R-S-hIL15-Ra) was tested in a humanized mouse model to confirm its translational potential.
Results: rVSVM51R-S-mIL15-Ra demonstrated superior antitumor activity compared to rVSVM51R-mIL15-Ra or rVSVM51R-S, enhancing immune activation and promoting tumor cell destruction. Single-cell RNA sequencing revealed that rVSVM51R-S-mIL15-Ra increased infiltration of antigen-presenting macrophages, Th1 and memory CD4+ T cells, and effector CD8+ T cells into the tumor microenvironment, resulting in enhanced tumor killing. Cell depletion experiments confirmed the essential roles of macrophages, CD4+ T cells, and CD8+ T cells in tumor inhibition. Importantly, rVSVM51R-S-hIL15-Ra exhibited significant therapeutic efficacy in humanized mouse models, demonstrating its potential for clinical application.
Conclusion: This study presents a multifunctional oncolytic virus capable of effectively targeting HBV-positive HCC by inducing tumor cell destruction, activating anti-HBsAg immunity, and modulating the tumor microenvironment. This novel approach holds promise not only for HBV-positive HCC but also for other tumor types, offering a potential new avenue for cancer immunotherapy.

THU-064
GPC3-based mRNA cancer vaccine for hepatocellular carcinoma immunotherapy

Yifan Jiang[1], Yu Li[1], Jian Wu[1]. [1]*Division of Hepatobiliary Pancreatic Surgery, First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China*
Email: 12118305@zju.edu.cn

Background and aims: Messenger RNA (mRNA) vaccine has emerged as a promising strategy for cancer therapy. While personalized mRNA vaccine based on tumor-specific antigen (TSA) has obtained attention for its strong specificity and therapeutic potential, the high cost and complexity limit broader clinical application. In contrast, tumour-associated antigen (TAA)-based vaccine may offer a potentially simpler and more accessible approach, addressing key challenges associated with personalized therapies. In this study, we aim to develop a universal mRNA cancer vaccine targeting tumour-associated antigen Glypican-3 (GPC3) for hepatocellular carcinoma (HCC).
Method: We designed a GPC3-based mRNA vaccine for HCC and evaluated the therapeutic efficacy and safety of the cancer vaccine. We employed single-cell sequencing, spatial transcriptomics and mass cytometry to characterize the tumour microenvironment (TME) in pre-clinical model following combination therapy and to elucidate the mechanism.
Results: Our novel vaccine showed effective antigen production and elicited potent anti-tumour immune responses. It markedly suppressed HCC progression, particularly when utilized in combination with immune adjuvant. This demonstrated the feasibility of developing cancer vaccine based on TAA. Mechanistically, the mRNA-GPC3 cancer vaccine reprogrammed the tumour microenvironment in HCC and significantly enhanced the interaction between cDC1 and $CD8^+$ T cells.
Conclusion: The GPC3-based mRNA cancer vaccine showed considerable therapeutic efficacy in HCC. The combination with an immune adjuvant disrupted immune tolerance in HCC, presenting a promising translational treatment strategy for HCC. This study also indicated the viability of TAA-based cancer vaccine and the potential adaptability to other solid tumours, providing a versatile platform for cancer immunotherapy.

THU-065
Targeting CDC7 enhances anti-PD-1 immunotherapy in hepatocellular carcinoma

Liang Zhang[1], Sheng Yan[1]. [1]*Department of Hepatobiliary and Pancreatic Surgery, The Second Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China*
Email: 2322062@zju.edu.cn

Background and aims: Improving the effectiveness of immune checkpoint blockade for patients with hepatocellular carcinoma (HCC) remains challenging. The aim of this study is to identify the role of cell division cycle 7 (CDC7) in resistance to anti-PD-1 therapy in HCC.
Method: Orthotopic and subcutaneous HCC tumors and hydrodynamic tail vein injection models were used, as well as the subcutaneous B16F10 and MC38 tumors. RNA-sequencing was performed to identify CDC7's downstream effectors.
Results: CDC7 was overexpressed in HCC tissues and correlated with inferior prognosis and responses to anti–PD-1 treatments in HCC patients. We confirmed the oncogenic role of CDC7 in promoting HCC cell growth and metastasis. Genetic depletion or pharmacological inhibition of CDC7 elicits an increased influx of T cells into tumors, reduces tumor burden and prolongs the survival in HCC mouse models, while overexpressing CDC7 generates the opposite effects. CDC7 promotes tumor-associated macrophages infiltration and M2 polarization. In addition, CDC7 negatively manipulates PD-L1 expression on HCC cells via mTOR signaling. Lastly, blocking CDC7 functions augments antitumor immunity and enhances the effectiveness of anti-PD-1 therapy without causing additional toxicity in HCC mouse models, as well as in syngeneic B16F10 tumor models.
Conclusion: Our findings unveil a previously unrecognized role for CDC7 in regulating HCC antitumor immunity, potentially advancing HCC immunotherapy.

THU-075

A naturally derived monoterpene potentiates sorafenib's anticancer efficacy in drug-induced-hepatocellular carcinoma animal model

Amr Amin[1]. [1]*University of Sharjah, Sharjah, United Arab Emirates*
Email: a.amin@sharjah.ac.ae

Background and aims: Sorafenib (SB) is a multikinase inhibitor and is currently one of the first-line treatments for advanced hepatocellular carcinoma (HCC). However, its clinical benefit often went along with extensive side effects and the development of drug resistance, reducing the possibility of its long-term use. In a view to widen its therapeutic possibilities, combination therapy with other agents is thus being pursued. Our previous studies identified a monoterpene, safranal (SF); one of the major bioactive constituents of saffron, as a promising inhibitor of HCC progression. These data justify the identification of whether synergy, such as between SB and SF, exists toward a desired outcome of HCC treatment.
Method: In this study, we investigated the therapeutic use of SF or the combination of SB with the cirrhosis rat model of HCC and assessed the efficacy of SB and SF in inhibiting tumor growth. In addition to developing an animal model, RNA-seq Libraries were constructed and analyzed, differential gene expression was assessed, gene ontology enrichment, pathway and network analyses were employed and both immunohistochemical and immunoblotting techniques were utilized.
Results: In the cirrhotic rat model of HCC, treatment with SF-SB combination increased the anticancer potential of SB. The study presents an inexpensive natural bioactive agent, SF, to extend therapeutic potency in SB. Transcriptome analysis eventually identified 45 genes associated with suppression of HCC and included cell proliferation, response to oxidative stress, apoptosis, and regulation of the cell cycle. The combination downregulated NF-κB-p65, COX-2, and β-catenin, pointing out the use of this combination as one of the low-cost oncological therapies. Further studies must be done to establish safe dosages and clinical applications.
Conclusion: NF-κB, β-catenin, COX-2, TNF-α, cyclin B1, and MMP-9 pathways have been suggested to be implicated in the development of liver cancer and promote tumor growth, angiogenesis, inflammation, and inhibit apoptosis. Combined treatment with SF and SB decreases Bcl-2 levels and increases pro-apoptotic proteins such as Bax, caspase-8, caspase-9, and caspase-3, resulting in apoptosis. The combined treatment reduces proliferative markers (Ki-67, PCNA, cyclin B1) and inflammatory markers (NF-κB, β-catenin, MMP-9, COX-2), demonstrating anti-proliferative, anti-inflammatory, and apoptotic effects in HCC models.

THU-076-YI

RIPK3 is a metabolic regulator impacting mitochondrial dysfunction, endoplasmic reticulum stress and tumour development during murine chemical-induced hepatocarcinogenesis

André F. L. Cardador[1], Marta B. Afonso[1], Ana C. Pêgo[2], Maria Manuela Gaspar[1], Raffaella Gozzelino[3], Jérémie Gautheron[4,5], Cecilia Rodrigues[1]. [1]*Research Institute for Medicines (iMed.ULisboa), Faculty of Pharmacy, Universidade de Lisboa, Lisbon, Portugal;* [2]*Chronic Diseases Research Center (CEDOC), Nova Medical School (NMS), Lisbon, Portugal, Lisbon, Portugal;* [3]*Chronic Diseases Research Center (CEDOC), Nova Medical School (NMS), Lisbon, Portugal, Lisboa, Portugal;* [4]*Institute of Cardiometabolism and Nutrition (ICAN), Paris, France, Paris, France;* [5]*Sorbonne Université, Inserm, Centre de Recherche Saint-Antoine (CRSA), Paris, France, Paris, France*
Email: aflcardador@gmail.com

Background and aims: Receptor-interacting protein kinase 3 (RIPK3)-dependent signalling is triggered under chronic liver injury in humans. We have previously shown that blocking RIPK3 arrested steatotic liver disease progression and ameliorated hepatic metabolic dysfunction in mice. Still, the precise metabolic role of RIPK3 during hepatocarcinogenesis remains elusive.
Method: Two-week-old male C57BL/6 wild-type mice (WT) or *Ripk3*-deficient ($Ripk3^{-/-}$) pups were injected with diethylnitrosamine (DEN; 25 mg/kg i.p.). At 42 weeks macroscopic tumours were counted and measured for phenotypic characterization. Gene expression and protein production were evaluated through qRT-PCR and immunoblotting, respectively. Liver samples were processed for immunophenotyping by flow cytometry.
Results: Ablation of *Ripk3* abrogated tumour frequency and tumour size in DEN-exposed mice, compared with WT counterparts. In line with our previous reports, peroxisome proliferator-activated receptor-gamma coactivator-1alpha (*Pgc-1α*), implicated in mitochondrial biogenesis, was markedly increased in $Ripk3^{-/-}$ mice, compared with WT counterparts, in all experimental conditions. In turn, the expression of mitochondrial fission 1 (*Fis1*) and dynamin-related protein 1 (*Drp1*) were decreased in tumour nodules from $Ripk3^{-/-}$ mice, consistent with improved mitochondrial quality. Mitochondrial dysfunction is known to be closely related to endoplasmic reticulum (ER) stress, while mitochondria-ER interplay is critical for cell fate and inflammation. In this regard, the absence of *Ripk3* downregulated the three major unfolded protein response pathways in the livers of DEN-exposed mice, as assessed by reduced levels of total activating transcription factor 6 (ATF6), X-box binding protein 1 (XBP1 s) and ATF4, as well as both protein kinase R-like ER kinase (PERK) and eukaryotic Initiation Factor 2 (EIF2α) phosphorylation. Further, *Ripk3* deficiency reduced the expression of the downstream inflammasome markers caspase-1 and interleukin-1β, together with reduced macrophage infiltration in DEN livers. Finally, blocking RIPK3 did not impact the hepatic infiltration of CD4+T or CD8+T cells. Still, the levels of programmed death-1 (*Pd-1*) and its ligand *Pd-l1* were reduced in tumour nodules from mice lacking *Ripk*3.
Conclusion: *Ripk3* deficiency reduced hepatic tumour burden in a murine model of chemical-induced hepatocarcinogenesis. Our results indicate that RIPK3 impacts mitochondrial and ER homeostasis, likely contributing to metabolic dysfunction and inflammation in liver carcinogenesis. Moreover, *Ripk3* deletion influenced the PD-L1/PD-1 axis, dampening T cell exhaustion within the tumour microenvironment.

THU-077-YI

E7386 enhances lenvatinib's antitumor efficacy and upregulates ATF4 signalling in preclinical models and human hepatocellular carcinoma

Agavni Mesropian[1], Albert Gris-Oliver[1], Ugne Balaseviciute[1], Martí Torres-Marcen[1], Jordi Abril-Fornaguera[1], Marta Piqué-Gili[1], David Camell[1], Judit Peix[1], Elisa Fernández-Martínez[1,2], Júlia Huguet-Pradell[1,2], Ieva Keraite[1,2], Roger Esteban-Fabró[1], Takayuki Kimura[3], Alka Potdar[4], Marina Barcena-Varela[2], Katherine E. Lindblad[2], Amaia Lujambio[2], Ernesto Guccione[5], Swan N Thung[2], Daniela Sia[2], Roser Pinyol[1], Josep Llovet[1,2]. [1]*Translational Research in Hepatic Oncology, Liver Unit, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Hospital Clinic, University of Barcelona, Barcelona, Spain;* [2]*Mount Sinai Liver Cancer Program (Divisions of Liver Diseases, Department of Hematology/Oncology, Department of Medicine), Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, United States;* [3]*Tsukuba Research Laboratories, Eisai Co., Ltd., Tsukuba, Ibaraki, Japan;* [4]*Clinical Evidence Generation, Eisai Inc., Nutley, New Jersey, United States;* [5]*Center for OncoGenomics and Innovative Therapeutics, Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, United States*
Email: josep.llovet@mountsinai.org

Background and aims: Lenvatinib monotherapy is an approved first-line therapy for advanced hepatocellular carcinoma (aHCC). ~30% of aHCC show aberrant activation of beta-catenin and is associated with

immune evasion and limited immunotherapy responses. However, it remains an undruggable target. Here, we studied the antitumor and antiangiogenic activity of combining E7386 (an oral CREB-binding protein (CBP)/beta-catenin protein-protein interaction inhibitor) with lenvatinib and elucidated an additional mechanism of action of E7386 that boosts antitumor response.
Method: We generated a genetically engineered *CTNNB1*-mutant (encoding for beta-catenin) murine HCC model and randomized the animals to receive vehicle, E7386, lenvatinib, or the combination (n = 22–23 per arm). We evaluated survival and analyzed the tumors transcriptomically (single-sample gene set enrichment analysis) and at the protein level (immunohistochemistry and western blotting), along with five patient-derived organoids (PDOs), four HCC cell lines, and seven paired pre-/post-treatment human HCC specimens receiving E7386 in combination with lenvatinib (NCT04008797).
Results: *In vivo*, E7386 + lenvatinib significantly prolonged mouse survival in comparison with either monotherapy ($p < 0.05$). Cell lines and PDOs corroborated that sensitivity to E7386 depends on processes beyond CBP/beta-catenin interaction blockade. Mechanistically, transcriptomic analysis revealed that E7386 dysregulated multiple pathways governed by CBP partners. One of the top dysregulated pathways *in vivo* and *in vitro* represented the activation of Activating Transcription Factor 4 (ATF4) assessed by *ATF4* gene expression and enrichment of pathway-related gene signatures. Among seven paired patient samples obtained, upregulation of ATF4 signatures was confirmed in four patients, three of which exhibited maximum tumor shrinkage (MTS) larger than 30%. *In vivo* and *in vitro*, E7386 triggered ATF4-mediated integrated stress response (ISR) governed by the GCN2/EIF2alfa/ATF4 pathway, altering the expression of targeted pathways related with protein synthesis, cell cycle and angiogenesis, as suggested by transcriptomic analysis. In addition, E7386 concomitantly potentiated the antiangiogenic effects of lenvatinib *in vivo*, assessed by deconvoluting transcriptomic data and immunostaining, resulting in reduced CD31+ cells and endothelial cell content, and increased hypoxia.
Conclusion: The combination of E7386 and lenvatinib enhanced survival in mice and achieved anti-tumor responses in patients. Mechanistically, E7386 induced ATF4-dependent ISR, thereby potentially altering protein synthesis, reducing cyclin levels and limiting cell cycle progression. E7386 potentiated the antiangiogenic effects of lenvatinib, resulting in reduced angiogenesis, contributing to extended survival in mice and enhanced antitumor activity compared with either monotherapy.

THU-078
Artificial intelligence-driven prediction of biology-related poor outcome and presence of vascular invasion in hepatocellular carcinoma

Email: josep.llovet@mountsinai.org

Background and aims: The median overall survival (OS) for patients with resectable hepatocellular carcinoma (HCC) is 5 years, but ~70% experience tumor recurrence. Advances in digital pathology and artificial intelligence (AI) are driving progress toward personalized clinical management. Here we aimed to develop an AI model capable of molecularly classifying HCC and the presence of microvascular invasion (mVI), providing information on the molecular biology associated with poor outcomes.
Method: A transformer-based deep-learning (DL) algorithm was developed using digitized hematoxylin and eosin (H&E) slides from an in-house cohort of 431 surgically resected HCC patients (training cohort). In the training cohort, 5-fold cross-validation was applied and the model was then deployed on two test sets: TCGA-LIHC (TCGA) (n = 363) and advanced-stage HCC (aHCC) (n = 64).
Results: In the TCGA cohort, patients with HCC molecular subclasses of proliferation (*S1* "stromal"; *S2* "stemness-angiogenesis") had a median survival of 3.8 years (5-year OS: 45%) vs non-proliferation subclass (*S3* "differentiated") patients, who had good outcome with a median survival of 5.8 years (5-year OS: 54%; $p < 0.005$). In the internal cross-validation, the DL-model showed significant prediction of molecular subclasses, achieving median area under the curve (AUC) values of 0.75 ± 0.11 for *S1*, 0.75 ± 0.07 for *S2*, and 0.79 ± 0.10 for *S3*. Consistently, the model's performance was reproduced in the test sets with AUCs of 0.72–0.80 on TCGA and 0.76–0.81 on aHCC. Patients from the TCGA classified into the *S3* non-proliferation subclass by the model had a median survival of 5.8 years (5-year OS: 52%), while patients classified into the *S1*/*S2* proliferation subclass had a median survival of 3.5 years (5-year OS: 44%; $p < 0.05$). In the same line, aHCC patients from the second test set stratified by the DL-model into the *S3* proliferation subclass showed an improved 3-year OS of 89% (95% CI: 71–100%) vs *S1*/*S2* proliferation subclass patients (42% [95% CI: 25–71%]; $p = 0.02$). In TCGA, 25% of the patients presented mVI. The prediction of mVI by the DL-model achieved a median AUC of 0.70 ± 0.08 in the internal cross-validation and 0.62 ± 0.07 in TCGA. Presence of mVI predicted by AI was associated with worse median OS (4.9 years vs 7.6 years for absence of mVI; $p < 0.005$) and an immunosuppressive microenvironment ($p < 0.001$).
Conclusion: The AI-based model presents a strong predictive capability for identifying HCC patients with favorable biology-related outcomes (*S3* molecular subclass) and mVI. The use of AI to predict molecular and pathological prognostic factors from routinely available H&E slides offers a personalized approach for assessing tumor biology.

THU-079
Beta klotho as a regulator of liver cancer cell proliferation and liver cancer development

Alexandra Aaldijk[1], Dicky Struik[1], Cristy Verzijl[1], Justina Wolters[2], Johan Jonker[1]. [1]*Laboratory of Pediatrics, University Medical Center Groningen (UMCG), Groningen, Netherlands;* [2]*Laboratory of Pediatrics, University Medical Center Groningen (UMCG), Interfaculty Proteomics Research Facility, Groningen, Netherlands*
Email: alexandraaaldijk@outlook.com

Background and aims: Hepatocellular carcinoma (HCC) is one of the most commonly diagnosed cancers and is ranked as the fourth leading cause of cancer morbidity worldwide. Abnormal fibroblast growth factor (FGF) signaling, mediated by FGF receptors (FGFR), has been identified as a driver of liver cancer in 20–30% of cases. However, selective FGFR inhibitors show only limited efficacy in patients with liver cancer, suggesting the involvement of other genes that control liver cancer progression. Recently, we identified KLB, a coreceptor involved in FGF signaling, as a regulator of cell proliferation in Hep3B cells, an FGF19-positive HCC cell line. However, how KLB regulates proliferation in these cells remains unclear. In this study, we aim to

investigate the molecular mechanism through which KLB regulates hepatocyte proliferation.
Method: KLB-deficient Hep3B cells were generated by lentiviral shRNA-mediated knockdown. Subsequently, the effect of KLB deficiency on hepatocyte growth, proliferation, and apoptosis was compared to wildtype cells. To identify the underlying mechanism of KLB-dependent regulation of liver cancer cell proliferation, transcriptomic and proteomic analyses of wildtype and KLB-deficient Hep3B cells were performed.
Results: Through analysis of the cancer dependency atlas (DepMap), we identified KLB as the top essential gene controlling Hep3B viability. Experimental validation of this finding through lentiviral knockdown of KLB in Hep3B cell revealed a 50% reduction of cell viability, which was explained by a 35% reduction in cellular proliferative capacity. Similar to previous studies, specific inhibition of FGFR4 using BLU9931 did not affect cell proliferation. However, pan-FGFR inhibition decreased cell proliferation to a similar extent as lentiviral knockdown of KLB, indicating the involvement of either FGFR1–3. Pathway enrichment analysis revealed that loss of KLB dysregulated many cancer-related pathways, including Hippo and Wnt signaling, cytokine-cytokine receptor interaction, and proteoglycans of cancer.
Conclusion: By inducing a lentiviral shRNA-mediated knockdown of KLB in Hep3B cells, we observed a decrease in cell proliferation upon a loss of KLB, suggesting that KLB can regulate liver cancer cell proliferation. Moreover, we identified that loss of KLB in Hep3B cells resulted in a dysregulation of cancer-related pathways, indicating a role for KLB in liver cancer cell development.

Platelet-derived extracellular vesicles (PEVs) in hepatocellular carcinoma. Emerging diagnostic biomarkers

Ángela Rojas[1,2], Rocío Munoz-Hernández[1,2], Sheila Gato-Zambrano[1,2], Antonio Gil-Gómez[1,2], Vanessa García-Fernández[1,2], Rocío Gallego-Durán[1,2], Douglas Maya-Miles[1,2], Teresa Ferrer[3], Isabel Fernández-Lizaranzu[1], Javier Ampuero[1,2,3], Manuel Romero-Gómez[1,2,3]. *[1]Seliver Group, Instituto De Biomedicina De Sevilla (IBiS), Hospital Universitario Virgen Del Rocío/CSIC/Universidad De Sevilla., Sevilla, Spain; [2]Centro De Investigación Biomédica En Red De Enfermedades Hepáticas y Digestivas (CIBEREHD)., Madrid, Spain; [3]UGC de Enfermedades Digestivas, Hospital Universitario Virgen Del Rocío, Sevilla., Sevilla, Spain*
Email: angela_rojas16@hotmail.com

Background and aims: Hepatocellular carcinoma is a primary liver cancer where platelets have been proposed as key mediators of carcinogenesis. Platelet activation induces the release of extracellular vesicles (PEVs). The study aims to determine the use of PEVs as a potential circulating biomarker of HCC.
Method: Two hundred thirty-five patients living with liver disorders were included: 53.6% (126/235) were MASLD (control group), 18.7% (44/235) cirrhotic patients followed for 5 years and 27.7% (65/235) had HCC. Plasma-heparin samples collected at the entry of the study were used to characterize PEVs by size, (0.2–1 µm Megamix Plus SC protocol, BD) and the expression of CD42b (glycoprotein Ib) and phosphatidylserine (the binding partner of annexin V) cell surface. Levels of PEVs Annexin V CD42b+ were quantified in plasma-heparin samples by flow cytometry. In a pilot study levels of PEVs were measured before and after HCC treatment. PEVs were isolated by FACs and the transcriptome profile was analyzed by the GeneChip™ miRNA 4.0 Array.
Results: The main sex 66.4% were male and average age 60 ± 11 years. Alpha-fetoprotein, GGT and AST serum level were increased significantly in HCC in comparison with non-HCC cirrhotic patients ($p = 0.016$, $p = 0.007$ and $p < 0.001$). In patients with HCC development a significant increase of PEVs was found (F4-HCC: 1785 ± 229; F4: 656 ± 156; Control: 525 ± 95 U/µl; $p < 0.0001$ and $p < 0.0001$ respectively), despite no significant differences in serum total platelets ($p = 0.33$). Diagnostic accuracy of PEVs-CD42b was addressed by AUROC: 0.80 (0.70–0.89; $p < 0.001$) with 70% sensitivity, 81.5% specificity; PPV 79% (Cut off: 463.75 U/µl). In multivariate analysis age, sex, AFP and PEVs-CD42b (OR: 1.001 (1.000–1.002; $p = 0.009$) were independently associated with HCC diagnosis. In addition, PEVs levels were also significantly increased in BCLC-A-HCC stage patients compared to the cirrhotic group ($p < 0.001$). In a subgroup of patients undergoing curative treatment ($n = 6$; 5 transplants and 1 resection) and 6 non-responders treated with sorafenib, PEVs levels decreased after treatment in the cured group, this trend was not observed in the non-responder group. We found significant differences in the transcriptomic profile of PEVs from BCLC-A HCC compared to cirrhotic patients; 9 microRNAs were upregulated (fold change >2, p value >0.01) and 10 were down regulated.
Conclusion: Circulating PEVs levels are raised in patients with HCC despite no changes in platelet levels. In clinical settings, PEVs showed potential as non-invasive biomarker for HCC diagnosis and treatment response. The preliminary data indicate a differential miRNA profile within platelet-derived EVs, but further studies are necessary to elucidate their potential contribution to HCC.

THU-081

Association of T cell epitope spreading with the clinical efficacy of HBV-TCR T cell therapy for HBV-related HCC

Anthony Tan[1], Shoukit Hang[2], Adeline Chia[1], Nicole Tan[1], Thinesh Krishnamoorthy[3], Wan Cheng Chow[3], Regina Wong[4], Alessandro Sidoli[2], Lu-en Wai[4], Antonio Bertoletti[1]. *[1]DUKE-NUS Medical School, Singapore, Singapore; [2]T Cell Diagnostics Pte. Ltd., Singapore, Singapore; [3]Singapore General Hospital, Singapore, Singapore; [4]Lion TCR Pte. Ltd., Singapore, Singapore*
Email: anthony.tan@duke-nus.edu.sg

Background and aims: The clinical success of therapies with T cells engineered with a Chimeric Antigen Receptor (CAR) or a T Cell Receptor (TCR) has been remarkable in hematological cancers but limited in solid cancers. By studying the immunological features of patients with HBV-related HCC treated with mRNA-TCR-engineered T cells, we observed that complete or partial response to the TCR-T cell treatment occurring in some patients was associated with the triggering of an inflammatory reaction, and it was not proportional to the quantity and persistence of TCR-T cells infused into the patients. We hypothesize that the efficacy of TCR-T cell therapy against HBV-related HCC can be associated not with their persistence but with an ability to alter the HCC microenvironment and induce novel antitumor T cells.
Method: Two patients with objective partial reduction of the HBV-HCC were studied during the course of multiple infusions of escalating doses of mRNA electroporated HBV-TCR T cells (maximal dose $3–10 \times 10^6$ CD8+TCR+ T cells/kg). Frequency of engineered and naturally induced HBV-specific T cells were quantified at multiple time points using two different methods (ELISPOT and whole blood cytokine release assay).
Results: Volumetric reduction of HCC metastasis (Pt1) and AFP values (Pt2) were associated with inflammatory events (CXCL-10 elevation/increased frequency of activated T cells) but were not proportional nor temporally related to TCR-T cell infusion. T cells specific for different HBV proteins were undetectable at the start of treatment but become detectable intermittently after the initial escalation phase of the treatment (<42 days after first infusion). Newly induced T cells were specific for HBV antigens not recognized by the adoptively transferred HBV-TCR T cells.
Conclusion: We provided preliminary evidences that clinical efficacy of TCR-T cell therapy in patients with HBV-related HCC is not directly proportional to the quantity and persistence of infused TCR-T cells but to their ability to induce inflammation and trigger a T cell response against novel T cell epitopes through a possible process of T cell epitope spreading.

THU-084

Comprehensive characterization of the peripheral immune landscape through single-cell transcriptomics in hepatocellular carcinoma patients undergoing immunotherapy

Monica Higuera[1], Agnes Soriano-Varela[1,2], Maria Torrens[1,2], Maria Montesinos[1], Xavier Merino[3], Beatriz Minguez[1,2,4,5]. Email: beatriz.minguez@vallhebron.cat

Background and aims: Immunotherapy combinations have enhanced prognosis for hepatocellular carcinoma (HCC) patients eligible for systemic therapy, with about 20% achieving durable radiological responses. However, the factors influencing response or resistance remain unclear, hindering patient selection and treatment customization. In this study, we focused on first-line treatment with atezolizumab (anti-PDL1) and bevacizumab (anti-VEGF) (atez/bev).
Method: cfDNA (Cell-free DNA) levels were quantified and the C228T mutation in TERT promoter was analyzed in 11 HCC patients treated with atez/bev. Peripheral CD45+ cells were sorted and labeled with a panel of 30 immune markers (AbSeq Immune Discovery Panel). Cells were isolated individually using the Rhapsody system and 400 genes were amplified. Cell annotation was performed using Celldex and the Monaco reference dataset.
Results: The majority of patients (72.7%) of patients were male (8/11) with a median age of 64 years. The most prevalent underlying cause of liver disease was hepatitis C virus infection (54.5%). The median follow-up period was 19 months. During follow-up, two patients (18.2%) exhibited a complete radiological response (CR), five patients (45.4%) demonstrated a partial radiological response (PR), and four patients (36.4%) exhibited disease progression (PD) as the best radiological response, assessed according to the mRECIST criteria. Patients who exhibited a response (CR/PR), demonstrated lower baseline levels of circulating cell-free DNA (cfDNA), with a mean of 3.95 ± 1.96 ng/µl compared to 5.80 ± 1.69 ng/µl in patients with PD. No statistically significant differences were observed in TERT C228 T mutation levels between patients who achieved CR/PR (14.06 ± 6.04) and those who exhibited PD (13.60 ± 12.15). The analysis of cell populations in peripheral blood revealed the presence of 17 distinct clusters of cells in the cohort under study. Patients with PD as the best radiological response exhibited a baseline level of 0.56% [0.37–0.83] of plasmablasts, compared with 0.19% [0.13–0.55] in patients with CR+RP (p = 0.03). Patients who achieved CR or PR exhibited alterations in the Th1/Th17 lymphocyte population between the baseline measurement (4.3% [1.19–5.29]) and the three-month follow-up (2.9% [0.79–3.3]) (p = 0.03).
Conclusion: In this preliminary analysis, significant differences in specific immune cell populations were identified utilizing single-cell technology. This approach may serve as a valuable tool for identifying patients with distinct prognostic outcomes under atezolizumab and bevacizumab (atez/bev) treatment. Molecular investigations aiming to elucidate gene and protein expression profiles are currently ongoing.

THU-085-YI

SMG7 as a potential driver of chronic liver disease progression to hepatocellular carcinoma

Betsaida Ojeda-Perez[1,2,3,4], Victor J. Fernandez-Ramirez[1,2,3,4], Antonio Garcia-Estrada[1,2,3,4], Jose Cordoba-Chacon[5], Raul M. Luque[1,2,3,4], Manuel L. Rodríguez-Perálvarez[1,3,6,7], Juan Luis López-Cánovas[1,2,3,4], Manuel D. Gahete[1,2,3,4]. Email: BetsaidaOjeda@gmail.com

Background and aims: SMG7 factor has a main role in the nonsense-mediated mRNA decay (NMD) pathway, which eliminates mRNAs with common errors, such as the presence of a premature termination codon (PTC), avoiding their translation. In addition, SMG7 promotes the survival of cells after genotoxic stress by inducing the ATR-Chk1 pathway. The continuous exposition of lipotoxic free fatty acids (FFA) in chronic liver disease (CLD) leads to cellular stress and liver damage. In fact, many NMD targets are implicated in cellular stress response. Therefore, this work aimed at studying the involvement of NMD, and specially SMG7, in the progression of metabolic dysfunction-associated steatotic liver disease (MASLD), metabolic-dysfunction associated steatohepatitis (MASH) and hepatocellular carcinoma (HCC).
Method: Expression (mRNA) of 22 NMD components was analyzed in two retrospective HCC cohorts (cohort 1 [n = 89 HCC and non-tumor paired adjacent tissues (NTAT)] by microfluidic-based qPCR array and cohort 2 [n = 31 HCC and n = 31 NTAT] by RNA-seq), and validated in six external cohorts with healthy, MASLD, MASH, HCC, and/or NTAT samples. Human (THLE2) and mouse primary hepatocytes (MPH) were treated with FFAs (oleate and palmitate). Pharmacological (NMDI14, which blocks SMG7-UPF1 interaction) and genetic modulation of SMG7 were carried out in two HCC-derived cell lines (Hep3B and SNU-387) to explore the functional effects on proliferation, migration, colony and tumorospheres formation. Additionally, NMD target genes expression (mRNA to pre-mRNA ratio) was measured.
Results: SMG7 is consistently overexpressed in samples of MASH, HCC, and MASH-derived HCC from different internal and external cohorts. Besides, the expression of SMG7 (mRNA) was induced by palmitate in THLE2 and MPH and its overexpression in HCC cell lines promotes proliferation, and colony and tumorospheres formation. The silencing of SMG7 decreased the proliferation and migration of SNU-387, while in Hep3B does not have major functional effects, possibly due to the compensatory increase in UPF1, another key NMD factor. In fact, the co-silencing of SMG7 and UPF1 reduced tumor aggressiveness in both HCC-cell lines. Accordingly, the treatment with NMDI14 (blocking the SMG7-UPF1 interaction) reduced the aggressiveness of the HCC cell lines, without affecting the viability of MPH. Mechanistically, there were no changes in the expression of NMD target genes when SMG7 was modulated, suggesting the implication of novel alternative pathways.
Conclusion: NMD, and especially the SMG7 factor, could play a relevant role in the MASLD-HCC progression, therefore, paving the way towards the identification of biomarkers and/or therapeutic targets in these pathologies. Email: caecilia.sukowati@fegato.it

Background and aims: Most hepatocellular carcinoma (HCC) cases develop in the context of severe liver fibrosis and cirrhosis, driven by chronic liver inflammation. A key hallmark of this process is the accumulation of hyaluronic acid (HA), a major component of the extracellular matrix. This study aimed to evaluate the potential of two potent HA synthesis inhibitors as a preventive strategy to impede hepatocarcinogenesis in HCC.
Method: HA synthesis genes *HAS2* and *HAS3* in human HCC clinical specimens were analyzed using qRT-PCR from 23 paired tumor and non-tumoral adjacent tissues collected from HCC resection. HA inhibition in vivo was performed in preclinical model of chronic inflammation using adult male transgenic HCC mouse model (HCC-TG) together with its wildtype counterpart (WT) using either non-glycosylated (4-MU) and novelly synthesized glycosylated-4-methylumbelliferone (4-MUR), the later targets only (pre)neoplastic cells. Following oral treatment with two concentrations of 12.5 and 25 mg/kg/day for 3 months, macroscopical and histological parameters of the livers, levels of serum transaminases, and in-depth molecular analysis of genes related to fibrosis, HA synthesis, and inflammation were assessed by qRT-PCR and Western blot.
Results: From human HCC specimens, *HAS2* was upregulated in adjacent non-tumoral compared to HCC ($p < 0.001$) while *HAS3* showed the opposite ($p < 0.05$). During and following in vivo treatment in mice, body and liver weight measurement indicated that both 4-MU and 4-MUR were safe. 4-MUR administration did not increase the levels of alanine transaminase and lactate dehydrogenases in HCC-TG mice. Histological analysis showed that compared to controls, both 4-MU and 4-MUR improved liver histology by reduction of inflammation and fibrosis grades ($p < 0.001$ compared to controls). Further, molecular analysis on 139 mouse liver tissues showed that both compounds dysregulated genes related to HA synthesis (*Has2, Has3, Hyal1, Hyal2*), HA receptor (*Cd44*), fibrosis (*Acta, Fsp1*) and inflammation (*Cxcl1, Il-6, Il1b*, and *TNFα*). The extent of fibrotic-associated genes down-regulations was more noticed for 4-MUR.
Conclusion: This study demonstrated that blocking HA synthesis using both 4-MU and 4-MUR effectively reduced liver damage and inhibited the process of hepatocarcinogenesis, likely through their specific targeting mechanism.

Email: cconter@cicbiogune.es

Background and aims: Tumors, including hepatocellular carcinoma (HCC), undergo extensive metabolic reprogramming to sustain their growth and survival. This study explores a novel, non-tumor-suppressive function of p53 in the metabolic reprogramming of HCC via one of its target genes, *TP53-Induced Glycolysis and Apoptosis Regulator* (TIGAR). While TIGAR is known for its protumorigenic role—shunting glucose from energy production toward nucleotide synthesis and DNA repair—the regulatory mechanisms driving its activation remain poorly understood. Recently, SUMOylation, a pivotal post-translational modification (PTM), has been implicated in liver cancer progression, potentially shedding light on TIGAR's activation.
Method: A comprehensive SUMO interactome analysis was performed using GST-tagged SUMO Binding Entities (SUBEs) for protein pulldown in multiple human hepatoma cell lines (HuH7, PLC, HepG2, and SNU449).
Results: TIGAR displayed a significantly elevated level of SUMOylation, particularly in the SNU449 cell line, which subsequently became the primary focus. Bioinformatic tools were employed to predict SUMOylation-prone sites on the TIGAR protein. Using these predictions, we developed stable cell lines expressing both wildtype and mutant TIGAR variants. The introduction of mutations led to a marked reduction in TIGAR SUMOylation levels. Cells expressing the mutant TIGAR exhibited diminished proliferation, migration, invasion, and spheroid formation. Furthermore, loss of TIGAR SUMOylation disrupted the pentose phosphate pathway, as evidenced by an increased NADP/NADPH ratio and a reduced GSH/GSSG ratio, resulting in heightened oxidative stress.
Conclusion: This study identifies SUMOylation as a novel regulatory mechanism for TIGAR, offering a promising therapeutic target in liver cancer. By disrupting TIGAR SUMOylation, we highlight a potential strategy to induce oxidative stress and inhibit tumor growth. Given TIGAR's dual roles in cancer and normal cellular function, we propose that inhibiting TIGAR SUMOylation, alone or in combination with existing therapies, may serve as an effective approach for HCC treatment. This underscores the broader significance of PTMs as therapeutic targets in oncology.

THU-088
MicroRNA-372-3p impairs fatty acid metabolism in hepatocellular carcinoma cells by targeting CPT1A and ACSL4

Chaiyaboot Ariyachet[1,2], Chinnatam Phetkong[1,2], Pisit Tangkijvanich[1,2]. *[1]Department of Biochemistry, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand; [2]Center of Excellence in Hepatitis and Liver Cancer, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand*
Email: Chaiyaboot.A@Chula.ac.th

Background and aims: Hepatocellular carcinoma (HCC) is a leading cause of cancer death worldwide; however, treatments remain ineffective for many patients. Understanding molecular mechanisms that promote HCC could yield a new therapeutic option. Recent studies suggest emerging roles of microRNAs in HCC biology, including microRNA-372-3p (miR-372-3p), which has been implicated in the pathogenesis of various cancers. Nevertheless, the role of miR-372-3p in HCC remains controversial. In this study, we employed a transcriptomic approach to dissect the molecular function of miR-372-3p in HCC cells.
Method: We generated control and miR-372-3p-overexpressing (372-OE) HCC cells from three independent lines and assessed their proliferation, migration, invasion, and colony formation. To identify the molecular function of miR-372-3p in HCC, we employed RNA-seq analysis of control and 372-OE HCC cells, followed by gene set enrichment analysis (GSEA). To investigate fatty acid metabolism, we

stained control and 372-OE HCC cells for their lipid droplets and determined levels of triglycerides and fatty acid oxidation (FAO). We used confocal and transmitted electron microscopy to examine the interactions of lipid droplets with mitochondria and lysosomes. Finally, we used the bioinformatic approach to identify potential targets of miR-372-3p in lipid metabolism and validated their direct interaction with dual luciferase assays.

Results: We showed that miR-372-3p levels were suppressed in HCC cell lines compared with normal hepatocyte cell lines. Overexpression of miR-372-3p impaired proliferation, migration, invasion, and colony formation of HCC cells, suggesting its tumor suppressing function. Transcriptomic analysis of 372-OE HCC cells revealed enrichment of downregulated genes in fatty acid metabolism, including *CPT1A*, *CPT2*, and *ACSL4*, which are known to facilitate FAO. Consistent with our transcriptomic analysis, we found that miR-372-3p promoted accumulation of lipid droplets and high levels of triglycerides while inhibiting FAO in HCC cells. Moreover, 372-OE HCC cells showed impairment in utilizing lipids in the absence of glucose. We further showed that the interactions of lipid droplets with mitochondria and lysosomes were significantly compromised in 372-OE HCC cells, consistent with decreasing FAO. Mechanistically, we computationally identified three potential direct targets of miR-372-3p in FAO and demonstrated the direct interaction between miR-372-3p and the 3' untranslated regions of *CPT1A* and *ACSL4* transcripts by dual luciferase assays.

Conclusion: miR-372-3p impairs lipid metabolism in HCC cells by suppressing expression of FAO genes and thus could serve as a new therapeutic target to control cancer growth.

THU-089-YI

Tumor microenvironment differences in liver cancer are lineage-dependent when controlled for oncogenic pathway activation

Chun-Shan Liu[1], Yu-Le Wu[2], Li-Chin Wang[3], Kieu Trinh Dinh[1], Philip Puchas[4], Pei-Chi Wei[3], Felix Hartmann[2], Michael Dill[5].

Background and aims: Intrahepatic cholangiocarcinoma (iCCA) is the second most common primary liver cancer, following hepatocellular carcinoma (HCC). ICCA and HCC resemble morphologically distinct liver epithelial cell compartments and exhibit different genetic alterations. They also display a unique tumor microenvironment (TME). Unlike HCC, iCCA is characterized by a stroma-rich TME that affects therapeutic responses to chemotherapy and immunotherapy. However, the molecular mechanisms driving stromal formation in iCCA remain largely undefined. This study aims to investigate the molecular mechanisms driving the stromal phenotype in iCCA while controlling for oncogenic pathway activation.

Method: We established a syngeneic mouse model using organoids derived from murine cholangiocytes and hepatocytes. Both were genetically engineered to carry *Trp53* deletion and $Kras^{G12D}$ mutation (chol-PK and hep-PK, respectively) to control liver tumor formation for both cell lineage and genetic alterations. After orthotopic implantation ($n \geq 9$ per group), liver tumors were systematically analyzed using multiplexed ion beam imaging (MIBI) with a 36-plex panel to map TME spatial distribution ($n \geq 4$ per group). Cell lineages were annotated semi-automatically with the self-organizing map, an unsupervised machine-learning algorithm. Transcriptome and secretome analyses of the organoids were performed to identify cell-intrinsic factors linked to stromal enrichment.

Results: Upon orthotopic implantation, chol-PK and hep-PK organoids formed tumors with 100% and 78% penetrance, respectively, reflecting human iCCA and HCC. Chol-PK tumors were stroma-dominant, with immune cells concentrated at the tumor border. In contrast, hep-PK tumors had a denser cancer cell architecture and more extensive immune infiltration. MIBI revealed distinct spatial patterns of myofibroblasts, T cells, and myeloid cells between tumor types. Transcriptome analysis revealed 186 shared genes ≥ 2-fold up-/downregulated (padj < 0.01) in both organoid lines upon *Trp53* deletion and Kras activation, but 2057 genes were uniquely altered in chol-orgs (≥2-fold, padj < 0.01). The 1011 uniquely upregulated genes in chol-PK were enriched in pathways related to stromal cell modulation, such as focal adhesion (padj < 0.00025).

Conclusion: Our novel, cell lineage-controlled liver cancer model effectively demonstrates relevant differences in TME architecture reminiscent of human iCCA and HCC despite activating the same oncogenic pathways. Lineage-dependent expression changes upon transformation may explain the distinct stromal responses observed in these two cancer entities.

Glutaminolysis-driven iron accumulation in the liver: a mechanism for aging through Lysosomal dysfunction

Claudia M. Rejano-Gordillo[1], Naroa Goikoetxea-Usandizaga[2], Claudia Gil-Pitarch[2], Pietro Guerra[3], Leidy Estefanía Zapata-Pavas[2], Carolina Conter[2], Patricia Peña-Sanfelix[2], Irene González-Recio[2], Mate Maus[4], Teresa C Delgado[5], Isabel Fabregat[6], Miguel Lafarga[7], Manuel Serrano[8], María Luz Martínez-Chantar[2]. *[1]Liver Disease Lab, Center for Cooperative Research in Biosciences (CIC bioGUNE), Basque Research and Technology Alliance (BRTA), 48160 Derio, Bizkaia, Spain, Biofisika Institute, Centro Superior de Investigaciones Científicas, and Department of Biochemisty, Faculty of Science and Technology, University of Basque Country, Spain, Derio, Spain; [2]Liver Disease Lab, Center for Cooperative Research in Biosciences (CIC bioGUNE), Basque Research and Technology Alliance (BRTA), 48160 Derio, Bizkaia, Spain, Derio, Spain; [3]Department of Medicine, University of Padova, Padova, Italy, Padova, Italy; [4]Institute for Research in Biomedicine (IRB Barcelona), Barcelona Institute of Science and Technology (BIST), Barcelona, Spain, Vall d'Hebron Institute of Oncology, Barcelona, Spain., Barcelona, Spain; [5]Liver Disease Lab, Center for Cooperative Research in Biosciences (CIC bioGUNE), Basque Research and Technology Alliance (BRTA), 48160 Derio, Bizkaia, Spain, Biobizkaia Health Research Institute, 48903 Barakaldo, Spain, IKERBASQUE, Basque Foundation for Science, Bilbao, Spain, Derio, Spain; [6]26TGF-β and Cancer Group, Oncobell Program, Bellvitge Biomedical Research Institute (IDIBELL), Gran Via de L'Hospitalet, Barcelona, Spain, Barcelona, Spain; [7]Departamento de Anatomía y Biología Celular, Universidad de Cantabria-IDIVAL, Santander, Spain, Santander, Spain; [8]Altos Labs, Cambridge Institute of Science, Granta Park, UK, Cambridge, United Kingdom*
Email: crejano@cicbiogune.es

Background and aims: Cellular senescence in the liver can be triggered by various factors, including the accumulation of hepatotoxic compounds such as ammonium and iron. Furthermore, metabolic alterations can enhance the hepatic susceptibility to aging. Glutaminase isoform 1 (GLS1) plays a crucial role in ammonium metabolism, converting glutamine to glutamate and ammonium in mitochondria. Our objective is to investigate the involvement of GLS1 and its functional consequences in liver cell senescence.

Method: We employed mouse models and primary hepatocyte cultures for our study. We also analysed aged individuals and obese patients.

Results: Our research indicates that aging individuals experience increased glutaminolysis and hepatic iron accumulation. We found that hepatocyte glutaminase (GLS1) overexpression promotes

hepatic iron accumulation and accelerates aging in vivo. Mechanistically, both in vivo and in vitro experiments demonstrate that toxic ammonia accumulation disrupts the lysosomal acidification capacity, impairing critical processes such as mitophagy and iron metabolism, thereby making hepatocytes more susceptible to ferroptotic stress. Furthermore, the use of an ammonia scavenger and an iron chelator mitigates metabolic dysfunction-associated steatohepatitis (MASH) and ameliorates age-related hallmarks in vitro by restoring lysosomal acidification capacity and enhancing mitochondrial function.
Conclusion: These findings identify a novel mechanism influencing hepatic susceptibility to aging and suggest that GLS1 may serve as a potential target for modulating mitochondrial function by reducing iron and ammonium levels in the context of cellular senescence. Additionally, these results support the potential of metabolite chelators as promising therapeutic options for aging.

THU-092
Modulation of the tumor microenvironment: targeted silencing of AATF suppresses TGF-β signaling via lncRNA MIR100HG in hepatocellular carcinoma
Diwakar Suresh[1], Akshatha Srinivas[1], Amith Bharadwaj[1], Bharathwaaj Gunaseelan[1], Suchita Satish[2], Manju Moorthy[3], Gopalakrishna Ramaswamy[3], Prasanna Santhekadur[1], Divya Kumar[4]. *[1]JSS Medical College, Mysore, India; [2]Department of Pathology, JSS Medical College and Hospital, Mysore, India; [3]TheraCUES Innovations Pvt. Ltd, Bangalore, India; [4]JSS Medical College and Hospital, Mysore, India*
Email: divyapk243@gmail.com

Background and aims: Hepatocellular carcinoma (HCC) is a fatal chronic liver disease with limited therapeutic options. Novel approaches targeting its molecular drivers could be effective in blocking the pathological signaling. Previously, we have shown the pivotal role of apoptosis antagonizing transcription factor (AATF) in promoting angiogenesis in HCC. However, the effect of targeting AATF in the tumor microenvironment (TME) and its effect on HCC development and progression remains unexplored. Here we aim to assess liver-specific silencing of AATF in TME and its effect on tumor growth in an orthotopic xenograft model of HCC.
Methods: Orthotopic xenograft models of HCC were generated by implanting human HCC cells, QGY-7703, into the livers of athymic nude mice. Liver-specific AATF silencing was accomplished via tail vein injection of an adeno-associated viral vector 8 (AAV8) containing siRNA sequences targeting AATF. Tumor progression was monitored over a 4-week period before euthanizing the mice. Whole transcriptomics analysis and functional validation were carried out using liver tissues of control and siAATF mice, and the data were mapped against human and mouse genomes separately to differentiate species-specific expression.
Results: The targeted silencing of AATF in the liver of the orthotopic HCC mouse model showed a notable decrease in tumor growth in comparison to the control mice. The RNA seq transcriptomic analysis showed a significant alteration in the TME (mouse) upon AATF silencing, as evidenced by decreased inflammation, immune response, epithelial-mesenchymal transition, extracellular matrix formation, and angiogenesis. Of note, in the tumor (human), pathways related to the cell cycle, cellular stress response, and metabolism were downregulated in siAATF mice compared to the controls. Furthermore, the integrative analysis of the human-mouse genome showed the transforming growth factor-beta (TGF-β) signaling pathway to be responsible for the tumor-TME interactions. The co-expression analysis of long non-coding RNA (lncRNA) and messenger RNA (mRNA) showed a positive correlation to the downregulated TME-related processes in siAATF mice. Consistently, six hub lncRNAs involved in extracellular matrix remodeling were found to be downregulated in siAATF mice compared to controls. Further analysis and functional validation revealed that silencing of AATF modulated the tumor microenvironment by suppressing the TGF-β signaling pathway via the lncRNA MIR100HG in HCC.
Conclusion: Thus, the study offers compelling molecular evidence supporting AATF's role in TME remodeling, suggesting its potential as a therapeutic target in HCC.

THU-095
Single-cell spatial proteomic landscape of intrahepatic cholangiocarcinoma immune microenvironment reveals immune evasion via FSTL1negative macrophage
Yongquan Chi[1], Wenzhu Li[1], Jianhua Rao[1]. *[1]The First Affiliated Hospital with Nanjing Medical University, Nanjing, China*
Email: raojh@njmu.edu.cn

Background and aims: Intrahepatic cholangiocarcinoma (ICC), an aggressive biliary malignancy, is usually diagnosed at advanced or metastatic stages, resulting in poor prognosis with five-year survival rate less than 5%, significantly lower than many other cancers. The incidence of ICC has risen steadily, yet effective treatments remain scarce. Understanding the ICC immune landscape while preserving the tumor microenvironment (TME) architecture could reveal potential targets for innovative therapies to improve patient outcomes.
Method: An imaging mass cytometry (IMC) panel was designed to analyze 36 biomarkers across 36 tissue regions from 12 each ICC patients, including tumor tissue, adjacent tumor and non-tumor tissue, and normal tissue. This approach produced single-cell resolution histology images, enabling cell-type clustering and assessment of spatial distribution and functional changes with subsequent in vivo and in vitro experiments validating results above.
Results: A comprehensive analysis of the ICC immune microenvironment was performed. In the tumor region, immune cell numbers decreased, while an unusual significant positive interaction between M1-phenotype macrophages and tumor cells were observed. At the tumor margin, an accumulation of M2 macrophages, CD4+ T cells, CD8+ T cells, Treg cells, and neutrophils was identified. M2 macrophages showed positive correlations with Kupffer cells and negative correlations with fibroblasts and endothelial cells, while neutrophils exhibited significant positive correlations with Treg cells. To further investigate, macrophages were re-clustered into seven subsets (C1–C7). Among M1 macrophages, only the FSTL1-negative Mac C6 subset demonstrated a positive correlation with tumor cells, suggesting its role in altering the tumor microenvironment, while Mac C1 and Mac C2 subsets were negatively correlated. Additionally, 8 cellular neighborhoods were defined, including an immune "barrier zone" at the tumor margin, primarily composed of neutrophils and Treg cells, which restricted the infiltration of tumor-killing immune cells. The Mac C6 subset was closely associated with this immune barrier. Functional validation using macrophage with characteristic proteins of the Mac C6 confirmed these findings through co-culture with tumor cells and immune cells.
Conclusion: Our study reveals for the first time a distinct immune landscape in ICC, highlighting the role of Mac C6 macrophage subset in immune regulation, promoting immune evasion and immune barrier. Targeting Mac C6 or disrupting the immune barrier may enhance anti-tumor immunity, offering new therapeutic strategies for ICC.

FSP1 inhibitor icFSP1 enhances lenvatinib sensitivity for hepatocellular carcinoma treatment by promoting ferroptosis through the FSP1/MIR4435-2HG pathway
Congyue Zhang[1,2], Mengjiao Sun[1], Yue Shi[1], Jiawei Cui[1], Yaoyao Mao[1], Zhandong Lin[1], Yuemin Nan[1]. *[1]Third Hospital of Hebei Medical University, Shijiazhuang, China; [2]Hebei Medical University, Shijiazhuang, China*
Email: drzcy@outlook.com

Background and aims: The tyrosine kinase inhibitor Lenvatinib treats advanced hepatocellular carcinoma (HCC). However, resistance hinders its therapeutic effect. Here, icFSP1, a ferroptosis suppressor protein 1 (FSP1) inhibitor, significantly enhances the anti-tumour effect of Lenvatinib in HCC both in vitro and in vivo. This study aimed to explore the effect of icFSP1 on lenvatinib sensitivity and understand its mechanism.
Method: The half-life of icFSP1 and lenvatinib and the synergy between the two drugs were observed in two hepatocellular carcinoma cell lines. The upstream target genes of FSP1 were traced in TCGA, FerrDb, and other databases, and the lncRNA MIR4435-2HG was positively correlated with FSP1. MIR44435-2HG was verified to be associated with ferroptosis in two different hepatocellular carcinoma cell lines using different assessments of ferroptosis markers. Next, apoptosis, proliferation, migration, and invasion assays further validated the regulatory mechanisms of MIR4435-2HG knockdown or overexpression and icFSP1 on tumorigenesis and development and sensitivity to lenvatinib in cells. Finally, the effects of MIR4435-2HG and icFSP1 on sensitivity to lenvatinib were verified in BALB/c-nu mice, and the changes in cells of mouse tumor tissues were verified by HE staining, and the proliferation and lipid peroxidation of mouse tumor tissues were verified by ki67 and 4-HNE staining.
Results: icFSP1 could inhibit tumor growth and enhance the sensitivity of lenvatinib for hepatocellular carcinoma treatment. MIR4435-2HG was closely associated with ferroptosis in hepatocellular carcinoma cells. Meanwhile, rescue assays yielded that MIR4435-2HG/FSP1 is a positive feedback pathway, and MIR4435-2HG plays a positive promoting role in hepatocellular carcinoma development. Finally, we found that the combination of MIR4435-2HG and icFSP1 modulated the sensitivity of in vitro and in vivo treated hepatocellular carcinomas to lenvatinib.
Conclusion: We identified a drug and molecular mechanism that enhances the sensitivity of lenvatinib for hepatocellular carcinoma treatment to transform lenvatinib resistance.

A syngeneic and orthotopic HCC mouse model demonstrating the high efficacy of combination therapies targeting the ECM and immune microenvironment

Emma Eichler[1], Sandrine Jansky[1], Hicham El Mard[1], Dominik Siegl[1], Dorothe Thies[1], Ernesto Bockamp[1,2,3], Detlef Schuppan[1,2,3,4].
[1]Institute of Translational Immunology (TIM), University Medical Center, Johannes Gutenberg University, Mainz, Germany; [2]Research Center for Immunotherapy, University Medical Center, Johannes Gutenberg University, Mainz, Germany; [3]ImmuneNTech GmbH, Mainz, Germany; [4]Division of Gastroenterology, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, United States
Email: eeichler@uni-mainz.de

Background and aims: The stromal composition of hepatocellular carcinoma (HCC) typically features a thin basement membrane-like ECM at its center, surrounded by a dense extracellular matrix (ECM) enriched with cancer-associated fibroblasts (CAFs) and tumor-associated macrophages (TAMs), which promote tumor progression. We explored novel therapeutic approaches targeting components of the HCC tumor microenvironment (TME) using a syngeneic and orthotopic HCC model in immunocompetent mice.
Method: Dt81Hepa1-6/βgeo HCC cells (1×10^5) were injected into the spleens of male C57BL/6 mice leading to a homogeneous colonization of the livers with HCC foci. At day 17 after inoculation, 5–8 mice per group received a) 0.075 mg/kg of the mTOR inhibitor rapamycin (Rapa) as monotherapy via daily intraperitoneal (i.p.) injection; b) 2 mg/kg i.p. of an antisense oligonucleotide (ASO) to the macrophage polarization modulator INT (ImmuneNTech)-12 twice a week; c) the combination of both agents. PBS only injected HCC-bearing mice served as controls (Ctrl). Five weeks post-surgery mice were sacrificed and the livers analyzed.
Results: Both monotherapies, Rapa and INT-12 ASO, induced a highly significant HCC reduction, as reflected by hepatic beta-galactosidase activity and reduction in liver weight and liver to body weight ratio compared to Ctrl. The combination of Rapa and INT-12 ASO was slightly superior to the monotherapies. Histological assessment via Sirius Red staining demonstrated a significant reduction of hepatic collagen content in treated livers vs Ctrl (1.5% vs 5% collagen area), indicating a strong anti-fibrotic effect. Quantitative immunohistochemistry showed a significant reduction in CD68+ macrophages across all treatment groups, most prominently with combination therapy. All treatments markedly reduced FoxP3+ regulatory T cells. qPCR revealed unconventional patterns in M1/M2 macrophage markers, suggesting a strong early inflammatory response in this HCC model. Treatment safety was confirmed by unchanged liver enzymes and creatinine.
Conclusion: Our highly reproducible orthotopic and syngeneic model of HCC in immunocompetent mice allows the rapid testing of novel anti-cancer combination therapies targeting the HCC TME. Our TME-targeting monotherapies, and particularly their combination, effectively prevented HCC progression. Beyond their direct anti-tumor effects, these therapies show anti-fibrotic activity as evidenced by reduced collagen levels.

miR-30e-3p/CXCL3 axis predicts early tumor escape in hepatocellular carcinoma patients undergoing sorafenib treatment

Elisa Monti[1,2], Clara Vianello[1,2], Ilaria Leoni[1,2], Giuseppe Galvani[1,2], Sara Marinelli[3], Giorgia Marisi[4], Andrea Casadei Giardini[5], Francesco Foschi[6], Catia Giovannini[1,3], Fabio Piscaglia[3], Massimo Negrini[7], Claudio Stefanelli[2], Laura Gramantieri[3], Francesca Fornari[1,2]. *[1]Centre for Applied Biomedical Research - CRBA, St. Orsola-Malpighi Hospital, University of Bologna, Bologna, Italy; [2]Department for Life Quality Studies, University of Bologna, Rimini, Italy; [3]Division of Internal Medicine, Hepatobiliary and Immunoallergic Diseases, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy; [4]Biosciences Laboratory, Istituto di Ricovero e Cura a Carattere Scientifico di Natura Pubblica, Istituto Romagnolo per lo Studio dei Tumori "Dino Amadori", Meldola, Italy; [5]Department of Oncology, Vita-Salute San Raffaele University, IRCCS San Raffaele Scientific Institute Hospital, Milan, Italy; [6]Department of Internal Medicine, Degli Infermi Hospital, AUSL Romagna, Faenza, Italy; [7]Dipartimento di Medicina Traslazionale, Università di Ferrara, Ferrara, Italy*
Email: elisa.monti10@unibo.it

Background and aims: Curative treatment options for hepatocellular carcinoma (HCC) remain largely limited to a minority of patients diagnosed at early disease stages. Immunotherapy and Tyrosine Kinase Inhibitors (sorafenib and lenvatinib) represent the first-line treatments in advanced cases. Although immunotherapy has revolutionized HCC treatment, only a limited number of patients achieves a prolonged response. The identification of biomarkers that stratify patients to tailored treatments or predict early tumor escape remains an unsolved clinical need. MicroRNAs and chemokines have crucial roles in HCC progression and drug resistance. We previously reported high miR-30e-3p levels in non-responder patients undergoing sorafenib treatment. Here, we aimed at identifying novel miR-30e-3p targets involved in sorafenib response, which could also serve as predictive biomarkers for treatment outcomes.
Method: miR-30e-3p and CXCL3 levels were measured by qPCR analysis in serum and tissue of HCC patients and DEN-induced HCC rat model. CXCL3 targeting by miR-30e-3p was assessed by functional studies (qPCR, Western Blot, ELISA) and dual-luciferase reporter assay in transiently transfected and stably infected HCC cell lines. CXCL3 levels were evaluated by ELISA assay in supernatant of HCC cell lines and serum of sorafenib-treated HCC patients and correlated with treatment response. Statistical analyses were performed to investigate correlations with clinicopathological features.

Results: CXCL3 was found to be upregulated in human and rat HCCs, showing a direct correlation with CXCR2 receptor and an inverse one with miR-30e-3p. Functional studies and dual-luciferase reporter assay demonstrated CXCL3 targeting by miR-30e-3p in HCC cell lines. In DEN-HCC rat model, higher CXCL3 tissue levels were associated with sorafenib resistance, showing a negative correlation with apoptotic markers and tumor suppressor genes and a positive one with tumor size. In HCCs, higher CXCL3 mRNA levels associated with microvascular invasion, while higher CXCL3 and miR-30e-3p levels at two-months follow-up were observed in serum samples of non-responder patients. Additionally, CXCL3 protein levels inversely correlated with days of sorafenib treatment and positively correlated with neutrophils count, whereas miR-30e-3p positively correlated with serum levels of HCC marker alfa-fetoprotein (AFP). CXCL3 and miR-30e-3p showed a promising predictive potential in ROC curve analysis.
Conclusion: CXCL3 is a novel miR-30e-3p target in HCC and predicts sorafenib resistance. If validated in larger cohorts, CXCL3 and miR-30e-3p represent promising circulating biomarkers for early detection of tumor escape in advanced HCCs undergoing sorafenib treatment.

THU-099
Atorvastatin and gene expression signatures in hepatocarcinogenesis

Ezequiel Ridruejo[1,2], Lucia Coli[1], Jimmy Daza[3], Giselle Romero Caimi[1], Timo Itzel[3], Andreas Teufel[3], laura alvarez[1]. *[1]Laboratory of Biological Effects of Environmental Contaminants, Department of Human Biochemistry, School of Medicine, Universidad de Buenos Aires, Buenos Aires, Argentina; [2]Hepatology Section, Department of Medicine, Centro de Educación Médica e Investigaciones Clínicas "Norberto Quirno" (CEMIC), Buenos Aires, Argentina; [3]Division of Hepatology, Department of Medicine II. Medical Faculty Mannheim, Heidelberg University, Mannheim, Germany*
Email: eridruejo@gmail.com

Background and aims: Hepatocellular carcinoma (HCC) represents a significant global health burden as the fourth leading cause of cancer-related deaths. While statins have shown promise in HCC prevention, their molecular mechanisms remain poorly understood. We investigated the effect of atorvastatin (AT) on gene expression profiles and hepatocarcinogenesis in a hexachlorobenzene (HCB)-induced HCC model.
Method: Male Wistar rats were divided into four groups: control, AT (5 mg/kg), HCB (100 mg/kg), and AT+HCB. After 30 days of treatment, we analyzed hepatosomatic index, liver histology, and performed RNA sequencing to evaluate transcriptomic changes. Gene Set Enrichment Analysis and KEGG pathway analysis were used to identify key molecular pathways. Protein expression of selected targets was confirmed by immunohistochemistry.
Results: HCB treatment significantly increased hepatosomatic index (28%, $p < 0.01$) and induced preneoplastic lesions, which were prevented by AT co-administration. RNA sequencing revealed HCB activated multiple oncogenic pathways, including RHO GTPase cycle, TGF-β, and receptor tyrosine kinase signaling, with 84.8% concordance with established cancer pathway genes. AT treatment upregulated protective PPAR signaling, autophagy, and cellular stress response pathways while downregulating oncogenic pathways activated by HCB. AT significantly reduced the expression of key oncogenic proteins including TGF-β1, p53, and c-Myc in HCB-treated liver tissue.
Conclusion: Atorvastatin effectively prevents HCB-induced hepatocarcinogenesis through multiple mechanisms, including modulation of key oncogenic pathways and promotion of protective cellular responses. These findings provide new insights into the molecular mechanisms of statin-mediated HCC prevention and identify potential therapeutic targets for future interventions.

Email: f.pagani@uke.de

Background and aims: Despite the revolution in personalised cancer care, primary liver cancer lacks early detection biomarkers and actionable mechanisms of carcinogenesis are poorly understood. We previously isolated blood extracellular vesicles (EVs) from patients and identified clusters of unannotated, small non-coding RNA (smRCs) with the ability to accurately detect early-stage HCC (von Felden et al. Gut 2022). Herein, we aim at delineating the functional role of our candidate smRCs during hepatocarcinogenesis.
Methods: Cell-of-origin analysis was performed by spatial transcriptomics (RNAscope™) on primary HCC tissue. Lentiviral CRISPR/Cas9-mediated genome editing was used to generate clonal smRC1 knockout Huh7 cells and validated by RTqPCR. We performed functional assays: proliferation curve, cell viability MTT colorimetric assay, morphogenesis assay on Matrigel® layer, colony formation assay and cell migration on Transwell® supports. Epithelial-to-mesenchymal-transition (EMT) specific markers were quantified by Western blot and immunocytochemistry. RNA sequencing was conducted on smRC-KO and wildtype control clones followed by differential gene expression analysis (DESeq2 package).
Results: We confirmed the expression of smRCs in tumour tissues and intratumoural stromal cells via spatial transcriptomic analysis. We established an in vitro model based on the lentiviral.
CRISPR/Cas9 system to reduce the expression of smRC1 in HCC cells. Functional assays suggest a role for smRC1 in the tumour cell biology, with a significant reduction of proliferation at 48 hours (70% of control), viability (75% of control), morphogenesis (5% of control), clonogenic ability (30% of control) and migration (10% of control) in the knockout clones compared to the smRC1-expressing clones. Moreover, smRC1 expression was associated with EMT, with increased Vimentin and decreased E-Cadherin levels. RNA sequencing analysis revealed an >8-fold upregulation of genes related to apoptosis (DYNLT3, NOXA), mitochondrial function (APOOL, CHM) and EGFR-pathway (EREG) (all adjusted $p < 0.01$). Further assays aiming to investigate the apoptotic process, mitochondrial functionality, EGFR-pathway activation and drug sensitivity are pending in order to validate these findings.
Conclusion: In conclusion, we demostrated a functional role for our previously identified small, non-coding RNA transcripts derived from unannotated genomic regions. Successful execution might reveal potential novel therapeutic strategies for primary cancer prevention.

Email: FCOJAVIER.CABALLEROCAMINO@bio-gipuzkoa.eus

Background and aims: Cholangiocarcinoma (CCA) includes a heterogeneous group of biliary tumors characterized by poor prognosis. Available systemic therapies for patients with advanced CCA are merely palliative, attesting the need to find novel effective approaches. Altered expression and/or function of certain epigenetic regulators such as histone deacetylases (HDACs) has been closely related to the development and progression of different types of cancer, including CCA. We have previously developed a new family of HDAC6 selective inhibitors derived from ursodeoxycholic acid (UDCA) that showed preferential enterohepatic biodistribution after oral administration (Caballero-Camino, FJ, *et al. Hepatology* 2021). Here, we hypothesize that selectively targeting the deregulated HDAC isoforms in CCA with novel UDCA-derived HDAC inhibitors could be a valuable epigenetic-based therapeutic strategy for CCA.
Method: The expression levels of the different HDACs were analyzed in tumor tissue samples from 4 international cohorts of patients with CCA. Advanced computational methods were applied to design and synthesize UDCA-derived drug candidates. Therapeutic potential of the lead compound was further characterized in experimental models of naïve and chemoresistant CCA, including human tumor spheroids and murine CCA organoids.
Results: Class I HDACs –1, 2 and 8– were found overexpressed in human CCA tumors from 4 cohorts of patients with CCA compared to control tissues. Computationally-aided rational design yielded 9 UDCA-derived drug candidates for selective targeting class I HDACs. Among them, the lead compound (Epi-UDCA) was selected based on class I HDAC inhibitory potency and selectivity on enzymatic assays. In CCA cell lines, Epi-UDCA displayed marked antiproliferative capacity at low doses (2 μM) and strong apoptotic induction at higher doses (10 μM). Epi-UDCA halted the growth of 3D human CCA spheroids and murine tumor organoids, promoting cancer cell death. Importantly, low doses of Epi-UDCA (2 μM) halted the invasion capacity of human CCA cells in extracellular matrix (ECM)-coated transwell migration assays. Proteomic analysis of CCA cells exposed to Epi-UDCA (2 μM) revealed significant changes in the expression of 396 proteins directly involved in important cancer-related processes such as cell cycle progression, angiogenesis, ferroptosis, and transcriptional regulation by tumor suppressor protein p53, among others. Finally, Epi-UDCA displayed strong antitumoral capacity against cisplatin-resistant CCA cells and spheroids, while combined administration of Epi-UDCA with cisplatin re-sensitized these cells to chemotherapy.
Conclusion: The unique properties of Epi-UDCA, a novel UDCA-derived class I selective HDAC inhibitor, provide this drug with promising therapeutic potential for the treatment of naïve and cisplatin-resistant cancers, including CCA.

THU-103-YI
Impact of PNPLA3 and TM6SF2 single nucleotide polymorphisms in metabolic dysfunction-associated steatohepatitis-linked hepatocellular carcinoma development in 3D extracellular matrix models

Giulia Lupo[1], Maria Castanho Martins[1], Stephanie Kucykowicz[2], Ginevra Pistocchi[2], George Finney[2], Laura J Pallett[2], Walid Al-Akkad[1], Krista Rombouts[1]. *[1]Regenerative Medicine and Fibrosis group, Institute for Liver and Digestive Health, University College London, London, United Kingdom; [2]Institute of Immunity and Transplantation, Division of Infection and Immunity, University College London, London, United Kingdom*
Email: k.rombouts@ucl.ac.uk

Background and aims: The PNPLA3 and TM6SF2 single nucleotide polymorphism (SNP) mutations are strongly implicated in increased susceptibility to Metabolic Dysfunction-Associated Steatohepatitis (MASH), accelerated liver fibrosis, and a heightened risk of Hepatocellular Carcinoma (HCC), underscoring their critical role in the pathogenesis of liver disease. Despite this, in vitro studies utilising hepatocytes and hepatic stellate cells (HSCs) have largely overlooked the impact of these mutations. This study aims to investigate the cellular behaviour associated with PNPLA3 and TM6SF2 SNPs using genotyped-paired human HCC cell lines and primary HSCs cultured within bioengineered 3D liver models, including human-derived extracellular matrix (ECM) scaffolds and ECM hydrogels.
Method: Human primary HSC and HCC cell lines were genotyped for SNPs PNPLA3 (rs738409) and TM6SF2 (rs58542926) and matched as: $PNPLA3^{WT}/TM6SF2^{WT}$ and $PNPLA3^{HOM}/TM6SF2^{WT}$. Cells were grown as mono- and co-cultures in healthy and cirrhotic decellularised 3D scaffolds and ECM hydrogels for 13 days and were treated with a MASH cocktail for 72 hrs. Cell behaviour was assessed using H&E, Live/Dead staining, qPCR and spectral flow cytometry.
Results: Co-cultures genotyped for $PNPLA3^{HOM}/TM6SF2^{WT}$ exhibited significantly higher profibrogenic markers, including mRNA for YAP and ACTA2, compared to $PNPLA3^{WT}/TM6SF2^{WT}$ cells. Flow cytometry and qPCR demonstrated a significant increase in TGFB1 expression in $PNPLA3^{HOM}/TM6SF2^{WT}$ mono- and co-cultures compared to $PNPLA3^{WT}/TM6SF2^{WT}$ cells grown in cirrhotic ECM scaffolds. Notably, flow cytometry analysis further demonstrated increased expression of Fibroblast Activating Protein (FAP) on $PNPLA3^{HOM}/TM6SF2^{WT}$ HSC in co-culture compared to $PNPLA3^{WT}/TM6SF2^{WT}$ HSC within healthy ECM (55.4% versus 40.6%) and cirrhotic ECM (36.6% versus 25.4%). Co-cultures within both healthy and cirrhotic scaffolds demonstrated increased PD-L1 expression relative to single cultures, indicating immune-modulatory effects. Furthermore, in human-derived liver 3D ECM hydrogels, MASH induced $PNPLA3^{HOM}/TM6SF2^{WT}$ co-cultures presented and enhanced increase of ACTA2 expression in both healthy and cirrhotic ECM conditions compared to $PNPLA3^{WT}/TM6SF2^{WT}$. These findings highlight the profound impact of PNPLA3 and TM6SF2 mutations on fibrotic and immunological responses in liver disease models.
Conclusion: This study demonstrates the utility of novel 3D models using human-derived healthy and cirrhotic liver ECM scaffolds and hydrogels to explore the impact of PNPLA3 and TM6SF2 genotypes on HSC and HCC behaviour, shedding light on their roles in MASH progression. These models offer significant potential for enhancing the reliability of future drug clinical trials by providing more physiologically relevant platforms to evaluate therapeutic responses and identify genotype-specific therapeutics.

THU-104-YI
A large-scale genetic analysis of hepatocellular carcinoma reveals novel mutational patterns and ancestry-linked mutations

Christoph Gerdes[1], Karthikeyan Murugesan[2], Shruthi Rengarajan[2], Anna Saborowski[1], Arndt Vogel[1,3]. *[1]Department of Gastroenterology, Hepatology, Infectious Diseases and Endocrinology, Hannover Medical School, Hannover, Germany; [2]Foundation Medicine, Inc., Cambridge, United States; [3]Division of Gastroenterology and Hepatology, Princess Margaret Cancer Centre, Toronto General Hospital, University of Toronto, Toronto, Canada*
Email: gerdes.christoph@mh-hannover.de

Background and aims: In recent years, the integration of next-generation sequencing (NGS) into routine clinical practice has revolutionized personalized cancer treatment. Hepatocellular carcinoma (HCC), the fifth most common cancer worldwide, has seen notable advancements in systemic treatments. However, despite the growing use of molecular and immunotherapies, no reliable

biomarkers exist to guide patient selection for specific therapies. To advance the development of targeted treatments in genetically defined subgroups of HCC, an understanding of the spectrum of genetic alterations (GAs) is essential. Here, we present what is, to our knowledge, the largest genomic analysis of real-world cohorts of HCC and combined HCC-cholangiocarcinoma (cHCC-CCA) patients, utilizing an extensive diagnostic panel to provide detailed insights into the full range of genomic alterations in these tumors.

Method: A retrospective analysis was conducted on 2,372 patients with HCC and 151 with cHCC-CCA using data from the FoundationCORE database. Tumor samples underwent genomic profiling with the FoundationOne platform, which assessed short variants, fusion-rearrangements, and copy number alterations in over 300 tumor-associated genes. Tumor mutational burden (TMB) and genetic ancestry status were determined for most of the cohort. Gene associations were identified using Fisher's exact test, with a significance threshold of $p < 0.05$.

Results: We present a comprehensive and representative analysis of the genomic landscape of HCC, highlighting mutational spectra across genetic ancestries, including African, American, European, East Asian, and South Asian populations. The most frequent GAs in HCC included *TERT* (59.3%), *TP53* (36.9%), *CTNNB1* (34.1%), *MYC* (14.1%), and *ARID1A* (12.3%). Female patients exhibited higher frequencies of GAs in *RB1*, *PTEN*, *CDKN2B*, and *BAP1*. Patients with East Asian ancestry had fewer *TERT*, *CTNNB1*, and *BAP1* GAs but showed enrichment for *TP53*, *MUTYH*, and *TET2* GAs. In contrast, patients of African ancestry had increased *TP53* and *TSC2* GAs but were otherwise similar to those with Western ancestries. Compared to HCC, cHCC-CCA exhibited higher frequencies of *IDH1/2* (11.2%) and *FGFR* (6.0%) GAs. Additionally, we will provide a detailed overview of potentially actionable GAs across both cohorts.

Conclusion: A comprehensive understanding of the most prevalent GAs is crucial for advancing molecular therapeutic and biomarker development in HCC. Our large-scale genomic analysis reveals subgroup-specific and ancestry-linked mutational signatures and defines the extensive landscape of GAs in HCC, offering valuable insights for the design of clinical trials targeting these alterations. Additionally, we provide novel insights into the genomic landscape of the rare cHCC-CCA subtype and defining the frequency of targetable GAs.

THU-105

Liver-derived mesenchymal stem cells promote epithelial-mesenchymal transition in a hepatocellular carcinoma spheroid coculture model

Grégory de Bodt[1,2], Joachim Ravau[1], Jonathan Evraerts[1], Xavier Stéphenne[1,2], Mustapha Najimi[1], Etienne Sokal[1,2]. [1]*UCLouvain, IREC, PEDI, Brussels, Belgium;* [2]*Cliniques Universitaires Saint-Luc, Paediatric Gastroenterology and Hepatology, Brussels, Belgium*
Email: gregory.debodt@uclouvain.be

Background and aims: Mesenchymal stem cells (MSC) play a highly debated role in cancer. Potent anti- and pro-tumour properties have been shown *in vitro* and *in vivo* depending on the type of tumour studied and the origin and priming of the MSC used. Here, we investigate the interaction between liver-derived MSC and hepatocellular carcinoma (HCC), with a focus on cancer cell proliferation, invasiveness and gene expression. We postulate that their shared hepatic origin can lead to unique insights on the potential implication of MSC in carcinogenesis.

Method: We established a 3D coculture spheroid model by combining Human Adult Liver Progenitor Cells (HALPC), a population of liver-derived mesenchymal stem cells described by our team, and one of three human hepatocellular carcinoma cell lines (HuH7, HepG2, and Hep3B). Cancer cell proliferation was studied through spheroid growth follow-up, chemiluminescent measurement of ATP, and Ki67 immunostaining using light sheet fluorescent microscopy. Cancer cell invasiveness was investigated using transwell and spheroid invasion assays. RNA sequencing was conducted on HALPC and cancer cells from control and coculture spheroids separated by fluorescence-activated cell sorting.

Results: HCC 3D coculture with HALPC resulted in a dose-dependent inhibition of spheroid growth. At 25 days post-formation, control spheroids were up to 70 times larger in volume than 50:50 coculture spheroids. This correlated with lower total ATP contents in coculture spheroids at several time points, indicative of lower amounts of cells per spheroids. The inhibition of cancer cell proliferation was then confirmed by a reduction of up to 66% in Ki67-positive cells in coculture conditions ($p = 4.6 \times 10^{-5}$), using light sheet microscopy. Invasion studies demonstrated the induction of an invasive phenotype in the cancer cell lines when co-cultured with HALPC. Comprehensive transcriptomic analysis showed massive changes in expression levels, with 2002 and 3601 up- or downregulated genes in HALPC and cancer cells, respectively ($| logFC | > 1$; p adj. < 0.05). In cancer cells, gene set enrichment analysis revealed dysregulation of several cancer hallmarks gene sets, with significant positive enrichment of the epithelial-mesenchymal transition (EMT) gene set (Normalized Enrichment score = + 2.7; p adj. = 1.1×10^{-18}).

Conclusion: We showed in a 3D coculture model that liver-derived MSC decreased the proliferation and induced the invasiveness of several human HCC cell lines. This was associated with the induction of an EMT phenotype at the transcriptomic level. These findings provide evidence for a potential role of organ resident MSC in HCC progression via EMT. Ongoing work will confirm the acquisition of the EMT phenotype at the protein level and validate the obtained results *in vivo*, using an orthotopic xenogeneic bioluminescent mouse model currently being established in our laboratory.

Macrophage-targeted biodegradable polymer nanocarriers loaded with a cytokine pathway activator effectively suppress orthotopic HCC growth in immune-competent mice

Hicham El Mard[1], Patric Komforth[2], Dominik Siegl[1], Adrian Hauck[3], Lutz Nuhn[2,3], Redouane Krini[1], Detlef Schuppan[1,4,5]. [1]*Institute of Translational Immunology, Research Center for Immune Therapy (FZI), University Medical Center of the Johannes Gutenberg University, Mainz, Germany;* [2]*Max Planck Institute for Polymer Research (MPIP), Mainz, Germany;* [3]*Julius-Maximilians-Universität Würzburg, Lehrstuhl für Makromolekulare Chemie, Würzburg, Germany;* [4]*ImmuneNTech GmbH, Mainz, Germany;* [5]*Division of Gastroenterology, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, United States*
Email: helmard@uni-mainz.de

Background and aims: Tolerogenic myeloid cells, tumor-associated macrophages (TAMs) are promising targets for immunological cancer therapies. However, systemic administration therapies addressing these cells often leads to side effects, including autoimmunity. The treatment of hepatocellular carcinoma (HCC), which is rich in TAMs, with checkpoint inhibitors has shown limited efficacy, including combination therapies. Therefore, specific reprogramming of TAMs from a T-cell-suppressive to a T-cell-activating state is an attractive novel therapeutic strategy. TAM modulation with small molecular immunomodulators has been hampered by poor water solubility or systemic toxicity. We therefore employed our prominently liver macrophage targeting, biodegradable polymer nanoparticles (NP; Kaps L et al, PNAS 2022) to deliver macrophage repolarizing small molecules to the liver and to HCC. NP were loaded with the cytokine-pathway modulator INT(ImmuneNTech)-16 and tested in our syngeneic orthotopic and immunocompetent mouse model of HCC.

Method: Multifocal hepatocellular carcinoma (HCC) was induced in C57BL/6 mice via intrasplenic injection of Dt81 HCC cells, leading to liver colonization and the development of advanced multifocal HCC within 3–5 weeks. Beginning in week 3 and continuing through week 5, mice were treated intravenously twice weekly with either unloaded nanoparticles (NPs), NPs loaded with INT-16 (at doses of 0.5 or 1.5 mg/kg), free INT-16, or vehicle control. Liver/body weight,

tumor load and tumor counts were determined. Liver histology was assessed using H&E staining and quantitative immunohistochemistry for CD3, CD8, CD68, YM1, iNOS, and Granzyme B. Hepatic proinflammatory transcripts and immune cell subtypes were quantified by qPCR and flow cytometry.
Results: The NP+INT-16 high-dose group achieved a highly significant antitumor effect, resulting in near-complete tumor regression, while all other therapies were largely ineffective. TAMs and immune suppressive cytokines were suppressed, whereas cytotoxic CD8+ T cells were significantly increased. The NP-mediated delivery of INT-16 significantly reduced the toxicity typically associated with systemic administration of the free drug.
Conclusion: NP+INT-16 monotherapy efficiently repolarized the suppressive tumor microenvironment towards anti-tumor immunity, resulting in a highly significant reduction of HCC growth. This approach can be translated to a phase 1b clinical development, coupled with new serological assays to assess immune activation in the tumor microenvironment.

Cryptochrome proteins as key regulators in circadian rhythm-enhanced photodynamic therapy for cholangiocarcinoma

Tianxiao Huang[1], Jiajin Li[2], Junzhou Zhao[3], Linlan Qiao[4], Yaoxing Ren[5], Jingming Lu[5], Rongqian Wu[5]. *[1]Xi'an Jiaotong University, Xi'an, China; [2]Peking University, Beijing, China; [3]Xi'an Jiaotong University, Xi'an City, China; [4]The University of Kansas Medical Center, Kansas City, United States; [5]Xi'an Jiaotong University, Xi'an, China*
Email: htx160@gmail.com

Background and aims: Cholangiocarcinoma (CCA) is an aggressive malignancy with limited treatment options. Photodynamic therapy (PDT) holds potential but is hindered by tumor-specific mechanisms and circadian rhythms. Cryptochrome proteins (CRY1/CRY2), key circadian regulators, influence metabolism and DNA repair, potentially reducing PDT efficacy. KL001, a CRY stabilizer, modulates these processes. This study examines KL001's role in enhancing PDT, evaluates circadian rhythm effects on PDT, and validates findings through chronotherapy.
Method: TCGA and GEO datasets were analyzed for CRY1/CRY2 expression and prognostic impact. DEG, WGCNA, and GO/KEGG enrichment identified pathways influencing PDT response. HUCC-T1 cells were treated with PBS, KL001, Ce6 (PDT photosensitizer), or KL001 + Ce6 under light irradiation (650 nm, 10 J/cm²). Proliferation, migration, and colony formation were assessed via CCK-8, Transwell, and colony assays. RNA-seq identified molecular pathways affected by KL001 and PDT. In vivo PDT chronotherapy in xenograft models compared circadian-aligned versus standard treatment.
Results: CRY1/CRY2 were overexpressed in CCA and correlated with poor prognosis. Pathway analysis linked CRY proteins to DNA repair and metabolism. KL001 + PDT synergistically inhibited cell proliferation (38% increase, $p < 0.01$), migration (45% reduction, $p < 0.01$), and colony formation (60% reduction, $p < 0.01$). RNA-seq showed modulation of DNA repair genes (e.g., RAD51, BRCA1) and metabolic pathways, with increased oxidative stress and cell death. Chronotherapy improved PDT efficacy, reducing tumor volume by 58% ($p < 0.01$) and extending survival.
Conclusion: KL001 enhances PDT by targeting DNA repair and metabolic pathways. Circadian-aligned PDT further amplifies therapeutic effects, demonstrating the importance of circadian biology in optimizing CCA treatment. These findings support integrating chronotherapy into PDT protocols for improved outcomes.

Proinflammatory cytokines drive peripheral Foxp3high Tregs into tumor sites: a reliable and accessible prognostic biomarker for HCC patients

Chien-Hao Huang[1], Tsung-Han Wu[2], Po-Ting Lin[3], Wei Teng[4], Rachel Wen-Juei Jeng[4], Chun-yen Lin[5]. *[1]Chang-Gung Memorial Hospital, Linkou Medical Center, Taoyuan, Taiwan, College of Medicine, Chang-Gung University, Taoyuan, Taiwan, TaoYuant, Taiwan; [2]Division of General Surgery, Chang-Gung Memorial Hospital, Linkou Medical Center, Taiwan, College of Medicine, Chang-Gung University, Taoyuan, Taiwan, TaoYuan, Taiwan; [3]Chang-Gung Memorial Hospital, Linkou Medical Center, Taoyuan, Taiwan, TaoYuan, Taiwan; [4]Chang-Gung Memorial Hospital, Linkou Medical Center, Taoyuan, Taiwan, College of Medicine, Chang-Gung University, Taoyuan, Taiwan, TaoYuan, Taiwan; [5]Chang-Gung Memorial Hospital, Linkou Medical Center, Taoyuan, Taiwan, College of Medicine, Chang-Gung University, Taoyuan, Taiwan, TaoYuan, Taiwan*
Email: huangchianhou@gmail.com

Background and aims: Regulatory T cells (Tregs) play a critical role in hepatocellular carcinoma (HCC) progression, but systemic Treg depletion risks autoimmunity. Despite known Treg heterogeneity, no consensus exists on their functional subtypes. This study aimed to classify Treg subpopulations using single-cell CITE-seq and validate their clinical and prognostic relevance in HCC patients.
Method: Single-cell CITE-seq was conducted on 51,067 $CD4^+$ T cells from eight HCC patients, analyzing samples from tumor, non-tumor, and peripheral blood. Validation involved 96 HCC patients and 53 healthy donors through flow cytometry, functional assays, and clinical data integration.
Results: Trajectory and TCR analyses identified a $Foxp3^{high}$ Treg subset in peripheral blood that preferentially migrates to tumor sites, acquiring a terminally differentiated, activated phenotype. Tumor-infiltrating $Foxp3^{high}$ Tregs exhibited elevated LAYN and tissue-resident memory (TRM) signatures and enhanced Foxp3 expression driven by proinflammatory cytokines in the tumor microenvironment. The CCL5/CCR5 axis mediated their recruitment from peripheral blood to tumors. A significant correlation was found between peripheral and intratumoral $Foxp3^{high}$ Tregs, supporting their potential as biomarkers. A predictive model using peripheral $Foxp3^{high}$ Tregs/$CD4^+$ T cells >3.5% was developed, demonstrating robust prognostic performance for overall survival and early recurrence, with AUROCs exceeding 0.75 in both training and validation cohorts.
Conclusion: Peripheral $Foxp3^{high}$ Tregs migrate to tumors via the CCR5-CCL5 axis and mature under proinflammatory cytokines influence. Their proportion in blood correlates with tumor presence, making them a promising biomarker for predicting HCC outcomes.

Distinct roles of SOS1 and SOS2 in lipid metabolism and tumorigenesis: implications for therapeutic targeting in cancer and metabolic disorders

Andrea Olarte[1], Rósula García[2], Nuria Calzada[3], Enrique De la Rosa[3], Pablo Ramos[3], Carmela Gomez[3], Fernando Calvo[4], Eugenio Santos[3]. *[1]Centro de investigación del Cáncer, Salamanca, Spain; [2]Centro de Investigación del Cáncer, Salamanca, Spain; [3]Centro de Investigación del Cáncer, Salamanca, Spain; [4]Instituto de Biomedicina de Sevilla (IBiS), Hospital Universitario Virgen del Rocío, CSIC, Universidad de Sevilla, 41013 Seville, Spain, Departamento de Fisiología Médica y Biofísica, Universidad de Sevilla, 41013 Seville, Spain, Sevilla, Spain*
Email: idu21998@usal.es

Background and aims: Mutations in RAS genes are implicated in approximately 30% of human cancers. RAS guanine nucleotide exchange factors (GEFs), SOS1 and SOS2, are broadly expressed across tissues and play key roles in metabolism, tissue homeostasis, and carcinogenesis, with emerging connections to obesity and lipid metabolism, both significant cancer risk factors. This study aims to investigate the regulatory roles of SOS1/2 in adipose and liver, focusing on their involvement in adipogenesis, High-Fat Diet (HFD)-induced changes, and hepatocellular carcinoma (HCC) progression.
Method: Conditional Cre-ER2 mice were used to study SOS1 and SOS2. Adipogenesis was analyzed in stromal vascular fractions (SVF), and mouse embryonic fibroblast (MEF) cells. SVF and MEF cells were

treated with 4-hydroxytamoxifen (4OHT) and then exposed to adipogenic induction media. Adipogenic capacity was measured using BODIPY staining and imaging at the Incucyte. In steatosis studies, SOS1 was depleted before the HFD began (pre-HFD); and after feeding them for 45 days with HFD, (post-HFD). Lipid content in the liver was measured in both cases, along with glucose tolerance testing. For diethylnitrosamine (DEN)-induced hepatocellular carcinoma studies, SOS1 was depleted one month after DEN treatment (DT1M), and after six months into DEN treatment (DT6M). Tumor number and burden, histological analyses, molecular analyses, bulk RNA-seq, and whole-exome sequencing (WES) were conducted. For therapeutic evaluation, the SOS1-RAS inhibitor BI-3406 was tested alone and in combination with sorafenib.
Results: SOS1 depletion significantly impaired lipid droplet accumulation in MEFs and SVFs, while SOS2-deficient cells maintained normal adipocyte differentiation and lipid storage. SOS1-depleted cells exhibited increased oxidative stress and mitochondrial dysfunction, impairing lipid metabolism. In vivo, SOS1 depletion reduced liver lipid accumulation in both pre-and post-HFD models. In HCC models, early SOS1 depletion (DT1M) greatly reduced tumor burden and number. Late depletion (DT6M) showed variable outcomes. SOS2 deletion consistently led to the highest tumor burden across experimental groups. Treatment with BI-3406 alone showed limited efficacy. However, combining BI-3406 with sorafenib reduced tumor number and burden.
Conclusion: SOS1 emerges as a potential therapeutic target due to its ability to reduce lipid accumulation, thereby protecting the liver from steatosis. Moreover, HCC experiments highlight a protective role of SOS1 during early tumorigenesis. In contrast, SOS2 is associated with increased tumor burden. While RAS::SOS1 inhibition alone shows limited efficacy, its combination with sorafenib yields promising results, paving the way for more effective therapeutic strategies.

THU-114
Liposomal doxorubicin and atezolizumab promote EMT regression by acting on the tumor microenvironment: preclinical in vitro and in vivo studies

Ilaria Zanotto[1], Daniela Gabbia[1], Antonella Grigoletto[1], Margherita Toffanin[1], Maria Calienni[1], Gianfranco Pasut[1], Sara De Martin[1]. [1]*University of Padova, Padova, Italy*
Email: sara.demartin@unipd.it

Background and aims: Hepatocellular carcinoma (HCC) is a highly aggressive liver cancer whose onset and progression is driven by immune-escape. HCC is characterized by the upregulation of the checkpoint inhibitor PD-L1, that helps immune evasion. The combination of the PD-L1 inhibitor atezolizumab and bevacizumab is the gold standard for advanced HCC treatment. Nevertheless, HCC management remains a significant challenge, highlighting the need for novel therapeutic approaches.
The aim of this study is to investigate the anticancer and immunomodulatory role of atezolizumab-targeted liposomal doxorubicin (Stealth Immunoliposomes, SIL), using as control its untargeted counterpart (Stealth Liposomes, SL) in vitro and in vivo models of HCC.
Method: The effect of SL and SIL was evaluated on HepG2 and Huh7 cells treated with TNF-alpha to obtain a model of EMT, by analyzing the expression of PD-L1, and the EMT markers by ICC and qPCR. The role of the two formulations on Akt-1 and p65 protein and gene expression was also assessed. In vivo efficacy was assessed in a syngeneic mouse model of HCC, obtained by injecting subcutaneously Hepa1-6 cells in C57BL/6J immunocompetent mice. The mice were then treated with vehicle (control), SIL, SL, Atezolizumab, or SL+Atezolizumab. Treatments were administered intraperitoneally (5 mg/kg every 3 days for 6 doses). Tumor volumes were measured and collected at sacrifice to evaluate Cytotoxic T Lymphocytes, M1 and M2 macrophages by flow cytometry.
Results: In the EMT in vitro model, SIL reduced PD-L1 protein ($p < 0.001$) and gene expression ($p < 0.05$), and increased E-cadherin ($p < 0.05$), decreased Vimentin ($p < 0.001$), and Beta-catenin ($p < 0.05$) protein expression. An increasing effect on p65 protein expression was observed after SIL treatment only in the EMT model obtained with Huh7 cells ($p < 0.05$), suggesting that the modulation of NFkBeta pathway occurs differently in the two cell lines. SIL decreased protein and gene expression of Akt-1 in both HepG2 ($p < 0.0001$ and $p < 0.01$ respectively) and Huh7 ($p < 0.0001$ and $p < 0.001$ respectively) cells, indicating that this formulation reduced EMT by acting on the Akt-1 pathway. In vivo, mice treated with Atezolizumab + SL was the most effective treatment in reducing tumor growth ($p < 0.05$ vs controls and atezolizumab-treated mice). Flow cytometry analysis revealed higher number of Cytotoxic T cells and M1/M2 ratio in the tumor microenvironment of these mice ($p < 0.05$ vs controls).
Conclusion: In vitro, SIL treatment, beside exerting an immunomodulatory role in the tumor microenvironment, reduces tumor cell invasiveness by acting on the EMT. Atezolizumab + SL treatment reduces cancer growth in vivo, increases macrophage polarization towards an antitumoral phenotype and the immune response against cancer cells, suggesting that the combination of immunotherapy and chemotherapy might be a suitable strategy in HCC management.

THU-115-YI
Targeting UBE2I-mediated protein hyper-SUMOylation halts cholangiocarcinoma progression and rewires the tumor-stroma crosstalk

Email: irene.olaizola@biodonostia.org

Background and aims: Cholangiocarcinoma (CCA) includes a diverse range of biliary malignant tumors characterized by dismal prognosis. Alterations in post-translational modifications contribute to abnormal protein dynamics, cellular disturbances, and disease. In this study, we investigated the role of SUMOylation in CCA progression and its potential as a therapeutic target.

Method: Using a combination of human CCA cells and primary tumours, we analysed the levels and function of protein SUMOylation, identifying deregulated SUMOylated proteins by immunoprecipitation and mass spectrometry analysis. The response to genetic (*UBE2I*-knockdown) or pharmacological (ML792 and SAMe) inhibition of SUMOylation was assessed *in vitro* and in two *in vivo* models of CCA. Co-culture experiments between wild-type or UBE2I-knockdown cancer cells and CCA-derived cancer-associated fibroblasts (CAFs) and human endothelial cells were carried out to unveil the impact of SUMOylation in the crosstalk between CCA cells and the TME.
Results: Analysis of human CCA cells and primary tumors revealed increased expression and activity of the SUMOylation machinery, correlating with unfavorable clinical outcomes. Critically, we found that the majority of SUMOylated proteins deregulated in CCA, identified after immunoprecipitation and mass spectrometry analysis, are implicated in cell proliferation, survival, or cellular homeostasis. The response to genetic (UBE2I-knockdown) or pharmacological (ML792 and SAMe) inhibition of SUMOylation was assessed in vitro and in two in vivo models of CCA. Depleting SUMOylation effectively halted tumorigenesis in subcutaneous and oncogene-driven models of CCA in vivo. Furthermore, the genetic and pharmacological inhibition of SUMOylation reduced CCA cell proliferation and hindered colony formation and spheroid growth in vitro. Co-culture experiments between wild-type or UBE2I-knockdown cancer cells and CCA-derived cancer-associated fibroblasts (CAFs) and human endothelial cells were then carried out to unveil the relevance of SUMOylation in the crosstalk between CCA cells and the tumor microenvironment (TME). Importantly, experimental depletion of SUMOylation encompasses a profound impact on the establishment of the TME as it arrests the growth of CAFs and vascular cells.
Conclusion: Aberrant protein SUMOylation contributes to CCA progression by promoting cell survival and proliferation and contributes to the conformation of the TME. Impairing SUMOylation halts CCA growth and, thus, may represent a potential novel therapeutic strategy for patients with CCA for whom current targeted therapies are limited.

Email: irene.olaizola@biodonostia.org

Background and aims: Cholangiocarcinoma (CCA) comprises a heterogeneous group of biliary malignant tumours characterized by dismal prognosis. Current first-line chemotherapy, including Cisplatin and Gemcitabine, provides limited survival benefits due to the development of chemoresistance. Cisplatin induces single-strand DNA breaks, activating DNA repair mechanisms that diminish its effectiveness. In this study, we present the design, chemical synthesis, and therapeutic evaluation of a new generation of chemotherapeutic agents with unique polyelectrophilic properties, capable of inducing high frequency of double-strand DNA breaks, thereby inhibiting DNA repair and promoting cancer cell death.
Method: We designed, chemically synthesized, and therapeutically evaluated two novel chemotherapeutic agents, Aurkine 16 and Aurkine 18. Their binding and damage to DNA were characterized by Atomic Force Microscopy (AFM), Transmission Electron Microscopy (TEM), comet assay, and electrophoretic mobility of the pUC18 plasmid. Their antitumour effects were tested in human naïve and cisplatin-resistant CCA cells, cancer-associated fibroblasts (CAFs), and healthy cholangiocytes as controls, as well as in xenograft models of CCA.
Results: Aurkines effectively induced double-strand DNA breaks, leading to increased DNA damage and elevated levels of reactive oxygen species, resulting in greater cytotoxicity compared to Cisplatin in CCA cells. Unlike Cisplatin, Aurkines did not activate key proteins involved in single-strand DNA repair, such as ATR and CHK1 phosphorylation. Importantly, these compounds also triggered apoptosis in Cisplatin-resistant CCA cells and CAFs while exhibiting no harmful effects in healthy cholangiocytes, demonstrating malignant selectivity. Additionally, Aurkines demonstrated cytotoxicity in other Cisplatin-resistant cancers, such as breast and ovarian cancer. This selective action against malignant cells was attributed to differences in histone deacetylase (HDAC)-dependent DNA packaging between normal and cancer cells. *In vivo*, Aurkines effectively halt naïve and Cisplatin-resistant CCA tumour growth without adverse effects. Transport studies revealed that Aurkines were selectively taken up by transport proteins OCT1, OCT3, CTR1, and OATP1A2, whereas Cisplatin only modestly utilizes CTR1.
Conclusion: Aurkines represent promising therapeutic candidates for both naïve and Cisplatin-resistant cancers due to their unique polyelectrophilic properties and selective targeting of cancer DNA.

THU-121

Claudin-1 modulates cell plasticity, carcinogenic signaling and proliferation in patient-derived cholangiocarcinoma organoids in vivo

Jade Brochon[1], Zeina Nehme[1], Marion Muller[1], Emilie Crouchet[1], Frank Jühling[1], Romain Desert[1], Fabio Del Zompo[1], Florine Zettl[1], Roberto Iacone[2], Markus Meyer[2], Alberto Toso[2], Lipika Goyal[3], Catherine Schuster[1], Thomas Baumert[1]. *[1]University of Strasbourg, Inserm, U1110, Institute of Translational Medicine and Liver Disease (ITM), Strasbourg, France; [2]Alentis Therapeutics, Allschwil, Switzerland; [3]Division of Oncology, Stanford School of Medicine, Palo Alto, CA, United States*
Email: thomas.baumert@unistra.fr

Background and aims: Cholangiocarcinoma (CCA) is a hepatobiliary adenocarcinoma with poor prognosis and unsatisfactory treatment options. Claudin-1 (CLDN1) is a transmembrane protein expressed in

tight junctions and exposed on the cell surface in liver fibrosis and cancer. We have previously shown that targeting exposed CLDN1 using highly specific CLDN1 monoclonal antibodies (mAbs) robustly inhibited tumor growth across CCA CDX and PDX mouse models. Here, we aimed to study the mechanisms by which CLDN1 drives cholangiocarcinogenesis using patient-derived CCA tissues and organoid models.

Method: Transcriptional regulation of CLDN1 expression was studied using a large panel of known key regulators of CCA progression in patient-tissues combined with pharmacological intervention and loss-of-function studies using CLDN1-specific mAbs and RNAi in patient-derived organoids and cell-based models. In vivo proof-of-concept studies using humanized CLDN1 mAbs were performed in a patient-derived organoid xenograft model.

Results: CLDN1 protein was overexpressed in cancer cells of patient CCA tumor tissues. Spatial transcriptomics revealed CLDN1 co-localization of well described CCA driver pathways. CLDN1 expression significantly increased in CCA patient-derived organoids upon the activation of TNFα/NF-kB or Wnt/β-catenin pathway signaling, both highly implicated in in CCA progression. Perturbation studies using CLDN1 mAbs in patient CCA organoids showed a marked modulation of the organoid phenotype with a robust decrease in viability. Targeting cancer cell CLDN1 using highly specific mAbs markedly inhibited tumor growth in a CCA patient-derived organoid xenograft mouse model. In line with morphological changes, transcriptomic profiling of CLDN1 mAb-treated organoids revealed a pronounced effect on cell architecture and proliferation, a downregulation of the expression of gene sets encoding for oncogenic signaling, hypoxia, metabolism, EMT and stemness. Mechanistically, targeting exposed CLDN1 using CLDN1 mAbs suppressed key CCA signaling pathways, including Notch1, SRC-FAK, Hippo-YAP and STAT3 signaling across patient-derived models. Genetic loss-of-function studies confirmed the functional impact of the pathways and findings for CLDN1 as a CCA driver and therapeutic target.

Conclusion: Transcriptional regulation and perturbation studies in patient-relevant models unravel a key functional role of CLDN1 as a signal transducer of multiple pro-tumorigenic signaling cascades which regulate CCA cell plasticity and fate, stemness and EMT. Robust CLDN1 overexpression in patient CCA combined with completed in vivo proof-of-concept studies provide an opportunity for the clinical development of CLDN1-specific mAbs to improve the dismal outcome of CCA patients.

Can fractal descriptors distinguish vascular organization within the tumor microenvironment?

Jake Penney[1,2], Victor Nardon[3], Aurélie Beaufrère[1,4], Miguel Albuquerque[4], Valérie Paradis[1,4], Ralph Sinkus[1,5]. *[1]Centre de recherche sur l'inflammation (CRI), Paris, France; [2]Siemens Healthcare SAS, Courbevoie, France; [3]CHRU Nancy, Nancy, France; [4]Hôpital Beaujon AP-HP, Clichy, France; [5]Faculty of Life Sciences and Medicine, King's College London, London, United Kingdom*
Email: jake.penney@siemens-healthineers.com

Background and aims: The architecture of tumor vasculature is known to impact response to therapy, especially in the field of anti-angiogenic drugs. This is particularly well-illustrated in hepatocellular carcinoma (HCC) arising in the context of cirrhosis, where anti-angiogenic therapies, either alone or in combination, have become a standard of care. Accordingly, providing a comprehensive landscape of tumor vasculature would be critical for predicting treatment response and adapting treatment strategies effectively. Our objective is to quantify vascular architecture and assess the presence of significant variations across distinct tissue environments, including tumoral and non-tumoral regions, as well as tissues with vascular invasion (VI+) and without vascular invasion (VI-).

Method: In this study, we characterized the vascular architecture of HCC using two complementary mathematical concepts: the fractal dimension D_f and the Hurst index H. We analyzed 29 histological samples of HCCs, immunostained for vessels using CD31 and segmented, and quantified via the classical boxcounting method D_f and via lagtime-distribution calculus H within the central tumoral zones, the peritumoral regions, and in distant non-tumoral liver tissue.

Results: Our analysis revealed distinct differences in fractal dimension between non-tumoral ($D_f^{non\text{-}tumoral} = 1.73 \pm 0.02$), peritumoral ($D_f^{peritumoral} = 1.57 \pm 0.03$), and tumoral tissues ($D_f^{tumoral} = 1.3 \pm 0.02$) ($p < 0.001$), and similar differences in the Hurst index ($H_{tumoral} = 0.32 \pm 0.008$ and $H_{non\text{-}tumoral} = 0.16 \pm 0.02$). Furthermore, the presence ($D_f^{tumoral\ VI-} = 1.27 \pm 0.02$) or absence ($D_f^{tumoral\ VI+} = 1.3 \pm 0.04$) of tumoral vascular invasion did not alter the fractal dimension of the vasculature, neither intra-tumoral nor peri-tumoral ($p = 0.68$).

Conclusion: In conclusion, our findings show that vascular architecture quantified via its fractal dimension is clearly different between the central regions of HCCs, its peritumoral zone, and liver parenchyma. Furthermore, we show that the presence/absence of vascular invasion is not impacting vascular fractality. These promising results provide motivation to further investigate non-invasive approaches that are able to quantify fractality whereby adding valuable diagnostic information.

THU-123-YI

YAP activity in cancer-associated fibroblasts is relevant for immune escape in cholangiocarcinoma

Kieu Trinh Dinh[1], Chun-Shan Liu[2], Viktorie Gabrielová[1], Daria Komkova[3], Nugzar Lekiashvili[2], Angela Goncalves[4], Michael Dill[5]. *[1]German Cancer Research Center (DKFZ) Heidelberg, Experimental Hepatology, Inflammation and Cancer, Faculty of Biosciences, Heidelberg University, Heidelberg, Germany; [2]German Cancer Research Center (DKFZ) Heidelberg, Experimental Hepatology, Inflammation and Cancer, Heidelberg, Germany; [3]German Cancer Research Center (DKFZ) Heidelberg, Experimental Hepatology, Inflammation and Cancer, German Cancer Research Center (DKFZ) Heidelberg, Division of Somatic Evolution and Early Detection, Heidelberg, Germany; [4]German Cancer Research Center (DKFZ) Heidelberg, Division of Somatic Evolution and Early Detection, Heidelberg, Germany; [5]German Cancer Research Center (DKFZ) Heidelberg, Experimental Hepatology, Inflammation and Cancer, Department of Gastroenterology, Hepatology, Infectious Diseases & Intoxications, Heidelberg University Hospital, Heidelberg, Germany*
Email: kieutrinh.dinh@dkfz-heidelberg.de

Background and aims: The transcriptional co-activator Yes-associated protein (YAP) is the main component of the Hippo pathway, playing an essential role in cholangiocarcinoma (CCA). YAP activity has emerged as relevant mediator of activation of resident fibroblasts into cancer-associated fibroblasts (CAFs) and important for tumor endothelial cells (TECs). This project aims to investigate the molecular role of YAP in CCA-resident CAFs and TECs.

Method: We established multiple organoid-based, syngeneic CCA models by intrahepatic implantation of murine cholangiocyte organoids, genetically engineered to obtain activating $Kras^{G12D}$ and deletary *Trp53* mutations, and combined with 1 out of 3 different co-alterations: deletion of *Smad4* (PKS), *Arid1a* (PKA), and *Msh2* (PKM). Intratumoral YAP activity was assessed in a Cyr61-GFP reporter mouse line. $Yap^{flox/flox}$ Tomato-reporter mice were crossed with $Col1a2^{CreERT2}$ and $Cdh5^{CreERT2}$ mice to generate fibroblast- and endothelial cell-specific, Tamoxifen-inducible Yap KO mice ($Yap^{\Delta CAF}$ and $Yap^{\Delta TEC}$), respectively. Tumors were collected 7 days after knock out for imaging and single-cell RNA sequencing analysis.

Results: All three organoid lines led to CCA formation upon intrahepatic implantation ($n \geq 5$ per group). PKS organoids exhibited the highest penetrance at 91%. The percentage of eGFP+ fibroblasts in CCAs in Cyr61-eGFP reporter mice was 8%, 26%, and 14% for PKA, PKS, and PKM, respectively ($p < 0.01$). Yap activity in endothelial cells was not measurable in this reporter system. Importantly, no differences in

CCA morphology and TME composition could be observed in $Yap^{\Delta TEC}$ mice 7 days after KO. Conversely, CCA in $Yap^{\Delta CAF}$ mice showed signs of tumor shrinkage after KO (tumor volume 51 mm^3 [KO] vs. 152 mm^3 [Ctrl], $p < 0.05$). Immunohistological analysis revealed increased infiltration of T cells in $Yap^{\Delta CAF}$ CCAs ($p < 0.01$). Notably, intratumoral CD8+ T cell percentage increased 3.4-fold ($p < 0.01$), while no significant differences were observed in the populations of LY6G/6C+, F4/80+, B220+, or NK1.1+ cells. Single-cell RNA-sequencing analysis is ongoing to explore the tumor microenvironment in $Yap^{KO\text{-}CAF}$ models.

Conclusion: The findings demonstrate that YAP activity in CAFs supports immune escape of CCAs via inhibition of CD8+ T cell infiltration and imply therapeutic potential. Further investigation into underlying molecular mechanisms is therefore warranted.

3,4-dihydroxyphenylpropionic acid deficiency in chronic hepatitis B promotes hepatocellular carcinoma

Zhixian Lan[1], Ziyan Wang[1], Yuxin Liu[1], Kaifeng Wang[1], Heqi Zhou[1], Yinghong Zhu[1], Ziqi Liu[1], Qiuhong You[1], Yuchuan Chen[1], Dekai Zheng[1], Kaikai Zhang[1], Xuelian Gao[1], Zhixin Fang[1], Wanying Li[1], Hongyan Liang[1], Sheng Shen[1], Xieer Liang[1], Pengcheng Bu[2], Rong Fan[1], Jinlin Hou[1], Peng Chen[3], jian sun[1]. *[1]State Key Laboratory of Organ Failure Research, Guangdong Provincial Key Laboratory of Viral Hepatitis Research, Department of Infectious Diseases, Nanfang Hospital, Southern Medical University, Guangzhou, China; [2]Key Laboratory of RNA Biology, Key Laboratory of Protein and Peptide Pharmaceutical, Institute of Biophysics, Chinese Academy of Sciences, Beijing, China; [3]Department of Pathophysiology, Guangdong Provincial Key Laboratory of Proteomics, School of Basic Medical Sciences, Southern Medical University, Guangzhou, China*
Email: sunjian@smu.edu.cn

Background and aims: Despite therapy with potent antiviral agents, chronic hepatitis B (CHB) patients remain at high risk of hepatocellular carcinoma (HCC). While metabolites have been rediscovered as active drivers of biological processes, the specific metabolites modulating HCC risk in CHB patients is largely unknown.

Method: We recruited 3368 CHB patients who were under nucleos(t)ide analogues treatment and achieved hepatitis B virus (HBV) DNA undetectable. Plasma samples have been collected when patients were enrolled in this cohort. During a median follow-up of 43.5 months, a total of 76 incident HCC cases were ascertained. Using a nested case-control design, 76 HCC cases and 76 controls without HCC development were selected by propensity score matching. Targeted metabolomics analysis was employed to examine metabolite compositions of baseline plasma. The role of 3,4-dihydroxyphenylpropionic acid (3,4-DHPPA) in hepatoma tumorigenesis was investigated both *in vitro* and *in vivo* studies.

Results: Baseline characteristics were comparable between the two groups, except for higher alanine aminotransferase (ALT) levels in cases (median, 24.5 vs 32.0 U/L). Metabolomics analysis annotated 190 compounds. Of them, 103 and 87 were increased and reduced in baseline plasma of CHB patients with HCC development, respectively. Notably, 3,4-DHPPA was significantly reduced in baseline plasma of patients with HCC development. Kaplan-Meier survival analyses showed that 4-year cumulative incidence of HCC decreased significantly in patients with higher 3,4-DHPPA levels at baseline. After adjusting age, sex, bilirubin, albumin, platelet and ALT elevation, individuals with higher 3,4-DHPPA exhibited a decreased risk of HCC. 3,4-DHPPA preferentially inhibit proliferation of HCC cells *in vitro*. Notably, in primary HCC mouse models induced with oncogenes or chemicals, 3,4-DHPPA significantly prevented HCC development.

Conclusion: The deficiency of circulating 3,4-DHPPA possibly contributes to HCC development in CHB patients with viral control. These insights hint at novel strategies to further reduce HCC risk in the antiviral era.

Email: yahima81@gmail.com

Background and aims: Venous thromboembolism in cancer patients remains a major health problem. In cholangiocarcinoma (CCA), the role of the tumor cells in the abnormal activation of the coagulation cascade and platelet aggregation has been poorly studied. A well-established risk factor of CCA is primary sclerosing cholangitis (PSC), where a hypercoagulation state was previously reported. Starting from these observations, in this study we aimed at assessing the expression of components of coagulation and fibrinolysis pathways along with the platelet function in PSC and CCA.

Method: Formalin-fixed, paraffin-embedded archival tissues from liver biopsy or surgical resection for PSC, intrahepatic CCA (iCCA), and implanted grafts (controls) (n = 10 in all) were stained by immunohistochemistry or immunofluorescence (IF) for the following: tissue factor (TF), factor (F) X, FXI, FXIIIA, von Willebrand factor (vWF), fibrinogen and endothelial protein C receptor (EPCR). Fibrin deposition within the portal vein radicle lumen (portal vein microthrombosis, PVMT) was assessed by Martius Scarlet Blue staining. Additionally, IF for TF and FX was performed in patient-derived organoids (OG) from PSC and iCCA (both n = 10). Quantitative evaluation of extracellular vesicles (EVs) isolated from conditioned medium of PSC-OG and iCCA-OG was quantified by cytometric analysis (FACS) by means of specific markers (Calcein-AM, EpCam-PE and Annexin V). Finally, FACS evaluated the effects of EVs on platelet aggregation using CD41, CD62P and Annexin V.

Results: Aberrant expression of coagulation factors was found in iCCA and PSC, but not in controls. TF and FX, but not FXI, were upregulated in cholangiocytes and stromal cells, more prominently in iCCA than in PSC. Fibrinogen was diffuse throughout the stroma, with marked fibrin deposition in the stroma, of both iCCA and PSC, where FXIIIA was expressed by both cholangiocytes and macrophages. Moreover, PVMT was observed in both PSC (n = 4/10) and iCCA (n = 2/10), particularly in samples showing the highest expression of TF. Endothelial cell (EC) expression of EPCR was significantly weaker in tumor than in PSC and controls, while vWF expression was increased in ECs of PSC and iCCA. Upregulated expression of TF and FX were

confirmed in PSC-OG and iCCA-OG. Additionally, EVs derived from either PSC-OG or iCCA-OG strongly induced platelet activation.
Conclusion: PSC and iCCA showed a phenotype of activated procoagulation and impaired fibrinolysis, regardless of the development of PVMT. Patient-derived organoids provide a novel *in-vitro* model to study effects on platelet activation, possibly mediated by EVs. Future studies are needed to understand if the perturbation of blood coagulation/fibrinolytic pathways may provide targets for therapeutic intervention to hamper progression of PSC and CCA, which are both short of effective treatments.

THU-126

So hot, yet so cold: bacterial lipopolysaccharides hinder tumor adaptive immunity by producing inflammatory and suppressive innate immunity in non- or poorly-infiltrated hepatocellular carcinoma

Lugien Al Asadi[1], Sylvie Job, Héloïse Halse[2], Alexandre Dos-Santos, Astrid Laurent Bellue[3], Nicolas Moniaux, Jonathan Pol[4], Alice Deshayes, Amelie Bigorgne[2], Mélodie Bonvalet[2], René Adam[5], Daniel Azoulay[1], Denis Castaing[1], Daniel Cherqui[1], Antonio Sa Cunha[1], Olivier Rosmorduc[1], Catherine Guettier[6], Eric Vibert[1], Aurélien Marabelle[7], Jamila Faivre. *[1]INSERM, U1193, Hôpital Universitaire Paul-Brousse, Centre Hépatobiliaire, Université Paris-Saclay, Faculté de Médecine Le Kremlin-Bicêtre, Villejuif, France; [2]Laboratoire de Recherche Translationnelle en Immunothérapie (LRTI), INSERM, U1015, Gustave Roussy, Villejuif, France; [3]Université Paris-Saclay, Faculté de Médecine Le Kremlin-Bicêtre, AP-HP.Université Paris-Saclay, Hôpital Kremlin-Bicêtre, Département de Pathologie, Le Kremlin-Bicêtre, France; [4]Centre de recherche des Cordeliers, Inserm U1138, Université Paris Cité, Sorbonne Université, Paris, France; [5]Université Paris-Saclay, Faculté de Médecine Le Kremlin-Bicêtre, Hôpital Universitaire Paul-Brousse, Centre Hépatobiliaire, Villejuif, France; [6]Université Paris-Saclay, Faculté de Médecine Le Kremlin-Bicêtre, AP-HP, Université Paris-Saclay, Hôpital Kremlin-Bicêtre, Département de Pathologie, Villejuif, France; [7]Université Paris-Saclay, Faculté de Médecine Le Kremlin-Bicêtre, Laboratoire de Recherche Translationnelle en Immunothérapie (LRTI), INSERM, U1015, Gustave Roussy, Villejuif, France*
Email: lugienalasadi@gmail.com

Background and aims: Immunologically silent (cold) liver tumors, with little or no infiltration, account for two-thirds of hepatocellular carcinomas (HCCs) and represent a major challenge for immune-based cancer therapies. Little is known about the molecular and cellular mechanisms involved in T-cell exclusion.
Method: We rigorously selected a set of low-infiltration human HCCs from patients managed at the Hepatobiliary Centre of Paul-Brousse Hospital (Villejuif), generated extensive molecular, transcriptomic (applying a workflow based on unsupervised machine learning algorithms) and immunophenotypic data using flow cytometry and tissue staining, as well as thorough clinicopathological data. This comprehensive and diverse dataset has been further integrated to better understand the molecular and cellular responses driving such a tumor ecosystem, and to discover new regulatory networks involved in the immune evasion of HCC.
Results: We show that cold human HCCs contain large amounts of bacterial lipopolysaccharides (LPS) from Gram-negative bacteria (a typical Pathogen-associated molecular pattern "PAMP"), associated with LPS/Toll-like receptor 4 (TLR4) signalling-mediated inflammatory response, recruitment of myeloid immunosuppression and increased expression of immune checkpoint molecules, that would prevent T cell infiltration into the TME. To substantiate the role of LPS-induced immunoinflammatory response in human cold HCC, we used a model of non-T-cell-infiltrated HCC in mice transgenic for the MYC oncogene, in which different TLR4 agonists (LPS formulated in liposomes from different Gram-negative bacterial strains) were administered. The exogenous LPS was confirmed to accumulate in the liver. We show that the level of tumor infiltration by myeloid-derived suppressor cells (MDSCs) expressing immune checkpoint molecules upon LPS challenge is highly dependent on the inflammatory potency (high, medium or low) of the LPS and, consequently, on the signalling pathway committed. The lower the LPS-dependent inflammatory response, the more myeloid immunosuppression is significantly reduced. Conversely, the more intense the inflammatory response, the more intense the recruitment of MDSCs.
Conclusion: Non/poorly infiltrated HCCs form a heterogeneous set of tumors in which different mechanisms of immune escape may exist/coexist, including a mechanism involving an inflammatory response mediated by LPS-TLR4 signaling in the recruitment of immunosuppressive myeloid cells and, ultimately, in the T-cell exclusion. This study highlights the contribution of tumor-extrinsic mechanisms originating from the gut microbiota to the failure of tumor immunity in HCC.

Engineering NK cell immunotherapy to optimise liver tumour homing and block PD-L1-mediated inhibition of T cells

Mariana Diniz[1], Yiya Zhong[1], Stephanie Kucykowicz[1], Daniel Brown Romero[1], Jessica Davies[1], Joseph McDowell[1], John Robert Counsell[1], Mala Maini[1]. *[1]University College London, London, United Kingdom*
Email: m.diniz@ucl.ac.uk

Background and aims: NK cells are being developed for adoptive cell therapy of cancer and chronic viral infections, such as hepatocellular carcinoma (HCC) and hepatitis B (HBV), with the advantages of intrinsic tumour-killing capacity, lack of MHC restriction and low toxicity. Cytokine activation (IL2/12/15/18) is widely used to promote memory-like NK cells with enhanced anti-tumour functionality. However, we recently showed that cytokine activation induces PD-L1 on human and murine NK cells, resulting in inhibition of HBV-specific T cells (*Diniz, SciTranslMed 2022*).
Method: The aims of this study were therefore to engineer primary NK cells to be retained within Hepatocellular carcinoma (HCC), exerting anti-tumour function without impeding the activity of neighbouring anti-tumour T cells through PD-L1. *To do this we genetically manipulated NK cells to express the chemokine receptor CXCR6 (which retains liver-resident NK cells) and to secrete anti-PD-L1 antibodies to counteract their checkpoint inhibition of T cells.*
Results: Using VSV-G pseudotyped lentivirus we achieved successful transduction of primary human NK cells confirmed by the significant induction of CXCR6 expression. Higher numbers of $CXCR6^{+}$NK-cells were recovered from matrigel containing CXCL16 (the ligand for CXCR6) or HepG2 supernatant compared to untransduced NK-cells, indicating that the encoded CXCR6 receptor was functional. Production and secretion of anti-PD-L1 was confirmed by its capacity to block PD-L1 on NK or hepatoma cells *in vitro*, preventing staining of this ligand by flow cytometry. Their secretion of anti-PD-L1 antibodies converted cytokine-activated transduced NK cells into predominant 'helpers', able to boost $CD8^{+}$T cell responses to HBV peptide stimulation or hepatoma cells.
Conclusion: In summary, we genetically engineered cytokine-activated NK cells to have enhanced homing/retention within liver tumours and to mediate anti-tumour activity whilst releasing their helper function to boost antigen-specific T cells. This approach should promote the dual anti-tumour functionality of NK cells and T cells, to work in tandem rather than in opposition, against HCC.

Email: maavila@unav.es

Background and aims: Trefoil factor (TFF3) is a small peptide secreted by epithelial mucous producing cells involved in the protective and reparative response triggered by epithelial injury. TFF3 is overexpressed in different solid tumors and contributes to carcinogenesis. We have evaluated TFF3 expression and its pro-tumorigenic role in hepatoblastoma (HB), the most common pediatric liver cancer.

Method: TFF3 expression was examined in three HB transcriptomic datasets (GSE75271, GSE81928 y GSE104766), in HB tissues (immunohistochemistry) and in the mouse HB model induced by mutant YAP/b-CAT hydrodynamic plasmid injection. TFF3 gene expression regulation and function were tested in human HB cell lines in which its expression was manipulated. The effect of TFF3 expression of HB growth in vivo was evaluated in a subcutaneous xenograft model in nude mice.

Results: TFF3 mRNA and protein were overexpressed in human HB tissues and in the lesions developed in the mouse YAP/b-CAT HB model. Normal liver tissues did not express TFF3. Overexpression of TFF3 in HepG2 cells potently induced cell proliferation, anchorage-independent growth and increased resistance to cisplatin treatment. TFF3 stable transfection promoted the downregulation of genes associated with liver differentiation, and induced that of inhibitors of hepatocellular differentiation, as well as genes associated with glucose uptake and glycolysis. SeaHorse experiments revealed that TFF3 markedly enhances glycolysis. *TFF3* expression was potently upregulated in hypoxia. Its overexpression enhanced that of genes involved in glycolysis under hypoxic conditions, as well as hypoxia-triggered cell growth. TFF3 expression enhanced the growth of HepG2 cells xenografted in nude mice.

Conclusion: *TFF3* is significantly overexpressed in clinical and experimental HB tumors, being almost undetectable in normal liver parenchyma. Activation of YAP and b-CAT pathways, predominant in HB, may trigger TFF3 expression in hepatocytes. In HB cells, TFF3 expression promotes the manifestation of neoplastic traits. TFF3 may be an important determinant in the adaptation of HB cells to hypoxia. Pharmacological targeting of TFF3 expression or activity may be leveraged to increase HB response to cisplatin.

SAT-075

Prediction of hepatocellular carcinoma using AI-driven MRI radiomics: development of the AI-HCC prediction model

Jakob Nolte[1], Maryam Amir Haeri[1], Donald Bouman[2], Stephanie van den Berg[1], Maureen Guichelaar[3]. *[1]CODE (Cognition, Data and Education) department, University of Twente, Enschede, Netherlands; [2]Department of Radiology, Medical Spectrum Twente, Enschede, Netherlands; [3]Department of Gastroenterology and Hepatology, Medical Spectrum Twente, Enschede, Netherlands*
Email: maureenguichelaar@yahoo.com

Background and aims: Early detection of hepatocellular carcinoma (HCC) is essential to improve patient survival for which annual HCC screening is recommended. Compared to ultrasound, MRI has improved early detection of HCC, but its use is limited by increased costs and reduced availability. Identification of patients at risk of HCC would target MRI screening and preventive measures to those patients most in need. The aim of this study is to develop an AI-based support system for the accurate prediction of future HCC development in patients with liver cirrhosis.

Method: A retrospective analysis was conducted on sequential MRI data from patients with liver cirrhosis who underwent HCC surveillance through annual MRI screening. In 2018, HCC surveillance changed in the study institution from an ultrasound-based to MRI-based surveillance regimen. MR images were analyzed by ensemble machine learning modeling (XGBoost), as an initial feasibility study. Consequently, a deep learning model (AI-HCC) was developed, utilizing ConvNeXt-based CNN for processing 3D MRI scans. The AI-HCC model was then combined with Transformer encoders to capture temporal dependencies across sequential MRI observations. Clinical data of all study patients were collected, including general demographic, disease-specific, HCC and survival data.

Results: MRI data of 243 patients (88 females, 36%) with liver cirrhosis were analyzed, of which 37 patients developed HCC. The majority of patients with HCC suffered from MASH (n = 15, 40.5%) or alcoholic liver disease (ALD, n = 8, 22%). Patients had long-term follow-up by MRI, with an average of 2.8 ± 1.9 MRI assessments per patient, and a mean follow-up duration of 23.2 ± 23 months. The AI-HCC prediction model was tested using a variety of MRI sequences in order to develop the final AI-HCC prediction model. The predictive power of the final AI-HCC model showed excellent predictive performance, achieving an AUC-ROC of 0.95, 0.94, and 0.98 for the 12-month, 24-month, and 36-month HCC prediction horizons, respectively. For patients with MASH, the model achieved an AUC-ROC of 0.956 ± 0.021, which was significantly higher than seen in

patients with alcoholic liver disease (AUC-ROC: 0.850 ± 0.045, p < 0.05), at the same prediction horizon.
Conclusion: Our study reports the development of an accurate AI-HCC prediction model, with high predictive power (AUC-ROC >0.94) for the prediction of hepatocellular carcinoma development in patients with liver cirrhosis. Predictive properties of the AI-HCC model were similar across three years leading up to HCC, illustrating the potential for early HCC risk stratification. The AI-HCC prediction model has great potential to target MRI screening to those at high risk for HCC, while avoiding unnecessary HCC surveillance in low-risk patients, thereby changing the HCC surveillance landscape.

SAT-076
Therapeutic potential of Human antigen R inhibition in chronic liver disease and hepatocellular carcinoma
Mickaël Jouve[1], Noémie Legrand[1], Fabrice Bray[2], Pierre-Jean Devaux[1], Viviane Gnemmi[3], Noémie Gellée[1], Laurent Dubuquoy[1], Cyril Sobolewski[1]. *[1]Institute for Translational Research in Inflammation, Lille, France; [2]Miniaturisation pour la Synthèse, l'Analyse et la Protéomique (MSAP), Lille, France; [3]CHU Lille, Lille, France*
Email: mickael.jouve@univ-lille.fr

Background and aims: The RNA-binding protein HuR (Human antigen R) importantly regulates the stability and translation of a wide range of transcripts involved in metabolism, inflammation, and cancer (e.g., TNFα, MYC). While several studies have highlighted the tumor-promoting function of HuR in hepatocellular carcinoma (HCC), emerging evidence indicates that HuR inhibition may promote Metabolic Dysfunction-Associated Steatohepatitis (MASH). Therefore, the role of HuR in these diseases remains unclear and the therapeutic potential of HuR inhibition in these diseases remains to be demonstrated. In this study, we have characterized the impact of HuR inhibition on both HCC and MASH development.
Method: HuR expression was measured in liver tissues from patients and mouse models of hepatic steatosis, MASH, HCC, and intrahepatic cholangiocarcinoma (ICC). The potential of HuR inhibition was evaluated by genetic (siRNA, AAV8) or pharmacologic approaches (HuR inhibitors: CMLD-2 and MS-444) in a panel of hepatic cancer cell lines, primary hepatocytes and mouse models of MASH (mice fed a choline-deficient amino acid-defined high-fat diet: CDAHFD). A proteomic analysis in hepatic cancer cells was performed to characterize the impact of HuR inhibition on cancer-related processes and identify potential targets.
Results: HuR is overexpressed in HCC and ICC as compared to non-tumoral tissues. Histological analyses revealed that some patients exhibit a strict nuclear localization pattern, while others display nuclear and cytoplasmic localization. HuR inhibitors markedly reduced hepatic cancer cell proliferation, viability and migration. For MS-444, but not for CMLD-2 or HuR silencing, cells accumulated in prophase, thus suggesting some HuR-independent effects. A proteomic analysis confirmed that HuR inhibitors alter a network of oncogenes and tumor suppressors, including known HuR targets (e.g., ATG5), associated with a poor prognosis. However, HuR inhibition promotes hepatic steatosis in primary hepatocytes and in mice fed a CDAHFD, through the downregulation of ApoB.
Conclusion: HuR is an important tumor promoter in HCC and HuR inhibitors display interesting anti-cancerous properties in hepatic cancer cells. However, HuR inhibition also exacerbates hepatic lipid metabolism and thus promotes MASH development, thus suggesting cautions regarding the use of HuR inhibitors in clinical practice.

SAT-077
OGT and c-Myc promote non-canonical activation of gene expression by EZH2 in hepatocellular carcinoma
Coline Kerbaj[1], Margot Thirion[1], Massimiliano Cocca[1], Marie-Laure Plissonnier[1], Vincenzo Alfano[1], Francesca Guerrieri[1], Claude Caron de Fromentel[1], Massimo Levrero[1,2], Mirjam Zeisel[1]. *[1]Inserm UMR1350 PaThLiv, Pathobiology and Therapy of Liver diseases, The Lyon Hepatology Institute, IHU EVEREST, Lyon, France; [2]Hospices Civils de Lyon, Service d'Hépato- Gastroentérologie, Lyon, France*
Email: mirjam.zeisel@inserm.fr

Background and aims: Hepatocellular carcinoma (HCC) is the most frequent form of liver cancer. The histone methyltransferase (HMT) EZH2 is frequently upregulated in HCC tissues and its expression correlates with HCC aggressivity and poor prognosis. As the catalytic subunit of PRC2, the canonical activity of EZH2 is to trimethylate H3K27 to mediate gene repression. In cancer, EZH2 can have non canonical roles including activation of gene expression in a PRC2- and/or HMT-independent manner. EZH2 is regulated by post-translational modifications, including O-GlcNAcylation by OGT, an enzyme that is also upregulated in HCC. We showed that OGT co-localizes with EZH2 at the promoter of a set of genes involved in cancer-associated pathways in human hepatoma cells.
Method: Here, we used chromatin immunoprecipitation followed by sequencing (ChIP-seq), RNA-sequencing (RNA-seq), computational analysis and functional studies to assess the role of OGT in the epigenetic and transcriptional regulation of cancer-associated genes by EZH2 in HCC.
Results: Our data indicate that OGT is more frequently associated with activation of gene expression by EZH2 than with EZH2-mediated gene repression. In line with our gene ontology and pathway analysis of EZH2/OGT co-activated genes that showed an enrichment of genes related to cell cycle and cancer pathways, including Myc targets, the majority of promoters with EZH2 and OGT co-recruitment also exhibit c-Myc binding.
Conclusion: Collectively, our data uncover that OGT and c-Myc promote non-canonical functions of EZH2 in transformed liver cells and provide important insights for epigenetic strategies as potential future anti-HCC therapies.

SAT-078
Immunoregulation and T cell paralysis mediated by MDSC induction in hepatocellular carcinoma following rVSV-NDV therapy
Mirta Jimenez[1], Sainitin Donakonda[1], Percy A. Knolle[1], Jennifer Altomonte[2], Bastian Höchst[1]. *[1]Institute of Molecular Immunology, TUM School of Medicine and Health, Technical University Munich, Munich, Germany; [2]Department of Internal Medicine II, Klinikum Rechts der Isar, Technical University of Munich, Municch, Germany*
Email: mirta.jimenez@tum.de

Background and aims: Hepatocellular carcinoma (HCC) is a leading cause of cancer-related mortality and is characterized by a profoundly immunosuppressive tumor microenvironment limiting effective immune responses. The therapeutical potential of a recombinant chimeric virus, rVSV-NDV, has been demonstrated to mediate therapeutic effects in preclinical models of HCC. This study evaluates the interplay between oncolytic virus therapy and tumor-induced immune suppression, focusing on identifying strategies to overcome immunotherapy resistance.
Method: Using an orthotopic model of HCC in mice, the therapeutic potential of the recombinant virus rVSV-NDV was evaluated. The immune infiltration into the tumor was analyzed using flow cytometry. Confocal microscopy examined the spatial relationship of $CD8^+$ T cell and MDSCs. *In vitro* assays were conducted to investigate the role of HCC tumor cells in driving monocyte differentiation into MDSCs and their suppression of T cell activity via methylglyoxal transfer. Single-cell RNA sequencing (scRNA-seq) was used to analyze MDSC populations and transitional states in murine HCC models.
Results: Treatment with rVSV-NDV resulted in the infiltration of monocytes and effector CD8+ T cells into the liver and tumor. However, infiltrating monocytes differentiated into myeloid-derived suppressor cells (MDSCs), which coincided with $CD8^+$ T cell infiltration and potentially neutralize their cytotoxic effects.

Confocal microscopy revealed that CD8$^+$ T cell–MDSC interactions were localized to the tumor border, thereby highlighting spatial dynamics of immune suppression. *In vitro*, HCC cells were shown to drive monocyte-to-MDSC differentiation, resulting in T cell suppression via methylglyoxal transfer. scRNA-seq analyses identified a distinct MDSC population and suggested an intermediate state between mononuclear phagocytes and MDSCs, indicating a transitional process.
Conclusion: This study elucidates the mechanism of MDSC-mediated immune suppression and the role in neutralizing T cell activity within the immunosuppressive microenvironment of HCC. The findings reveal a complex interaction between oncolytic viral therapy and tumor-induced immune resistance, providing insights that could guide the development of more effective immunotherapies for HCC. Further research is ongoing to elucidate the processes driving mononuclear phagocyte differentiation into MDSCs and identify potential therapeutic targets.

SAT-079
Metabolic and functional characterization of CD8+ T-cell subpopulations in hepatocellular carcinoma: implications of tumor microenvironment on T-cell dysfunction
Anna Montali[1], Valentina Reverberi[1], Alessio Pelagatti[1], Andrea Vecchi[2], Marzia Rossi[1], Sara Doselli[1], Benedetta Farina[1], Andrea Olivani[2], Giorgio Economopoulos[1], Raffaelle Dalla Valle[1], Paola Fisicaro[2], Carolina Boni[1], Gabriele Missale[1]. [1]*University of Parma, Parma, Italy;* [2]*Azienda Ospedaliero–Universitaria of Parma, Parma, Italy*
Email: anna.montali@unipr.it

Background and aims: CD8 T-cells are crucial in adaptive immune response, against viral infections and tumors. The tumor immune microenvironment (TIME) can disrupt immunological pathways. In Hepatocellular Carcinoma (HCC), CD8 T-cell functional defects correlate with disease stage and clinical outcomes, but the molecular bases of their dysfunction are not fully understood. Recent studies reveal the importance of specific CD8+ T-cell subpopulations in the tumor microenvironment, highlighting that within tumor-infiltrating lymphocytes (TILs), CD103+CD39+ cells are enriched for tumor-reactive T cells in solid tumors. Additionally, in liver and tumor tissues two distinct CD8+ T-cell populations can be found with opposing clinical implications: Terminally exhausted (TEX) and Tissue resident memory (TRM) cells. A high TRM/TEX ratio predicts better patient outcomes, while tumor-reactive T cells show the greatest functional improvement after anti-PD-1 therapy. These findings underscore the complementary roles of TRM and TEX cells in immune responses during checkpoint therapy. Our study aims to comprehensively characterize metabolic and functional differences between tumor-infiltrating and liver-infiltrating CD8+ T-cell subpopulations.
Method: We performed phenotypic expression of surface markers (CD103, CD39 and PD1) that can define different CD8 subsets: Tissue resident memory (TRM), Tumor reactive and Terminally exhausted cells (TEX). By analyzing metabolic status, DNA damage response, and cytokine production, we seek to elucidate TIME's impact on T-cell functionality.
Results: The tumor microenvironment was enriched of TEX cells (CD39+ CD103- PD1+) and CD39+/CD103+ Tumor-reactive-cells. Exposure to TIME led to dysfunction, with a higher percentage of PD1+/Tim3+ Tumor-reactive cells. TRM cells (CD103+CD39-PD1+) in the liver were less exhausted (CD103+CD39-PD1lo) than their tumor counterparts (CD103+CD39-PD1hi and CD103+CD39-PD1+Tim3+). Metabolic analyses revealed that tumor-infiltrating subpopulations had lower glucose uptake and higher mitochondrial membrane depolarization, indicating significant metabolic strain, and higher histone H2AX phosphorylation, indicating more DNA damage. TEX showed highest H2AX phosphorylation, while TRM the lowest. In tumor-infiltrating CD8+ T-cells, mitochondrial membrane depolarization correlated positively with p-H2AX+ cells and negatively with glucose uptake. Functional analysis revealed an overall lack of functionality in tumor-infiltrating TEX cells. Finally, an enrichment of TEX cells was observed in patients with larger tumor nodules size, while Tumor-reactive and TRM cells were reduced in the same group of patients.
Conclusion: The TIME imposes significant metabolic and DNA damage stress on CD8+ T-cell subpopulations, leading to functional impairments. Therapeutic strategies targeting these metabolic challenges are essential for enhancing anti-tumor immunity.

SAT-080-YI
The NLRP3 inflammasome and its downstream target Il1R, but not IL18R drive hepatocarcinogenesis
Mona Peltzer[1], Antje Mohs[1], Lena Susanna Candels[1], Ines Volkert[1], Jan G. Hengstler[2], Carolin V. Schneider, Serena Pelusi[3], Luca Valenti[3,4], Eicke Latz[5], Christian Trautwein[2], Kai Markus Schneider[1,6,7,8]. [1]*Clinic for Gastroenterology, Metabolic Diseases and Internal Intensive Care Medicine, Uniklinik RWTH Aachen, Aachen, Germany;* [2]*Systems Toxicology, Leibniz Research Centre for Working Environment and Human Factors at the Technical University Dortmund (IfADo), Dortmund, Germany;* [3]*Biological Resource Center, Fondazione IRCCS Ca' Granda Policlinico, Milano, Italy;* [4]*Department of Pathophysiology and Transplantation, Università degli Studi Milano, Milano, Italy;* [5]*Deutsches Rheuma-Forschungszentrum Berlin, Berlin, Germany;* [6]*Center for Regenerative Therapies Dresden (CRTD), Technische Universität (TU) Dresden, Dresden, Germany;* [7]*Department of Medicine I, Dept. of Gastroenterology and Hepatology, Faculty of Medicine and University Hospital Carl Gustav Carus, TU Dresden University of Technology, Dresden, Germany;* [8]*Else Kroener Fresenius Center for Digital Health, Faculty of Medicine and University Hospital Carl Gustav Carus, TU Dresden University of Technology, Dresden, Germany*
Email: mpeltzer@ukaachen.de

Background and aims: Hepatocellular carcinoma (HCC) is the most common form of liver cancer and often arises in the chronically inflamed liver, which can lead to liver injury and the malignant transformation of hepatocytes. The NLR Family Pyrin Domain Containing 3 (NLRP3) inflammasome is a key regulator of sterile inflammation in liver disease, but its role in hepatocyte malignant transformation remains incompletely understood. Activation of the NLRP3 inflammasome by pathogen- or damage-associated molecular patterns (PAMPs/DAMPs) initiates the secretion of the pro-inflammatory cytokines interleukin-1β (IL-1β) and interleukin-18 (IL-18). This study aimed to investigate the role of NLRP3 and its downstream targets (IL-1β and IL-18) in inflammation- and primary sclerosing cholangitis (PSC)-related hepatocarcinogenesis.
Method: NLRP3 expression was analyzed in liver tissue samples obtained from hepatocellular carcinoma (HCC) patients (n = 6) and non-cancerous controls (n = 5). In mice, HCC was induced using the N-nitrosodiethylamine/carbon tetrachloride (DEN/CCl_4) model in wild-type (WT), *Nlrp3*$^{-/-}$, *Il1r*$^{-/-}$ and *Il18r*$^{-/-}$ mice. PSC-related hepatocarcinogenesis was modeled by crossing *Nlrp3*$^{-/-}$ mice with multidrug resistance gene 2 knockout mice (*Mdr2*$^{-/-}$/*Nlrp3*$^{-/-}$), which were analyzed at 64 weeks of age. Tumor development, immune cell infiltration, and proliferation were assessed in both models.
Results: Analysis of human HCC tissue demonstrated a significant upregulation of NLRP3 expression compared to non-tumor controls. In both murine tumor models (DEN/CCl_4 and genetic modified *Mdr2*$^{-/-}$) NLRP3 deletion significantly reduced tumor burden and inflammation. Reduced inflammation was evidenced by decreased staining for Kupffer cells and activated hepatic stellate cells. Additionally, NLRP3 deletion reduced hepatocyte proliferation, as confirmed by Western blot and immunostaining. To further dissect the downstream pathways, tumor development was assessed in *Il1r*$^{-/-}$ and *Il18r*$^{-/-}$ mice. Interestingly, *Il1r*$^{-/-}$ but not *Il18r*$^{-/-}$ mice exhibited reduced tumor burden, inflammation, Kupffer cell and hepatic stellate cell activation. The deletion of *Nlrp3* or *Il1r*, but not *Il18r*, led to increased CD8$^+$ T cells infiltration and elevated *Interferon-γ*

(*Ifnγ*) expression. RNA-Seq analysis supported these findings by revealing upregulation of T-cell activation pathways in tumor tissues from NLRP3-deficient mice compared to WT controls. Thus, the deletion of NLRP3 or IL1R, but not of IL18R showed protective effects for HCC development.
Conclusion: NLRP3 is overexpressed in human HCC tissue and promotes hepatocarcinogenesis in murine models. Deletion of NLRP3 or IL1R, but not IL18R, reduces HCC development, highlighting their roles as key drivers of tumorigenesis. These findings suggest that potential therapeutic strategies for HCC may include targeting the NLRP3 inflammasome or IL-1 signalling.

SAT-081

Development and performance of AI in supporting the diagnosis of liver tumors using B-mode ultrasound

Naoshi Nishida[1], Masatoshi Kudo[1]. [1]*Department of Gastroenterology and Hepatology, Kindai University Faculty of Medicine, Osakasayama, Japan*
Email: naoshi@med.kindai.ac.jp

Background and aims: Early diagnosis of liver tumours is crucial for timely intervention in liver cancer. Abdominal ultrasound (US) is recommended as a screening tool for hepatocellular carcinoma (HCC). However, diagnostic performance in US examinations depends on the operator's expertise. We developed an artificial intelligence (AI) to assist the diagnosis of four types of lesions—HCC, metastatic tumors (META), haemangiomas (HEM), and cysts—enabling beginners to achieve expert-level diagnostic performance. The efficacy of AI was evaluated through clinical trials.
Method: B-mode US images of liver mass labelled with diagnoses from other modalities were collected from 11 institutions. Using the 104,908 still US images, the AI was trained; the detection module used YOLOv5 with DeepSORT, while the classification module used VGG-19. In the clinical trials, B-mode US videos, collected in clinical practice, were used. Human readers diagnosed the lesions with and without AI assistance and results were compared. Two tests were conducted, with results standardized using Z-scores for analysis.
For detection, the first trial used 59 cases (36 solitary, 14 multiple, 9 non-lesion images), and the second trial involved 60 cases (40 solitary, 12 multiple, 8 non-lesion images). For classification, the first trial included 50 cases (15 HCCs, 13 METAs, 18 HEMs, 4 cysts), and the second trial used 50 cases (15 HCCs, 15 METAs, 15 HEMs, 5 cysts). Thirty-six readers participated, comprising 16 experts (certified specialists) and 20 beginners.
Results: The performance of AI with cross-validation were as follows; recall = 0.929, precision = 0.906, and F1 score = 0.917 for detection, the accuracy = 0.890 for 4-disease classification, and accuracy = 0.937, sensitivity = 0.897, and specificity = 0.957 in malignant discrimination. In the clinical trials, recall and F1 score improved significantly under AI assistance (both $p < 0.0001$), while precision showed a trend toward improvement ($p = 0.2377$). Subgroup analysis revealed significant improvements in recall in the expert's group ($p = 0.0002$). In the beginner's group, significant improvements were observed in recall, precision, and F1 score ($p < 0.0001$, $p = 0.0192$, $p < 0.0001$, respectively). In 4-disease and malignant discrimination, accuracy improved significantly under AI assistance (both $p < 0.0001$). Subgroup analysis confirmed significant improvements in both tasks for experts and beginners ($p < 0.0001$ for both groups in 4-disease classification, $p = 0.0184$ for experts and $p < 0.0001$ for beginners in malignant discrimination,). Diagnostic accuracy, sensitivity, specificity, and Matthews correlation coefficient improved across all lesion types under the AI-support.
Conclusion: The developed AI demonstrated significant diagnostic support for both beginners and experts, underscoring its potential as a valuable tool for enhancing the diagnosis of liver mass in US practice. This AI shows a promising step toward societal implementation of AI-powered US diagnostics.

SAT-082-YI

The metabolic heterogeneity induced by different genetic mutations in hepatocellular carcinoma leads to a particular response to feeding a lipid-enriched diet

Natalia Sainz-Ramirez[1], Francisco Gonzalez-Romero[1], Igor Aurrekoetxea[1,2], Cesar Merino[1], Kendall Alfaro-Jiménez[1], Paul Gómez-Jauregui[1], Ane Ortiz-Palma[1], Idoia Fernández-Puertas[1], Ane Nieva-Zuluaga[1], Maider Apodaka-Biguri[1], Mikel Ruiz de Gauna[1], Estibaliz Castillero[1], Mikel Azkargorta[3], Felix Elortza[3,4], Maria Sendino[5], Javier Muñoz[6], Amaia Lujambio[7,8], Xabier Buque[1], Patricia Aspichueta[1,2,4]. Email: patricia.aspichueta@ehu.eus

Background and aims: Hepatocellular carcinoma (HCC) represents 75% to 85% of primary liver cancers. The heterogeneity among HCC patients, due at least in part to metabolic reprogramming, makes it difficult to find more specific treatments. This highlights the need to distinguish between different HCC subtypes. Our previous research has demonstrated the pivotal role of E2F transcription factors in the development and progression of metabolic dysfunction-associated steatotic liver disease (MASLD) and related metabolic dysregulation. The objectives here were: 1) to study the metabolic heterogeneity of two HCC subtypes (more and less dedifferentiated) and the influence of a high-fat diet on their development and progression; and 2) to analyze the role of E2F transcription factors in the metabolic reprogramming associated with each HCC subtype.
Method: the two HCC subtypes were developed in C57BL/6J mice fed a chow (CD) or high-fat diet (HFD) by the *Sleeping Beauty* technique. One of the HCC subtypes was highly dedifferentiated, overexpressing *MYC* and β-catenin oncogenes (*mHCC1*), while the other was highly differentiated overexpressing β-catenin and repressing the tumor suppressor *PTEN* (*mHCC3*). Weight was monitored weekly and a glucose tolerance test was performed. Tumor number and size, white adipose tissue (WAT) lipolysis, serum and hepatic lipid levels were determined. In addition, E2F1 and E2F2 factors were quantified by western blotting and a proteomic study was performed on tumor (T) and healthy (CT) tissues. The TCGA cohort was also analyzed using the cBioPortal tool.
Results: The *mHCC1* model showed a higher tumor formation rate and a pronounced response to HFD while the *mHCC3* model didńt. Tumor development did not lead to changes in either body weight or serum glucose management, regardless of the animal model or diet. The accelerated tumor growth observed in the *mHCC1*-HFD model was associated with a reduction in the tumor storage of triglycerides (TG) and diglycerides (DG), and an increase in serum fatty acids (FA), cholesterol and TG. According to the proteome profile, this phenotype was associated to changes in biological pathways affecting TG degradation, FA oxidation and lipoprotein clearance. This phenotype was not observed in the *mHCC1*-CD model or when *mHCC3* was developed under a CD or HFD diet, where a marked increase in the accumulation of tumor lipids (cholesteryl ester, DG and TG) was found. The upregulation of β-catenin in both mouse models fed a CD or a HFD was related with a decrease in tumor E2F1 levels, consistent with the decrease observed in HCC in patients with β-catenin mutations.

Conclusion: The combination of genetic mutations linked to highly dedifferentiated HCC subtypes leads to the metabolic heterogeneity that promotes progression of HCC. Treatments aimed at preventing TG degradation, FA oxidation and lipoprotein clearance should be evaluated.

SAT-083-YI

Clinical potential and non-canonical roles of the cytosolic aspartyl-tRNA synthetase (DARS1) in hepatocellular carcinoma

Rodríguez-Perálvarez[1,8], Juan Luis López-Cánovas[1,2,3,4], Manuel D. Gahete[1,2,3,4]. *[1]Department of Cell Biology, Physiology and Immunology, University of Córdoba, 14004, Córdoba, Spain; [2]Maimónides Institute of Biomedical Research of Córdoba (IMIBIC), 14004, Córdoba, Spain; [3]Reina Sofía University Hospital, 14004, Córdoba, Spain; [4]CIBER Pathophysiology of Obesity and Nutrition (CIBERobn), 14004, Córdoba, Spain; [5]Hepatology Laboratory, Solid Tumors Program, CIMA, CCUN, University of Navarra, Pamplona, Spain; [6]Instituto de Investigaciones Sanitarias de Navarra IdiSNA, Pamplona, Spain; [7]CIBEREHD (Center for Biomedical Network Research in Liver and Digestive Diseases), Instituto de Salud Carlos III, Pamplona, Spain; [8]Department of Hepatology and Liver Transplantation, Reina Sofía University Hospital, 14004, Córdoba, Spain*
Email: nataliahermansan@gmail.com

Background and aims: Aminoacyl-tRNA synthetases (ARSs) catalyze the transfer of amino acids to tRNAs for protein synthesis. Here, we explore the potential of the cytosolic aspartyl-tRNA synthetase (DARS1) as diagnostic biomarker and therapeutic target, as its molecular implication in hepatocellular carcinoma (HCC).
Method: DARS1 levels were analyzed in cytosolic/nuclear protein fractions of HCC patients ($n = 42$ patients) and seven *in silico* cohorts (mRNA/protein). DARS1 levels were detected in plasma samples of two cohorts (Discovery: 8 HCC vs. 8 controls; Validation: 32 HCC vs. 15 MASLD vs. 14 cirrhosis vs. 21 controls). Functional assays were performed in three liver cancer-derived cell lines (HepG2, Hep3B, SNU-387) after DARS1 modulation (silencing, overexpression, pharmacological inhibition). DARS1-overexpressing Hep3B cells were used for *in vivo* orthotopic tumor formation. Immunoprecipitation of DARS1 and quantitative proteomics were performed in cytosolic/nuclear Hep3B fractions.
Results: DARS1 abundance was increased in HCC tissues (mRNA/protein), and in plasma samples of HCC patients [Area Under Curve (AUC) HCC *vs.* controls: 0.8376; HCC *vs.* MASLD: 0.9016; HCC *vs.* cirrhosis: 0.8095]. DARS1 levels were higher in aggressive tumors (i.e. invasive, dedifferentiated) and in patients with adrenal/lung metastasis. Consistently, *DARS1* silencing and pharmacological inhibition reduced, while *DARS1* overexpression increased, functional parameters of aggressiveness *in vitro*. In fact, orthotopic tumors formed by *DARS1*-overexpressing Hep3B cells had increased establishment capacity and growth *in vivo*. Mechanistically, DARS1 protein levels were higher in nuclear, but not cytosolic, samples of HCC. An immunoprecipitation assay revealed 182 cytosolic and 132 nuclear DARS1 interactors, three of the latter being members of the Spt-Ada-Gcn5 acetyltransferase (SAGA) complex, which regulates MYC acetylation and stability. This non-canonical interaction was confirmed by *in silico* docking of DARS1/SAGA crystal structures. Additionally, *DARS1* silencing reduced MYC protein levels and phosphorylation, and the expression of MYC targets was reduced in RNA-seq data of *DARS1*-silenced HepG2 cells. Consistently, *DARS1* silencing reduced drug-induced senescence (Gemcitabine, Etoposide, Cisplatin), suggesting a link between DARS1-SAGA interaction and MYC-regulated senescence.
Conclusion: The aspartyl-tRNA synthetase (DARS1) is overexpressed in HCC tissues and is a potential biomarker in liquid biopsy. DARS1 targeting could represent a therapeutic strategy for HCC though a mechanism that might involve its non-canonical nuclear interaction with the SAGA complex and the modulation of MYC activity. Fundings: ISCIII (ERDF/ESF, "Investing in your future"; PI20/01301, PI23/00652), MINECO (FPU20/03957), JdA (PEMP-0036-2020, BIO-0139), FSEEN and CIBERobn/ehd.

SAT-084

Microscale detection of selenium in liver tissue using laser ablation-inductively coupled plasma time-of-flight mass spectrometry

Nataliya Rohr-Udilova[1], Lyndsey Hendriks[2], Linda Bjorkhem-Bergman[3], Matthias Pinter[1], Michael Trauner, Gunda Koellensperger[2]. *[1]Medical University of Vienna, Internal Medicine III, Division of Gastroenterology and Hepatology, Vienna, Austria; [2]University of Vienna, Institute of Analytical Chemistry, Vienna, Austria; [3]Karolinska Institutet, Huddinge, Sweden*
Email: nataliya.rohr-udilova@meduniwien.ac.at

Background and aims: Selenium (Se) is an essential trace element absorbed into the body from the soil through food consumption. In biological systems, selenium plays a crucial role in defense against oxidative stress as an integral part of the active centers of antioxidative enzymes such as glutathione peroxidases. The distribution of selenium in the body follows a complex hierarchy among organs and selenoenzymes and may be altered in the presence of cancer. Chronic selenium deficiency has been linked to the development of hepatocellular carcinoma. As a trace element, selenium concentrations in biological samples are low, necessitating the use of macroscopic tissue amounts for bulk quantification. Laser ablation (LA) combined with inductively coupled plasma time-of-flight mass spectrometry (ICP-TOFMS) is a state-of-the-art micro-analytical technique. In LA-ICP-TOFMS, a focused laser beam rasters across the sample, with each laser pulse ablating material that is transported to the mass spectrometer. Each laser shot corresponds to a pixel in the resulting elemental map, enabling high-resolution spatial analysis. The unique capability of ICP-TOFMS to simultaneously measure the full mass spectrum allows for the detection endogenous elements such as phosphorus (P) and iron (Fe) alongside with Selenium. Recent advancements in hardware, software, and methodology have further improved the technique's spatial resolution, sensitivity, and data acquisition speed, making it a powerful tool for studying trace elements in biological tissues with unprecedented detail and efficiency. This study aimed to evaluate the feasibility of detecting selenium in the liver using the novel LA-ICP-TOFMS technique.
Method: We employed a chemically induced hepatocellular carcinoma (HCC) model in Wistar rats, with and without selenium supplementation in their drinking water. Tissue sections with 5 µm thickness were prepared from formalin-fixed paraffin-embedded (FFPE) liver samples and subsequently analyzed by LA-ICP-TOFMS.
Results: The LA-ICP-TOFMS results showed that through concurrent detection of endogenous of elements such as iron (Fe) and phosphorus (P), imaging of Selenium in liver tissue was possible. Measurement conditions were optimized to allow the detection of hepatic selenium at a resolution of 2.5 µm, corresponding to subcellular scale. Selenium detection in the liver was achieved in both Se-supplemented and non-supplemented animals.
Conclusion: For the first time, we report microscale measurements of selenium distribution in the liver using the recent technological advancements of LA-ICP-TOFMS. This novel technique offers promising applications in understanding the relationship between selenium and liver tumor development at the single-cell resolution, contributing to a broader understanding of selenium's role in cancer prevention.

SAT-085-YI

The role of CNNM4 in the progression of cholangiocarcinoma: implications for ferroptosis and therapeutic potential

Maria Mercado[1], Naroa Goikoetxea-Usandizaga[1,2], Alvaro Eguilero Giné[1], Miguel Angel Merlos Rodrigo[3], Marta B. Afonso[4], Mikel Azkargorta[5,6], Leidy Estefanía Zapata-Pavas[1], Marta Romero[7,8], Isabel Mendizabal[9], Pedro M Rodrigues[5,10,11], Hanghang Wu[12], Rubén Rodríguez[1], Marina Serrano-Maciá[1], Paula Olaizola[5,10], Claudia M. Email: ngoikoetxea@cicbiogune.es

Background and aims: Cholangiocarcinoma (CCA) is a heterogeneous neoplasm of the biliary epithelium that easily infiltrates, metastasizes and recurs. Magnesium disbalance is a hallmark of CCA, being the magnesium transporter CNNM4 a key driver of various hepatic diseases. This study aims to unravel the role of CNNM4 in the initiation and progression of CCA.
Method: CNNM4 protein and gene expression were assessed *in vitro*, *in vivo* and in patients with CCA. Silencing of *CNNM4* was effectively achieved by using siRNA or shRNA in CCA cell lines and GalNAc-conjugated siRNA in a transposon-based CCA mice model. The impact of CNNM4 on tumor cell proliferation, migration and invasion to the lungs was evaluated using the chicken chorioallantoic membrane model. Proteomic analysis was employed to elucidate the underlying molecular mechanisms.
Results: CNNM4 was upregulated in CCA samples from eight independent patient cohorts, comparing resected CCA samples (both iCCA and eCCA) with controls. Overexpression of CNNM4 was also confirmed in AKT/NICD, AKT/YapS127A and AKT/Fbxw7ΔF mouse models, as well as in human iCCA and eCCA cell lines, which also exhibited reduced intracellular Mg2+ levels, demonstrating a role for CNNM4 in Mg2+ extrusion in CCA. Functional studies showed that CNNM4 deficiency attenuated cell growth, chemoresistance, migration, invasion, tumorigenesis, cancer stem cell properties and the Warburg effect both *in vitro* and *in vivo*. Interestingly, proteomic analysis identified nuclear protein 1 (NUPR-1), an inhibitor of ferroptosis, as critical for the observed effects in CCA cells when CNNM4 levels are reduced. Knockdown of CNNM4 led to a significant reduction in NUPR-1 levels and increased iron accumulation and lipid peroxidation *in vitro* and *in vivo*. Furthermore, both the iron chelator deferiprone and overexpression of NUPR-1 were able to reverse the reduced proliferation induced by CNNM4 silencing, highlighting the specificity of ferroptosis in CNNM4-associated effects.
Conclusion: This study demonstrates that increased CNNM4 expression drives CCA progression and malignancy and that its inhibition may be an effective therapeutic strategy to limit proliferation and metastasis in CCA patients.

SAT-086

Tumour-infiltrating regulatory T cells engage Nrf2 signalling to support their metabolic adaptation in hepatocellular carcinoma

Email: niloufar.1.safinia@kcl.ac.uk

Background and aims: Hepatocellular carcinoma (HCC), the predominant form of primary liver cancer, represents the third leading cause of cancer-related mortality worldwide. Within HCC tumours, regulatory T cells (Tregs), a specialized subset of CD4+ T cells, accumulate in substantial numbers. This accumulation inversely correlates with patient survival rates, indicating their crucial role in suppressing anti-tumour immune responses. Despite their clinical significance, the molecular mechanisms enabling Treg adaptation and persistence within the HCC microenvironment remain poorly understood. Our previous research demonstrated that in cirrhosis, a condition underlying the majority of HCC cases, Tregs exhibit functional impairment and increased susceptibility to apoptosis. This dysfunction stems from a compromised antioxidant response pathway associated with dysregulated nuclear factor erythroid 2-related factor 2 (Nrf2) signalling. Building upon these findings, we hypothesised that intratumoral Tregs engage Nrf2 signalling for their adaptation within the HCC microenvironment, thereby promoting their metabolic fitness and expansion.
Method: Integrating cutting-edge omics technologies with advanced in vivo models, we investigated the metabolic regulation of intratumoral Tregs through three distinct approaches: characterisation of Nrf2-dependent signalling networks governing human intratumoral Treg metabolism; assessment of tumour microenvironment-derived metabolic signals, specifically lactate, on Treg metabolic programming; and evaluation of targeted Nrf2 pathway modulation through both pharmacological and genetic approaches in an established HCC mouse model.
Results: Our analysis revealed that Tregs in non-tumoral liver tissue exhibit metabolic quiescence and increased susceptibility to apoptosis. However, upon exposure to the lactate-enriched tumour microenvironment, Tregs demonstrate enhanced Nrf2 activation, which coordinates metabolic reprogramming essential for their survival and immunosuppressive capacity. Genetic deletion of Nfe2l2 (encoding Nrf2) in Tregs significantly reduced intratumoral Treg infiltration and attenuated tumour progression in vivo. Notably, pharmacological Nrf2 inhibition favourably modulated the ratio of effector to regulatory immune cells within the tumour microenvironment while preserving systemic immune homeostasis.
Conclusion: Our findings establish Nrf2 as a critical immune checkpoint regulator that governs Treg metabolic adaptation within the tumour microenvironment. This discovery reveals a promising therapeutic strategy for HCC treatment through selective modulation of Nrf2 signalling, potentially enabling the reversal of tumour-associated immunosuppression and enhancement of anti-tumour immune responses.

SAT-087

MiR-485-3p as a predictor of therapeutic response and its role of the PIAS3/STAT3/VEGF signal in Atezolizumab plus Bevacizumab therapy for hepatocellular carcinoma

Kyoko Oura[1], Asahiro Morishita[1], Rie Yano[1], Kei Takuma[1], Mai Nakahara[1], Tomoko Tadokoro[1], Koji Fujita[1], Joji Tani[1], HIdeki Kobara[1]. [1]*Kagawa University, Kita-gun, Kagawa, Japan*
Email: oura.kyoko@kagawa-u.ac.jp

Background and aims: In atezolizumab/bevacizumab (atezo/bev) therapy for unresectable hepatocellular carcinoma (uHCC), the tumor immune environment is regulated through vascular endothelial growth factor (VEGF) inhibition to maximize immune checkpoint blockade; however, evidence for VEGF as a biomarker is limited. This study aimed to investigate serum VEGF and associated microRNAs (miRNAs) as rapid biomarkers and their regulatory mechanisms in atezo/bev therapy.
Method: Fifty-four patients with uHCC who were treated with atezo/bev therapy were enrolled and assigned into objective response (OR) and non-OR groups according to the best therapeutic response in 12 weeks using the modified response evaluation criteria in solid tumors. Serum VEGF levels and associated miRNA expression were compared. Furthermore, the effect of cell transfection with specific miRNA was investigated.
Results: There was no significant difference in the pretreatment serum VEGF levels between the groups; however, the 3-week/pretreatment ratio of serum VEGF levels was significantly lower in the OR group than in the non-OR group. The pretreatment serum levels of 10 miRNAs, especially miR-485-3p involved in VEGF expression, were higher in the OR group than in the non-OR group and were further elevated after 1–7 days and 3 weeks. miR-485-3p suppressed HuH-7 migration, enhanced the expression of protein inhibitor of activated (PIA) signal transducer and activator of transcription 3 (STAT3) (PIAS3), and suppressed the expression of phosphorylated STAT3/VEGF.
Conclusion: Serum miR-485-3p is a more sensitive biomarker than VEGF for the early prediction of therapeutic response in atezo/bev therapy for uHCC.

SAT-088

Integrated multi-omics profiling of pan heat shock proteins in hepatocellular carcinoma identifies CCT3 and CCT7 as druggable oncogenes in hepatocytes

Manju Nidagodu Jayakumar[1,2], Bilal Rah[1], Jasmin Shafarin[1], Mainak Dutta[2,3], Sainitin Donakonda[4], Jibran Sualeh Muhammad[1,5]. Email: j.sualehmuhammad@bham.ac.uk

Background and aims: Hepatocellular carcinoma (HCC) is associated with poor prognosis due to limited targeted therapies, necessitating the identification of novel therapeutic targets. Heat shock proteins (HSPs) are recognized as carcinogen regulators; however, their function in HCC remains unclear. This study aims to screen and characterize pan HSP expression in HCC at the multi-omic level and to enhance our understanding of disease pathogenesis.
Method: We created a comprehensive atlas of 132 human HSPs and assessed their expression in HCC patients using a bulk RNA-sequencing analysis. We utilized weighted gene co-expression network analysis (WGCNA), and intramodular connectivity to discover key HSPs in HCC. We validated key HSPs with three independent single-cell RNA-seq (scRNA-seq) datasets (two from

HCC, one from healthy subjects) in combination with high-dimensional WGCNA and proteomics datasets. Furthermore, we performed a comprehensive bioinformatic analysis and integrated a multi-omic network of key HSPs at bulk, single-cell, and proteome levels. Subsequently, we conducted *in-vitro* assays with HCC cell lines, employing RT-PCR, western blotting, and gene silencing by RNA interference to assess their impact on proliferation, apoptosis, and cell cycle. Finally, we screened clinically approved anticancer therapeutic compounds against the key HSPs by using molecular docking and molecular dynamics simulations.
Results: Gene set enrichment analysis revealed proteostasis and HSPs are upregulated in HCC. Further, WGCNA identified thirteen hub HSPs contributing to cancer-related pathways. The scRNA-seq analysis in combination with high-dimensional WGCNA, revealed two key HSP genes, *CCT3*, and *CCT7* as highly upregulated in hepatocyte cells. Comprehensive bioinformatic analysis with publicly available transcriptome and proteomic datasets confirmed elevated expression of CCT3 and CCT7 in HCC at gene and protein levels, highlighting their role in poor prognosis. Multi-omic network of these HSPs revealed that they regulate crucial cancer-related pathways. *In-vitro* silencing of CCT3 and CCT7 in HCC cell lines induced cell cycle arrest and apoptosis via caspase-3, PARP, and Bcl-xL pathways, suggesting their proto-oncogenic role. Finally, drug repurposing by molecular docking and molecular dynamics of 286 clinically approved anti-cancer drugs showed that talazoparib and irinotecan could be potential inhibitors of CCT3 and CCT7, respectively.
Conclusion: This study provides the first multi-omics characterization of pan-HSP expression in HCC, uncovering CCT3 and CCT7 as oncogenic drivers and novel druggable targets.

SAT-089-YI

mRNA-based vaccination for tumor neoantigens to induce a therapeutic T cell response in HCC

Paul Schneider[1], Jenny Schunke[2], Frederic Speier[1], Michael Fichter[1,3], Barbara Schroers[2], Fulvia Vascotto[2], Jörn M. Schattenberg[4], Stephan Grabbe[1], Matthias Bros[1], Mustafa Diken[2], Leonard Kaps[1,4].
[1]University Medical Center, Mainz, Germany; [2]TRON gGmbH, Mainz, Germany; [3]Max Planck Institute for Polymer Research, Mainz, Germany; [4]Saarland University Medical Center, Homburg, Germany
Email: leonard.kaps@uks.eu

Background and aims: Hepatocellular carcinoma (HCC) develops through a stepwise mutational process that gives rise to neoantigens (NA), which are aberrant proteins restricted to tumor cells. NA can be exploited to elicit a T cell-mediated immune response by priming T cells with mRNA vaccines encoding these specific targets. While this approach has demonstrated success in clinical trials for patients with metastatic melanoma, data on its efficacy in HCC remains unavailable (Ott, Wu, Nature, 2017; Lang, Sahin, Nature reviews drug discovery, 2021).
Method: RNA-Seq. of Dt81Hepa1-6 HCC cells were performed to detect NA derived from single nucleotide variants (SNV), splice variants (SV), fusion genes (FG) as well as insertion and deletion (InDel) using a bioinformatic algorithm. The top ten most promising NA of each mutation class were selected from all ranked NA candidates based on VaxRank, MHC class I/II binding and expression. MHC class I and PD-L1 expression was quantified in the Dt81Hepa1-6 cells via flow cytometry. Sequence-specific immunogenicity of NA-coding decatopes was evaluated via IFN-γ ELISpot. C57BL/6JRj mice (8-10 w, ♂) were intrasplenically injected with Dt81Hepa1-6 cells to develop macroscopic HCC lesion during 28 days. For in vivo therapy, HCC mice were injected (i.v.) with lipoplexes (LPX) loaded with NA coding mRNA (LPX:NAmRNA, according to 16 mg/kg NAmRNA) at day 7, 14 and 21 post tumor inoculation. Vaccination-derived effects were analyzed at day 28.
Results: Dt81Hepa1-6 cells displayed a complex mutanome with high expression of HCC key genes (e.g., *Afp, Spats, Mcm6, Mcm3, Nt5dc2*) as well as MHCI and PD-L1 which provided a suitable platform for NA vaccination approaches against HCC. We identified highly immunogenic NA while SNV, SV, FG and InDel-derived candidates induced strong sequence-specific $CD8^+$ and $CD4^+$ T cell responses to Dt81Hepa1-6 cells as assessed by ELISpot. Mice vaccinated with LPX:NAmRNA showed reduced hepatic tumor burden compared to LPX controls (serum AFP: −53%, liver weight: −27%, histological quantification: −46%), while the treatment was well-tolerated as indicated by normal behavior of the mice and laboratory safety parameter profiles for liver, kidney and hemolysis. T cell infiltration was significantly increased in the liver (+63%, $^{****}p < 0.0001$) in the spleen (+18%, $^{****}p < 0.0001$) and in the blood (+55%, $^{****}p < 0.0001$) in treated mice versus controls. Among T cells, $CD8^+$ were the dominant subgroup while being substantially increased in the liver (+24%) in the spleen (+38%) and in the blood (+25%).
Conclusion: Vaccination with immunogenic NA-based mRNA LPX resulted in a convincing T-cell mediated anti-tumor response in HCC mice, paving the way for further in vivo studies with optimized vaccines.

SAT-090

MFAP-5 siRNA nanohydrogels for antiangiogenic stromal-targeting HCC therapy

Paul Schneider[1], Alexander Fuchs[2], Michael Fichter[1,3], Jenny Schunke[4], Oezlem Akilli-Oeztuerk[4], Andreas Keller[5], Lutz Nuhn[2], Stephan Grabbe[1], Jörn M. Schattenberg[6], Leonard Kaps[1,6].
[1]University Medical Center, Mainz, Germany; [2]Justus-Maximillians University, Würzburg, Germany; [3]Max Planck Institute for Polymer Research, Mainz, Germany; [4]TRON gGmbH, Mainz, Germany; [5]Saarland University, Saarbrücken, Germany; [6]Saarland University Medical Center, Homburg, Germany
Email: leonard.kaps@uks.eu

Background and aims: Hepatocellular carcinoma (HCC) is the most frequent type of primary liver cancer and the third leading cause for cancer-related death worldwide. Cancer-associated fibroblasts (CAF) were previously identified as target cells in the tumor-microenvironment (TME), highly releasing microfibril-associated protein 5 (MFAP-5), a proangiogenic protein supporting HCC tumor growth (Schneider P. et al., Adv. Mat., 2024.).
Method: Biodegradable nanohydrogels (NG) with strong liver tropism were used as carriers for anti-MFAP-5 small interfering RNA (siRNA). C57BL/6JRj mice (8–10w, ♂) were gavaged with increasing doses of CCl_4 over a period of 6 weeks. After induction of liver fibrosis, mice were intrasplenically injected with Dt81Hepa1-6 HCC cells to develop macroscopic HCC lesion during 28 days. After intravenous injection, biodistribution of co-florescent labeled NG loaded with Cy5.5-siRNA (F-NG:siCy5.5) was assessed by In Vivo Imaging System (IVIS) on organ level and also on cellular level in single cell suspension of enzymatically digested livers by flow cytometric analysis. For tumor therapy, mice were intravenously injected with three doses of anti-MFAP-5 siRNA (siMFAP5) loaded NG (NG:siMFAP5, according to 1 or 2 mg/kg siRNA) in week 4 after tumor inoculation. Translational studies were conducted to reveal insights in molecular pathways of MFAP-5 interference in human and murine cells and the presence of MFAP-5 in patient-derived resectates of primary liver tumors.
Results: F-NG:siCy5.5 co-localized in the liver of HCC mice and were efficiently taken up by CAF> dendritic cells> macrophages in the liver. NG:siMFAP-5 induced a convincing anti-tumor effect by knockdown of MFAP-5 (−52% on mRNA level and −87% on protein level in CAF) compared to untreated control (n = 5). Treated mice showed a dose dependent reduced hepatic tumor burden as reflected by the surrogates reduced liver weight (−63%), morphometric quantification of tumor load in liver sections (−32%) and serum AFP levels (−48%). RNA-Seq. analysis of whole liver tissue (NG:siMFAP-5 vs. control, n = 3) revealed downregulated angiogenesis pathways via NOTCH signaling interference, which could be confirmed on protein level by RNA-scope staining of liver sections for Hes1 as marker for

NOTCH activation. MFAP-5 was highly expressed in surgical tumor resectates of patients with HCC and cholangiocarcinoma (CCC). A correlation of NOTCH activation (Hes1) and upregulated markers for angiogenesis (CD34, CD105) as well as tumor growth (Ki/67, AFP) could also be observed in human and murine cell lines (HepG2, HUVEC, Dt81Hepa1-6, 2H-11) following MFAP-5 incubation.
Conclusion: Biodegradable NG:siMFAP-5 induced a convincing anti-tumor effect by inhibition of NOTCH mediated angiogenesis in a clinical relevant murine HCC model. The translational relevance of MFAP-5 could be demonstrated in human cell lines and patient-derived resectates for HCC and CCC.

SAT-091-YI
Using patient-led genetics to identify new therapeutic targets in metastatic cholangiocarcinoma
Paula Olaizola[1], Mollie Wilson[1], Nicholas Younger[1], Kostas Gournopanos[1], Aleksandra Rozyczko[1], Andreea Gradinaru[1], Kyle Davies[1], Colm O. Rourke[2], Jesper Andersen[2], Luke Boulter[1].
[1]*Institute of Genetics and Cancer, University of Edinburgh, MRC Human Genetics Unit, Edinburgh, United Kingdom;* [2]*Biotech Research and Innovation Centre (BRIC), Department of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark*
Email: paula.olaizola@ed.ac.uk

Background and aims: Cholangiocarcinoma (CCA) includes a diverse range of biliary malignant tumors characterized by dismal prognosis. Tumors are commonly diagnosed when patients present locally-advanced or metastatic disease, limiting the access to potentially curative surgery. The genetic heterogeneity of CCAs has been reported, indicating that the most common gain-of-function mutations in *K-RAS* and *IDH1*, and *FGFR2*-translocations only occur in 16%, 10% and 15% of patients, respectively. These activating mutations are found in a complex genomic landscape where large number of genes are mutated at low frequencies. The role of these heterogeneously mutated genes in CCA progression is unknown and whether these accessory mutations modify the effect of more common mutations to promote tumor metastasis remains to be studied. Here, we investigate the genetics behind CCA dissemination, describing how cell intrinsic changes impact on cancer cell behavior and shape the tumor microenvironment making it more permissive to metastasis.
Method: Analysing whole genome/exome sequencing data from 277 patients diagnosed with intrahepatic CCA we identified a patient-led list of CCA mutations. We then developed an *in vivo* screen where we expressed gain of function *K-Ras*^{G12D} with a CRISPR/Cas9 gRNA library targeting genes mutated in the patient data. Immunohistochemistry analysis was performed to characterize the primary and metastatic tumors and their microenvironments. Using CRISPR/Cas9-mediated gene silencing, we interrogated whether these low frequency mutations promote epithelial-to-mesenchymal transition, migration and tumor dissemination in human CCA cells.
Results: The in vivo screening showed that *K-Ras* alone was insufficient to initiate tumor formation. In combination with our gRNA library, however *K-Ras*-driven tumors developed within 8 weeks. Exome sequencing of these tumors identified CRISPR-induced mutations in 53 genes which facilitated mutant *K-Ras*-induced tumor growth. We found a range of chromatin modifiers, including Ncor1, that upon deletion, together with *Tp53* loss and *K-Ras*^{G12D} over-expression, resulted in metastatic CCA. Although animal survival and tumor burden were not significantly different compared to those harboring *K-Ras*^{G12D};*Tp53*$^{-/-}$ tumors, *K-Ras*^{G12D};*Tp53*$^{-/-}$;*Ncor1*$^{-/-}$ mice presented tumors in various sites other than the liver. Importantly, histological analysis of the primary tumors with metastatic potential revealed phenotypic changes in cancer cells as well as differences in the stroma. Furthermore, deletion of *NCOR1* in human CCA cell lines increased their migratory capacity.
Conclusion: Low-frequency mutations in chromatin modifying genes, such as Ncor1, cooperate with common driver mutations to promote tumor progression and dissemination by altering cancer cell properties and modifying the tumor microenvironment.

SAT-092
Brown adipose tissue activation: a novel strategy to prevent/treat the hepatocarcinogenesis promoted by metabolic lipotoxicity
Aleix Gavaldà-Navarro[1], Mercè Vilaró Blay[1], Marta Giralt[1], Francesc Villarroya[1], Marion Peyrou[1]. [1]*University of Barcelona, Barcelona, Spain*
Email: peyrou.marion@gmail.com

Background and aims: Metabolic dysfunction-associated steatotic liver diseases (MASLD) reached pandemic proportions, resulting in increased incidence of hepatocellular carcinoma (HCC). Brown adipose tissue (BAT) is composed of brown adipocytes consuming fatty acids and glucose to produce heat, thanks to uncoupled respiration in their mitochondria. In addition to its thermogenic function, evidence showed a secretory role for BAT which releases "batokines." Interestingly, among the batokines already described, some are known to be involved in hepatocarcinogenesis. We aim to show that active BAT protects against MASLD-promoted HCC by releasing protective factors targeting the liver.
Method: We displayed a set of animal and cell-based experimental strategies: HCC-induced mouse model was obtained with diethylnitrosamine injection followed by carbon tetrachloride treatment for 3.5 months. Mice were maintained at 21°C (active BAT) or at 30°C (inactive BAT) during all procedure. Parameters of carcinogenic development (number/size of tumors), potentially altered intracellular pathways (immunoblot) and gene expression were determined. To mimic hepatic steatosis and the first steps of MASLD *in vitro*, hepatocytes were treated with palmitate prior to brown adipocyte exposure. Trans-well co-culture technique was then employed to study hepatocyte/brown adipocyte direct interactions. Intracellular proliferative signaling and metabolism were analyzed by qPCR and immunoblots.
Results: The exposure of mice to 30°C produced a suppression of BAT activity (*Ucp1*, *Pgc1a* repression). An increase in the size of tumors was observed in this group, although the quantity of tumors remained unchanged compared to control animals. This was associated with increased activity of p44-MAPK in the liver. *In vitro*, the exposure of brown adipocytes with hepatocytes induced an increased expression of batokines (*Fgf21, Cxcl14, Gdf15, Metrnl, Kng*) in brown adipocytes, while palmitate-treated hepatocytes induced a reduction of *Ucp1* expression in brown adipocytes, indicating a possible inactivation of the cells. On the other side, the presence of brown adipocytes caused the hepatocytes to decrease their proliferation (decreased PCNA).
Conclusion: All together those results point out a crosstalk between BAT and liver encouraging the idea that active BAT could secrete molecules able to protect against hepatocarcinogenesis. Further research remains necessary to identify those factors, which may be valuable to treat/prevent HCC.

SAT-095
Selective targeting of integrin avβ8 effectively suppresses tumor growth in the new PSC-associated cholangiocarcinoma model (SB CCA.Mdr2-/- mouse)
Pinzhu Huang[1], Wen Gao[1], Heansika Matta[1], Andrew Farag[1], Zaur Abilov[1], Disha Skelton-Badlani[1], Zhensheng Zhang[1], Maram Alenzi[1], Natalia Blanco[2], Min Lu[2], Blaise Lippa[2], Bruce Rogers[2], Yury Popov[1]. [1]*Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, United States;* [2]*Morphic Therapeutics, Waltham, United States*
Email: phuang2@bidmc.harvard.edu

Background and aims: We have published a new model of cholangiocarcinoma (CCA) in Mdr2-/- with primary sclerosis cholangitis (PSC)-like disease (termed SB CCA.*Mdr2-/-*) which recapitulates predisposition to CCA in human PSC. Systemic TGF-β blockade

has been reported to enhance anti-tumor efficacy of immune checkpoint inhibitors, but its development has been hindered by systemic toxicity. Here we report therapeutic efficacy of selective antibody targeting of TGFb-activating integrins avβ6 and avβ8 in comparison to pan-TGFb inhibition in our SB CCA.*Mdr2*-/- model.
Method: Ten-week old Mdr2-/- mice with advanced congenital PSC-like progressive biliary disease were subjected to hydrodynamic tail vein injection of sleeping beauty transposon-transposase system with activated forms of AKT (myr-AKT) and Yap (YapS127A). Neutralizing antibodies for pan-TGF-β (1D11), integrin avβ8 (C6D4), or integrin avb6 (3G9) alone and with anti-PD-1 mAb were administered into tumor-bearing mice 1–4 weeks post transduction, in comparison to IgG control or anti-PD1 (n = 10–16/group). Expression of TGF-β1, integrin β6, PD-1, PD-L1, and CK7 were analyzed by immunohistochemistry (IHC), integrin β8 was determined by in situ hybridization. Tumor burden was analyzed by CK7+ tumor numbers and mRNA levels of AKT and YAP1. Desmoplastic stroma of the tumors was analyzed via Sirius Red morphometry.
Results: In our SB CCA.*Mdr2*-/- model, TGF-β1 expression was prevalent in all CCA tumors and 88.2% of CCA tumors expressed various levels of integrin b6 and were positive for integrin β8 mRNA. PD-L1+ tumor cells, PD-1+ and CD8+ infiltrating lymphocytes were enriched in desmoplastic CCA tumors. However, anti-PD-1 alone was not efficacious. Monotherapy with 1D11 or 3G9 led to a trend of decreased tumor burden, but only C6D4 significantly reduced tumor growth (CK7+ tumor numbers) compared to the IgG group (30.00 ± 4.68 vs. 59.87 ± 5.67, p = 0.0109). Combination of 1D11/anti-PD-1 showed only a trend to enhance the efficacy of pan-TGFβ mAb alone. Interestingly, C6D4/anti-PD-1and 3G9/anti-PD-1 combinations did not show synergistic anti-tumor activity. Tumor burden assessed by mRNA levels of transgene oncogenes YAP1/AKT or morphometric analysis of CK7+ tumors showed that monotherapy with the C6D4 alone was superior to combination therapy with anti-PD-1 as a CCA treatment. Collagen morphometric analysis showed that the 1D11 potently attenuated desmoplastic reaction in all CCA tumors. Integrin avβ8- or avβ6-targeting resulted in diminished desmoplastic reaction in only a subset (about 50%) of tumors, which suggested that anti-tumor efficacy was not primarily driven by suppression of desmoplastic tumor stroma.
Conclusion: We show that integrin avβ8 is required for desmoplastic CCA growth and represents a novel therapeutic target for CCA. These data support clinical development of avβ8 integrin-selective inhibitors for CCA.

SAT-096-YI

Reduction in lipid accumulation, inflammation and hepatocellular carcinoma development after protease-activated receptor 2 inhibition through 1-Piperidinepropionic acid

Pietro Guerra[1], Gianmarco Villano[2], Claudia M. Rejano-Gordillo[3], Mariagrazia Ruvoletto[1], Alessandra Biasiolo[1], Santina Quarta[1], Patricia Peña-Sanfelix[3], Silvia De Siervi[4], Silvia Cagnin[1], Cristian Turato[4], María Luz Martínez-Chantar[5], Patrizia Pontisso[1], Andrea Martini[6]. [1]*Department of Medicine, University of Padova, Padova, Italy;* [2]*Department of Surgical, Oncological and Gastroenterological Sciences, University of Padova, Padova, Italy;* [3]*Liver Disease and Liver Metabolism Laboratory, CIC bioGUNE-BRTA (Basque Research & Technology Alliance), Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Derio, Spain;* [4]*Department of Molecular Medicine, University of Pavia, Pavia, Italy;* [5]*Liver Disease and Liver Metabolism Laboratory, CIC bioGUNE-BRTA (Basque Research & Technology Alliance), Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Derio, Italy;* [6]*Department of Medicine, Azienda Ospedale-Università di Padova, Padova, Italy*
Email: andrea.martini@aopd.veneto.it

Background and aims: the lack of specific treatments, combined with a rising incidence, has made Hepatocellular carcinoma (HCC), Metabolic-Associated Steatotic Liver Disease (MASLD) and Metabolic-Associated Steatohepatitis (MASH) major challenges in modern hepatology. Protease-Activated Receptor 2 (PAR2) is a membrane receptor involved in inflammation, lipid accumulation and tumour development. Recently 1-Piperidinepropionic acid has been discovered as an effective inhibitor of PAR2. This study aims to evaluate the effect of 1-PPA on liver steatosis, inflammation and HCC development.
Method: C57BL/6J mice transgenic overexpressing SerpinB3 (C57/TG), fed on a CDAA diet and injected with diethylnitrosamine (DEN) were divided into two groups (n = 8 each) and treated with 1-PPA or placebo. HCC development was confirmed by liver histology. Microsomal triglyceride transfer protein (MTP) activity was quantified in liver tissue using a specific assay. qPCR of macrophage M2-polarization markers was also carried out. Human liver organoids were cultured with different steatogenic conditions (Oleic Acid and SB3) and treated with 1-PPA and lomitapide, an inhibitor of VLDL export. Lipid and ROS accumulation was quantified using BodiPY and MitoSOX respectively.
Results: 1-PPA treatment led to a lower number of hepatic nodules development (n = 1.5 vs n = 5, p < 0.05), a reduced mean tumoral mass (0.04 vs 0.1 g, p < 0.01) and a blunted expression of different markers of macrophage M2-polarization (ARG2, YM1, MRC1, COX2, NOX2, TNF-alpha). An increased MTP activity in the liver resulted in a reduction in histological steatosis score and paralleled an elevation in serum triglycerides in 1-PPA-treated mice (0.23 vs 0.16 mg/dL, p < 0.05). Human liver organoids cultured with both Oleic Acid and SB3 showed a significant increase in lipid and ROS accumulation and treatment with 1-PPA reverted this effect which was erased by contemporary treatment with lomitapide, suggesting a role in VLDL export mediated by this molecule.
Conclusion: 1-PPA treatment reduced lipid accumulation and M2-macrophage polarization in a mouse model of MASH-induced liver carcinogenesis resulting in lower HCC development. 1-PPA treatment affects lipid accumulation stimulating VLDL secretion.

SAT-097

Protein kinase R-like endoplasmic reticulum kinase in hepatic stellate cells promotes hepatocellular carcinoma progression via the p38delta mitogen-activated protein kinase/interleukin-1beta axis

Makoto Morita[1], Yoshio Tokumoto[1], Takao Watanabe[1], Yusuke Imai[1], Atsushi Yukimoto[1], Toyoki Shimamoto[1], Ryo Yano[1], Yuki Okazaki[1], Yoshiko Nakamura[1], Teruki Miyake[1], Osamu Yoshida[1], Masashi Hirooka[1], Masanori Abe[1], Yoichi Hiasa[1]. [1]*Department of Gastroenterology and Metabology, Ehime University Graduate School of Medicine, Toon, Japan*
Email: project.of.life20080308@gmail.com

Background and aims: Palmitic acid (PA), whose absorption from the intestines is increased in metabolic dysfunction-associated steatohepatitis (MASH), is involved in endoplasmic reticulum (ER) stress and interleukin (IL)-1beta production in hepatic stellate cells (HSCs). In this study, we focused on Protein kinase R-like endoplasmic reticulum kinase (PERK), an ER stress sensor protein, and aimed to clarify the process of IL-1beta production via PERK in HSCs and the mechanism of MASH-related hepatocellular carcinoma (HCC) progression.
Method: The human HSC cell line (LX-2) was treated with PA. Reverse transcriptase–polymerase chain reactions and western blotting were used to measure PERK and IL-1beta levels. LX-2 cells were transfected with PERK siRNA and PERK plasmids, and the IL-1beta levels were measured. In addition, the PERK knockdown cells were treated with PA, and the change in IL-1beta was examined. Enzyme-linked immunosorbent assays were used to measure the IL-1beta concentration in the conditioned medium (CM) from LX-2 cells treated with PA. The human HCC cell line (HepG2) was cultured with the CM from LX-2 cells under different conditions, and its proliferative, migratory,

and invasiveness abilities were assessed by MTS (3-(4,5-dimethylthiazol-2-yl)-5-(3-carboxymethoxyphenyl)-2-(4-sulfophenyl)-2H-tetrazolium), scratch, and Transwell assays. RNA-seq was performed using RNA extracted from the control and the PERK knockdown cells treated with PA to identify intermediate molecules in the PERK-mediated IL-1beta production pathway. Changes in the identified molecule's levels due to PERK modulation were examined. We also investigated whether modulating the identified molecule's levels changes IL-1beta production.
Results: PA increased the PERK and IL-1beta levels in LX-2 cells. IL-1beta was increased by PERK plasmid transfection and decreased by PERK siRNA transfection. The increase in PERK and IL-1beta induced by PA treatment was suppressed in PERK knockdown cells. The IL-1beta concentration in the CM from LX-2 cells treated with PA was increased. The CM from LX-2 cells treated with PA enhanced the proliferation, migration, and invasion of HepG2 cells; however, these effects were suppressed by PERK knockdown. RNA-seq analysis identified p38delta mitogen-activated protein kinase (MAPK) as an intermediate molecule between PERK and IL-1beta. PERK modulation changed the p38delta MAPK expression. Furthermore, p38delta MAPK modulation changed the IL-1beta production.
Conclusion: In the MASH-related HCC tumor microenvironment, PA induces ER stress and activates PERK in HSCs. PERK promotes IL-1beta production via p38delta MAPK. The IL-1beta secreted by HSCs promotes HCC progression by enhancing the proliferation, migration, and invasiveness of HCC cells. Targeting the p38delta MAPK/IL-1beta axis via PERK in HSCs may be a novel therapy for MASH-related HCC.

SAT-098

Infiltration of CD69- T cells in tumor tissue reflects longer recurrence-free survival in surgically resected hepatocellular carcinoma

Pil Soo Sung, Gil Won Lee[1], Mi Hyun Kwon[1], Kwon Yong Tak[2], Seung Kew Yoon[2]. *[1]The Catholic University Liver Research Center, Department of Biomedical Sciences, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea, Seoul, Korea, Rep. of South; [2]The Catholic University Liver Research Center, Department of Biomedical Sciences, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea, Division of Hepatology, Department of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea, Seoul, Korea, Rep. of South*
Email: pssung@catholic.ac.kr

Background and aims: Tumor-infiltrating T cells in hepatocellular carcinoma (HCC) are heterogeneous, which can be separated into the CD69+ tissue-resident T cell population and the CD69- circulating T cell population. However, the impact of these distinct T cell populations on patient prognosis remains controversial and further studies are needed.
Method: We collected HCC (tumor) and farthest liver tissues (non-tumor) obtained during hepatectomy in 57 HCC patients with various etiologies of chronic liver disease. The patient cohort included the following etiologies: hepatitis B virus (HBV, 49%), alcohol-related liver disease (16%), HBV combined with alcohol-related liver disease (HBV+Alc, 21%), and unknown etiology (14%). Single-cell dissociation and flow cytometry were performed to assess the expression of CD69+ and CD69- T cells, and the correlation between these populations and recurrence-free survival (RFS) was evaluated.
Results: The expression levels of CD69+/CD69- subpopulations within CD4+ and CD8+ T cells in both non-tumor and tumor tissues exhibited patient-specific variability. These populations exhibited different phenotypes depending on alcohol etiology. The frequency of the CD69- population was lower in both non-tumor and tumor tissues, while the CD69+CD103+ and CD69+CD103- subpopulations were significantly increased in patients with alcohol etiology compared to those with non-alcohol etiology ($p < 0.05$). In tumor tissues, the mean fluorescence intensity (MFI) of PD-1 was significantly lower in CD69- cells compared to CD69+ cells across both CD4 and CD8 T cell populations ($p < 0.05$), suggesting that CD69- cells may possess a less exhausted phenotype. Additionally, we observed in further analysis of tumor tissues that the MFI of PD-1 in the CD69- population of both CD4+ and CD8+ T cells was higher in patients with alcohol etiology compared to those with non-alcohol etiology. Importantly, higher frequencies of CD69- T cells in tumor tissues correlated with decreased recurrence risk, suggesting a potential protective role against HCC recurrence.
Conclusion: We have identified distinct roles for tumor-infiltrating T cells in HCC tissues. CD69+ population is associated with immune exhaustion, which might be related to tumor aggressiveness. In contrast, the CD69- population among tumor-infiltrating T cells appears to play a crucial role within the tumor microenvironment, potentially related to liver inflammation and alcohol intake. Further studies are needed to elucidate the functional differences between these populations.

SAT-099

The liver artificial intelligence (lai) consortium: a benchmark dataset and optimised machine learning methods for MRI-based diagnosis of solid-appearing liver lesions

Ruben Niemantsverdriet[1], Frederik Hartmann[1], Mara Veenstra[1], Michail Doukas[1], Roy Dwarkasing[1], Valerie Vilgrain[2], Maxime Ronot[2], Bachir Taouli[3], Razvan Miclea[4], Giuseppe Brancatelli[5], Maria Antonietta Bali[6], Jip Prince[7], Robbert de Haas[8], Vincent de Meijer[8], Otto van Delden[9], Joris Erdmann[9], Numan Kutaiba[10], Maciej Bobowicz[11], Lorenzo Faggioni[12], Karim Lekadir[13], Kathryn Fowler[14], Fredrik Illerstam[15], Maarten Thomeer[1], Stefan Klein[1], Martijn Starmans[1], LAI Consortium[1]. *[1]Erasmus MC, Rotterdam, Netherlands; [2]Hopital Beaujon, Paris, France; [3]Icahn School of Medicine at Mount Sinai, New York, United States; [4]Maastricht UMC, Maastricht, Netherlands; [5]University of Palermo, Palermo, Netherlands; [6]Institut Jules Bordet, Brussels, Belgium; [7]Utrecht UMC, Utrecht, Netherlands; [8]UMC Groningen, Groningen, Netherlands; [9]Amsterdam UMC, Amsterdam, Netherlands; [10]Austin Health, Melbourne, Australia; [11]Medical University of Gdańsk, Gdańsk, Poland; [12]University of Pisa, Pisa, Italy; [13]University of Barcelona, Barcelona, Spain; [14]University of California, San Diego, United States; [15]Collective Minds Radiology, Stockholm, Sweden*
Email: r.niemantsverdriet@erasmusmc.nl

Background and aims: The diagnosis of solid-appearing liver lesions on MRI is critical for determining treatment and prognosis. The complexity and variety of phenotypes and imaging across patients often makes this challenging, subjective, and time-consuming. To fast-forward the use of AI for liver imaging, the Liver Artificial Intelligence (LAI) consortium is constructing a large-scale benchmark dataset, developing optimized machine learning models, and rigorously validating the models in realistic clinical settings. All consortium members are available at https://lai-consortium.org/.
Method: Twelve hospitals across three continents are retrospectively collecting routine MRI scans of pathologically confirmed solid-appearing liver lesions. The dataset will contain both common and rare types of malignant (primary/metastatic) and benign lesions, with multiple MRI sequences. The project has no restrictions on age, sex, or underlying liver disease and aims to collect data from more than 3,000 patients, making it the largest publicly available MRI dataset of solid-appearing liver lesions.
Results: To date, the LAI dataset includes 486 patients, exceeding 2,500 MRI scans. These include 156 patients with hepatocellular carcinoma, 65 with intrahepatic cholangiocarcinoma, 139 with hepatocellular adenoma, and 126 with focal nodular hyperplasia. Each patient has minimally one T2-weighted MRI scan, with many also having dynamic contrast-enhanced T1-weighted scans covering pre-contrast, arterial, portal venous, delayed, or hepatobiliary phases.
Conclusion: The LAI dataset will serve as a key resource for the development and evaluation of AI algorithms designed to automate

the diagnosis of solid-appearing liver lesions using MRI. This dataset and the resulting algorithms have the potential to aid radiologists in their decision-making and assist in patient referrals to specialized centres.

Email: roystonliew@u.duke.nus.edu

Background and aims: Hepatocellular carcinoma (HCC) is the sixth most diagnosed cancer globally and the third leading cause of cancer death. Metabolic-associated HCC is rising in prevalence. Early-stage HCC is often asymptomatic; a cure is possible only if detected early. With serum α-fetoprotein (AFP) and ultrasound, current surveillance has limited early detection sensitivity (63%). Previously, we identified significant plasma bile acid (BA) dysregulation among metabolic-associated HCC patients. These findings, consistent with research from the Singapore Chinese Health Study (SCHS) and HELIOS, prompted further investigation into the mechanisms of BA dysregulation and their utility as early detection biomarkers superior to today's guidelines.
Method: We applied a multi-omics approach encompassing metagenomic, metabolomic, transcriptomic, and epigenetic analyses. Metagenomic and targeted BA metabolomic analyses were performed on 50 stool samples from ELEGANCE, including 16 HCC controls and 9 high-risk patients who later developed HCC, using shotgun sequencing and LC-MS/MS. Validation involved 196 high-risk patients (27 progressed to HCC) and 64 HCC-positive controls. Bulk RNA sequencing was conducted on tumours and adjacent tissues from 115 PLANet patients. To assess epigenetic involvement, preliminary Nano-ChIP sequencing on three patients explored histone modifications, focusing on H3K27 acetylation (H3K27ac).
Results: Metagenomic profiling showed reduced protective gut bacteria (e.g., R. bromii) and increased pathogenic species (e.g., C. hylemonae) in HCC patients' stool. Similarly, functional profiling of stools highlighted elevated BA metabolism enzymes (log10 relative abundance $\sim$1.7, $p = 5.2 \times 10^{-4}$). Metabolomic analysis confirmed dysregulated BA homeostasis, with severe plasma BA derangements preceding the clinical diagnosis of HCC (FDR < 0.05). Transcriptomic analysis showed significant upregulation of CYP7A1 (log2FC = 1.68, $p = 1.41 \times 10^{-4}$) and Small Heterodimer Protein (SHP) downregulation (log2FC = −1.28, $p = 8.18 \times 10^{-6}$), indicating a critically disrupted Farsenoid X Receptor (FXR) – SHP axis. Nano-ChIP sequencing revealed increased H3k27ac at the CYP7A1 promoter, implicating histone acetylation in the upregulation of BA synthesis.
Conclusion: This study uncovers a novel mechanism linking sustained bile acid dysregulation with HCC development through metabolic and epigenetic pathways. Alterations in gut microbiota composition, toxic BA metabolites, and disrupted FXR/SHP feedback loops contribute to hepatotoxicity and inflammation. Plasma BA profiles emerge as promising early biomarkers, potentially surpassing current surveillance methods. These findings provide a foundation for microbiome-targeted interventions, epigenetic therapies, and enhanced early detection strategies, offering new opportunities to improve HCC outcomes.

SAT-101

Defective liver endothelial autophagy occurring in metabolic dysfunction-associated steatotic liver disease promotes hepatocellular carcinoma

Samira Laouirem[1], Hammoutene Adel[1], Victoria Priori[1], Aurélie Beaufrère[2], Miguel Albuquerque[2], Marion Tanguy[1], BeriL Eren[1], Etienne Becht[1], sabrina doblas[1], Bernard Van Beers[1], Pierre-Emmanuel Rautou[3], Valérie Paradis[2]. *[1]Université Paris-Cité, Inserm, Centre de Recherche sur l'Inflammation, Paris, France; [2]Département de Pathologie, Hôpital Beaujon, Assistance Publique-Hôpitaux de Paris, Clichy, France; [3]AP-HP, Service d'Hépatologie, Hôpital Beaujon, DMU DIGEST, Centre de Référence des Maladies Vasculaires du Foie, FILFOIE, ERN RARE-LIVER, Clichy, France*
Email: samira.laouirem@inserm.fr

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) is becoming the main risk factor for hepatocellular carcinoma (HCC). Although the key role of liver endothelial cells (LEC) in the progression of chronic liver diseases towards cirrhosis is recognized, their role in HCC development is less described. Moreover, the role of LEC autophagy in HCC development

remains to be discovered. We aimed to evaluate the role of endothelial autophagy in HCC development.
Method: (1) LEC were isolated from fresh human liver. We compared the transcriptome (RNAseq) of non-tumoral (NT) LEC of patients without (n = 10) or with MASLD (n = 15). Within the MASLD-LEC, we compared patients who developed (n = 10) or not (n = 5) HCC, and the LEC from NT and tumoral MASLD patients. (2) Endothelial autophagy-deficient mice (*Atg5$^{lox/lox}$;VE-cadh-Cre+;* n = 18) and littermate controls (*Atg5$^{lox/lox}$*, n = 16) received diethylnitrosamine to induce HCC, and High-fat diet (HFD) to mime MASLD. We used MRI to assess the development of HCC and RNAseq and mass spectrometry analysis (LC-MS/MS) to compare the transcriptome and the proteome NTL in the different groups of mice.
Results: (1) We showed that autophagy genes of NT-LEC in MASLD patients were downregulated compared to NT-LEC from patients without MASLD (NES = –2.65; p = 1e-10). Additionally, autophagy was further reduced in NT-LEC of patients with HCC compared to NT-LEC of MASLD patients without HCC. Compared to NT-LEC, LEC from HCC of MASLD patients displayed increased autophagy (NES 2.35; p = 2e-09). (2) In vivo, tumors were detected earlier in *Atg5$^{lox/lox}$;VE-cadh-Cre+* mice than in *Atg5$^{lox/lox}$*. In addition, tumors in *Atg5$^{lox/lox}$;VE-cadh-Cre+* mice were larger than those observed in *Atg5$^{lox/lox}$* mice (23 mm^3 vs 2 mm^3, p = 0.03). Tumors appeared earlier (10 vs. 11 months old, respectively) and grew faster in *Atg5$^{lox/lox}$* on HFD than in *Atg5$^{lox/lox}$* on CD (58.8 mm^3 vs 18.8 mm^3, respectively). We found that (i) autophagy deficiency in LEC promotes liver carcinogenesis, acting as an initial trigger, and (ii) that HFD is an additional trigger promoting tumor growth. Comparative transcriptomic and proteomic analysis of the NTL showed *Atg5$^{lox/lox}$;VE-cadh-Cre+* CD mice have decreased autophagy genes (Atg5, Beclin-1), downregulated anti-oxidative genes stress response, increased expression of pro-apoptotic (Bax) and liver DNA damages (Xrcc1) markers compared to *Atg5$^{lox/lox}$* CD mice. Deficient mice revealed an important modulation of oxidative stress pathways.
Conclusion: Our results provide evidence of the oncogenic effect of endothelial autophagy deficiency in the development of MASLD-related HCC. This highlighting the contributive role of liver endothelial cells, could provide a therapeutic target.

SAT-102

The role of Activating Factor 4 (ATF4) in the immunosuppressive phenotype of beta-catenin mutant hepatocellular carcinoma

Email: jargemi@unav.es

Background and aims: Endoplasmic Reticulum Stress (ERS) and Unfolded Protein Response (UPR) are elevated in cancer, but their role in cancer immunogenicity remains unclear. This study aimed to: (1) identify ERS/UPR activation signatures in human Hepatocellular Carcinoma (HCC) and their relationship with the Tumor Immune Microenvironment (TIME); (2) develop a syngeneic immunocompetent model to study UPR under CTNNB1 mutation background; (3) explore synergies between UPR modulation and anti-PD1 therapy in HCC.
Method: HCC cohorts from TCGA and ICGC were analyzed using graph-based methods to define gene regulatory networks linked to ERS/UPR. Hydrodynamic tail vein injection of plasmids with the Sleepy Beauty transposon system was used to create Ctnnb1-mutated cell lines overexpressing Myc. In vivo subcutaneous tumor models were developed in immunocompetent mice. Cellular and molecular mechanisms were studied using primary macrophages, flow cytometry, western blot, RT-PCR, RNA sequencing, and metabolic assays.
Results: UPR activation is altered in HCC, as evidenced by increased HSPA5/BIP expression and hyperactivation of UPR transcription factors (TFs) across HCC datasets. UPR activation stratified patients into three clusters: protein synthesis and folding (PFS), protein turnover (PT), and DNA damage response (DDR). The PT cluster correlated with beta-catenin-mutated HCC and an immunosuppressive TIME. Knockout (KO) of UPR TFs in Ctnnb1-mutant cell lines led to reduced UPR gene expression. Viability assays revealed that these cells were highly dependent on UPR signaling and more sensitive to ER stress. Tumor growth studies showed variable results: ATF4 KO slowed tumor growth, ATF6 KO increased growth, and XBP1 KO had no effect. ATF4 KO tumors exhibited enhanced antitumor immune infiltration with elevated CD4+ T cells and reduced tumor-associated macrophages (TAMs) and myeloid-derived suppressor cells (MDSCs). Additionally, dendritic cells and CD4+ T cells expressed low levels of PD-L1 and PD-1, respectively.
Conclusion: Three distinct UPR activation states characterize HCC subsets, correlating with genetic drivers, metabolism, and immune infiltration. ATF4, but not XBP1 or ATF6, is essential for immune evasion in Ctnnb1-mutated HCC. Targeting ATF4 presents a promising therapeutic strategy in HCC.

SAT-103

HDAC7 drives malignancy by preventing FBXW7-mediated ubiquitination degradation of YAP1 in hepatocellular carcinoma

Penghong Song[1]. *[1]The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China*
Email: songpenghong@zju.edu.cn

Background and aims: Liver cancer is a malignancy with high morbidity and mortality rates. Histone deacetylase 7 (HDAC7), a member of the histone deacetylase family, participates in multiple cellular pathophysiological processes and activates relevant signaling pathways to facilitate the progression of different tumors. It is urgent to investigate the potential mechanism of HDAC7 in liver cancer.
Method: The Cancer Genome Atlas database (TCGA), including DNA methylation and transcriptome sequencing data, was utilized to identify the crucial oncogene associated with DNA methylation and cancer progression in liver cancer. Data from the TCGA and RNA sequencing for 94 pairs of liver cancer tissues was used to explore the correlation between HDAC7 expression and clinical parameters of patients. DNA methylation sequencing was used to detect the DNA methylation levels in liver cancer tissues and cells. RNA sequencing, cytokine assays, immunoprecipitation (IP) and mass spectrometry (MS) assays, protein stability assays, and ubiquitination assays were performed to explore the regulatory mechanism of HDAC7 in liver cancer progression. Patient-derived xenografts and tumor organoid models were established to determine the role of HDAC7 in the treatment of liver cancer using Lenvatinib.
Results: Based on the public database screening, HDAC7 was identified as a tumor promoter regulated by DNA methylation.

HDAC7 expression was significantly higher in liver cancer tissues and was associated with the dismal prognosis in patients with liver cancer. RNA sequencing showed that HDAC7 is associated with the Hippo signaling pathway, focal adhesion, wound healing, regulation of epithelial-mesenchymal transition (EMT), and ubiquitin-protein ligase binding. IP/MS assays confirmed that HDAC7 activated Yes-associated protein 1 (YAP1) and its downstream signaling pathways by interacting with YAP1. Mechanistically, HDAC7 inhibited YAP1 ubiquitination and maintained its protein stability by competing with the E3 ubiquitin ligase, FBXW7. Additionally, HDAC7 knockdown-induced YAP1 downregulation significantly enhanced the therapeutic efficacy of Lenvatinib against liver cancer.
Conclusion: HDAC7 promotes liver cancer progression by preventing FBXW7-mediated YAP1 ubiquitination and degradation, suggesting that inhibition of the HDAC7-YAP1 axis may be a potential target for liver cancer treatment.

SAT-104
Impact of environmental pollution and the aryl hydrocarbon receptor signaling pathway on hepatic carcinogenesis
Sri-Kamini Soocheta[1,2], Gwladys Berge[2,3], Marianne Gervais-Taurel[2,3], Jean-Michel Pawlotsky[1,2], Fatima Teixeira-Clerc[1,2]. *[1]INSERM U955, Team « Virology, Hepatology, Cancer », Henri Mondor Hospital, Créteil, CRETEIL, France; [2]Université Paris-Est-Créteil, UMR-S955, Créteil, CRETEIL, France; [3]INSERM U955, Team « Biology of the neuromuscular system », Faculty of Medicine, Créteil, CRETEIL, France*
Email: sri-kamini.soocheta@inserm.fr

Background and aims: Hepatocellular carcinoma (HCC) is the most common primary liver cancer and the third leading cause of cancer-related mortality worldwide. Although alcohol consumption, viral hepatitis and metabolic dysfunction-associated steatohepatitis (MASH) are established risk factors for HCC, exposure to persistent organic pollutants (POPs) also contributes to this global burden. Among POPs, 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) is the most toxic dioxin. Its effects are largely mediated by activation of the aryl hydrocarbon receptor (AhR), a ligand-activated transcription factor that regulates the expression of detoxification enzymes. Although exposure to TCDD has been associated with the development of liver cancer, the effects of TCDD on the liver at the cellular and molecular level remain poorly understood. This study aimed to characterize the mechanisms underlying the hepatotoxic effects of TCDD.
Method: C57BL/6 male mice were used in two experimental protocols: the first protocol involved chronic exposure to TCDD (4 μg/kg per week by gavage) for 12 months, the second protocol combined TCDD exposure with an HCC induction model, where mice received a single injection of N-nitrosodiethylamine (DEN, 25 mg/kg) at 14 days old and biweekly carbon tetrachloride (CCl_4, 0.2 ml/kg) starting at 8 weeks for 7 weeks, along with TCDD at the same dose. AhR pathway activation was assessed through immunofluorescence labeling of Cyp1A1, a target gene of the AhR pathway, and CD31, a marker of endothelial cells. The hepatotoxic effects were studied by analyzing inflammation, fibrosis, tumor development, and endothelial dysfunction using RT-qPCR and histological methods. These endpoints were further analyzed in genetically modified mice with endothelial-specific AhR signaling pathway loss (Cdh5CreErt2; AhRflox/flox) to assess the role of the endothelial AhR pathway on the hepatotoxic effects of TCDD.
Results: Chronic exposure to TCDD induces liver inflammation, fibrosis and tumor development. Furthermore, chronic administration of TCDD to mice subjected to a model of HCC exacerbates liver inflammation, fibrosis, and tumor development. In both models, TCDD strongly activates the AHR pathway, as expected in hepatocytes due to their role in xenobiotic metabolism, but also in liver sinusoidal endothelial cells (LSECs). In addition, TCDD increases the hepatic expression of markers of endothelial dysfunction. Importantly, liver inflammation, fibrosis and hepatic carcinogenesis are reduced in mice with conditional AhR deletion in endothelial cells and exposed to TCDD.
Conclusion: Our results demonstrate that TCDD promotes liver inflammation, fibrosis and HCC development, which are partly mediated through the endothelial AhR pathway. This study contributes to the understanding of how environmental pollutants impact liver carcinogenesis and points to potential therapeutic targets to mitigate these effects.

SAT-105
Spatiogenomic characterization of malignant transformation in dysplastic nodules
Jihyun An[1], Ju Hyun Shim[2], Bora Oh[2], Jin-Sung Ju[2]. *[1]Hanyang University College of Medicine, Guri, Korea, Rep. of South, [2]Asan Medical Center, Seoul, Korea, Rep. of South*
Email: starlit1@naver.com

Background and aims: Although hepatocellular carcinomas (HCC) frequently arise from dysplastic nodules (DN) in cirrhotic livers, the molecular mechanisms driving this progression remain unclear. We aimed to identify key components and mechanisms of liver cancer development from DN.
Method: We performed high-resolution spatial transcriptomics on nodule-in-nodule HCCs, analysing 56,528 tissue spots from 11 patients. Concurrently, we conducted deep whole-genome sequencing on matched nontumor, DN, and HCC tissues.
Results: Spatial transcriptome sequencing identified a total of 36 final ST clusters, comprising 17 HCCs, 11 DNs, 1 HCC/DN border, 2 cirrhotic tissues, and 5 stroma-related clusters. Based on differential gene expression analysis on the ST clusters, DN clusters exhibited significantly higher activity of the Insulin-like Growth Factor pathway and inflammation-related pathways than RN clusters. HCC clusters were characterized by high activities of cell cycle signaling and beta-catenin-related pathways. Notably, AFP expression was confined to advanced HCC clusters, limiting its utility as an early-stage HCC marker. Deep WGS results for the nodule-in-nodule samples was revealed that most prevalent mutation event was *CTNNB1* mutations (40.0%). Hepatitis B virus integration into *TERT* promoter was found in 71.4% of the HBV-related tumor cases.
Conclusion: Our ST data identified the distinct characteristics of DN and HCC clusters across tumours. Hepatitis B virus integration and CTNNBI1 may be the key events in the malignant transformation from the DN.

SAT-106
CD40–Integrin α5β1 and CD27-CD70 axes: novel mechanisms driving HCC progression in chronic hepatitis C
Le Thi Thanh Thuy[1], Minh Phuong Dong[2], Hanh Ngo Vinh[3], Hoang Hai[4], Sawako Uchida-Kobayashi[4], Masaru Enomoto[4], Norifumi Kawada[4]. *[1]Global Education and Medical Sciences, Graduate School of Medicine, Osaka Metropolitan University, Osaka, Japan; [2]Loma Linda University, California, United States; [3]Department of Hepatology, Graduate School of Medicine, Osaka Metropolitan University (primary affiliation), Osaka, Japan; [4]Department of Hepatology, Graduate School of Medicine, Osaka Metropolitan University, Osaka, Japan*
Email: kawadanori@omu.ac.jp

Background and aims: Hepatocellular carcinoma (HCC), a leading cause of cancer-related mortality worldwide, often arises in the context of chronic hepatitis C (HCV). Even after achieving a sustained virological response (SVR) with antiviral therapy, HCV patients remain at risk for HCC. Immune checkpoint proteins (ICPs), such as soluble (s) and membrane-bound (m) forms of CD27, CD28, and CD40, play critical roles in immune regulation and tumor progression. This study investigates the prognostic and mechanistic roles of these ICPs in HCC development and progression.
Method: Using multiplexed immunoassays, the levels of 16 sICPs were profiled in serum samples from 168 HCV-SVR patients over 17 years. Additionally, mCD27, mCD40, and their ligands were examined

in HCC tissues and cell lines. The CD27-CD70 and CD40-integrin α5β1 pathways were explored through methylation analysis, co-culture experiments, RNA sequencing, and inhibitor studies.
Results: At baseline, elevated levels of AFP and nine sICPs, including sCD27, sCD28, and sCD40, were observed in patients who later developed HCC. These levels declined during antiviral therapy but rebounded at the time of HCC occurrence. Baseline levels of sCD27 ≥4104, sCD28 ≥1530, and sCD40 ≥688 pg/mL were significant predictors of HCC development. Mechanistically, sCD27 promoted HCC cell proliferation through the CD27-CD70 axis, with CD70 hypomethylation contributing to its robust expression in tumor areas. CD27-CD70 interaction activated ERK1/2 signaling, enhancing cell cycle progression. In poorly differentiated HCC, mCD40 was highly expressed, correlating with low promoter methylation. Co-culture of HCC cells with CD40L+ CD4+ T cells elevated CD40 expression and activated IFN-γ-mediated JAK1/STAT3 signaling, enhancing tumor survival. Blocking both CD40 and integrin α5β1 reduced apoptosis avoidance, highlighting their interplay in tumor progression.
Conclusion: Elevated baseline sCD27, sCD28, and sCD40 levels are potential biomarkers for HCC in HCV-SVR patients, reflecting immune dysregulation even before antiviral therapy. Mechanistically, the CD27-CD70 and CD40–CD40L-integrin α5β1 pathways promote HCC progression by supporting cell proliferation and survival. These findings provide insights into immune-tumor interactions and suggest targeting these pathways as therapeutic strategies in HCC.

Carbonic anhydrase 9 as a circulating biomarker and therapeutic target in patients with hepatocellular carcinoma treated with atezolizumab plus bevacizumab
Takahiro Kodama[1], Yu Sato[1], Kazuki Maesaka[1], Machiko Kai[1], Kazuhiro Murai[1], Yuki Tahata[1], Yoshinobu Saito[1], Hayato Hikita[1], Tomohide Tatsumi[1], Tetsuo Takehara[1]. [1]*Osaka University Graduate School of Medicine, Suita, Japan*
Email: t-kodama@gh.med.osaka-u.ac.jp

Background and aims: Two combinational Immunotherapies, atezolizumab/bevacizumab (Atez/Bev) and durvalumab/tremelimumab (Dur/Tre) are currently recommended as a 1st line therapy for unresectable hepatocellular carcinoma (HCC). This study aimed to identify blood-based biomarkers for predicting the response and guiding treatment selection for combination immunotherapy in patients with advanced HCC.
Method: We profiled 92 pre-treatment plasma proteins using Proximity Extension Assay (PEA) technology in a discovery cohort of 78 unresectable HCC patients treated with Atez/Bev. Carbonic anhydrase 9 (CA9) levels were evaluated via Enzyme-Linked Immunosorbent Assay in a validation cohort of 89 Atez/Bev-treated HCC patients and 48 patients treated with Dur/Tre. The impact of CA9 modulation on the tumor immune microenvironment and combination treatment efficacy was tested in a syngeneic HCC model.
Results: PEA identified elevated circulating proteins, including CA9, IL-8, CSF-1, and IL-6, in patients with progressive disease under Atez/Bev. High plasma CA9 levels were linked to poor disease control and shorter survival under Atez/Bev in both discovery and validation cohorts. Circulating CA9 protein was the independent predictor of therapeutic resistance and poor survival upon Atez/Bev therapy. Circulating CA9 proteins were derived from HCC tumor cells and tumoral CA9 conferred resistance to the combinational immunotherapy of anti-PD-L1/VEGF antibodies via immunosuppressive phenotype and enhanced angiogenesis signaling. The inhibition of CA9 improved the efficacy of anti-PD-L1/VEGF therapy. Pre-treatment CA9 levels could stratify patients likely to benefit from Atez/Bev versus Dur/Tre therapy.
Conclusion: CA9 is a circulating biomarker predicting response to combination immunotherapy and a potential therapeutic target in advanced HCC.

Email: tpays@unileon.es

Background and aims: Primary liver cancer, being hepatocellular carcinoma (HCC) the main type, remains on the most fatal neoplasm, with increasing incidence and mortality rates worldwide. Although hepatocarcinogenesis can be triggered by a variety of exogenous and endogenous factors, hypoxia -a reduction in the oxygen supply to cells- plays a crucial role in tumor progression and chemotherapy resistance through dysregulation of multiple cellular pathways. Hypoxia-inducible factor 1 alpha (HIF-1 alpha) is the primary regulator of the cell's adaptive response to hypoxia in HCC, driving alterations in several molecular pathways involved in tumorigenesis and poor patient prognosis. Therefore, our aim was to determine the impact of HIF-1 alpha on HCC in our bi- and tri- dimensional (2D and 3D) models.
Method: We analyzed HIF-1 alpha expression in Huh-7 and PLC/PRF/5 cell lines, using 100 µM $CoCl_2$ to simulate and activate the adaptive hypoxic response. Protein expression and localization were examined by Western blot and immunofluorescence with laser confocal imaging, respectively, while gene expression was evaluated using qRT-PCR. CRISPR/Cas9 technology was employed to create HIF1A knockout (KO) clones to assess the role of this factor, and KO efficiency was confirmed by DNA sequencing. Cell viability and proliferation were assessed using the MTT assay and nuclear Ki67 protein level determination, respectively. Wound healing capacity was analyzed through inverted optical microscopy. Additionally, 3D models derived from both wild-type (WT) and KO cell lines were generated. Tumor growth was monitored in all 3D models, with hypoxia and cell death evaluated using the Image-iT Red Hypoxia Reagent and Calcein-AM with propidium iodide staining, respectively. Statistical analyses were conducted with GraphPad Prism 8, considering differences significant at $p < 0.05$.
Results: Huh-7 and PLC/PRF/5 cell lines demonstrated elevated HIF-1 alpha expression under hypoxic conditions. Following gene modification with CRISPR/Cas9 technology, HIF1A KO clones exhibited a marked reduction in cell viability and a lower proliferation index. Wound healing capacity was also diminished in the absence of HIF-1 alpha. Furthermore, the HIF1A KO 3D models showed a slower growth rate compared to the WT model, with a physiological hypoxic state observed in the tumor core of both HCC spheroid types (WT and KO). However, the KO spheroids displayed significantly larger regions of cell death. These findings highlight a critical pro-survival role of HIF-1 alpha in HCC.
Conclusion: Altogether, these findings suggest that HIF-1 alpha expression and stabilization promotes tumor cell survival and progression under hypoxia in our HCC cell models, highlighting the inhibition of HIF-1 alpha activity as a potential therapeutic target to restrain tumor progression and increase patients' survival.

Email: m.heikenwaelder@dkfz-heidelberg.de

Background and aims: Intratumoral bacteria are increasingly recognized as influential within the tumor microenvironment (TME), impacting cancer progression and response to therapy. However, their role remains poorly unexplored in hepatocellular carcinoma (HCC), the third most common cause of cancer-related mortality worldwide. We recently reported two distinct HCC TME subtypes in patients treated with atezolizumab+bevacizumab (atezo+bev): *ImmunePos*, characterized by CD8+ T effector cells and CXCL10+ macrophages and associated with atezo+bev responses, and *ImmuneNeg*, lacking immune cell infiltration. Here we aimed to investigate the clinical significance of tumor resident bacteria in response to atezo+bev in HCC.

Method: We characterized the intratumoral microbiome in 247 HCC samples from patients treated with atezo+bev from the IMbrave150 and GO30140 clinical trials. RNAseq was used to profile the HCC-resident microbiome at the genus level. Transcriptomic reads were screened for microbial content with the PathSeq pipeline in the Genome Analysis Toolkit. Reads aligning to the human GRCh38 genome were removed, and the remaining reads were mapped to microbial reference genomes. To filter out contaminants and adjust for batch effects, we retained only genera with a relative abundance of $\geq 10^{-3}$. The association between bacterial prevalence (relative abundance present in >10% of samples) and abundance with progression-free survival (PFS), overall survival (OS), and our TME classification was evaluated.

Results: Previous analysis revealed a unique microbiome signature for HCC. Here we show that the prevalence of *Bacillus* in HCCs of atezo+bev treated patients, was associated with a significantly longer PFS ($p = 0.006$) and a trend toward prolonged OS ($p = 0.075$) compared to those without *Bacillus*. In addition, *Bacillus* prevalence and abundance were significantly higher in atezo+bev responders (prevalence: $p = 0.0029$, abundance: $p = 0.0032$ vs non-responders), and especially increased in ImmunePos responder tumors (prevalence: $p = 0.0019$ vs non-responders; abundance: $p = 0.031$ vs ImmuneNeg responders; $p = 0.0005$ vs non-responders).

Conclusion: We identified *Bacillus* associated with a significantly longer PFS and with a trend towards longer OS in atezo+bev-treated patients. Moreover, responders, particularly those associated with ImmunoPos features, showed significantly higher abundance and prevalence of *Bacillus*.

SAT-114

Modulation of mitotic stress-induced activation of the cGAS/STING signaling pathway by DNA demethylation

Umar Mukhamedaliev[1], Peter R. Galle[1], Susanne Strand[1]. *[1]Department of Internal Medicine I, University Medical Center of the Johannes Gutenberg University, Mainz, Germany*
Email: umukhame@students.uni-mainz.de

Background and aims: Hepatocellular carcinoma (HCC) is classified as a "genomically unstable" cancer due to the typical presentation of chromosome breakage and aneuploidy. Recent investigations demonstrate that micronuclei, which are formed as a consequence of such genotoxic stress, have the capacity to induce an innate immune response through the cytosolic DNA-sensing cGAS/STING pathway. Inhibition of the spindle assembly checkpoint kinase TTK/MPS1 by novel compounds such as CFI-402257 targets these effects through deteriorated aneuploidy, followed by increased activation of the cGAS/STING signaling axis and Type I interferon expression. However, cancer cells have evolved mechanisms that enable them to tolerate aneuploidy. These include epigenetic silencing of the key signaling proteins cGAS and STING by DNA methylation. The objective of this study was to examine the impact of the DNA methyltransferase inhibitor decitabine on these relationships.

Method: The effects of the DNA-demethylating agent decitabine on cGAS and STING expression was assessed in Hep3B hepatocellular carcinoma cells (cGAS- and STING-absent) and non-tumorigenic THLE5b cells (cGAS- and STING-low). Cells were pre-treated with decitabine prior to TTK/MPS1-inhibition by CFI-402257. We investigated the level of aneuploidy by FACS analysis, performed proliferation and cytotoxicity assays, investigated the activation of the cGAS/STING signaling axis using Western blotting, and quantified the expression of related cytokines by qPCR.

Results: Western blot analysis of THLE5b cells, pre-treated with decitabine revealed an increase in the expression of both cGAS and STING, as well as an enhanced activation of the cGAS/STING pathway following consecutive CFI-402257 treatment. Quantitative PCR demonstrated elevated expression of cGAS/STING-specific cytokines, including IFNβ and CXCL10. In Hep3B cells, decitabine was observed to restore STING expression; however, it failed to affect cGAS expression and did not influence the activation of the pathway or the cytokine response. Cytotoxicity induced by CFI-402257 was observed to be significant in both cell lines. Prior decitabine treatment did not augment this effect; rather, it led to a decrease in proliferation rate.

Conclusion: The present study demonstrates that decitabine is capable of reversing the epigenetic silencing of STING in Hep3B and THLE5B cells. However, this does not appear to be sufficient to restore the activation of the cGAS/STING signaling pathway and the associated innate immune response. Further investigation is required to evaluate the impact of decitabine on cGAS/STING activation, particularly with regard to its antiproliferative effect, which counteract mitotic stress-induced cytotoxicity.

SAT-115-YI

A novel panel of Methylated DNA markers for hepatocellular carcinoma

Background and aims: There is increasing interest in the use of blood based Methylated DNA Markers (MDM) to detect Hepatocellular Carcinoma (HCC) recurrence after treatment.
This study aims to develop an MDM panel to supplement existing surveillance methods, to monitor and detect early HCC recurrence following therapy.
Method: A literature search was performed to identify MDM candidates, followed by bioinformatic analysis of publicly available Illumina 450 K and EPIC methylation array databases of tissue and cell free DNA (cfDNA). Assay candidates were designed, undergoing stepwise validation, first *in-silico*, then against bisulfite modified cell line DNA with quantitative PCR.
The 4 marker MDM panel (MDM4) was validated in 23 paired tissues samples of HCC and background non-HCC liver using digital PCR (dPCR). For proof-of-concept, the MDM4 was tested in plasma samples, which were collected prior to HCC therapy, then every 3–6 months until disease progression or study dropout.
Results: 26 MDM candidates were identified. Bioinformatic analysis was performed to demonstrate test performance of MDM candidates across 9 methylation array datasets of 720 HCC, 389 non-HCC liver tissue and cfDNA datasets. Logistic regression train-test sets in a 70:30 proportion demonstrated good theoretical performance of the MDM4 panel in tissue with a test set AUC 0.95, and AUC 0.90–0.95 in 4 validation sets. Wet lab validation was performed with cell line DNA, allowing selection of assay candidates and identification of positive and negative cell line controls. A control MDM assay (*COL2A1*) was validated. For tissue validation with dPCR, the MDM4 and control demonstrated sensitivity 0.96 (95% CI 0.79–1.00), specificity 1.0 (95% CI 0.83–1.00) using logistic regression.
For proof-of-concept, plasma sample results of 8 patients are presented. 3 patients who received surgical resection, SIRT or TACE had detectable MDM4 despite radiological complete response (CR). Of these, 2 patients had elevated AFP (37 and 430 IU/mL). All developed progressive disease within 3 months of detectable MDM4. Three patients who remained in CR during follow up (14–16 months) had undetectable MDM4 and AFP at each time point. Two patients with radiological detectable disease for 11 months while receiving systemic therapy (1 had a preceding TACE) had detectable MDM4 at each time point. Of these, 1 had persistently elevated AFP (2090–18000 IU/mL) and another with AFP in the normal range (2–7 IU/mL).
Conclusion: A dry and wet lab biomarker pipeline allowed the development and validation of an MDM4 and COL2A1 control, a novel assay panel to detect HCC recurrence following treatment. This panel performed well in tissue validation and shows early promise in proof-of-concept plasma sample analysis. A prospective observational study (ACTRN 12623000762651) has completed recruitment of 160 patients and continues to accrue plasma samples.

Singel-cell transcriptomics reveal DDX1 as a driver of cancer stemness and tumorigenesis in hepatocellular carcinoma

Yao Yang[1,2,3], Hongsong Chen[2,3,4,5,6]. *[1]Peking University People's Hospital, Peking University Hepatology Institute, Infectious Disease and Hepatology Center of Peking University People's Hospital, Beijing, China; [2]Peking University Hepatology Institute, Beijing, China; [3]Infectious Disease and Hepatology Center of Peking University People's Hospital, Beijing, China; [4]Peking University People's Hospital, Beijing, China; [5]Beijing Key Laboratory of Hepatitis C and Immunotherapy for Liver Diseases, Beijing, China; [6]Beijing International Cooperation Base for Science and Technology on NAFLD Diagnosis, Beijing, China*
Email: yangyao927@163.com

Background and aims: Hepatocellular carcinoma (HCC) comprise diverse cells with distinct biological characteristics. Within a tumor bulk, liver cancer stem cells or stem-cell like cells play a pivotal role in tumor initiation, progression, metastasis and chemoresistance of HCC. We aim to explore the intratumor heterogeneity through single-cell transcriptomic profiling and find out the key driver of cancer stemness in HCC.
Method: We integrated single-cell RNA sequencing (scRNA-seq) and bulk RNA sequencing of HCC to reveal key cell subpopulation and therapeutic target that determine the stemness and tumorigenesis of HCC. Furthermore, in vitro and in vivo study were performed to unveil the underlying mechanism.
Results: scRNA-seq was conducted on 19518 cells from twelve primary HCC samples. After cluster analysis, Cytotrace analysis and Scissor analysis of heterogeneous malignant cells revealed that cells with high stemness were enriched in Scissor+ cell subpopulation, which was associated with poor prognosis. Next, integrated analysis with bulk RNA-sequencing profiles indicated that dead box helicase 1 (DDX1) was a key driver of cancer stemness and tumorigenesis in HCC. Furthermore, DDX1 was found to be highly expressed in HCC tissues and liver cancer stem-cell like cells. In vitro and in vivo assays for the first time showed that the stem cell-like properties of HCC cells were inhibited by DDX1 depletion, as evidenced by the decreased size and number of formatted spheres, the downregulated expressions of C-MYC, OCT4, and NANOG proteins, as well as the reduced proportion of CD133+ cells. In addition, depletion of DDX1 expression also restrained proliferation, migration and invasion, yet facilitated apoptosis of HCC cells. Overexpression of DDX1 exhibited opposite effects on regulating stemness and tumorigenesis of HCC. Mechanically, high-throughput sequencing, IP-MS, and RIP analysis unveiled that DDX1, as an RNA binding protein, can bind to C-MYC mRNA to enhance its mRNA stability, leading to enhanced C-MYC target genes expression. In addition, DDX1 can bind to FSCN1 mRNA to improve its mRNA translation efficiency, resulted in increased cell motility and metastasis. Furthermore, depletion of DDX1 significantly enhanced the efficacy of sorafenib in HCC in vitro and in vivo.
Conclusion: We revealed intratumor heterogeneity of malignant cells of HCC through single-cell transcriptomic profiling and highlighted the crucial role of DDX1 in regulating stemness and tumorigenesis of HCC, and provided potential therapeutic strategy for HCC patient.

High-resolution quantitative reconstruction of microvascular architectures in mouse hepatocellular carcinoma models

Yan Zhao[1], Haogang Zhao[2], Guohong Cai[3]. *[1]Department of Liver Diseases and Interventional Radiology, Digestive Diseases Hospital, Xi'an International Medical Center Hospital, Xi'an, China; [2]Department of Chemical Engineering, State Key Laboratory of Chemical Engineering, Tsinghua University, Beijing, China; [3]Department of Nuclear Medicine, Xijing Hospital, Fourth Military Medical University, Xi'an, China*
Email: yanzhao211@163.com

Background and aims: Alterations in liver vascularization play a remarkable role in liver disease development, including

hepatocellular carcinoma (HCC), but remain understudied. This study evaluated the hepatic microvascular imaging method and provided high-resolution quantitative anatomical data on the characteristics and architecture of liver vasculature in wild-type (WT) mice and HCC mouse models.

Method: C57BL/6 mice were injected with Akt/Ras or Sleeping Beauty transposon to induce HCC. Liver tissues from normal and Akt/Ras mice underwent hematoxylin and eosin, Masson's trichrome, Ki67, and lymphatic endothelial receptor-1 staining. Using cutting-edge high-definition fluorescence micro-optical sectioning tomography, high-precision microvascular visualization of the liver was performed in WT and Akt/Ras HCC mice. The distinctive feature of the fMOST technique lies in its continuous liver tissue slicing with an axial step size of 2 μm, capture images simultaneously, and real-time counterstaining using PI. As a result, our approach obviates the need for a decellularization process.

Results: The sectioned volumes of normal and HCC liver tissues were 204.8 mm^3 and 212.8 mm^3, respectively. The microvascular systems associated with the tissues of Akt/Ras HCC mice were twisted, disordered, and compressed by tumor nodules. In the four tumor nodules, the path of the hepatic artery was more around the tumor edge, whereas the portal vein occupied the central position and constituted the main blood vessel entering the tumors. The porosity of HCC and paracancerous cirrhotic tissues was significantly less than that of normal tissues. The radii of the central vessels in the hepatic sinusoid of paratumoral cirrhotic tissues were significantly higher than those of normal tissues; however, the hepatic sinusoid density of paratumoral cirrhotic tissues was lower.

Conclusion: This research provides a deeper understanding of the normal liver microvasculature and alterations in cases of cirrhosis and HCC, which complements scientific insights into liver morphology and physiology. This straightforward research approach involving the novel 3D liver microvasculature can be used in multiscale physiological and pathophysiological studies regarding liver diseases.

SAT-118

The liver microenvironment of MASH and MetALD HCCs: a spatial transcriptomics analysis

Email: massimo.levrero@inserm.fr

Background and aims: MASH accounts for 20% of HCCs in the Western world and is the leading cause of HCC in patients without cirrhosis. The higher propensity for HCC development without cirrhosis in MASH compared with other etiologies underscores the unique metabolic and inflammatory micro-environment that cooperate with extrahepatic cancer drivers associated with metabolic syndrome and, when present, alcohol consumption. Here we investigate the metabolic and inflammatory microenvironment of MASH HCC using Digital Spatial Profiling (DSP) technology in multiple tumour (T) and non tumour (NT) regions of interest (ROIs) from surgical resection samples of cirrhotic and non cirrhotic patients with HCC related to MASH and MetALD.

Method: The study population comprised 5 cirrhotic (K) and 4 non cirrhotic (F1/F2/F2/F3) SLD HCC patients. Six had no alcohol consumption (F1/F2/K/K/K) and 3 were MASLD predominant MetALD (F2/F3/K). Spatial resolution of RNA expression from >1,800 genes was assessed using the GeoMx® Cancer Transcriptome Atlas in T and NT ROIs of FFPE (Formalin-Fixed Paraffin-Embedded) tissue samples. A masking approach was used to define homogeneous areas of interest (AOI) containing PanCK or CD45 labelled cells in each ROI. All cells present in each AOI in the tumor or in the non-tumoral liver were analyzed separately as a mini-bulk RNA-Seq.

Results: 95 ROIs (range 9–17 ROIs per sample) have been analyzed. After QC 82 ROIs were retained for a total number of 38938 PanCK positive cells (hepatocytes, cholangiocytes and tumor cells) and of 4239 CD45 positive cells. Principal Component Analysis of all ROIs showed a clear separation between PanCK AOIs and CD45 AOIs in T vs NT. Focusing on CD45 ROIs, we found that the inflammatory infiltrate, richer in NT liver, displays distinct transcriptional profiles in T vs NT; with 13 down-regulated and 26 up-regulated differentially expressed genes. CD45 AOIs enrich oxidative phosphorylation and integrins signaling pathways and downregulate lymphocyte effector pathways in T tissues. WGCNA (weighted gene co-expression network analysis) of all CD45 ROIs identified 5 modules of highly connected and co-expressed genes (hub genes) associated with the tumor status. Additional modules were specific for CD45 AOIs stratified according to the presence of cirrhosis, MASH or Met-ALD. Cell type deconvolution analysis of CD45 and PanCK AOIs stratified according to tumor status show an enrichment of Tregs, central venous LSECs and stellate cells in tumor vs non-tumor tissue.

Conclusion: Our DSP analysis allowed to obtain a highly granular spatial resolution of the transcriptome and the microenvironment in specific subgroups of MASH HCCs.

Harnessing human immune system mouse models to validate NADPH oxidase 1 inhibition as a treatment for hepatocellular carcinoma

Zenzi De Vos[1,2], Lander Heyerick[1,2], Hannah Stocks[3,4], Andy Wullaert[3,4,5], Anne Hoorens[6], Sander Lefere[2,7], Sarah Raevens[2,7], Anja Geerts[2,7], Xavier Verhelst[2,7], Hans Van Vlierberghe[2,7], Lindsey Devisscher[1,2]. *[1]Department of Basic & Applied Medical Sciences, Gut-Liver Immunopharmacology Unit, Ghent University, Ghent, Belgium; [2]Liver Research Center Ghent, Ghent University, Ghent University Hospital, Ghent, Belgium; [3]VIB-UGent Center for Inflammation Research, VIB, Ghent, Belgium; [4]Department of Internal Medicine and Paediatrics, Ghent University, Ghent, Belgium; [5]Cell Death Signaling Lab, Department of Biomedical Sciences, University of Antwerp, Antwerp, Belgium; [6]Department of Pathology, Ghent University Hospital, Ghent, Belgium; [7]Department of Internal Medicine and Paediatrics, Hepatology Research Unit, Ghent University, Ghent, Belgium*
Email: zenzi.devos@ugent.be

Background and aims: NADPH oxidases (NOX) are reactive oxygen-producing enzymes of which the isoform NOX1 is present in the tumor microenvironment (TME) of hepatocellular carcinoma (HCC) and promotes HCC development and metastasis. NOX1 inhibition (NOX1i) has been shown to alter the TME in classical HCC models and might serve as a therapeutic target. However, implementation in the clinic is hampered by low translatability of these classical HCC models. Here, we employed next-generation human immune system (HIS)-HCC models that enable investigation of treatments in the context of human immune responses, and provide evidence for NOX1 inhibition as strategy to target the TME in HCC.

Method: Two HIS-HCC models were set up to investigate NOX1i in the context of human innate or adaptive immune responses, with a focus on the monocyte/macrophage or T-cell compartment respectively. For the myeloid model (My-HIS), irradiated NSG-QUAD mice were reconstituted with human cord blood-derived CD34+ cells, and human orthotopic HCC tumors were induced 4 weeks post engraftment. For the T cell-HIS model, orthotopic HCC tumors were induced in NSG mice, and mice were reconstituted with human T cells

using healthy peripheral blood mononuclear cells. Mice received NOX1i (ML171) or vehicle twice per week for 3 weeks.
Results: In the My-HIS-HCC model, humanization in livers and tumors reached 30–50% and consisted of monocytes, macrophages, dendritic cells, NK cells and B cells. Significantly lower human CD45+ cells were observed in tumor and surrounding tissue of NOX1i-treated My-HIS-HCC mice. NOX1i did not affect macroscopic tumor growth in My-HIS-HCC mice. However, the expression of HCC and proliferation markers was lower in tumors of NOX1i-treated My-HIS-HCC mice. This was accompanied with significantly lower expression of cytokines, chemokines, growth factors and markers involved in cancer progression upon NOX1i. Humanization in the T cell-HIS-HCC model reached up to 70% and primarily consisted of T cells, with significantly reduced percentages in livers of NOX1i-treated mice. Within the population of CD4+ T cells, mainly Th2 cells were encountered in liver and tumor tissue without differences between groups. NOX1i did not affect tumor size nor the expression of HCC and proliferation markers in the T cell-HIS-HCC model. However, as in the My-HIS-HCC model, the expression of cytokines and markers involved in cancer progression was significantly lower in tumor tissue of NOX1i-treated, compared to untreated, T cell-HIS-HCC mice.
Conclusion: Our data show that NOX1i effectively alters the TME in humanized HCC models, with the most pronounced effects observed in mice harboring human monocytes and macrophages, the My-HIS-HCC model. This aligns with previous reports on the therapeutic potential of NOX1i in classical HCC models by affecting monocyte/macrophage function and favors translation to the clinic.

SAT-125
Targeting Annexin A1 improves immunotherapy efficacy by remodeling the macrophage-related immunosuppression for hepatocellular carcinoma
Zhenghui Song[1], Chen Yang[2], Minying Li[2], Yijing Ye[3]. [1]*Department of Radiation Oncology, Zhongshan City People's Hospital, Zhongshan, China;* [2]*Department of Thoracic Tumor Radiotherapy, Zhongshan City People's Hospital, Zhongshan, China;* [3]*Department of Abdominal Tumor Radiotherapy, Zhongshan City People's Hospital, Zhongshan, China*
Email: zhenghui_song@163.com

Background and aims: Anti-PD-L1-based immunotherapy combination strategy as first-line treatment for unresectable hepatocellular carcinoma (HCC). However, the objective response rates remain limited. It is an urgent need to find biomarker targets that can predict responses to anti-PD-L1 therapy and overcome resistance to immunotherapy. Annexin A1 (ANXA1) plays a critical role in inflammation, immunity and tumorigenesis. We previously demonstrated ANXA1 facilitates HCC progression by modulating macrophage-induced immunosuppressive microenvironment (Song ZH, et al. BIOCHEM PHARMACOL 2023). In this study, we sought to investigate the potential of ANXA1 as a target for immunotherapy in HCC.
Method: We employed bioinformatics to evaluate the relationship between ANXA1 expression and immune cell infiltration, as well as its correlation with immune checkpoints in HCC. Single-cell analysis elucidated the role of ANXA1 in shaping the heterogeneity of the HCC tumor microenvironment. We investigated its expression, prognostic significance, and clinical relevance in HCC tissue microarrays. We used a co-culture system to evaluate the immunomodulatory effects of ANXA1 in crosstalk between macrophages and lymphocytes. Flow cytometry was conducted to validate the effects of ANXA1 on promoting immune escape in various HCC animal models. Furthermore, we examined different levels of ANXA1 expression influenced the efficacy of anti-PD-L1 immunotherapy and synergistic therapy *in vivo*.
Results: We found that ANXA1 expression was associated with immunity, and positively correlated with PD-L1 expression. The single-cell analysis highlighted ANXA1's critical role in development and differentiation of immune cells. In HCC samples, ANXA1 was overexpressed in the macrophages and correlated with poor prognosis and advanced clinical stages. ANXA1 contributed to an immunosuppressive microenvironment and facilitated immune escape in HCC, mainly by promoting macrophages M2-like polarization, thus inhibiting CD8+ T cells infiltration and functional activation, enhancing regulatory T cells infiltration, and PD-L1 expression. Lower levels of ANXA1 were found to sensitize responses to anti-PD-L1 therapy.
Conclusion: Our results suggest that ANXA1 induces immune escape through remodeling macrophage phenotypes and may serve as a predictive biomarker of response to anti-PD-L1 therapy. Targeting ANXA1 could be considered an effective immunotherapeutic strategy for overcoming resistance to immunotherapy in HCC.

SAT-126
The genetic alterations in circulating tumor cells correlate with the clinical outcomes of hepatocellular carcinoma by large-scale whole-genome sequencing
Zhihang Zhou[1], Li Zhou[1], Mengsu Yang[2], Song He[1]. Email: 350596287zl@sina.cn

Background and aims: Hepatocellular carcinoma (HCC), typically occurring in the setting of chronic liver disease and cirrhosis is the third leading cause of cancer death globally. However, less than 20% of HCC patients are diagnosed at an early stage and may undergo curative therapies. On most occasions, liver biopsy is inaccessible in HCC patients due to the potential risk of hemorrhage and tumor dissemination. Moreover, a single biopsy specimen containing a small amount of tumor tissue may not represent the whole HCC tumor due to heterogeneity. In this context, individualized treatment for HCC patients remains to be defined, and predictive biomarkers are urgently needed to inform treatment selection, prognostication, and monitoring for treatment response. Circulating tumor cells (CTCs) are tumor cells that have been shed or migrated from the primary tumor into circulation. Although CTCs are usually very rare in blood and may be highly heterogeneous, they contain complete genomic and proteomic information that may reflect both the evolution of the tumor and the current status of the disease. Therefore, CTCs should be regarded as a less invasive alternative to tissue biopsy and a novel way to obtain a comprehensive understanding of the heterogeneous tumor and its progression. Microfluidic-based technology for enriching and isolating CTCs could increase the detection rate and meanwhile maintain CTC viability such that subsequent analysis can be done to reveal molecular features of CTCs.
Method: In the present study, we applied a microfluidic-based platform to obtain CTCs in 276 HCC patients, 60 cirrhosis patients and 20 healthy donors. The isolated CTCs were then subjected to whole genome sequencing.
Results: The number of CTCs was associated with advanced stage and unfavorable prognosis. Through analyzing the genetic spectrum of HCC CTCs, we found the combination of mutations in NAV2, SPTAN1, DOCK6, PI4KA was significantly associated with HCC patient overall survival. Specific gene panels can predict the prognosis of HCC patients in the BCLC-C stage, receiving targeted therapy, immunotherapy or intervention therapy. Two molecular subtypes could be identified according to CTC mutations. Cluster 1 and cluster 2 patients respectively response better to targeted therapy and immunotherapy. Finally, we found several CTC-specific mutated genes that might drive the formation of CTCs.
Conclusion: The present study revealed the genomic landscape of HCC CTCs in a large-scale cohort and the clinical significance of genetic alterations in CTCs. We also generated a novel sub-typing system according to CTC mutations, which are associated with clinical

outcomes. Finally, we identified the CTC-specific mutated genes. This study demonstrates the clinical utility of CTCs genome sequencing. It provides insights into the genomic features of HCC CTCs, which lay the foundation for further basic and clinical studies.

Deep learning derived radiomics with advanced machine learning outperforms clinical biomarkers in predicting outcomes after atezolizumab plus bevacizumab for advanced hepatocellular carcinoma

Mathew Vithayathil[1], Deniz Koku[1], Claudia Campani[2], Jean Charles Nault[3], Olivier Sutter[4], Nathalie Ganne-Carrié[5], Eric Aboagye[1], Rohini Sharma[1]. *[1]Department of Surgery & Cancer, Imperial College London, London, United Kingdom; [2]Department of Experimental and Clinical Medicine, Internal Medicine and Hepatology Unit, University of Firenze, Florence, Italy; Cordeliers Research Center, Sorbonne University, Inserm, Paris Citė University, "Functional Genomics of Solid Tumours" team, Ligue Nationale Contre le Cancer accredited team, Labex OncoImmunology, Paris, France; [3]Cordeliers Research Center, Sorbonne University, Inserm, Paris Citė University, "Functional Genomics of Solid Tumours" team, Ligue Nationale Contre le Cancer accredited team, Labex OncoImmunology, Liver Unit, Avicenne Hospital, Paris-Seine-Saint-Denis Universitary Hospitas, AP-HP, Paris, France; [4]University of Bordeaux, IMB, UMR CNRS 5251, INRIA Project team Monc, Talence, Diagnostic and Interventional Imaging Department, Avicenne Hospital, AP-HP, Paris, France; [5]Liver Unit, Avicenne Hospital, Paris-Seine-Saint-Denis Universitary Hospitas, AP-HP, Bobigny, France, Cordeliers Research Center, Sorbonne University, Inserm, Paris Citė University, "Functional Genomics of Solid Tumours" team, Ligue Nationale Contre le Cancer accredited team, Labex OncoImmunology, Paris, France*
Email: mathew.vithayathil@doctors.org.uk

Background and aims: Atezolizumab plus bevacizumab is a first-line therapy for advanced hepatocellular carcinoma (HCC). However, only a small proportion of patients respond to therapy, and pretreatment precision biomarkers are lacking. This study integrated clinical data and radiomic data derived from pre-treatment imaging to predict post-treatment outcomes in patients receiving immunotherapy (ICI).
Method: 162 consecutive patients from two international centres (ICL and AP-HP) receiving atezolizumab plus bevacizumab for advanced HCC were retrospectively reviewed. Deep learning auto-segmentation models were used to generate whole liver and cancer masks from pre-treatment CT imaging. Radiomic features derived from segmented masks and baseline clinical variables were used to predict 12-month mortality, using seven supervised machine learning models in combination with thirteen feature selection techniques in the ICL cohort. Radiomic, clinical and integrated radiomic-clinical models were developed using ensemble learning. Unsupervised K-means clustering identified high- and low-risk patient groups. Model performance was evaluated on the AP-HP cohort.
Results: The radiomic and integrated radiomic-clinical models had AUCs of 0.91 (95% confidence interval (CI) 0.81–0.98) and 0.73 (95% CI 0.55–0.87) respectively, significantly outperforming ALBI grade (AUC 0.48, 95% CI 0.32–0.64, $p < 0.001$) and Barcelona Clinic Liver Cancer (BCLC) stage (AUC 0.61, 95% CI 0.44–0.71; $p < 0.001$) in the ICL cohort. The models maintained good performance in the AP-HP cohort (radiomic: AUC 0.69, 95% CI 0.57–0.80; integrated radiomic-clinical: 0.75, 95% CI 0.64–0.85), with the integrated model outperforming ALBI grade (AUC 0.59, 0.48–0.69, $p = 0.030$) and BCLC stage (AUC 0.59, 95% CI 0.50–0.69, $p < 0.001$). Integrated model-derived high-risk patients had significantly shorter median overall survival in both the ICL (5.9 months, 95% CI 2.6–9.7 vs. 28.2 months, 95% CI 18.1–38.6 months; $p < 0.001$) and AP-HP cohorts (6.6 months, 95% CI 3.2–10.3 vs. 16.0 months, 95% CI 11.3–27.2 months; $p < 0.001$). Similarly, the model stratified high- and low-risk patients based on progression-free survival (ICL: 2.7 months, 95% CI 1.8–6.7 vs. 15.4 months, 95% CI 8.8–20.8 months; $p < 0.001$; AP-HP: 2.9 months, 95% CI 2.0–7.4 vs. 6.4 months, 95%CI 5.1–10.7 months; $p = 0.016$).
Conclusion: Radiomic-based models can predict mortality after ICI therapy in patients with advanced HCC. Deep learning in combination with machine learning model can stratify patients into risk groups, allowing for precision treatment strategies.

Multi-omics analyses identify a novel HCC subtype with better response to immune checkpoint inhibitor therapies

Junjie Xu[1]. *[1]Department of General Surgery, Sir Run-Run Shaw Hospital, Zhejiang University School of Medicine, Hangzhou, China*
Email: walter235@zju.edu.cn

Background and aims: The overall efficacy of the comprehensive treatment for hepatocellular carcinoma (HCC) patients is unsatisfactory. It is imperative to discover distinct molecular subtypes to achieve accurate diagnosis and treatment.
Method: In this study, whole transcriptome sequencing was performed on tumor and adjacent non-tumor tissues across 242 patients with hepatocellular carcinoma (HCC) and 51 patients with intrahepatic cholangiocarcinoma (ICC). Whole exome sequencing was performed in selected samples of each cancer subtype. Single-cell RNA sequencing was performed on fresh primary tumor samples from 15 HCC patients and 8 ICC patients.
Results: The HCC tumors were clustered into four subtypes, and we identified a new subtype of HCC called immune checkpoint inhibitors (ICI) therapies response HCC (IR-HCC). This subtype exhibits transcriptional similarities to intrahepatic cholangiocarcinoma (ICC) rather than the other subtypes of HCC. Single-cell RNA sequencing and multiplex immunofluorescence analyses provided evidences of a pre-dysfunctional immune microenvironment in IR-HCC tumors, indicating they may have a better response to immunotherapy. Importantly, IR-HCC exhibited a notably unfavorable outcome in the absence of immunotherapy. However, it showed a more favorable response to ICI therapies in a prospective cohort of HCC patients. TP53, PIK3R1, OR6P1, and CHIT1 were identified as the driver genes of the IR-HCC subtype. A 29-gene expression signature was developed and externally validated to distinguish the IR-HCC subtype from the broad HCC patient.
Conclusion: Collectively, our comprehensive multi-omics analyses have identified a novel HCC subtype called IR-HCC, exhibiting significant similarities in metabolism, immune infiltration, gene mutations, and overall survival to ICC. IR-HCC showed superior responsiveness to ICI therapies, providing a promising option for precision medicine-based treatments of HCC.

Microwave ablation versus single-needle radiofrequency ablation for the treatment of HCC up to 4 cm: a randomized control trial

Shunsuke Nakamura[1], Katsutoshi Sugimoto[1], Kento Imajo[2], Hidekatsu Kuroda[3], Go Murohisa[4], Kazue Shiozawa[5], Kentaro Sakamaki[6], Takuya Wada[1], Hirohito Takeuchi[1], Kei Endo[3], Tamami Abe, Takashi Matsui[5], Takahiro Murakami[5], Masato Yoneda[2], Atsushi Nakajima[2], Shigehiro Kokubu[7], Takao Itoi[1]. *[1]Tokyo Medical University, Tokyo, Japan; [2]Yokohama City University Graduate School of Medicine, Yokohama, Japan; [3]Iwate Medical University School of Medicine, Iwate, Japan; [4]Seirei Hamamatsu General Hospital, Shizuoka, Japan; [5]Toho University Ohashi Medical Center, Tokyo, Japan; [6]Juntendo University, Tokyo, Japan; [7]Shin-yurigaoka General Hospital, Kawasaki, Japan*
Email: zerogou@gmail.com

Background & Aims: Radiofrequency ablation (RFA) is the standard treatment for small hepatocellular carcinoma (HCC), specifically for tumors less than 3 cm in size and numbering fewer than 3, excluding surgical candidates. Microwave ablation (MWA) is an innovative approach believed to have theoretical benefits over RFA; however, these advantages are yet to be empirically verified. Therefore, we aimed to evaluate and compare the effectiveness of MWA and RFA in managing HCC tumors up to 4 cm in size.
Methods: In this multicenter randomized controlled trial conducted across five centers in Japan, eligible participants had up to four tumors, each up to 4 cm in size, and were not considered for surgery. Patients were randomly assigned to undergo MWA or RFA. The primary outcome was the rate of local tumor progression (LTP), while secondary outcomes included overall survival (OS) and intra- and extrahepatic recurrence-free survival (RFS) at the end of the 2-year follow-up.
Results: A total of 240 participants were screened from July 12, 2018, to December 7, 2021. Four participants were excluded: three did not meet inclusion criteria, and one died of unknown cause during treatment. Consequently, 119 (130 lesions) and 117 (136 lesions) participants were treated with MWA and RFA, respectively. The proportion of lesions with LTP at the 2-year follow-up was significantly lower in the MWA group (20 [16.4%] lesions) than in the RFA group (38 [30.4%] lesions) (risk ratio, 0.54; p = 0.007). OS and both intra- and extrahepatic RFS did not significantly differ between groups.
Conclusion: MWA is more effective than RFA in reducing local tumor progression for HCC tumors up to 4 cm.However, no differences were observed in OS and RFS.

Prognostic value of early change in neutrophil to lymphocyte ratio after atezolizumab plus bevacizumab treatment for hepatocellular carcinoma

Young Mi Hong[1], Hyun Myung Cho[2]. [1]*Pusan National University School of Medicine, Yangsan, Korea, Rep. of South;* [2]*Pusan National University Yangsan Hospital, Yangsan, Korea, Rep. of South*
Email: 00gurum@hanmail.net

Background and aims: Atezolizumab puls bevacizumab has been used for advanced hepatocellular carcinoma (HCC). However, there is lack of predictive biomarkers for assessing response to atezolizumab plus bevacizumab. The aim of this study was to investigate the predictive value of early changes in neutrophil to lymphocyte ratio (NLR) in patients with advanced HCC treated with atezolizumab plus bevacizumab.
Method: This retrospective study enrolled 59 patients receiving atezolizumab plus bevacizumab for advanced HCC. NLR was calculated at the initiation of atezolizumab plus bevacizumab and repeated at 3 weeks.
Results: According to the Response Evaluation in Solid Tumors at an initial evaluation after 3 cycles of treatment, rates of partial response (PR), stable disease (SD), and progressive disease (PD) were 22.0%, 49.2%, and 28.8%, respectively. Median overall survival (OS) were significantly associated with initial tumor responses. Median OS of PR, SD, and PR were 20 months, 14 months, and 12 months, respectively (P = 0.041). NLR changes at 3 weeks was confirmed as predictor of initial tumor response. The mean NLR ratios in patients who achieved PR, SD, and PD were 1.81, 2.99, and 3.42, respectively (P = 0.043). Additionally, a mean NLR ratio of 1.95 or higher at 3 weeks had a specificity of 78.3% and a sensitivity of 69.2% for predicting non-objective responses.
Conclusion: A change in NLR at 3 weeks is associated with initial tumor responses, which in turn, are related to survival outcomes. This association suggests that monitoring NLR changes during treatment can provide valuable prognostic insights into tumor response and subsequent patient survival.

FRI-080
TACE combined with ICIs plus MTT after 125I irradiation stent placement in patients with hepatocellular carcinoma and main portal vein tumor thrombosis (PATENCY II)

Junhao Mei[1], Jian Lu[1], Gao-Jun Teng[1]. [1]*Department of Radiology, Center of Interventional Radiology and Vascular Surgery, Zhongda Hospital, Medical School, Southeast University, Nanjing, China*
Email: 1241694780@qq.com

Background and aims: Patients with hepatocellular carcinoma (HCC) and main trunk (Vp4) portal vein tumor thrombosis (PVTT) have a poor prognosis, and current treatment options provide limited benefits. We aimed to assess the safety and efficacy of transcatheter arterial chemoembolization (TACE) combined with immune checkpoint inhibitors (ICIs) plus molecular targeted therapy (MTT) after irradiation stent placement (ISP) as first-line treatment for these patients.
Method: This multicenter retrospective cohort study enrolled 444 patients with HCC and Vp4 PVTT treated with either ISP, TACE, ICIs, and MTT (ISP-containing quadruple group, n = 131) or with ICIs and MTT (ICIs-MTT group, n = 313) between January 2020 and May 2023. Propensity score matching was used to balance the groups. The primary endpoint was overall survival (OS). The secondary endpoints included progression-free survival (PFS), objective response rate (ORR), PVTT response, patency of portal vein, and safety.
Results: After propensity score matching (1:2), 127 patients from the ISP-containing quadruple group were matched with 220 patients from the ICIs-MTT group. The median OS (10.3 months, interquartile range [IQR]: 9.1–11.5 vs 8.6 months, IQR: 7.6–9.6; *P* = 0.004), PFS (6.1 months, IQR: 4.9–7.3 vs 3.5 months, IQR: 2.9–4.1; *P* < 0.001), and ORR (52.8% vs 27.7% with RECIST version 1.1; 58.3% vs 29.1% with mRECIST) were higher in the ISP-containing quadruple group than in the ICIs-MTT group. The ISP-containing quadruple group also demonstrated a higher PVTT positive response rate (64.6%) than the ICIs-MTT group (20.5%). Median stent patency was 10.4 months (IQR: 8.2–12.7). Grade ≥3 adverse events were observed in 37 patients (29.1%) in the ISP-containing quadruple group and 56 patients (25.5%) in the ICIs-MTT group (*P* = 0.456).
Conclusion: Following ISP, treatment combining TACE with ICIs plus MTT can significantly prolong OS and PFS in patients with HCC and Vp4 PVTT and is generally well-tolerated.

The ISP-containing quadruple group also demonstrated a higher PVTT positive response rate (64.6%) than the ICIs-MTT group (20.5%). Median stent patency was 10.4 months (IQR: 8.2–12.7). Grade ≥3 adverse events were observed in 37 patients (29.1%) in the ISP-containing quadruple group and 56 patients (25.5%) in the ICIs-MTT group (p = 0.456).
Conclusion: Following ISP, treatment combining TACE with ICIs plus MTT can significantly prolong OS and PFS in patients with HCC and Vp4 PVTT and is generally well-tolerated.

FRI-082
Conversion ability of systemic therapy in patients with hepatocellular carcinoma: a multicenter international study. On behalf of the converse survey collaborative study group
Alessandro Vitale[1], Hong Jae Chon[2], Francesco Tovoli[3]. *[1]Padua University, Padova, Italy; [2]Division of Medical Oncology, Department of Internal Medicine, CHA Bundang Medical Center, CHA University School of Medicine, Seongnam, Korea, Seongnam, Korea, Rep. of South; [3]Bologna University, Bologna, Italy*
Email: alessandro.vitale@unipd.it

Background and aims: Novel Systemic treatments have profoundly revolutionised the treatment of hepatocellular carcinoma (HCC), with relevant advantages in terms of objective response rate (ORR) and duration of response. This multicentre study aims to evaluate the "real-life" conversion ability of systemic therapies to curative options (liver transplant, hepatic resection, or ablation) in patients with HCC.
Method: This multicentre retrospective study used aggregate data from Italian and International centres, treating at least ten adult patients with Atezolizumab plus Bevacizumab (AB) or Lenvatinib (LE) as 1 line therapy from 2019 to 2023. Patient-level exclusion criteria were: suitability for curative or loco-regional therapies; Child C; BCLC stages 0, A; previous systemic treatment for HCC; previous liver transplantation. The primary end-point was the rate of "actual conversion" to curative treatment options (liver transplant, hepatic resection or ablation). Secondary end-points were the "potential conversion" rate and ORR. Potential conversion was defined as HCCs with a tumour burden score <8 (without extra-hepatic disease) and alpha-fetoprotein level <1000 ng/ml at the maximum objective response (partial or complete) to therapy. A meta-analytic approach was used to analyse centre-level aggregate data.
Results: We enrolled 32 Italian centres (Italian database) that treated 1,247 patients (597 with LE, 650 with AB) and 14 international centres (International database) that treated 1,044 patients (333 with LE, 711 with AB). Although the ORR rates were high in the Italian (29% with AB and 22% with LE) and International databases (29% with AB and 27% with LE), the actual conversion rates were meagre (3% with AB and 2% with LE in Italy; 5% with AB and 4% with LE in the International database). Conversely, the potential conversion rates were consistent: 17% with AB and 12% with LE in Italy, 19% with AB and 15% with LE in the International database.
Conclusion: The results of this multicentre study confirm LE and AB's worldwide effectiveness. However, they also highlight a significant discrepancy between actual and potential conversion rates in real life. These findings suggest that there is probably a clinical underestimation of the conversion potentialities of systemic therapy in HCC, with the majority of clinicians preferring to maintain patients in systemic treatment. Only well-designed prospective studies will prove whether this "under-conversion" has a negative prognostic impact on these patients.

FRI-083-YI
Histologic predictors of response to atezolizumab and bevacizumab in hepatocellular carcinoma biopsies
Alexandre Sayadi[1], Mohamed Bouattour[2], Marco Dioguardi Burgio[3], Miguel Albuquerque[1], Valérie Paradis[1], Aurélie Beaufrère[1].
[1]Department of Pathology, Hôpital Beaujon, AP-HP.Nord, Clichy, France; [2]Department of Digestive Oncology, Hôpital Beaujon, AP-HP.Nord, Clichy, France; [3]Department of Radiology, Hôpital Beaujon, AP-HP.Nord, Clichy, France
Email: alexandre.sayadi@aphp.fr

Background and aims: Hepatocellular carcinoma (HCC) is the third leading cause of cancer-related death worldwide. Atezolizumab and bevacizumab is the first line therapy in unresectable HCC, which has shown superiority over sorafenib. Only 33% of patients respond to treatment according to mRECIST in the original trial (IMbrave150). Whereas few molecular factors has been associated to response, no routinely histological factors has been described. Our objective was to identify histologic features associated with response to atezolizumab-bevacizumab.
Method: We conducted a monocentric retrospective study between 2019 and 2023 including 108 pre-treatment biopsies of patients with unresectable HCC treated by atezolizumab-bevacizumab. CT scans at 3 months were used to define responders as partial or complete response according to mRECIST (modified Response Criteria In Solid Tumors). Histologic criteria were reviewed by two liver pathologists, including subtype according to the World Health Organization (WHO) classification based on predominant pattern and VETC phenotype (>55% of Vessels Encapsulating Tumoral Clusters, based on HES stain and confirmed with CD34 immunohistochemistry).
Results: HCC was mainly observed in male patients (n = 96, 89%) and in cirrhotic liver (n = 67, 62%). HCCs were mainly classified as "not other specified" (NOS, 48%). The most frequent observed subtypes were macrotrabecular massive (MTM, 26%), squirrhous (SQ, 10%) and steatohepatitic (SH, 9%). Clear cell subtype (CC) was rarely observed (4%). VETC phenotype was present in 12 patients (11%). Response at 3 months was assessable in 93 patients (86%), the remaining 15 patients having been lost to follow-up or died before the 3-month CT scan. 40% of patients (n = 43) were classified as responders, distributed as follow: 70% in NOS group (n = 30), 16% in MTM group (n = 7), 5% in SQ group (n = 2) and 5% in SH group (n = 2) (p = 0.015). In univariate analyses, factors negatively impacting response were MTM subtype (Odds ratio (OR): 0.30 [0.10; 0.83], p = 0.025) and SH subtype (OR: 0.16 [0.02; 0.71], p = 0.029), whereas VETC phenotype positively impact response (OR: 5.49 [1.28; 37.9], p = 0.038). In multivariate analysis, adjusted for clinical variables that may influence outcome (AFP, Child-Pugh, macrovascular invasion, extra-hepatic disease and previous locoregional treatment), VETC phenotype, MTM and SH subtype were still impacting response.
Conclusion: VETC phenotype, MTM and SH subtypes impact the response to atezolizumab-bevacizumab in unresectable HCC. These criteria, easily assessable on biopsy, could be used to stratify patients on response to atezolizumab-bevacizumab. These results should be confirmed in a larger cohort.

FRI-084
Real world treatment patterns and outcomes for hepatocellular carcinoma (HCC) patients receiving transarterial chemoembolization (TACE) or transarterial radioembolization (TARE) in the TARGET-HCC registry
Amit Singal[1], Sami Mahrus[2], Aliramazan Jaffer[3], Heather Morris[4], Andrea Mospan[4], Breda Munoz[4], Katie Kelley[5]. *[1]UT Southwestern, Dallas, United States; [2]Genentech, San Francisco, United States; [3]Roche, Basel, Switzerland; [4]Target RWE, Durham, United States; [5]UCSF,*

San Francisco, United States
Email: amit.singal@utsouthwestern.edu

Background and aims: The goal of this study was to describe baseline characteristics, treatment patterns, and outcomes among patients with intermediate or advanced HCC who received TACE or TARE as their first treatment in a real-world setting.
Method: The TARGET-HCC registry includes patients with HCC receiving standard of care treatment. Medical records are collected retrospectively for up to 3 years before enrollment and prospectively for up to 5 years. Adults (≥18 years) diagnosed with HCC (Barcelona Clinic Liver Cancer (BCLC) stage B or C) within 3 years of enrollment between January 2017–July 2024 in the United States, who received TACE or TARE as first HCC treatment were eligible for this study. Evaluated outcomes included real world tumor response to TACE or TARE based on radiology reports or clinical notes, overall survival, and TACE or TARE unsuitability defined by tumor size, portal vein thrombosis, extrahepatic metastases, or liver dysfunction.
Results: Of 230 patients, most had stage (BCLC) B at diagnosis (71%), median age was 64 years, White (67%), and 15% were Hispanic or Latino. Among response-evaluable patients after the first round of TACE or TARE, the most common response was partial response (PR, 56%), followed by progressive disease (PD, 21%), complete response (CR, 13%) and stable disease (SD, 10%). Across two rounds, the most common response pattern was CR/PR – CR/PR (52%), CR/PR – SD/PD (22%), SD/PD – SD/PD (14%), and SD/PD – CR/PR (12%). After initial TACE or TARE treatments, 57% of patients in this cohort were subsequently treated with systemic therapy, 21% with ablation, and 12% underwent liver transplantation. Median overall survival from initial diagnosis among patients with at least one round was 42 months (95% CI: 36 – NE) for those with a CR or PR in the first round, and 25 months (95% CI: 19–44) for those with SD or PD. Median overall survival from initial diagnosis among patients with at least two rounds of therapy was 38 months (95% CI: 32 – NE) for those with a response pattern of CR/PR – CR/PR across the first two rounds and 24 months (95% CI: 18 – NE) for those with CR/PR – SD/PD. The rate of TACE or TARE unsuitability was 66% after the first round of TACE or TARE, and 69% after the second round. Only 20% of patients received systemic therapy after the first round of TACE or TARE, and only 24% of patients received systemic therapy after the second round.
Conclusion: Patterns of follow-up treatment and outcomes varied among patients with intermediate/advanced HCC receiving TACE or TARE as their first treatment in a real-world setting. Approximately two thirds of evaluated patients may be considered unsuitable for TACE or TARE after a first or second round of treatment, but less than a quarter of these patients received systemic therapy. Educational efforts and multidisciplinary care can help increase guideline-concordant care aiming to improve outcomes for patients with unresectable HCC.

FRI-085
Microwave ablation versus liver resection for patinets with hepatocellular carcinomas

Hyundam Gu[1], Jihye Lim[2], Dong Jin Chung[3], Kwang Yeol Paik[4], Seung Kew Yoon[5], Yeonjoo Seo[6]. *[1]Epidemiologic and Biostatical Methods for Public Health and Clinical Research, Master of Public Health Program, Johns Hopkins Bloomberg School of Public Health, Baltimore, United States; [2]Division of Gastroenterology and Hepatology, Department of Internal Medicine, Yeouido St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Rep. of South; [3]Department of Radiology, Yeouido St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Rep. of South; [4]Department of Surgery, Yeouido St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Seoul, Korea, Rep. of South; [5]Department of Internal Medicine, Seoul St. Mary's Hospital, The Catholic University Liver Research Center, The Catholic University of Korea, Seoul, Korea, Rep. of South; [6]Division of Gastroenterology and Hepatology, Department of Internal Medicine, Yeouido St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Rep. of South*
Email: amyhyd89@gmail.com

Background and aims: Microwave ablation (MWA) represents an emerging ablative therapy that surpasses previous methods by achieving higher temperatures and creating larger ablation zones within shorter time periods. This study aimed to compare therapeutic outcomes of MWA and liver resection in real-world clinical practice.
Method: This study enrolled 178 patients with 259 nodules who underwent either MWA or liver resection between January 2015 and July 2023. Local tumor progression (LTP)-free survival, overall progression (OP)-free survival, and overall survival (OS) were assessed based on treatment modality of the index nodule.
Results: Of a total of 178 patients, 134 patients with 214 nodules received MWA and 44 patients with 45 nodules underwent liver resection. The median follow-up period was 2.0 ± 1.5 years. Annual incidence of LTP was 3.7% for MWA and 1.4% for liver resection. Treatment modality showed no significant impact on LTP-free survival. For nodules larger than 3 cm, LTP-free survival was not affected by treatment modality. Similarly, OP-free survival and OS were not influenced by the choice of treatment modality.
Conclusion: In conclusion, MWA and liver resection demonstrated comparable treatment outcomes in terms of local tumor control, overall recurrence, and survival.

FRI-086-YI
Long-term survival outcomes in patients receiving atezolizumab plus bevacizumab for unresectable hepatocellular carcinoma: an update of the AB-real study

Email: bernardo.stefanini@gmail.com

Background and aims: Atezolizumab plus bevacizumab (A+B) is an established first-line treatment option in patients with unresectable hepatocellular carcinoma (HCC). Long-term survival outcome data are sparse and identification of patients achieving durable benefit from A+B remains an unmet need.
Method: From the AB-real cohort, a prospectively maintained registry of 1426 patients treated with A+B across 23 centres in Europe, Asia and America, we accrued 1284 patients receiving A+B as frontline systemic treatment and included those within Child-Pugh Class A and Eastern Cooperative Oncology Group and (ECOG) performance status 0–2 (n = 989). We estimated median overall (OS) and progression-free survival (PFS) and performed landmark survival analyses at 24 and 36 months (m) from A+B initiation. We explored characteristics associated to long-term survival, including radiologic response by RECIST v1.1 criteria, using uni- and multivariate regression.
Results: We included 989 patients with unresectable HCC. Overall, 770 (77.9%) had Barcelona Clinic Liver Cancer stage C, due to the presence of either macrovascular invasion (n = 243, 24.6%) and/or extrahepatic spread (n = 504, 51.0%) and ECOG PS 0–1 (n = 971, 98.2%). Viral aetiology was the most common cause of liver disease (HCV n = 199, 20.1% and HBV n = 471, 47.6%). After a median follow-up of 22.8 months (95%CI 21.6–24.0), 407 patients progressed to A+B and 540 patients died. Median OS was 18.5 months (95%CI 14.9–18.8 months) and median PFS was 7.9 months (95%CI 6.9–8.9 months). Overall response rate (ORR) was 29.0%, including 5.6% complete responses, whereas disease control rate was 75.3%. In the whole study population, landmark 24 m OS rate was 26.1% and 36 m OS rate was 9.6%. Patients achieving a radiologic response had higher 24 m (53.6%) and 36 m (30,5%) OS rates compared to those achieving disease control, with 24 m OS rate of 34.2% and 36 m OS rate of 14.2%. In landmark analyses at 6 m, achievement of a radiologic response was significantly associated with long-term benefit when compared to achieving a stable disease (HR 0.40, 95%CI 0.23–0.68) or a PD (HR 0.22, 95%CI 0.19–0.42, p < 0.001).
Conclusion: More than a quarter of A+B recipients with unresectable HCC are alive 2 years from treatment initiation. Probability of long-term survivorship is predicated upon achievement of an objective response, highlighting the importance of radiologic reassessment as a method to individualise prognostication in A+B recipients.

FRI-087
Immune cell profiling predicts response to Atezolizumab-Bevacizumab in advanced hepatocellular carcinoma

Eunho Choi[1], Ha Seok Lee[1], Young-Sun Lee[1], Youngwoo Lee[1], Yang Jae Yoo[1], Seong Hee Kang[1], Sun Young Yim[1], Young Kul Jung[1], Ji Hoon Kim[1], Yeon Seok Seo[1], Hyung Joon Yim[1], Jong Eun Yeon[1], Kwan Soo Byun[1]. *[1]Korea University College of Medicine, Seoul, Korea, Rep. of South*
Email: lys810@korea.ac.kr

Background and aims: Atezolizumab combined with bevacizumab is the current frontline treatment for advanced hepatocellular carcinoma. Despite numerous studies, predicting patient response to this therapy remains challenging.
Method: Patients with advanced hepatocellular carcinoma receiving atezolizumab-bevacizumab therapy were enrolled. Blood samples were taken at baseline and two weeks after treatment initiation. Peripheral blood mononuclear cells (PBMCs) were isolated for analysis. Eight patients were selected based on initial response: four responders (complete or partial response) and four non-responders (progressive disease). Single-cell RNA sequencing (scRNA-seq) was performed on the PBMC samples.
Results: Patients with favorable prognoses exhibited higher frequencies of γδ T cells, CD4+ T cells, CD8+ T cells, and both classical and non-classical monocytes in their peripheral blood mononuclear cells (PBMCs) before treatment compared to those with poor prognoses. After treatment, patients with positive outcomes showed a notable increase in proliferating lymphocytes. Importantly, a specific subpopulation of CD8+ T cells, designated as cluster 4, emerged as a potential biomarker for treatment response. This cluster, characterized by high expression of the proliferation marker MKI67 and inhibitory checkpoint genes such as PDCD1, HAVCR2, and CTLA4, was more prevalent in the pre-treatment PBMCs of patients with favorable prognoses. Moreover, patients with better outcomes exhibited a significant increase in the frequency of this cluster after treatment, suggesting its potential role in predicting and mediating response to the combination therapy.
Conclusion: This study mapped the diverse circulating immune cell populations in advanced hepatocellular carcinoma patients before and after atezolizumab-bevacizumab treatment. A distinct subgroup of CD8+ T cells emerged as a promising biomarker for predicting

treatment response, potentially aiding in personalized therapy decisions for this aggressive cancer.

FRI-088

Exosomal miR-30a-5p: a promising biomarker for predicting response to Atezolizumab-Bevacizumab therapy in advanced hepatocellular carcinoma

Eunho Choi[1], Young-Sun Lee[1], Jeong-An Gim[2], Wonhyo Seo[3], Ha Seok Lee[1], Youngwoo Lee[1], Yang Jae Yoo[1], Seong Hee Kang[1], Sun Young Yim[1], Young Kul Jung[1], Ji Hoon Kim[1], Yeon Seok Seo[1], Hyung Joon Yim[1], Jong Eun Yeon[1], Kwan Soo Byun[1]. *[1]Korea University College of Medicine, Seoul, Korea, Rep. of South; [2]Department of Medical Science, Soonchunhyang University, Cheon-An, Korea, Rep. of South; [3]College of Pharmacy, Ewha Womans University, Seoul, Korea, Rep. of South*
Email: lys810@korea.ac.kr

Background and aims: Atezolizumab and bevacizumab combination therapy is currently the first-line treatment for advanced hepatocellular carcinoma. However, iVdentifying a reliable biomarker to predict treatment response remains challenging. This study aimed to discover exosomal miRNA biomarkers that could forecast positive responses to this combination therapy.
Method: Blood samples were collected from patients with advanced hepatocellular carcinoma before they began treatment with atezolizumab and bevacizumab. Patients were categorized into two groups: responders, who exhibited stable disease or showed partial or complete response to the treatment, and non-responders, who demonstrated disease progression. To isolate the exosomes, the serum samples were concentrated using a qEV concentration and isolation kit. Following this, exosomal RNA were extracted from the concentrated samples. The extracted RNA was then subjected to small RNA sequencing using next-generation sequencing (NGS) technology to identify the miRNAs present in the samples. Decision tree analysis was employed to identify miRNAs from the top 100 most expressed that effectively differentiated between responders and non-responders.
Results: The research included a total of 16 patients, evenly divided between responders and non-responders, with a predominance of male subjects and a high prevalence of viral-induced hepatocellular carcinoma in both groups. Next-generation sequencing analysis identified a total of 1076 miRNAs, among which 12 exhibited significant differential expression between the responder and non-responder groups. Notably, three miRNAs - let7c-5p, miR-30a-5p, and miR192-5p - were found to be significantly elevated in the responder group. Further analysis using decision tree methodology identified 30 miRNAs from the top 100 most expressed, with miR-30a-5p emerging as a particularly promising candidate, showing significantly higher levels in responders ($p = 0.0047$). The increased expression of miR-30a-5p in responders was subsequently confirmed through quantitative reverse transcription PCR validation. Additionally, in vitro experiments demonstrated that transfection of miR-30a-5p into HepG2 cells resulted in decreased cell migration and proliferation, suggesting a potential mechanistic link between this miRNA and treatment response.
Conclusion: Exosomal miRNAs show promise as potential biomarkers for predicting response to atezolizumab-bevacizumab therapy in advanced hepatocellular carcinoma. This research provides a foundation for further investigation into using these biomarkers to optimize treatment strategies for patients with this aggressive form of liver cancer.

Avogadro," Novara, Italy, Novara, Italy*
Email: david.pinato@imperial.ac.uk

Background and aims: While overall survival(OS) remains the primary endpoint in the treatment of unresectable/advanced hepatocellular carcinoma(HCC), health-related quality of life(HR-QoL) is a crucial complementary outcome in the face of widening treatment options. Whilst various immune checkpoint inhibitor(ICI) combinations have been proven superior to tyrosine kinase inhibitor (TKI), no comparative evidence exists for their impact on HR-QoL. This network meta-analysis(NMA) aims to compare the effect of different first-line treatments for advanced HCC on HR-QoL and integrate treatment-induced survival benefit with impact on HR-QoL.
Method: We performed a systematic literature search of databases to identify all randomized phase 3 clinical trials published through November 2024. Studies were included if they compared TKI monotherapy with ICI-based therapies in first-line for unresectable/advanced HCC and report time to deterioration of HR-QoL scores. Only HR-QoL items reported ≥5 studies were analysed. A frequentist NMA was performed using sorafenib as the comparator. The minimum distance criterion(MDC) approach was employed to combine HR-QoL and OS by minimizing the statistical distance between observed results and a theoretical optimal point where both outcomes are maximized. Lower MDC corresponds to improved net benefit across both HR-QoL and OS.
Results: Ten studies, enrolling 7,268 patients treated with Sorafenib, Lenvatinib, Nivolumab, Tislelizumab, Durvalumab, Atezolizumab+Bevacizumab, Sintilimab+IBI305, Durvalumab+Tremelimumab, Nivolumab+Ipilimumab, Atezolizumab+Cabozantinib, Lenvatinib+Pembrolizumab, Camrelizumab+Apatinib were included. Seven HR-QoL items were reported in ≥5 studies: global health status/

quality of life(GHS/QoL), physical functioning(PF) and fatigue, assessed by EORTC quality of life questionnaire(QLQ)-C30 and jaundice, pain, abdominal swelling, and fatigue, assessed by EORTC QLQ-HCC18. Atezolizumab +Bevacizumab showed the highest probability of reducing the risk of deterioration of GHS/QoL(85%), abdominal swelling(95%), jaundice(89%), and pain(86%). Tislelizumab showed the highest probability of reducing the risk of deterioration of PF(96%) and fatigue, assessed by both QLQ-C30(98%) and QLQ-HCC 18(86%). When GHS/QoL was combined with OS, Atezolizumab+Bevacizumab outperformed other treatments, with the best MDC(0.19), followed by Sintilimab+IBI305(0.37) and Lenvatinib+Pembrolizumab(0.56).
Conclusion: Atezolizumab plus Bevacizumab was associated with the highest magnitude in reducing the risk of deterioration of most HR-QoL domains compared to other systemic therapies. Integrated assessment of OS with HR-QoL assessed by MDC suggests atezolizumab plus bevacizumab to provide the best balance between QoL preservation and OS benefit compared to other systemic therapy options in unresectable/advanced HCC.

FRI-090
Incidence of radiation pneumonitis following resin-based yttrium-90 selective internal radiation therapy

Kaina Chen[1], Aaron Kian Ti Tong[1], Timothy Ong[2], Pierce Chow[3].
[1]*Singapore General Hospital, Duke-NUS Medical School, Singapore, Singapore;* [2]*Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore;* [3]*Program in Translational and Clinical Liver Cancer Research, National Cancer Centre Singapore, Department of Hepatopancreatobiliary and Transplant Surgery, Singapore General Hospital and National Cancer Centre Singapore, Duke-NUS Medical School, Singapore, Singapore*
Email: pierce.chow@duke-nus.edu.sg

Background and aims: Selective Internal Radiation Therapy (SIRT) with Yttrum-90 (Y-90) microspheres is a widely used locoregional therapy for a broad spectrum of hepatocellular carcinoma (HCC). Radiation pneumonitis is a rare but potentially fatal complication that occurs due to tumour-induced arteriovenous shunting of radiation particles into the lung. The safety dose to the lung was not well established for resin-based Y-90 SIRT but up to 30Gy is accepted as the safety limit. This study aims to evaluate the incidence of radiation pneumonitis after resin-based Y-90 SIRT for unresectable HCC.
Method: Consecutive patients treated with SIRT Y-90 resin microspheres for unresectable HCC between January 2008 and May 2019 at the National Cancer Centre Singapore and Singapore General Hospital were reviewed. Patient demographics, liver function, HCC tumour burden, chest computer-tomography (CT) findings, dosimetry parameters were recorded. Radiation pneumonitis was diagnosed based on the presence of respiratory symptoms and/or pulmonary infiltrates on imaging for which radiation pneumonitis cannot be excluded radiologically. Pre-treatment angiography and technetium-99m-labelled macroaggregated album (Tc-99 m MAA) study were performed for all patients to calculate lung shunt fraction and to estimate the lung dose. Dosimetry analysis was performed using either the partition model or body surface area (BSA) model.
Results: Of the 472 patients reviewed, 8 patients (1.6%) were diagnosed with radiation pneumonitis. The median follow up is 9.9 months (range, 4.5–13.2 months). One patient had Child-Pugh B7 liver cirrhosis whereas the rest of the patients were Child-Pugh A5-6. All 8 patients had HCC beyond the up-to-seven criteria. Half of the patients had no reported respiratory symptoms despite pulmonary infiltrates reported on CT thorax. All except one patient had bilateral pulmonary infiltrates or ground glass changes on CT thorax for which radiation pneumonitis is a differential diagnosis. Lung-shunt fractions range from 10.3% to 25% (median 9.6%; range, 8.4%–14.1%) and the predicted lung dose ranges from 10.3–21.9 Gy (median 13.5 Gy; range, 12.7–19.9 Gy). Onset of symptoms or imaging diagnosis ranges from 2–7.1 months post Y-90 SIRT (median 3.0 months; range, 2.6–3.7 months). Two patients required a tapering course of prednisolone for persistent dyspnoea or dry cough, but none required supplementary oxygen or other respiratory support.
Conclusion: Radiation pneumonitis is a rare complication of resin Y-90 SIRT and patients may be completely asymptomatic despite routine imaging shows pulmonary infiltrates suspicious of radiation pneumonitis. It may occur despite limiting the predicted lung dose to 25Gy. Only a small proportion of the patients require a tapering course of prednisolone treatment for persistent symptoms.

FRI-091-YI
The "A-B-C" cluster-based classification reveals distinct outcome trajectories in patients with hepatocellular carcinoma under atezolizumab/bevacizumab

Email: claudiacampani.cc@gmail.com

Background and aims: Patients with unresectable hepatocellular carcinoma (HCC) treated with atezolizumab and bevacizumab exhibit variable outcomes. We aimed to identify clinically meaningful subgroups using machine learning to assess their association with oncological outcomes.
Method: In this international multicenter study across 12 centers, we included patients with unresectable HCC receiving first-line atezolizumab and bevacizumab. Baseline clinical, biological, and tumor characteristics were collected. Hierarchical clustering analysis was performed on a derivation cohort and validated in a validation cohort. Clusters were correlated with overall survival (OS), progression-free survival (PFS) and radiological response per RECIST 1.1.
Results: Among 1,399 patients (85% male; 75% with cirrhosis; 39% with portal vein invasion; 35% with metastasis), divided into derivation (n = 958) and validation (n = 409) cohorts, we identified three distinct subgroups: Cluster A (47.5% of patients): older age, higher body mass index, preserved liver function, multiple small tumors; Cluster B (11%): presence of VP1/VP2 portal vein thrombosis, higher hepatitis B and lower metabolic syndrome prevalence; Cluster C (41.2%): moderate liver dysfunction, elevated alpha-fetoprotein levels, and either VP3/VP4 portal vein thrombosis or high tumor burden. Cluster A had longer OS (median not reached) compared to Clusters B (18.2 months) and C (14.1 months; $p < 0.0001$), lower rates of progressive disease (25.1% vs. 34.3% and 41.2%; $p < 0.0001$), and longer PFS (median 10.93 vs. 7.73 and 6.10 months; $p < 0.0001$). Clusters correlated with prognosis across BCLC stages and specific patterns of disease progression ($p < 0.001$).
Conclusion: The Atezolizumab-Bevacizumab-Cluster (A-B-C) classification identified subgroups of patients with different prognostic trajectories. These clusters were associated with survival outcomes and patterns of disease progression, potentially informing personalized therapeutic strategies and clinical trial design in patients with unresectable HCC.

FRI-092-YI
Patterns and outcomes of recurrence after thermal ablation for hepatocellular carcinoma
Chi-Ping Tan[1], I-Cheng Lee[1,2], Kuo-Cheng Wu[1,3], Jiing-Chyuan Luo[1,2], Ming-Chih Hou[1,2], Yi-Hsiang Huang[1,2,4,5]. *[1]Division of Gastroenterology and Hepatology, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan; [2]School of Medicine, College of Medicine, National Yang Ming Chiao Tung University, Taipei, Taiwan; [3]Division of Gastroenterology and Hepatology, Department of Medicine, Keelung Hospital, Ministry of Health and Welfare, Taipei, Taiwan; [4]Institute of Clinical Medicine, National Yang Ming Chiao Tung University, Taipei, Taiwan; [5]Healthcare and Service Center, Taipei Veterans General Hospital, Taipei, Taiwan*
Email: iclee@vghtpe.gov.tw

Background and aims: Recurrence rates after thermal ablation for hepatocellular carcinoma (HCC) remain high, but the patterns of recurrence and post-recurrence outcomes are not well characterized. This study aimed to investigate the recurrence patterns and long-term post-recurrence survival (PRS) in patients with HCC after thermal ablation.
Method: A retrospective analysis was conducted on 824 patients who underwent thermal ablation for HCC between 2007 and 2023. Recurrence patterns, post-recurrence treatments, and factors influencing PRS in patients with recurrence within and beyond Milan criteria were evaluated.
Results: During the median follow up of 54.5 month, 536 patients developed HCC recurrence. Among them, 67.4% and 32.6% patients experienced early and late recurrence, respectively, while 83.8% and 16.2% had recurrence within and beyond Milan criteria, respectively. Among patients with recurrence within Milan criteria, early recurrence (hazard ratio (HR) = 1.412, $p = 0.015$), recurrence tumor size >2 cm (HR = 1.510, $p = 0.002$), AFP >20 ng/mL (HR = 1.391, $p = 0.009$), ALBI grade 2–3 (HR = 1.675, $p < 0.001$), and FIB-4 score >3.25 (HR = 1.761, $p < 0.001$) were independent predictors of PRS. Among patients with recurrence beyond Milan criteria, diabetes mellitus (HR = 4.011, $p < 0.001$), macrovascular invasion (HR = 2.542, $p = 0.001$), AFP >400 ng/mL (HR = 1.867, $p = 0.039$), ALBI grade 2–3 (HR = 2.722, $p = 0.002$), and FIB-4 score >3.25 (HR = 2.421, $p = 0.018$) were independent predictors of PRS. Based on the predictors of RFS, a risk model for recurrence within Milan criteria stratified patients into 4 risk groups, with median PRS of 103.7, 65, 48.7 and 28.6 months, respectively ($p < 0.001$). A risk model for recurrence beyond Milan criteria stratified patients into 3 risk groups, with median PRS of 70.1, 24.7 and 8.1 months, and probability of downstaging to Milan criteria of 70.4%, 39.3% and 3.4%, respectively ($p < 0.001$).
Conclusion: Post-recurrence survival in patients with recurrent HCC after thermal ablation is significantly influenced by the pattern of recurrence, tumor burden, and host-related factors. These findings may guide post-recurrence treatment strategies, informing the timing of referral for salvage liver transplantation, and designing future clinical trials.

FRI-095
Hepatic artery infusion chemotherapy(HAIC) combined with Lenvatinib and Camrelizumab for hepatocellular carcinoma(HCC) with portal vein tumor thrombus(PVTT): a prospective longitudinal real-world study
Qingxian Cai[1], Yong Xu[1], Fang Luo[1]. *[1]The Third People's Hospital of Shenzhen, Shenzhen, China*
Email: cqx200000@163.com

Background and aims: Hepatocellular carcinoma (HCC) with portal vein tumor thrombus (PVTT) predicts a poor prognosis. The aim of this study was to evaluate the efficacy and safety of hepatic artery infusion chemotherapy(HAIC) combined with lenvatinib and camrelizumab in patients with hepatocellular carcinoma (HCC) and portal vein tumor thrombus (PVTT).
Method: This study was a single-arm, open-label prospective trial (ChiCTR2200063129). Eligible patients with advanced HCC accompanied by PVTT were enrolled to receive HAIC combined with lenvatinib and camrelizumab. The primary endpoint was progression-free survival (PFS), while the secondary endpoints included objective response rate (ORR), overall survival (OS), and safety.
Results: Between September 2022 and October 2023, 70 patients were successfully enrolled. The objective response rate (ORR) was 88.6% (62 out of 70 patients) based on the modified Response Evaluation Criteria in Solid Tumors (mRECIST), which included 14 cases (20%) of complete response (CR) and 48 cases (68.6%) of partial response (PR). Additionally, 14.3% (10 out of 70 patients) underwent surgery, achieving a complete resection (R0) in all cases. The median PFS (mPFS) and median OS (mOS) were 11.3 and 23.6 months, respectively. The most common treatment-related adverse events were hypertension, proteinuria, rash, hand-foot syndrome, and

hematologic abnormalities. The incidence rates of grade 1, 2, 3, and 4 adverse events were 32.9%, 48.6%, 18.6%, and 11.4%.
Conclusion: For patients with HCC complicated by PVTT, the combination of HAIC with camrelizumab and lenvatinib shows promising clinical efficacy, and the toxicity is acceptable.

FRI-096
Effects of pre-transplant locoregional therapies on dropout rates and survival outcomes in patients with hepatocellular carcinoma: a propensity-matched analysis of the United Network for Organ Sharing (UNOS) database

Mohammad Mirza-Aghazadeh-Attari[1], Peiman Habibollahi[2], Emil Cohen[3], Nora Tabori[3], Nima Kokabi[4], Juan Camacho[5], Pejman Radkani[3], Parissa Tabrizian[6], Rohit Satoskar[3], Arul Thomas[3], Aiwa He[3], Nariman Nezami[3]. *[1]Johns Hopkins Medical Institute, Baltimore, United States; [2]Department of Interventional Radiology, The University of Texas MD Anderson Cancer Center, Houston, Texas, Houston, United States; [3]Medstar Georgetown University Hospital, Washington DC, United States; [4]University of North Carolina, Chapel Hill, Chapel Hill, United States; [5]Florida State University, Gainesville, United States; [6]Mount Sinai Health System, NYC, United States*
Email: dr.nezami@gmail.com

Background and aims: Locoregional therapies (LRTs) ranging from thermal ablation to intraarterial therapies are the cornerstone of treatment for hepatocellular carcinoma (HCC), however the long-term outcome of these therapies in patients undergoing liver transplantation is not well understood. This study aims to determine the effect of undergoing locoregional therapy prior to orthotropic liver transplantation on rates of dropout from transplant lists, and survival rates.
Method: This study analyzed data from the UNOS registry spanning January 2002 to January 2024, focusing on patients with HCC who were on the liver transplantation waiting list. Patients were divided according to the type of LRTs they received. A propensity score matched analysis was performed, incorporating covariates such as exemption score, alpha-fetoprotein (AFP) levels, MELD score, Child-Pugh, AlBI score, age, and gender to evaluate the effect of LRT on dropout. Furthermore, an inverse probability of treatment weighting (IPTW) Cox regression was utilized to assess the impact of LRTs on survival outcomes.
Results: The UNOS database had 150,274 patients with HCC listed for liver transplantation. Out of these patients, 117,271 patients were maintained on the list and were granted an exception point for receiving a new liver, while 48,836 have had different types of LRTs. Of the 33,003 patients who did not receive an exception point, 8,411 had received LRTs. Patients who underwent any form of LRTs exhibited a significantly lower risk of dropout from the transplant list (hazard ratio [HR]: 0.783, $P < 0.01$). Among the different types of LRTs, arterial therapies had the most pronounced effect on reducing the likelihood of dropout (HR: 0.756), followed by percutaneous ablative therapies (HR: 0.781) and external beam radiation therapy (HR: 0.84). Survival data post-liver transplantation was available for 24,963 patients who had received LRTs. The findings indicated that LRTs were significantly linked to a lower overall risk of mortality, showing an HR of 0.6 ($P < 0.01$). More specifically, the HRs for survival were 0.38 at 1 year ($P < 0.01$), 0.19 at 5 years ($P < 0.01$), and 0.18 at 10 years ($P < 0.01$). All LRT groups exhibited significant improvements in survival rates, with intra-arterial therapies leading to the most significant decrease in 5-year mortality, followed by percutaneous ablation and external beam radiation therapy (HR: 0.21, HR: 0.22, and HR: 0.24, respectively; all $P < 0.01$).
Conclusion: LRTs result in a significant reduction in dropout rates and improvement in post-transplant survival in patients with HCC. Patients who underwent arterial therapies had the most substantial benefit and lowest dropout rate. Additionally, LRTs were linked to better long-term survival outcomes, especially for intra-arterial therapies, which showed a significant decrease in mortality rates at 1-, 5-, and 10-years following transplantation.

FRI-097
Bridging and long-term impact of pre-orthotopic liver transplant transjugular intrahepatic portosystemic shunt (TIPS) creation: a propensity-matched analysis using the united network for organ sharing (UNOS) database

Mohammad Mirza-Aghazadeh-Attari[1], Peiman Habibollahi[2], Saher Sabri[3], Emil Cohen[3], Nima Kokabi[4], Juan Camacho[5], Pejman Radkani[3], Rohit Satoskar[3], Arul Thomas[3], Bill Majdalany[6], Wael Saad[7], Nariman Nezami[8]. *[1]Johns Hopkins Medical Institute, Baltimore, United States; [2]Department of Interventional Radiology, The University of Texas MD Anderson Cancer Center, Houston, Texas, Houston, United States; [3]Medstar Georgetown University Hospital, Washington DC, United States; [4]University of North Carolina, Chapel Hill, Chapel Hill, United States; [5]Florida State University, Gainesville, United States; [6]University of Vermont, Vermont, United States; [7]University of Utah, Salt Lake City, United States; [8]Division of Vascular and Interventional Radiology, Department of Radiology, MedStar Georgetown University Hospital, Washington, DC, Washington DC, United States*
Email: dr.nezami@gmail.com

Background and aims: Transjugular Intrahepatic Portosystemic Shunt (TIPS) plays a crucial role in bridging patients with portal hypertension and its complications while they await a transplant. However, there is a paucity of evidence regarding the pretransplant bridging and long-term survival effects of TIPS. This study aims to determine the pretransplant bridging and long-term overall survival (OS) effects of TIPS creation in patients undergoing orthotropic liver transplantation (OLT) by performing a propensity-matched analysis.
Method: The UNOS database was retrieved on Jan 2024, containing data from 1992 to 2023. Patients who underwent TIPS prior to liver transplantation were matched to non-TIPS patients using propensity score matching based on key demographic and clinical variables, including age, gender, BMI, hepatocellular carcinoma (HCC) status, and pre-transplant MELD/PELD scores. A Cox proportional hazards regression model was used to assess associations between TIPS placement and survival.
Results: The matched analysis revealed no significant differences between the TIPS and non-TIPS groups in terms of age (mean age: 56.3 years in TIPS vs. 56.2 years in non-TIPS), gender distribution (69% male in both TIPS and non-TIPS), BMI (mean: 28.00 in both TIPS and non-TIPS), or pre-transplant MELD/PELD scores (mean: 23.3 in TIPS vs. 23.2 in non-TIPS). The propensity score distance measure equaled 0.098 in both groups. Among TIPS patients, 11,178 (52.9%) underwent OLT, compared to 153,884 non-TIPS patients, of whom 58.8% underwent OLT. The TIPS patients were significantly more likely to be delisted from OLT waitlist in subsequent follow-ups ($P = 0.01$). A log-rank test performed on delisting data also showed a significant difference between the TIPS and non-TIPS groups ($p = 0.0001$). When focusing only on patients with HCC, 918 (64.8%) of TIPS patients underwent OLT, compared to 14,710 (62.4%) of non-TIPS patients, without statistically significant difference ($P = 0.072$). Sub-analysis of patients with HCC showed no significant difference in OS between TIPS and non-TIPS patients ($p = 0.8$).
Conclusion: Our findings show that while TIPS is essential for managing acute or chronic complications of portal hypertension in cirrhotic patients, liver transplant candidates who undergo TIPS creation are at a higher risk of drop out. TIPS creation in liver transplant candidates may be associated with lower survival rates during long term post-OLT, with the difference being most apparent in 5 year follow up. In patients with HCC, TIPS was not associated with significant differences in overall survival post-OLT. These findings highlight the nuanced impact of TIPS on post-transplant outcomes, emphasizing the need for individualized risk assessment and further

research to refine patient selection criteria for TIPS in the context of liver transplantation.

FRI-098

Nodule US-elastography: enhancing diagnostic and monitoring toolkits for predicting treatment response and prognosis in hepatocellular carcinoma post-TACE

Teodor-Marcel Puiu[1], Letitia Toma[2], Razvan Rababoc[3], Cristian Mugur Grasu[2], Laura Iliescu[3]. [1]*Fundeni Clinic Institute, Bucharest Romania, Carol Davila University of Medicine and Pharmacy, Bucharest Romania, Bucharest, Romania;* [2]*Fundeni Clinical Institute, Bucharest Romania, Carol Davila University of Medicine and Pharmacy, Bucharest Romania, Bucharest, Romania;* [3]*Fundeni Clinical Institute, Bucharest Romania, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania*
Email: dr.teopuiu@gmail.com

Background and aims: Transarterial chemoembolization (TACE) is a minimally invasive procedure primarily used for treating hepatocellular carcinoma (HCC), especially in patients with BCLC stage B. Post-TACE evaluations typically use enhanced CT or MRI after 4–6 weeks to minimize inflammation and artifact interference. However, this delay may hinder early identification of residual tumors in patients with incomplete ablation. This study aims to investigate the potential of US-Elastography (US-E) to predict therapeutic response and recurrence of HCC after TACE by measuring tumor stiffness (TS) before and after treatment.
Method: This prospective cohort study included 108 patients undergoing TACE for solitary HCC. Tumor evaluation included Contrast-Enhanced Ultrasound (CEUS) imaging before TACE, at 3 days post-therapy, and at 1, 3, and 6-month intervals during follow-up. Tumors were classified based on the CEUS LI-RADS TRA 2024 algorithm. US-E was used to assess TS pre-TACE and at 1, 3, and 6 months post-TACE. Nodule size and location, as well as biological markers were also collected. Follow-up lasted for a median of 12 months, with tumor recurrence and survival as primary outcomes. Statistical analyses, including Log-Rank tests and Cox regression, were performed to identify predictors of recurrence and survival.
Results: The average recurrence time after TACE was 7.2 months, and the 1-year overall survival rate was 88.7%. 51.3% of patients had progression-free survival over the 1-year follow-up period. Tumor size and prothrombin time were significant predictors of survival, while AST levels predicted recurrence. US-E measurements indicated an average TS of 41.3 ± 10.8 kPa pre-TACE, reducing to 22.7 ± 8.8 kPa 1 month after TACE. Higher TS levels before and after TACE were associated with lower overall survival rates and shorter progression-free periods. Kaplan-Meier analysis demonstrated marked differences in survival and progression-free survival between high and low TS groups.
Conclusion: US-Elastography provides valuable prognostic information by measuring tumor stiffness in HCC patients treated with TACE. High TS levels correlate with greater recurrence risk and poorer survival outcomes. Additionally, TS measured 1 month post-TACE significantly predicts treatment response and recurrence, suggesting that US-E could serve as a useful tool for early post-treatment evaluation.

FRI-099

Systematic review of stereotactic body radiation therapy (SBRT) for hepatocellular carcinoma with tumor thrombus extension to the inferior vena cava or right atrium

Divya Khosla[1], Treshita Dey[1], Rakesh Kapoor[1], Deepti Sharma[2], Renu Madan[1], Shikha Goyal[1]. [1]*Postgraduate Institute of Medical Education and Research (PGIMER), Chandigarh, India;* [2]*Institute of Liver and Biliary Sciences, New Delhi, India*
Email: dr_divya_khosla@yahoo.com

Background and aims: Hepatocellular carcinoma (HCC) is a leading cause of cancer-related deaths and represents a significant global health challenge. In advanced stages, a subset of patients may develop tumor thrombosis in the inferior vena cava (IVC) with extension into the right atrium (RA), potentially leading to complications such as pulmonary embolism and cardiac tamponade, which can significantly reduce survival. This systematic review aims to assess the efficacy of stereotactic body radiation therapy (SBRT) in managing HCC patients presenting with tumor thrombus involvement of IVC or RA.
Method: As per the SWIM (Synthesis Without Meta-analysis) guidelines, systematic search of PubMed, EMBASE and Cochrane library was performed from inception until Nov 15th, 2024 with manual searches of reference lists to identify articles published in English language using the MeSH terms like 'HCC', 'SBRT', 'tumor thrombus', 'inferior vena cava extension', and 'right atrium' combined with different Boolean operators (and/or). Statistical analysis was done using SPSS version 23. Primary endpoint of survival analysis was done using Kaplan–Meier method. Secondary end point was overall response rates and toxicities. *p*-value <0.05 was considered significant.
Results: Our search yielded a total of 3 case reports and 5 case series with a total of 67 patients. The median age was 68.8 years (range 49–81), predominantly male (83.5%), AFP >400 was noted in 38 patients (56.8%). Due to macrovascular invasion, all patients were BCLC stage C and included patients with Child Pugh A5-B7 (CP-A 77.7%). Median gross tumor volume was 29.8 (24.04–41.19) cc. All patients were treated synchronously for the intrahepatic tumor and right atrial tumor thrombus. All patients received prior therapies (TACE, surgery, TKI etc). The median disease-free survival and overall survival (OS) for all reviewed patients were 9.7 months and 12.2 months, respectively. The OS at 1 year, 2 year, and 3 year was 52.8%, 20.4% and 12.9%, respectively. Complete response was noted in 14 (21%), partial response in 37 (55.1%) and stable disease in 10 (15%) patients. Grade 1 toxicities were noted in almost all patients and grade 2 in 13 (19.5%) patients. No patients experienced grade 3 or higher toxicities or any elevation of myocardial enzymes. Worsening of CP scores by ≥2 points was noted in 3 (2.9%) patients.
Conclusion: This systematic review highlights the potential of SBRT as a feasible and effective treatment option for HCC with tumor thrombus extension to the inferior vena cava or right atrium. The therapy demonstrated encouraging outcomes, with median overall survival reaching 12.2 months and manageable toxicity profiles. Most patients experienced either a partial or complete tumor response, with minimal severe adverse effects or significant hepatic function deterioration. These findings support SBRT as a safe and viable therapeutic approach in this challenging clinical scenario.

FRI-100

Laparoscopic liver resection as a treatment for early-stage hepatocellular carcinoma in patients with and without portal hypertension: a case-control study

Deycies Gaete[1], Alex Saure[1], Alvaro Urzúa[1], Omar Orellana[1], Hans Lembach[1], Carlos Mandiola[1], Jaime Castillo[1], Juan Carlos Diaz[1]. [1]*Hospital Clinico Universidad de Chile, Santiago, Chile*
Email: dey.gaete@gmail.com

Background and aims: Early-stage Hepatocellular Carcinoma (HCC) involves patients with single tumors or up to three nodules, each no larger than 3 cm, preserved liver function, and good performance status. Liver transplantation is the ideal treatment, but it is not universally available. In this context, Laparoscopic Liver Resection (LLR) offers comparable outcomes and is recommended for patients with a Hepatic Venous Pressure Gradient (HVPG) <10 mmHg, i.e., without clinically significant portal hypertension (CSPH). However, no definitive HVPG cutoff contraindicating LLR exists. This study aimed to compare perioperative and short-term outcomes of LLR in cirrhotic patients with early-stage HCC, with and without CSPH.
Method: This retrospective case-control study included 40 cirrhotic patients with early-stage HCC who underwent LLR between 2016 and

2023 at a university hospital. Clinical and demographic variables, indirect signs of portal hypertension, and HVPG were recorded. Patients were divided into two groups based on the presence or absence of CSPH (HVPG > 10 mmHg or clinical signs of portal hypertension). The non-CSPH group included 15 patients (37.5%), and the CSPH group included 25 patients (62.5%), with a median HVPG of 16 mmHg (range: 11–26). The median follow-up was 25 months (range: 2–89 months). Perioperative variables and outcomes up to 90 days post-surgery, as well as clinical follow-up data, were compared. Fisher's exact test and Kaplan-Meier survival analysis with the log-rank test were used for statistical analysis. A p-value <0.05 was considered statistically significant.

Results: There were no differences in baseline characteristics or preoperative tumor size between the groups. A total of 78% of LLRs were anatomical segmentectomies. Four hemi-hepatectomies were performed in the non-CSPH group, while only segmentectomies were performed in the CSPH group. Intraoperative variables, including blood loss, transfusion requirements, operative time, use of the Pringle maneuver, and conversion to laparotomy rates, showed no significant differences. No 90-day mortality was observed, and severe morbidity rates were comparable between groups (Clavien-Dindo ≥III: 7% in non-CSPH vs. 8% in CSPH). Similarly, no significant differences were found in postoperative rates of ascites (13.3% vs. 24%), post-hepatectomy liver failure (13.3% vs. 0%), encephalopathy (0 vs. 4%), postoperative hepatic decompensation (20% in both groups), or pulmonary or abdominal infections. The median ICU stay was 4 days for both groups. Positive surgical margins (R1) were also similar (7% in non-CSPH vs. 12.5%). Overall survival rates at 1 and 3 years were 100% and 78%, respectively, with no significant differences between groups (p = 0.1448).

Conclusion: In cirrhotic patients with CSPH, early postoperative outcomes and short-term overall survival were comparable to those in cirrhotic patients without CSPH at our center.

FRI-101

Viral etiology of hepatocellular carcinoma as an independent determinant of survival for patients receiving tyrosine kinase inhibitor treatment

Lu Li[1], Matthew Shing Hin Chung[1], Rex Wan-Hin Hui[1], Xianhua Mao[1], CL Chiang[1], Man-Fung Yuen[1], Lung-Yi Mak[1], Wai-Kay Seto[1].
[1]Department of Medicine, The University of Hong Kong, Hong Kong, China
Email: ellie825@connect.hku.hk

Background and aims: Increasing evidence indicate the etiology of hepatocellular carcinoma (HCC) influencing response to systemic therapy. Tyrosine kinase inhibiors (TKIs) play a key role in systemic therapy of HCC; however, studies exploring the effect of HCC etiology on TKI treatment outcomes are limited. We aim to investigate whether viral etiology impacts the therapeutic response to TKIs.

Method: We identified HCC patients treated with TKIs (sorafenib, lenvatinib, cabozantinib, regorafenib) from January 2008 to June 2024 from a population-wide registry in Hong Kong. Virus-related HCC was defined as patients with any virological or serological evidence of hepatitis B virus (HBV) or hepatitis C virus (HCV) infection, including a positive hepatitis B surface antigen, detectable HBV DNA or positive antibody to HCV (anti-HCV). Propensity score matching (PSM) in a 2:1 ratio for viral vs non-viral HCC was applied to match for age, gender, presence of type 2 diabetes (T2D), prior oncological therapies & metastatic status. The primary outcome was overall survival (OS) stratified by etiology of HCC (viral vs non-viral) in the propensity score matched population; secondary outcomes included subgroup analysis of OS stratified by viral types (HBV & HCV), TKI types, prior oncological therapies (curative & non-curative), age groups (≥65 & <65 years), and the presence or absence of T2D. The OS outcomes were evaluated using the Kaplan–Meier method and adjusted hazard ratios (HRs) were calculated using the Cox proportional hazards model.

Results: Among 2,995 HCC patients receiving TKI treatment, 2,434 (81.3%) patients were identified as virus-related HCC (90.4% HBV, 9.1% HCV, 0.5% co-infection); 561 patients (18.7%) were non-viral HCC. After 2:1 PSM, 1,074 viral HCC & 537 non-viral HCC were included. Kaplan-Meier analysis showed virus-related HCC, when compared to non-viral HCC, had worse OS (median 6.6 vs 7.0 months, p < 0.001) & higher risk of all-cause death (HR 1.23; 95% CI 1.10–1.38; p < 0.001). Subgroup analysis of HBV-related HCC showed similar findings, with a worse OS (median 6.6 vs 6.9 months, p < 0.001) & a 26% increased risk of all-cause death (HR 1.26; 95% CI 1.13–1.41; p < 0.001), as compared to non-viral HCC. Among patients receiving lenvatinib, a significantly better OS was observed in non-viral HCC versus viral HCC (median 10.0 vs 8.2 months, p = 0.02). Similar results were observed in patients receiving prior non-curative therapy (median 10.0 vs. 8.1 months, p = 0.014), patients <65 years (median 5.7 vs. 5.1 months, p < 0.001), patients with T2D (median 7.3 vs 7.2 months, p = 0.038) & patients without T2D (median 6.1 vs. 5.8 months, p = 0.0047).

Conclusion: Non-viral HCC patients receiving TKI treatment had significantly better OS when compared to viral HCC. The presence of a viral etiology may impact management decisions on the choice of first-line systemic therapy for advanced HCC.

FRI-102

Selective internal radiation therapy (SIRT) for HCC: real-world experience from a tertiary care center

Ilkay Ergenc[1], Maria Guerra Veloz[1], Matthew Seager[2], Neil Heraghty[3], Nabil Kibriya[2], Jonathan Green[2], Sarah Selemani[4], Krishna Menon[4], Rosa Miquel[4], Paul Ross[5], Praveen Peddu[2], Abid Suddle[4]. *[1]Institute of Liver Studies, King's College Hospital, London, United Kingdom; [2]Department of Radiology, Institute of Liver Studies, King's College Hospital, London, United Kingdom; [3]Department of Nuclear Medicine, King's College Hospital, London, United Kingdom; [4]Institute of Liver Studies, King's College Hospital, London, United Kingdom; [5]Medical Oncology, Institute of Liver Studies, King's College Hospital, London, United Kingdom*
Email: ergencilkay@gmail.com

Background and aims: Selective internal radiation therapy (SIRT) with yttrium-90 is an endovascular treatment modality for patients with HCC across various clinical stages. The aims of study were to evaluate safety, tumour response and overall survival (OS) of SIRT in patients with HCC across the spectrum of the cancer stage.

Method: Patients treated with SIRT between February 2019 and September 2023 at King's College Hospital were retrospectively included from a prospective database. Demographic data and clinical details, prior and subsequent therapies, and adverse events, were collected. Tumour response was assessed by two experienced HPB radiologists independently using mRECIST criteria at 6 and 9 months post-procedure. OS was calculated from treatment to death or last visit.

Results: Fifty-six patients were identified, 87.5% male, with a median age of 68 years (IQR 61–75). The majority had cirrhosis (64%) with the most frequent underlying aetiologies of viral hepatitis (33.9%). For those who progressed to delivery of SIRT (n = 49) the median follow-up time was 24.5 (SD ± 14.4) months. Most patients were BCLC stage A (27, 54%), followed by stage B (32%) and stage C (14%), with 57% of the stage C patients having Vp3-4 involvement. The median number of tumours was 1 (IQR 1–2), with a median size of 7 cm (IQR 4.8–10.3). SIRT was the initial treatment in 68% of patients. By mRECIST criteria at 6 months, 18% achieved complete response (CR), 46% partial response (PR), 16% stable disease (SD), and 16% progressive disease (PD). At 9 months, 12% maintained CR, 32% PR, 6% SD, and 6% progressed further. Among patients with cancer progression, the

median time to progression was 9 months (IQR 3–14). Mean OS was 44.3 months (95% CI 34–53) for BCLC A, 32.5 months (95% CI 25–40) for BCLC B, and 32 months (95% CI 17–47) for BCLC C (log-rank p = 0.733). In patients who did not receive radical treatments post-SIRT, OS was 32 months (95% CI 20–44), 30.2 months (95% CI 22–39), and 32 months (95% CI 17–47) for BCLC A, B, and C, respectively (log-rank p = 0.822). Following SIRT, radical treatments were provided to 28% of patients, including 4 liver transplants and 10 resections, with 11 patients at BCLC stage A and 3 at BCLC stage B. Histological regression rates were as follows: 100% in two patients, > 90% in two, 50–90% in four, and 30–50% in five patients. Adverse events occurred in 19.6% (n = 11) of patients, including two arterial dissections, one pulmonary embolism, one right-sided portal vein thrombosis, three cases of decompensation with ascites, one case of radiation-induced liver injury, as well as a hypertensive crisis and atrial flutter with chest pain.

Conclusion: SIRT is a safe and effective treatment modality for HCC across various stages. We observed promising radiological response rates at 6–9 months, particularly for large lesions, whether used as a primary treatment or as part of a down staging strategy for curative interventions.

FRI-103

Prognosis of patients undergoing curative surgery for combined hepatocellular-choloangiocarcinoma

Eung-Ho Cho[1], Jung Hoon Lee[2], Sang Bum Kim[1]. *[1]Korea Cancer Center Hospital, Seoul, Korea, Rep. of South; [2]Asan medical center, Seoul, Korea, Rep. of South*
Email: gsceh@kcch.re.kr

Background and aims: Combined hepatocellular and cholangiocarcinoma(cHCC-CC) is one of the primary cancers that occur in the liver. Its prognosis has been compared to hepatocellular carcinoma (HCC) or intrahepatic cholangiocarcinoma(ICC), but the results are yet controversial. We analyzed the prognosis of cHCC-CC and compared to HCC and ICC at single center.

Method: The numbers of patients who underwent curative liver resections from April 1992 to January 2022 were 844 for HCC, 78 for ICC, and 26 for cHCC-CC in KCCH Seoul, South Korea. We retrospectively analyzed these three groups of patients. We used inverted probability treatment of weighting analysis (IPTW) to compare the prognoses of three groups of patients.

Results: After IPTW analysis, five-year overall survival of the HCC group, the ICC group, and the cHCC-CC group as 72% vs 85% vs 50% respectively (p = 0.025). Five-year recurrence free survival of the HCC group, the ICC group, and the cHCC-CC group as 46% vs 74% vs 42% respectively (p = 0.151).

Conclusion: cHCC-CC shows worst prognosis and survival among three groups. However, because of small sample size and limitations of retrospective study, additional large scale prospective studies are necessary.

FRI-104

Sorafenib plus transarterial chemoembolization versus sorafenib alone in advanced hepatocellular carcinoma (SELECT): a multicenter, phase 3, randomized, controlled trial

Yan Zhao[1], Wei Bai[1], Rong Ding[2], Nan You[3], Lin Zheng[4], Lei Li[5], Jianbing Wu[6], Peng Zhang[7], Wukui Huang[8], Hui Zhang[9], Yongjin Zhang[10], Diwen Zhu[11], Haiping Li[12], Jie Yuan[1], Dongdong Xia[1], Zhanxin Yin[1], Yong Lv[13], Guohong Han[14]. *[1]Department of Liver Diseases and Interventional Radiology, Digestive Diseases Hospital, Xi'an International Medical Center Hospital, Xi'an, China; [2]Yunan Cancer Hospital, Kunming, China; [3]Xinqiao Hospital, Third Military Medical University, Chongqing, China; [4]Henan Cancer Hospital, Affiliated Cancer Hospital of Zhengzhou University, Zhengzhou, China; [5]First Affiliated Hospital of Lanzhou University, Lanzhou, China; [6]Second Affiliated Hospital of Nanchang University, Nanchang, China; [7]Affiliated Hospital of Qinghai University, Xining, China; [8]Affiliated Tumor Hospital of Xinjiang Medical University, Urumqi, China; [9]Southwest Hospital, Third Military Medical University, Chongqing, China; [10]Department of Interventional Radiology and Vascular Surgery, Hunan Provincial People's Hospital, Changsha, China; [11]Department of Interventional Radiology, First Affiliated Hospital of Xinjiang Medical University, Urumqi, China; [12]Department of Radiology, Xiangya Hospital, Central South University, Changsha, China; [13]National Clinical Research Centre for Digestive Disease, Xijing Hospital of Digestive Diseases, Fourth Military Medical University, Xi'an, China; [14]Department of Liver Diseases and Interventional Radiology, Digestive Diseases Hospital, Xi'an International Medical Center Hospital, National Clinical Research Centre for Digestive Disease, Xijing Hospital of Digestive Diseases, Fourth Military Medical University, Xi'an, China*
Email: yanzhao211@163.com

Background and aims: Hepatocellular carcinoma (HCC) is the third-leading cause of cancer-related mortality, with a particularly poor prognosis for advanced-stage disease (Barcelona Clinic Liver Cancer stage C). This study aimed to assess the efficacy of sorafenib combined with transarterial chemoembolization (TACE) in patients with advanced HCC.

Method: SELECT was a randomized, multi-centre, controlled, phase 3 trial done at twelve centres in China. Eligible patients were aged 18 years or older and had advanced-stage HCC, Barcelona Clinic Liver Cancer stage C diseases, Child-Pugh class A liver disease. Participants were randomly assigned (1:1) with a computer-generated random sequence to sorafenib combined with transarterial chemoembolization or sorafenib alone. The primary endpoint was overall survival. Secondary endpoints were time to progression, tumor response rate, disease control rate and safety. Efficacy was analyzed in the intention-to-treat, per-protocol and as-treated populations. Safety outcomes were analyzed in the safety population. This trial is registered with ClinicalTrials.gov, number NCT01906216.

Results: Between September 7, 2013 and Dec 4, 2019, 199 patients were randomly assigned, 99 to the combination group and 100 to the sorafenib alone group. Hepatic virus infection was the predominant cause of HCC. At a median follow-up of 13.6 months (IQR 6.8–28.2), in the intention-to-treat population, median overall survival was 14.9 months (95%CI 10.5–19.3 months) in the combination group versus 11.9 months (95%CI 9.0–14.8 months) in the sorafenib alone group (HR 0.862 [95%CI 0.645–1.150]; P = 0.312). Median time to progression survival was significantly longer in the combination group than the sorafenib alone group (10.0 months [95%CI 6.4–13.6 months] vs 5.9 months [95%CI 3.1–8.7 months]; HR 0.686 [95%CI 0.515–0.954]; P = 0.016). In the per-protocol population, the median overall survival in the combination group was significantly longer than that in the sorafenib monotherapy group (HR 0.539 [95%CI 0.378–0.769]; P = 0.001). In the as-treated population, the median overall survival was also significantly longer in the combination group than in the sorafenib monotherapy group (16.9 months [95%CI 13.4–20.4] versus 9.5 months [95%CI 6.5–12.5]; HR 0.576 [95%CI 0.420–0.789]; P = 0.001). The time to progression was significantly improved in the combination group compared with sorafenib alone group in both the per-protocol and as-treated analyses. The overall incidence of adverse events was similar between the two groups.

Conclusion: Sorafenib combined with TACE improved survival in the per-protocol population but not in the intention-to-treat population. The significance of overall survival when combing systemic therapy with locoregional treatment for managing of advanced-stage HCC warrants further investigation.

Evolutionary learning-derived multimodal models integrating comprehensive imaging features to predict early recurrence of hepatocellular carcinoma after curative resection

I-Cheng Lee[1], Hao-Cyuan Chu[2], Rex Wan-Hin Hui[3], Wai-Kay Seto[3], Shinn-Ying Ho[2], Yi-Hsiang Huang[1]. *[1]Taipei Veterans General Hospital, National Yang Ming Chiao Tung University, Taipei, Taiwan; [2]National*

Yang Ming Chiao Tung University, Hsinchu, Taiwan; [3]The University of Hong Kong, Hong Kong, Hong Kong, Hong Kong
Email: iclee@vghtpe.gov.tw

Background and aims: The accuracy of existing models for predicting early recurrence of hepatocellular carcinoma (HCC) after curative resection remains suboptimal. This study aimed to develop artificial intelligence-based multimodal models to enhance predictive accuracy by incorporating a larger dataset and integrating comprehensive imaging features.
Method: This study enrolled patients with HCC who underwent curative resection with complete clinical data (clinical cohort, n = 1477), complete dynamic CT images (clinical-image cohort, n = 588), and an external validation cohort from Hong Kong (n = 122). Patients were randomly assigned to training and test sets in a 7:3 ratio. Multimodal imaging features, including radiomics, 3D geometric properties, tumor morphology, and deep learning-derived latent features, were analyzed. Two evolutionary learning-based models, EL-CERSL (clinical features only) and EL-MERSL (clinical and imaging features), were developed to predict early recurrence of HCC within 2 years post-resection.
Results: The EL-CERSL and EL-MERSL models provided personalized predictions of 2-year recurrence-free survival (RFS). In the test set, the area under the receiver operating characteristic curves (AUCs) for EL-CERSL-preoperative, EL-CERSL-postoperative, EL-MERSL-preoperative, and EL-MERSL-postoperative models were 0.791, 0.774, 0.857, and 0.861, respectively, significantly outperforming the ERASL-pre and ERASL-post models (AUCs 0.733 and 0.747) and high-risk criteria from IMBrave050, KEYNOTE-937, EMERALD-2, and CheckMate-9DX trials (AUCs 0.607, 0.622, 0.643, and 0.543, respectively). In the external validation cohort, the AUCs of the EL-MERSL-preoperative and EL-MERSL-postoperative models were 0.801 and 0.808, respectively. Among IMBrave050-defined high-risk patients, the EL-MERSL-postoperative model classified 72.4% as low-risk and 27.6% as high-risk, with corresponding 2-year RFS rates of 70.2% and 20.6%, respectively.
Conclusion: The EL-CERSL and EL-MERSL models demonstrated significantly improved accuracy in predicting early HCC recurrence after resection. These models hold potential for guiding post-resection surveillance strategies and optimizing clinical trial designs by identifying high-risk candidates for adjuvant therapies.

FRI-106
Real-world treatment patterns and survival outcomes in patients with unresectable hepatocellular carcinoma (uHCC): the OREIOS - Middle East and North Africa (MENA) cohort

Ashwaq Alolayan[1], Faisal M. Sanai[2], Amr Abdel-Aziz[3], Ali Alfakeeh[4], Ali Alzahrani[5], Samir Shehata[6], Jasem AlBarrak[7], Gamal Esmat[8], Itrat Mehdi[9], Diaeddine Trad[10], Adnan Alzanbagi[11], Heba Farag[12], Ahmed Aboutaleb[12], Imam Waked[13]. *[1]National Guard, Riyadh, Saudi Arabia; [2]King Abdulaziz Medical City, Jeddah, Saudi Arabia; [3]Alexandria University, Alexandria, Egypt; [4]King Fahad Medical City, Riyadh, Egypt; [5]King Fahad Medical City, Riyadh, Saudi Arabia; [6]Assiut University, Assiut, Egypt; [7]Kuwait Cancer Control Center, Kuwait, Kuwait; [8]Cairo University, Cairo, Egypt; [9]Royal Hospital, Muscat, Oman; [10]Tawam Hospital, Abu Dhabi, United Arab Emirates; [11]King Abdullah Medical City, Makkah, Saudi Arabia; [12]AstraZeneca, Cairo, Egypt; [13]National Liver Institute - Menoufia University, Menoufia, Egypt*
Email: iwaked@liver-eg.org

Background and aims: With evolving systemic treatment (Tx) options for uHCC, OREIOS (NCT05239507) study was conducted to determine the Tx patterns and survival outcomes in patients (pts) with uHCC across Asia, Latin America and MENA.
Method: The MENA cohort of this non-interventional, retrospective study enrolled pts with unresectable Barcelona Clinic Liver Cancer (BCLC) (stage B or C advanced/metastatic HCC from Egypt, Kuwait, Oman, Saudi Arabia, and United Arab Emirates) during Jan 2017–Dec 2019. The primary endpoints were median overall survival (mOS) and survival rates at 12 and 24 months (m).
Results: Of 216 pts enrolled (median [range] age: 64.0 [35.0–97.0] yrs), 78.2% (169/216) were males, and 33.1% (52/157) were current/ex-smokers. The most common etiology was hepatitis C (54.5%, 114/209). At the index date (date of diagnosis of unresectable or advanced/metastatic HCC), most (70.8%, 153/216) pts had BCLC stage C with main portal vein invasion in 26.4% (57/216), > 50% liver involvement in 47.7% (103/216) and extrahepatic metastases in 40.7% (88/216). After index date, 8.4% (18/215) received loco-regional Tx and 13.4% (29/216) received transarterial chemoembolization (TACE). Majority (85.1% 126/148) received sorafenib in 1st line (1L) Tx; 15.3% (33/216) pts received 2nd line (2L) Tx, mainly nivolumab (57.6%, 19/33). The mOS (95% CI) of overall cohort was 14.2 (11.5–18.6) m, with OS rate of 55.4% at 12 m and 35.2% at 24 m. The mOS for BCLC B (N = 63) and BCLC C (N = 153) were 23.5 (18.6–27.9) m and 9.9 (8.0–14.1) m with 12 m OS rate of 74.6% and 47.4% and 24 m OS rate of 48.1% and 29.9%, respectively. The mOS (95% CI) for pts receiving tyrosine kinase inhibitors (TKIs; N = 135), immune checkpoint inhibitors (ICIs; N = 30), vascular endothelial growth factor (VEGF/VEGFR2) inhibitors (N = 4), and TACE (post index date) (N = 29) were 13.2 (8.7–18.3) m, 18.8 (10.7–27.9) m, 31.0 (25.2 – NA) m and 18.5 (13.2 – NA) m, with 12 m OS rate of 50.1%, 66.7%, 71.4%, 100% and 24 m OS rate of 33.5%, 40.0%, 100% and 48.6%, respectively. The median progression-free survival (mPFS) (95% CI) for overall was 9.1 (7.2–13.3) m, for pts with BCLC B was 9.0 (6.9–13.7) m and for BCLC C 9.7 (6.7–14.4) m and for pts receiving TKIs, ICIs, and VEGF/VEGFR2 inhibitors were 6.7 (4.8–8.9) m, 4.8 (3.2–8.1) m, and 3.6 (0.5–NA) m, respectively. BCLC stage B, alpha-fetoprotein level <400 ng/mL, Tx line, TKIs and ICIs were significantly ($p < 0.01$) associated with reduced risk of death whereas albumin level ≤4 g/dL, performance status >1 and portal vein invasion were significantly ($p < 0.05$) associated with increased risk of death.
Conclusion: In the OREIOS-MENA cohort, sorafenib was the most common Tx in 1L; however, only 15.3% received 2LTx. A mOS of about 14 m indicates the need for integration of optimum Tx strategies with novel agents and combination therapies in routine care to improve prognosis.

FRI-111
The role of immune cell composition potentially predicts response to atezolizumab plus bevacizumab in patients with advanced hepatocellular carcinoma

Jana Knorr-Klocke[1], Marlene Kohlhepp[1], Fabian Artusa[1], Frank Tacke[1], Tobias Puengel[1], Alexander Wree[1], Raphael Mohr[1]. *[1]Department of Hepatology and Gastroenterology, Campus Charité Mitte | Campus Virchow-Klinikum, Charité - Universitätsmedizin Berlin, Berlin, Germany*
Email: jana.knorr@charite.de

Background and aims: Hepatocellular carcinoma (HCC) is one of the leading causes of cancer-related death worldwide with limited therapeutic options especially at advanced stages. Recently, immune checkpoint inhibitors have shown remarkable efficacy in various kinds of solid cancers. The combination of atezolizumab plus bevacizumab is a first-line treatment in patients with advanced HCC, but is only effective in 30% of patients. Therefore, we elucidate the heterogeneity and plasticity of the various immune cell subsets in the course of checkpoint inhibitor-based treatment regimens in order to predict treatment responses and potentially identify optimal therapy candidates.
Method: We evaluated 98 patients with unresectable HCC, who received atezolizumab plus bevacizumab at our center (outpatient clinic of Charité - Universitätsmedizin Berlin) between April 2021 and March 2023 as first line therapy. We established a 27-color full spectrum flow cytometry panel in order to analyze blood-circulating, peripheral immune cell populations including checkpoint expression patterns and activation markers. Flow cytometry was performed

consecutively upon treatment application within the first three months and later on every three months at the timepoint of tumor staging. The correlation between the various immune cell populations and overall survival (OS) as well as progression-free survival (PFS) was statistically determined. Multiplex immunostainings on corresponding liver biopsies taken before therapy will additionally provide spatial and functional information.

Results: Immune-associated biomarkers like the expression of programmed cell death-ligand 1 (PD-L1) that correlate with therapeutic response in other solid tumors are not suitable for HCC. Interestingly, patients with a low number of neutrophils and low inflammatory marker show a better response and OS. In addition, the number of lymphocytes, especially of activated (CD25+ and HLA-DR+) T cells and their changes during therapy affected treatment responses. Differences between etiologies and therapeutic response or OS were not observed.

Conclusion: The peripheral immune cell composition and their changes during therapy with atezolizumab plus bevacizumab may serve as predictor checkpoint inhibitor-based treatment responses in patients with unresectable HCC.

FRI-112

Local control and survival after stereotactic body radiotherapy for hepatocellular carcinoma without macrovascular invasion

Email: josepaulmmc@gmail.com

Background and aims: Emerging evidence supports the use of stereotactic body radiotherapy (SBRT) in hepatocellular carcinoma (HCC). Existing literature is mainly from North America/East Asia where the etiology is predominantly viral. The study analyses the outcomes of SBRT in our HCC patients without macrovascular invasion (MVI).

Method: Patients diagnosed to have HCC without MVI who underwent SBRT at our institution between 1st December 2019 and 30th June 2024 were evaluated. Patients with extrahepatic disease, prior rupture and more than 6 parenchymal lesions were excluded. Primary outcome of interest was local control. Overall survival (OS), Progression free survival (PFS) and adverse events (AE) were secondary end points.

Results: This retrospective study included 188 patients of whom 175 were eligible for analysis. Total number of lesions was 358. The Cohort was predominantly male (90%), non-viral (96.5%) with a median age of 68 years (44–87). Forty one (23.4%) patients received prior liver directed local treatment. Baseline Child Pugh Score (CPS) was A5/A6 in 58.8%, B7/B8/B9 in 36% and C10/C11 in 5.1%. Baseline albumin-bilirubin (ALBI) grade was 1 in 25.7%, 2 in 59.4% and 3 in 14.8% patients. Multiple HCCs were present in 44.5% patients. Median serum alpha fetoprotein (AFP) was 15 ng/ml (1–6389). Median size of largest lesion on a per patient basis was 4.2 cm (1.5–14). Median tumor size as a sum of all lesions per patient was 5.9 cm. Median gross tumor volume (GTV) was 42cc (1–900) while median total liver volume was 1208 cc. Median prescription dose was 35 Gray (Gy) in 5 fractions (27.5–50 Gy). Median value of mean uninvolved liver (liver-GTV) dose was 9.67 Gy. At the last follow-up (FU), 93 patients were alive. At a median FU of 16 months, the median OS was 24 months for the entire cohort. Median PFS was 17.6 months. Median OS for CPS A5/A6 patients was not yet reached. Median OS was 13.8 months for CPS B7/B8/B9 patients. Median OS for BCLC 0/A patients was not yet reached. Median OS for BCLC B patients was 24 months while median OS for BCLC C/D patients was 11.7 months. Local progression occurred in 18(10.2%) patients amounting to 28(7.8%) lesions. CPS decline >2 points in the absence of intrahepatic tumor progression occurred in 8.5% patients while ALBI grade declined in 19% patients. SBRT related gastrointestinal bleed occurred in 5 patients while one patient had a biliary stricture.

Conclusion: SBRT gives high rates of local control and comparable survival with acceptable AE profile despite significant number of patients with multiple lesions and relatively worse CPS in comparison to existing literature. Results from our large, mainly non-viral cohort, support the use of SBRT as an alternative to other local treatments in HCC patients without MVI.

FRI-113

Clinical outcomes of stereotactic body radiotherapy for hepatocellular carcinoma with macrovascular invasion in a predominantly non-viral cohort

Email: josepaulmmc@gmail.com

Background and aims: Non-viral etiology predominates Hepatocellular carcinoma(HCC) patients in our region distinct from North American/East Asian cohorts and is a minority in existing literature on Stereotactic Body Radiotherapy (SBRT) for HCC with macrovascular invasion (MVI). Aim of the study is to report clinical outcomes of SBRT in a large cohort of patients with HCC and MVI treated at our institution.

Method: Patients diagnosed to have HCC with MVI who underwent SBRT at our institution between 1st December 2019 and 30th June 2024 were evaluated. Patients with extrahepatic disease, retroviral infection, prior rupture and active second malignancy were excluded.

Primary outcome of interest was overall survival (OS). Progression free survival(PFS) and adverse events were secondary outcomes.
Results: The retrospective study included 112 patients of which 103 were eligible for analysis. Cohort was predominantly male (92%), non-viral (96.2%) with median age of 66 yrs. Baseline Child Pugh Score (CPS) was A5/A6 in 65%, B7 in 14.5% and B8 or higher in 20.5%. Baseline albumin-bilirubin(ALBI) grade was 1 in 21.3%, 2 in 63.1% and 3 in 15.5% patients. Degree of MVI was vp1/2 in 17.4%, vp3 in 29.1%, vp4 in 44.6% and hepatic vein or vena cava in 8.7%. Multiple HCCs were present in 47% patients. Median alpha fetoprotein (AFP) was 444 ng/ml. Median tumor size was 9 cm. Median gross tumor volume (GTV) was 348cc. Median total liver volume was 1407cc. Median prescription dose was 33 Gray(Gy) in 5 fractions. Median value of mean uninvolved liver dose was 14.18 Gy. At last follow-up (FU) 20 patients were alive. At a median FU of 12 months, median OS was 13.5 months for entire cohort, 14.8 months for CPS A5/A6 patients and 13.8 months for CPS A5/A6 patients with vp4 MVI. Median PFS was 6.6 months. Local progression occurred in 20 patients. CPS decline >2 points in absence of intrahepatic tumor progression occurred in 16.5% patients while ALBI grade declined in 31.5% patients. SBRT related gastrointestinal bleed occurred in 4 patients. On univariate analysis better CPS, ALBI Grade, lower mean dose to uninvolved liver, higher dose to GTV was significantly associated with better OS. On multivariate analysis only lower mean dose to uninvolved liver retained significance.
Conclusion: In our predominantly non-viral patient cohort, good clinical outcomes were obtained despite limited access to immunotherapy (IO), larger tumors, high median AFP and worse CPS. Median OS of 13.8 months in patients with CPS A and vp4 MVI far exceeds the reported survival for same subset in existing literature. Results from our large cohort adds to evidence for SBRT in HCC with MVI patients more so in non-viral etiology where inferior outcomes with IO have been reported. Patients with larger tumors in terms of size and tumor volume relative to liver volume than mostly reported can be treated with comparable degree of safety using appropriately tailored dose.

FRI-114

Liver resection versus trans-arterial chemoembolization for huge hepatocellular carcinoma (>10 cm): a nationwide propensity score adjusted analysis

Jai Young Cho[1], Boram Lee[1], Hae Won Lee[1]. [1]*Seoul National University Bundang Hospital, Seoul National University College of Medicine, Seoul, Korea, Rep. of South*
Email: jychogs@gmail.com

Background and aims: The treatment of hepatocellular carcinoma (HCC) >10 cm remains controversial. The ongoing debate regarding the treatment of patients with HCC > 10 cm is partly due to the necessity of tailoring treatment to individual patient conditions. This study aims to address the important controversy regarding the management of large HCC, focusing on providing insights into the comparative effectiveness of liver resection (LR) and Transarterial Chemoembolization (TACE).
Method: Patients registered in the Korean Primary Liver Cancer Registry (KPLCR) were selected. The KPLCR is a random sample consisting of approximately 15% of patients newly diagnosed with primary liver cancer registered in the Korean Central Cancer Registry (KCCR), which is a nationwide cancer registry and includes more than 95% of all cancer cases in Korea. The study design utilizes data from the KPLCR covering the years 2008 to 2017 to investigate the treatment outcomes for HCC larger than 10 cm. Starting with 15,307 cases, the study identified 9,310 HCC patients with follow-up data, excluding those with missing initial treatment data (n = 5,863) and follow-up loss (n = 132). From these, 7,662 patients with single HCC were selected, further excluding cases with multiple HCC (n = 1,394) and distant metastasis (n = 254). This refined the cohort to 504 patients with HCC tumors larger than 10 cm, who were then divided into two treatment groups: 122 patients underwent liver resection (LR), and 382 patients received TACE.
Results: After PSM, the baseline characteristics showed no significant differences between the LR group (n = 99) and the TACE group (n = 99). Before propensity score matching (PSM), the hazard ratio (HR) for LR was 3.41 (95% CI: 2.62–4.43, $p < 0.001$), indicating a significantly better survival probability for the LR group compared to the TACE group. After PSM, the HR for LR was slightly reduced to 3.06 (95% CI: 2.18–4.29, $p < 0.001$), but the survival advantage of LR over TACE remained highly significant. Before PSM, the HR for LR was 3.29 (95% CI: 2.59–4.17, $p < 0.001$), indicating a markedly better recurrence-free survival (RFS) for the LR group compared to the TACE group. After PSM, the HR for LR increased slightly to 3.37 (95% CI: 2.43–4.68, $p < 0.001$), maintaining the significant survival advantage of LR over TACE.
Conclusion: This study provides a comprehensive analysis of treatment outcomes for HCC > 10 cm, comparing LR and TACE using data from the KPLCR. The results indicate that LR is associated with significantly better OS and RFS compared to TACE, both before and after PSM.

FRI-115

Improving outcomes in unresectable hepatocellular carcinoma through proactive adverse event management with Atezolizumab-Bevacizumab therapy

Jeayeon Park[1], Dong Ho Lee[1], Moon Haeng Hur[1], Yun Bin Lee, Eun Ju Cho[1], Jeong-Hoon Lee[1], Yoon Jun Kim[1], Jung-Hwan Yoon[1], Su Jong Yu[1]. [1]*Seoul National University Hospital, Seoul, Korea, Rep. of South*
Email: ydoctor2@snu.ac.kr

Background and aims: Since the success of IMbrave 150 and HIMALAYA trial, immune checkpoint inhibitors (ICIs) have become the first line systemic treatment for unresectable hepatocellular carcinoma (HCC). Recent studies also suggest that immune-related adverse events (irAEs) may enhance ICI efficacy and improve clinical outcomes. However, comprehensive evaluation of relationship between adverse event during the treatment and clinical outcome is still under investigation. Therefore, this study aims to comprehensively evaluate the clinical impact of adverse events during the atezolizumab plus bevacizumab for unresectable HCC patients on the clinical outcome.
Method: Consecutive patients treated with atezolizumab plus bevacizumab as first-line therapy for unresectable HCC were retrospectively reviewed. IrAEs and bevacizumab-related adverse events were evaluated using the National Cancer Institute's Common Terminology Criteria for Adverse Events, version 5.0. In addition, all imaging studies obtained during the treatment course were reviewed to detect any imaging findings related to immune adverse reaction. The primary endpoint was the overall survival (OS), and the secondary endpoints was disease control rate (DCR).
Results: Among 198 enrolled patients, 12 had irAEs identified solely through computed tomography (asymptomatic imaging-detected adverse events group), while 56 experienced clinical symptoms of either irAEs (n = 28), bevacizumab-related adverse events (n = 19) or both (n = 9) (symptomatic adverse events group). The overall survival rate at 6, 12, 18, and 24 months were 100.0%, 82.5%, 82.5%, and 82.5% for asymptomatic AE group, 89.1%, 64.1%, 41.7%, and 40.5% for symptomatic AE group, and 72.3%, 48.3%, 31.3%, and 19.4% for no AE group, respectively. OS was significantly improved in both the asymptomatic and symptomatic AE groups compared to the no AE group (hazard ratio [HR]: 0.15, 95% confidence interval [CI]: 0.03–0.65, P = 0.01 for the asymptomatic AE group; and HR: 0.60, 95% CI: 0.40–0.89, P = 0.01 for the symptomatic AE group, both adjusted by inverse probability of treatment weighting). The DCR was significantly higher in the asymptomatic AE group (100.0%) and the symptomatic AE group (91.8%) compared to the no AE group (60.0%) (P < 0.001).

Conclusion: The occurrence of adverse events related to atezolizumab and bevacizumab in patients with advanced HCC, when appropriately managed, significantly improves OS and treatment response. Furthermore, as asymptomatic imaging-detected irAEs may serve as favorable prognostic factors, proactive detection through imaging studies could be beneficial.

FRI-116

The changing epidemiology of patients with HCC receiving a first-line systemic therapy: insights from ARPES and ARTE databases (2008–2024)

Email: francesco.tovoli@unibo.it

Background and aims: The epidemiological characteristics of patients starting first-line systemic therapy for hepatocellular carcinoma (HCC) have changed over time. This study examines shifts in demographics and disease profiles since the first systemic therapy was introduced.

Method: We compared baseline characteristics of patients receiving frontline systemic treatments from two Italian multicenter nationwide datasets of systemic treatments: ARPES (sorafenib, 656 patients, 2008–2019) and ARTE (atezolizumab and bevacizumab [atezo/bev], 393 patients, 2022–2024). ARPES included cardiometabolic risk factors, allowing reclassification from NAFLD to MASLD.

Results: Compared to ARPES, patients in ARTE showed a higher prevalence of females (19.9% vs. 15.1%; $p = 0.047$), a trend toward older age, and an increase in single-etiology MASLD (17.6% vs. 8.8%, $p < 0.001$), with fewer viral cases. More patients with HCV were in sustained virologic response at treatment start (72.8 vs 9.1%, $p < 0.001$). Additionally, patients included in ARTE had better liver function (ALBI grade-1: 52.6 vs 18.7%, $p < 0.001$), highest rate of no prior surgical/locoregional HCC treatments (38.5% vs. 28.1%, $p < 0.001$), less prevalent BCLC-C stage due to fewer cases with macrovascular invasion (31.0% vs. 43.1%, $p < 0.001$) and similar rate of metastatic disease. Lower likelihood of previous surgical/locoregional treatments was confirmed in the intermediate-stage subgroup (19.9 vs 35.2%, $p < 0.001$). Tumors larger > 6 cm (14.9% vs. 10.0%, $p < 0.001$) and ECOG-PS > 0, (32.0% vs. 23.3%, $p < 0.001$) were also more common in the ARTE database.

Conclusion: The increased prevalence of MASLD, a decline in viral cases, high SVR rates in HCV, and less previous locoregional treatments are likely to contribute to better liver function and more patients with intermediate stage. The challenges of surveillance in patients with MASLD may explain the increase in cases with no prior treatment, larger tumors, and higher ECOG-PS scores.

FRI-117

Impact of sarcopenia on medium-long-term survival of patients with hepatocellular carcinoma treated with lenvatinib

Lorenzo Lani[1,2], Nicola Reggidorl[3], Matteo Renzulli[4], Alessandro Granito[1,5], Francesco Tovoli[1,5], Nicolò Brandi[6], Luca Ielasi[3], Selion Haxhi[1,2], Giovanni Monaco[1,5], Fabio Piscaglia[1,5], Maurizio Baldassarre[1], Paolo Caraceni, Maurizio Biselli[1,2]. *[1]Department of Medical and Surgical Sciences (DIMEC), University of Bologna, Bologna, Italy; [2]Unit of Semeiotics, Liver and Alcohol-related Diseases, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy; [3]Department of Internal Medicine, Ospedale per gli Infermi di Faenza, Faenza, Italy; [4]Radiology Unit, Morgagni-Pierantoni Hospital, AUSL Romagna, Forlì, Italy; [5]Division of Internal Medicine, Hepatobiliary and Immunoallergic Diseases, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy; [6]Department of Radiology, AUSL Romagna, Faenza, Italy*
Email: lorenzo.lani@studio.unibo.it

Background and aims: Sarcopenia, defined as the loss of skeletal muscle mass and function, represents a prognostic factor in patients with hepatocellular carcinoma (HCC). Lenvatinib, a tyrosine kinase inhibitor, has shown comparable efficacy to sorafenib but lacks data on the prognostic role of sarcopenia in Caucasian patients. Therefore, this study aims to evaluate the predictive value of sarcopenia and other clinical factors on survival in Italian HCC patients treated with lenvatinib.

Method: A retrospective analysis was conducted on 41 patients receiving lenvatinib. Sarcopenia was defined on skeletal muscle index (SMI) measurements from pre-treatment abdominal CT scans on transverse images crossing the 3rd lumbar vertebra. Data collected included patient demographics and laboratory data, liver function (MELD and Child-Pugh score), tumor characteristics, performance status, and survival outcomes. Male patients with SMI <53 cm^2/m^2 with a body mass index (BMI) ≥25 or with SMI <43 cm^2/m^2 with a BMI <25, and female patients with SMI <41 cm^2/m^2 regardless of BMI were identified as having sarcopenia. The primary outcome was overall survival (OS). The Kaplan-Meier method was used to estimate survival curves, and they were compared using the log-rank test. Univariate and multivariate analyses for OS were made using the Cox proportional hazards model and hazard ratio (HR) and corresponding 95% confidence interval (95%CI). The area under the receiver operating characteristic curve (AUROC) was used to evaluate the cut-off values ensuring the lowest false negative and false positive results (best cut-off) to dichotomize continuous variables.

Results: Sarcopenia was identified in 20 (48.8%) patients. The Cox analysis selected as independent prognostic factors significantly associated with low OS alpha1-fetoprotein (AFP) >150 ng/mL (HR 2.22; 95%CI 1.042–4.73; $p = 0.039$) and serum albumin <3.5 gr/dL (HR 3.33; 95%CI 1.42–7.83; $p = 0.006$) but not sarcopenia. However,

evaluating prognostic factors influencing medium-long-term survival [>12 months after lenvatinib start: 21 patients, with 12 (57.1%) sarcopenics], only the presence of sarcopenia (HR 3.66; 95%CI 1.07–12.5; p = 0.039) and serum albumin <3.5 gr/dL (HR 5.94; 95%CI 1.07–32.94; p = 0.042) emerged as independent prognostic factors associated with reduced medium-long term survival. Cumulative survival rates of patients with sarcopenia and/or serum albumin <3.5 gr/dL at 15, 18, 21 and 24 months were lower than those with normal albumin and no sarcopenia (46.2%, 36.9%, 9.2% and 0% vs 100%, 87.5%, 62.5% and 62.5%, respectively; p = 0.002).
Conclusion: Sarcopenia associated with low albumin levels significantly influences medium-long term survival of HCC patients treated with lenvatinib. Studies with larger cohorts of enrolled patients are warranted to validate these findings.

Background and aims: Statins have been suggested to exert anticancer properties by modulating angiogenesis, fibrosis, inflammation, and the tumor microenvironment, generating interest in their clinical use for chronic liver diseases (CLD) and hepatocellular carcinoma (HCC) chemoprevention. However, the effects of statin therapy in patients treated with immune checkpoint inhibitors for CLD-associated HCC remain unknown. This study primarily aimed to assess the potential effects of statins on overall survival (OS) and progression-free survival (PFS) in patients with advanced HCC treated with atezolizumab and bevacizumab (A+B).
Method: The ARTE dataset, a retro-prospectively maintained database, includes 305 consecutive patients with unresectable HCC treated with A+B, enrolled from 12 tertiary care centers in Italy. From the original cohort, a 1:1 propensity score matching was performed to balance potential confounding factors between 63 patients on statin therapy and those not on statins. The primary outcomes were OS and PFS, while secondary outcomes included all-cause mortality, liver-related death, treatment interruption, and the incidence of liver decompensation events.
Results: Among the matched population of 126 patients, 75% had liver cirrhosis, with metabolic disfunction-associated steatotic liver disease (MASLD) being the most common etiology. Ninety-seven patients (32%) had diabetes. No significant differences were found between statin users and non-usersin terms of OS, PFS, or liver-related death. Additionally, the log-rank test revealed no significant difference between the groups in terms of treatment interruption due to liver decompensation events (p = 0.28).
Conclusion: Statin use did not have any impact on OS, PFS, or on reducing mortality or treatment interruption due to liver-related decompensation events in patients with advanced HCC treated with A+B.

Email: mariastellafranze@gmail.com

Background and aims: Selective internal radiation therapy (SIRT) is a promising treatment for locally advanced HCC, particularly as a bridge to liver resection (LR) or transplantation (LT), but its effect on tumor microenvironment/immune activation must be understood. The study aimed to evaluate the intra-tumoral immune microenvironment and gene expression profiles in HCC patients who underwent LR/LT post-SIRT and its impact on outcomes.

Method: Thirty-six HCC patients down-staged with SIRT before LR or LT at two French University Hospitals (Henri Mondor, Beaujon) between December 2014 and October 2023 were included. RNA was extracted from tumoral tissue of formalin-fixed paraffin-embedded surgical liver samples. RNA sequencing was performed to identify differentially expressed genes (DEGs). Immune infiltrates were estimated using the MCP-counter method. All statistical analyses were performed with R 4.2.0.
Results: Twenty-five HCC patients (84% male, median age 67 years, 80% with cirrhosis) treated with LR/LT post-SIRT were included in the final analysis. Thirteen patients (52%) were BCLC-C, 10 BCLC-B (40%), 2 BCLC-A (8%). According to RECIST1.1, ten patients (40%) achieved a complete response (CR) 6 months post-SIRT, 12 (48%) partial response (PR), and 3 (12%) stable disease (SD). Fourteen patients (56%) experienced tumor recurrence post-surgery, 11 (44%) died. Sixty-five DEGs were found in patients with CR *vs*. others. Enrichment analysis revealed that the *under*-expression of gene set pathways is related to the regulation of immune response, proliferation/carcinogenesis of an aggressive subtype of HCC, and prediction of early recurrence in CR cases compared to others. SD milieu showed significantly lower neutrophils (p = 0.027) than CR and myeloid dendritic cells (p = 0.049) than PR. No significant differences in immune infiltrates were observed between patients with and without HCC recurrence. Forty-nine DEGs were found in patients who developed recurrence compared to others: *up*-regulated genes were involved in the inflammatory response, HCC progression, and cell differentiation/growth. Gene enrichment analysis showed that *over*-expression of gene set pathways was related to immune response. The six genes more expressed in the top 10 enriched pathways were CXCL5, CXCL8, CLN8, EREG, TRIM29, and MT1G. Patients with MT1G and CLN8 > mean values had lower recurrence-free survival than those without (p = 0.044, p = 0.0022, respectively). Cox univariate analysis showed the mean of the six most *over*-expressed genes as independent predictors of recurrence (p = 0.002), also confirmed in the multivariate model (p = 0.010).
Conclusion: SIRT modulates the HCC immune microenvironment. CR showed a downregulated immune response, and patients with recurrence had an inflammatory profile in the tumor tissue. Thus, this may provide a rationale for testing neoadjuvant and adjuvant immunotherapy in this setting of patients.

FRI-120

Recompensation before first-line systemic therapy for hepatocellular carcinoma yields comparable survival to compensated cirrhosis

Federico Piñero[1], Maria Margarita Anders[2], Carla Bermudez[3], Diego Arufe[4], Adriana Varon[5], Ana Palazzo[6], Jorge Rodríguez[7], Oscar BeltraN[5], Daniela Simian[8], Leonardo Gomes da Fonseca[9], Ezequiel Ridruejo[10], Norberto Tamagnone[11], Hugo Cheinquer[12], Diana Bejarano Ramirez[13], Juan Ignacio Marín Zuluaga[14], Josefina Pages[15], Orlando Orozno Ganem[2], Jaime Poniachik[8], Sebastián Marciano[3], Maria Virginia Reggiardo[11], Marcelo Silva[1], Manuel Mendizabal[1]. *[1]Hospital Universitario Austral, Pilar, Argentina; [2]Hospital Alemán, BUENOS AIRES, Argentina; [3]Hospital Italiano de Buenos Aires, BUENOS AIRES, Argentina; [4]Sanatorio Sagrado Corazón, Buenos Aires, Argentina; [5]Fundación Cardioinfantil, Bogota, Colombia; [6]Hospital Padilla, TUCUMÁN, Argentina; [7]Hospital Central de Mendoza, Mendoza, Argentina; [8]Hospital Clínico de la Universidad de Chile, Santiago, Chile; [9]Instituto do Cancer do Estado de São Paulo, Hospital das Clínicas, Universidade São Paulo, Sao Paulo, Brazil; [10]Centro de Educación Médica e Investigaciones Clínicas (CEMIC), Buenos Aires, Argentina; [11]Hospital Centenario de Rosario, Rosario, Santa Fe, Argentina; [12]Hospital das Clínicas de Porto Alegre, Universidade Federal do Rio Grande do Sul, PORTO ALEGRE, Brazil; [13]Hospital Universitario Fundación Santa Fe de Bogotá, Bogota, Colombia; [14]Hospital Pablo Tobón Uribe, Medellin, Colombia; [15]Hospital Universitario Austral, Pilar, Argentina*
Email: fpinerof@cas.austral.edu.ar

Background and aims: The concept of "recompensation" in cirrhosis underscores the dynamic nature of the disease and its impact on prognosis. However, the effect of recompensation in patients with hepatocellular carcinoma (HCC) undergoing first-line systemic therapy remains unclear. We compared survival outcomes following first-line systemic treatments for advanced HCC among patients with compensated, decompensated, and recompensated cirrhosis.
Method: A Latin American multicenter, prospective cohort study was conducted from 2018 to 2024, involving patients with HCC and Child-Pugh class A or B7 who received systemic therapy. Patients with moderate to severe ascites, clinical jaundice, hepatic encephalopathy grades III-IV, or ECOG >2 were excluded. At the initiation of first-line therapy, patients with cirrhosis were categorized as compensated (never decompensated), decompensated, or recompensated. Kaplan-Meier survival analysis and Cox proportional hazard models were estimated.
Results: Among 306 patients receiving first-line systemic therapy (sorafenib 60.5%, atezolizumab + bevacizumab 29.7%, lenvatinib 9.1%). The median follow-up since first line systemic therapy was 9.2 months, with a median survival of 16.0 months (95% CI 12.9–18.3 months). Significantly lower survival was observed in patients with cirrhosis (n = 240) compared to non-cirrhotic patients HR 1.75 (P = 0.015), and in those with baseline Child Pugh score B (vs A) [adjusted HR 1.87; P = 0.005]. Among patients with cirrhosis, 30.4% had a history of hepatic decompensation. Of these, 57.5% (95% CI 45.4–69.0%) achieved recompensation over a median period of 12 months. At the time of first-line therapy initiation, 69.6% were compensated, 17.5% recompensated, and 12.9% decompensated. Median survival was significantly shorter in decompensated patients (8.6 months) compared to compensated patients (17.2 months) [aHR 1.91 (95% CI 1.04–3.5); P = 0.03]. No significant difference in survival was observed between recompensated and compensated groups [aHR 1.28 (95% CI 0.79–2.1); P = 0.31]. The primary reason for treatment discontinuation in both compensated and recompensated groups was tumor progression, and similar access to second-line therapies was observed.
Conclusion: Patients with advanced HCC and recompensated cirrhosis may benefit from systemic therapies. Therefore, a follow-up observation period is recommended before ruling out systemic treatment in decompensated cirrhosis.

FRI-121

Radiofrequency ablation is safe in patients with hepatocellular carcinoma and thrombocytopenia

Songchi Xiao[1]. *[1]West China Hospital of Sichuan University, Chengdu, China*
Email: neoxiao1994@qq.com

Background and aims: Radiofrequency ablation (RFA) is widely used in clinical practice because it is the curative and safe interventional procedure for very early and early-stage hepatocellular carcinoma (HCC). Thrombocytopenia is often considered a relative contraindication to RFA owing to a concern about an increased bleeding risk. Current clinical guidelines recommend a platelet count of 50×10^9/L as a safe threshold for patients undergoing RFA. This study aims to evaluate the efficacy and safety of RFA in cirrhotic patients with HCC and severe thrombocytopenia.
Method: A retrospective analysis was conducted on 166 cirrhotic HCC patients who underwent RFA at West China Hospital from January 2017 to January 2024. Patients were categorized into two groups based on preoperative platelet counts: Group A ($<50 \times 10^9$/L) and Group B ($\geq 50 \times 10^9$/L). The primary outcome was perioperative major hemorrhage, while secondary outcomes included overall survival (OS), tumor response, and postoperative complications.
Results: Perioperative major hemorrhage occurred in 2.4% of the patients, all of whom were in Group B. Postoperative complications were observed at similar rates in both groups, with no significant differences noted. There were also no statistically significant

differences between the two groups in overall survival (OS), with 1-year OS rates of 97.6% in Group A and 96.6% in Group B, and 3-year OS rates of 86.3% in Group A and 94.6% in Group B. Tumor responses were comparable between the groups as well.
Conclusion: RFA is a effective and safe treatment for cirrhotic patients with HCC, even with severe thrombocytopenia. A platelet count below 50×10^9/L should not contraindicate RFA.

FRI-122
Impact of hepatocellular carcinoma multidisciplinary team on treatment outcomes: an analysis from the Middle East and North Africa region

Al Naamani Khalid[1,2], Coskun Ozer Demirtas[3,4], Adnan Alzanbagi[5], Mohamed Elbadry[6], Khalid Bzeizi[7], Hamdan Alghamdi[8], Omar AlSiyabi[9], Majed Almaghrabi[10], Hassan O. Alfakieh[10], Saleh A. Alqahtani[7,11], Mohamed El-Kassas[6], Faisal M. Sanai[10]. *[1]The Medical City for Military and Security Services, Department of Medicine, Division of Gastroenterology and Hepatology, Muscat, Oman; [2]The Global NASH Council, Washington DC, United States; [3]Marmara University, School of Medicine, Division of Gastroenterology and Hepatology, Istanbul, Türkiye; [4]Marmara University, Institute of Gastroenterology, Istanbul, Türkiye; [5]King Abdullah Medical City, Gastroenterology Department, Makkah, Saudi Arabia; [6]Helwan University, Endemic Medicine Department, Faculty of Medicine, Helwan, Cairo Governorate, Egypt; [7]King Faisal Specialist Hospital and Research Center, Liver, Digestive, and Lifestyle Health Research Section, and Organ Transplant Center of Excellence, Riyadh, Saudi Arabia; [8]King Abdulaziz Medical City, Riyadh, Saudi Arabia; [9]Royal Hospital, Department of Gastroenterology and Hepatology, Muscat, Oman; [10]King Abdulaziz Medical City, King Abdullah International Medical Research Center, Gastroenterology Section, Department of Medicine, Jeddah, Saudi Arabia; [11]Weill Cornell Medicine, Division of Gastroenterology & Hepatology, New York, United States*
Email: noumani73@gmail.com

Background and aims: Hepatocellular carcinoma (HCC) is the sixth most common cancer and the third leading cause of cancer-related mortality worldwide. Its management is complex, requiring a multidisciplinary team (MDT) approach to optimize outcomes. This study aimed to evaluate the impact of MDT involvement on survival outcomes in HCC patients across the Middle East and North Africa (MENA) region.
Method: This retrospective cohort study included 1,250 HCC patients from Egypt, Oman, Saudi Arabia, and Türkiye (2016–2023). Diagnoses were based on the Liver Imaging Reporting and Data System (LI-RADS). Patients were grouped by MDT involvement: Group 1 (808 patients) and Group 2 (442 patients). Kaplan-Meier survival analysis assessed survival outcomes, with survival defined as the time from diagnosis to death or last follow-up. Statistical significance was evaluated using the log-rank test.
Results: The mean age was 66 ± 12 years, with 74.7% male and 99% having cirrhosis. One-third (32.8%) had advanced disease, and 34.7% had end-stage disease. Half (50.5%) had Child-Pugh class B/C liver function. Group 1 had significantly longer mean survival (25.18 months, 95% CI: 23.27–27.10) compared to Group 2 (14.81 months, 95% CI: 12.88–16.75). Median survival was 14.0 months for Group 1 and 7.0 months for Group 2. Survival at 12 months was 55.4% for Group 1 versus 34.2% for Group 2 ($P < 0.0001$). Group 2 had a 67.7% higher mortality risk (HR = 1.6771, 95% CI: 1.4712–1.9118).
Conclusion: MDT involvement significantly improves survival outcomes in HCC patients. This emphasizes the need for coordinated, specialized care to improve prognosis in diverse healthcare settings.

FRI-123
The dose of radiation absorbed by the tumor and the non-tumoral compartments does not impact peripheral immune markers after SIRT

Email: bsangro@unav.es

Background and aims: Selective Internal Radiation Therapy (SIRT) with Y90 microspheres is used to treat hepatocellular carcinoma (HCC) across tumor stages. Besides modulating the tumor micro-environment, SIRT may influence the immune response via a by-stander effect on immune cells that circulate through the tumor and non-tumor volume that absorbed radioactive beads. The NASIR trial has investigated the safety and efficacy of SIRT followed by nivolumab. This study investigates the peripheral immunological changes triggered by SIRT and their correlation with dosimetry parameters.
Method: Blood samples were collected from 39 patients enrolled in the NASIR trial before SIRT (t1) and three weeks after the procedure (t2). Immunological profiling was conducted using multiparametric flow cytometry. Voxel-based dosimetry analysis in post-SIRT PET imaging included a) the highest mean absorbed dose (Dmean) among the treated nodules for each patient, and the total tumor volume exposed to at least 120 Gy (V120), and b) the Dmean, maximum absorbed dose, and non-tumor liver volume receiving at least 30 Gy (V30).
Results: A significant reduction in total lymphocyte count was observed at t2 (−66.93%, CI 95% −68.71; −52.72; $p < 0.0001$), while other leukocyte populations remained unchanged. When subset populations were studied, a decline was observed in CD4, CD8, B, NK and NKT cells together with a marked increase in activated cells expressing programmed cell death protein 1 (PD-1), cytotoxic T-lymphocyte antigen 4 (CTLA-4), lymphocyte activation gene 3 (LAG3), and T cell immunoglobulin and mucin-domain containing-3 (TIM3), as well as functional markers like CD39 and PD-1 ligand (PDL1). These changes were noted across CD4 and CD8 T cells, regulatory T cells, myeloid-derived suppressor cells (MDSCs), monocytes, and dendritic cells. However, these alterations were in most cases not linked to the dose of radiation absorbed by the tumor or non-tumor liver volumes. Exceptions included significant correlations between the highest Dmean or V120 with CD4 T cells expressing CTLA-4 or LAG3. Additionally, increases in NK cells and

dendritic cells were correlated with radiation exposure to the non-tumor liver, as measured by Dmean and V30.
Conclusion: SIRT-induced lymphopenia suggests immune modulation. However, the increase in immune checkpoints and functional markers across various immune subsets indicates a potential antigen recognition response, associated to activation or exhaustion, and provides a rationale for combining Y90 with immune check-point inhibition beyond anti-PD1 antibodies. These findings highlight the complex relationship between radiation and immune modulation, suggesting that radiation dose may influence immune pathways.

FRI-124

Sub-symptomatic Child-Pugh score 7 shows comparable survival outcomes to Child-Pugh score 6 in hepatocellular carcinoma patients treated with Atezolizumab and Bevacizumab

Jaejun Lee[1], Soon Kyu Lee[1], Jung Hyun Kwon[1]. [1]*The Catholic University of Korea, Seoul, Korea, Rep. of South*
Email: doctorkwon@catholic.ac.kr

Background and aims: Atezolizumab plus bevacizumab (Ate/Bev) has demonstrated remarkable outcomes and is now established as a first-line treatment for patients with advanced hepatocellular carcinoma (HCC), particularly those with a Child-Pugh score (CPS) of 5 or 6. However, given the limited data regarding its efficacy in patients with CPS 7, this study aims to evaluate the effectiveness of Ate/Bev in CPS 7 patients and to identify specific subgroups within CPS 7 that may benefit from this treatment.
Method: This study included patients with advanced HCC who received Ate/Bev as first-line therapy between September 2020 and December 2023 at six university hospitals. The primary outcome was overall survival (OS), while secondary outcomes included progression-free survival (PFS) at six months and treatment response. Within the CPS 7 group, patients were further subdivided into two groups based on combinations of CPS variables and their associated survival risks.
Results: Among the 340 included patients, those with CPS 5 (n = 169) demonstrated the highest overall survival (OS) and progression-free survival (PFS), followed by patients with CPS 6 (n = 87) and CPS 7 (n = 84) ($P < 0.05$). For the variables comprising CPS, the hazard ratio (HR) for OS increased with elevated total bilirubin (TB) levels and was lower in patients with mild ascites ($P < 0.05$). Regarding albumin levels, the HR for OS tended to decrease as albumin levels dropped to 2.8 g/dL. Based on these findings, CPS 7 patients were further classified into two subgroups: sub-symptomatic (TB <2 mg/dL, 3.5 > Alb ≥2.8 g/dL, and mild ascites) and symptomatic (other CPS 7). Compared to patients with CPS 6, those in the sub-symptomatic CPS 7 group exhibited comparable OS and PFS at six months, while symptomatic CPS 7 patients had significantly lower OS and PFS at six months ($P < 0.05$). Multivariate analysis identified symptomatic CPS 7 as a significant risk factor for both OS and PFS ($P < 0.01$).
Conclusion: This study suggests that Ate/Bev treatment can be effective in sub-symptomatic CPS 7 patients, highlighting the potential to broaden treatment eligibility for this population.

FRI-125

Real-world treatment patterns and outcomes among patients with hepatocellular carcinoma managed at a single centre in Switzerland

Pompilia Radu[1], Maximilian Thormann[2], Birgit Schwacha-Eipper[1], Cesar Oniangue-Ndza[3], Emanuel Gabrielle[4], Annalisa Berzigotti[5,6], Jean-François Dufour[7]. [1]*Department of Visceral Surgery and Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland;* [2]*Clinic for Radiology and Nuclear Medicine, University Hospital Magdeburg, Magdeburg, Germany;* [3]*Bristol Myers Squibb SA, Steinhausen, Switzerland;* [4]*Bristol Myers Squibb Ltd, Uxbridge Business Park, Uxbridge, United Kingdom;* [5]*Department for Visceral Medicine and Surgery, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland;* [6]*Department of Biomedical Research, University of Bern, Bern, Switzerland;* [7]*Centre des Maladies Digestives, Lausanne, Switzerland*
Email: radupompilia@yahoo.com

Background and aims: Data on hepatocellular carcinoma (HCC) treatment patterns in Europe are limited, with no existing studies specifically focusing on Switzerland. This retrospective, observational study aimed to present real-world data on the characteristics, treatment patterns, and outcomes among patients with HCC in Switzerland.
Method: We performed a retrospective study between 1 January 2010 and 30 June 2022 on patients with HCC included in a prospective cohort at Inselspital in Switzerland. The index date was HCC diagnosis date. The analysis included patients with newly diagnosed HCC of Barcelona Clinic Liver Cancer (BCLC) stage 0 (very early), A (early), B (intermediate), or C (advanced) who were assigned to therapy. Patients were excluded if they had undergone liver transplantation, had fibrolamellar, sarcomatoid, or mixed cholangiocarcinoma/HCC subtypes, or had less than 6 months of follow-up. Treatment patterns were assessed using descriptive statistics and time-to-event outcomes using the Kaplan–Meier method.
Results: Overall, 362 patients were included. Mean age was 67.1 years (standard deviation [SD] 9.9), 82% were male, and 75% had cirrhosis (of which 61% had Child-Pugh score A). The most common aetiology was alcohol-related liver disease (44%), and the most common comorbidities were diabetes (32%) and chronic hepatitis C virus (31%). Baseline disease stages were BCLC 0 (10%), BCLC A (44%), BCLC B (28%), and BCLC C (16%). The most common first treatment was ablation (41%) for BCLC A, embolisation (26%) for BCLC B, and first line (1L) systemic tyrosine kinase inhibitor therapy (54%) for BCLC C. Of BCLC C patients, 3.4% received 1L immunotherapy (atezolizumab/bevacizumab). In BCLC stage C patients, the median duration of 1L systemic therapy was 5.1 months (95% confidence interval [CI], 3.1–7.2). Sankey plots showed heterogeneous treatment patterns from baseline to end of follow-up for BCLC stages A–C, with some patients receiving up to 7 treatments. In BCLC stage A patients, the median time to recurrence following resection was 56.1 months (95% CI, 21.1-not available) and median time to relapse following ablation was 16.6 months (95% CI, 12.4–48.8), with 75% of patients who experienced recurrence having an early recurrence (within ≤2 years). In BCLC stage B patients, the median time to progression (TTP) following embolisation was 16.3 months (95% CI, 9.0–21.3). In BCLC stage C patients, from the start of 1L systemic therapy, the median TTP was 6.3 months (95% CI, 4.7–9.9), and median overall survival was 11.3 months (95% CI, 9.1–19.6).
Conclusion: These findings underscore the need for tailored treatments, enhanced surveillance, and novel therapies to improve patient outcomes. Further research should focus on optimizing treatment sequences and integrating emerging therapies to improve HCC management.

FRI-126

Predictors for postembolization syndrome in a cohort of patients with hepatocellular carcinoma

Razvan Rababoc[1], Mihai Daniel Dodot[1], Cristian Mugur Grasu[2], Radu Dumitru[2], Mihai Toma[2], Laura Iliescu[1]. [1]*Department of Internal Medicine, Fundeni Clinical Institute, Bucharest, Romania, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania, Bucharest, Romania;* [2]*Department of Interventional Radiology, Fundeni Clinical Institute, Bucharest, Romania, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania, Bucharest, Romania*
Email: razvan.rababoc@rez.umfcd.ro

Background and aims: Postembolization syndrome (PES) is a frequent complication of transarterial chemoembolization (TACE) in patients with hepatocellular carcinoma (HCC). Evolution of PES varies from complete remission under symptomatic therapy to decompensation of liver disease and increased mortality. The aim of this study is to determine predictive factors for the development of PES, thus

establishing a pre-interventional risk and possibly change the therapeutic strategy in these patients.
Method: We performed a retrospective observational study in 539 patients who underwent a first TACE procedure in our center between June 2017 and June 2024. We recorded demographic data, etiology and staging of liver disease, presence of comorbidities, liver function tests, inflammatory markers, location and size of HCC treated nodule. PES was defined as fever and upper right quadrant pain appearing 24–48 hours after the procedure. All procedures were performed using highly selective catheters, via the femoral artery.
Results: The mean age in the study lot was 63.25 ± 25.13 years, with a predominance of male gender (71.8%). Etiology of liver disease was as follows: 33.9% HCV, 19.4% HBV, 10.3% HBV + HDV, 15.7% MASLD, 17.4% alcohol-related and 2.9% idiopathic. The most frequent comorbidities in the group were: diabetes (24.4%), arterial hypertension (33.0%) and chronic kidney disease (14.2%). PES appeared in 48 patients (8.9%) and was managed medically; 3 patients presented acute decompensation of cirrhosis. The following risk factors for PES were demonstrated: viral etiology (OR = 1.45 95% CI [1.21–1.76] p = 0.03), age over 60 (OR 2.21 95% CI [1.98–2.52] p = 0.01), diabetes (OR 1.98, 95% CI [1.56–2.05] p = 0.03), nodule larger than 5 cm (OR 3.13, 95% CI [2.78–3.42] p < 0.01). Biochemical markers associated with PES were: C reactive protein >10 mg/dL (OR 1.87, 95% CI [1.51–2.07] p = 0.03) fibrinogen over 400 mg/dL (OR 2.13, 95% CI [1.95–2.43] p = 0.02) and ALT over 100 U/L (OR = 2.52 95% CI [2.31–2.83] p < 0.01).
Conclusion: In patients with risk factors for PES, close monitoring as well as preventive anti-inflammatory therapies may be indicated. Further analysis is required to make recommendations regarding treatment option changes to avoid PES occurrence if technically possible.

FRI-131
Updated network meta-analysis of first-line systemic therapies for advanced hepatocellular carcinoma: consistent role of TACE
Jihyun An[1], Ye Rim Kim[2], Seungbong Han[3], Ju Hyun Shim[2]. *[1]Hanyang University College of Medicine, Guri, Korea, Rep. of South; [2]Asan Medical Center, Seoul, Korea, Rep. of South; [3]Korea University, Seoul, Korea, Rep. of South*
Email: starlit1@naver.com

Background and aims: We conducted an updated network meta-analysis to evaluate and identify the optimal first-line treatment for advanced hepatocellular carcinoma (HCC) among all relevant transarterial and targeted therapies.
Method: We analyzed 25 phase 2 or 3 randomized controlled trials involving 14,148 patients with metastatic or unresectable HCC between 2008 and 2024, which evaluated 20 systemic agents and 4 transarterial interventions combined with systemic therapy, using sorafenib or lenvatinib as standard controls. Primary outcome was overall survival (OS), and secondary outcomes included progression-free survival (PFS) and grade 3–4 adverse events. Subgroup analyses were conducted to assess individual treatment efficacies in specific clinical settings.
Results: Transarterial chemoembolization (TACE) combined with lenvatinib provided the greatest improvement in OS compared to sorafenib, with a hazard ratio of 0.41 (95% confidence interval, 0.30–0.58), followed by sintilimab+IBI305 (0.57; 0.43–0.75), camrelizumab+rivoceranib (0.62; 0.48–0.80), atezolizumab+bevacizumab (0.66; 0.51–0.85), lenvatinib+pembrolizumab (0.77; 0.62–0.97), and tremelimumab+durvalumab (0.78; 0.64–0.95). These combinations, except tremelimumab+durvalumab, were also regimens significantly superior to sorafenib regarding PFS. TACE+lenvatinib was ranked first in OS analyses with the other current standard-of-cares (lenvatinib, atezolizumab+bevacizumab, and tremelimumab +durvalumab) as a control. TACE+lenvatinib, sintilimab+IBI305, and atezolizumab+bevacizumab demonstrated consistent significance in extending OS over sorafenib in subsets with portal invasion, extrahepatic metastasis, and hepatitis B. All immunotherapy-based combinations were significantly associated with a higher risk of adverse events than sorafenib.
Conclusion: Our first-line analysis consistently scored TACE+lenvatinib best for survival outcomes, followed by various immunotherapy-based combinations in advanced HCC. This hierarchy was sustained in aggressive tumors or hepatitis B carriers.

FRI-132
Non-selective beta blockers: mitigating hepatocellular carcinoma progression and enhancing sorafenib efficacy through Wnt/beta-catenin pathway modulation
Tasnim Mahmoud[1], Olfat Hamam[2], Mahmoud Khattab[3], Aiman El-Khatib[3], Yasmeen Attia[1]. *[1]The British University in Egypt, Cairo, Egypt; [2]Theodor Bilharz Research, Cairo, Egypt; [3]Cairo University, Cairo, Egypt*
Email: Tasnim120764@bue.edu.eg

Background and aims: One of the main causes of cancer-related death globally is hepatocellular carcinoma (HCC). HCC is characterized by aggressive tumour growth and resistance to standard treatments like sorafenib (SOR). Growing evidence suggests that carvedilol (CAR) and other non-selective beta-blockers (NSBBs) may enhance therapeutic outcomes by modulating apoptotic pathways thereby slowing down tumour growth. Therefore, this study evaluates the effect of combined therapy of CAR and SOR on HCC growth, inflammatory cytokines, apoptosis induction, epithelial-to-mesenchymal transition (EMT) markers, and the Wnt/beta-catenin signalling pathway.
Method: A diethylnitrosamine (DEN)-induced HCC model was established in male Sprague Dawley rats, followed by treatment with SOR, CAR, or their combination. Tumour progression was assessed through macroscopic and histological analysis. Relative gene expression of EMT markers (Twist-1, Snail-1, Axin-1) and apoptotic markers (BAX, Bcl-2) was quantified using qRT-PCR across normal, positive control, and treated groups. Caspase-3 levels were measured by immunohistochemistry, whereas the levels of inflammatory markers (tumour necrosis factor alpha; TNF- α and IL-6), EMT markers (Twist-1 and Snail-1), and the apoptotic marker GSK-3beta were assessed using ELISA.
Results: Combination therapy reduced malignant nodules and preserved liver architecture compared to DEN-treated group. CAR treatment increased caspase-3 immunoreactivity and BAX expression as well as decreased Bcl2 levels, suggesting enhanced anti-proliferative potential. Notably, the combination therapy depicted anti-inflammatory potential by reducing IL-6 and TNF-α levels by 51% and 59%, respectively, in comparison to the DEN-treated group. Significant modulation was seen in EMT markers, with Snail-1 and Twist-1 downregulated in the combination group. Furthermore, an increase in both Axin-1 gene expression and GSK-3beta levels was observed, suggesting an interference with the Wnt/beta-catenin pathway.
Conclusion: These results might imply that CAR improves SOR's efficacy in HCC by suppressing tumour growth, promoting apoptosis, regulating inflammatory cytokines, and blocking EMT via Wnt/beta-catenin signalling pathway inhibition.

FRI-133
Immunoprofiling-based machine learning model predicts outcomes to pembrolizumab plus lenvatinib in patients with unresectable hepatocellular carcinoma
Pei-Chang Lee[1], Po-Yu Li[2], Cheng-Yun Lee[2], Shian-Ren Lin[2], Chi-Jung Wu[1], Ya-Wen Hung[3], Jun-Wen Chan[2], Yu-Hua Chen[2], Hsien-Chen Mon[1], Chieh-Ju Lee[1], Chen-Ta Chi[1], I-Cheng Lee[1], Ming-Chih Hou[1], Yee Chao[2], Jan-Mou Lee[2], Yi-Hsiang Huang[1]. *[1]Taipei Veterans General Hospital, Taipei, Taiwan; [2]FullHope Biomedical Co., Ltd, New Taipei City, Taiwan; [3]Taipei Veterans General Hospital, Taoyuan Branch, Taoyuan, Taiwan*
Email: yhhuang@vghtpe.gov.tw

Background and aims: Immunotherapy combinations are front-line treatment for unresectable hepatocellular carcinoma (uHCC), but outcome predictors remain challenging. Despite LEAP-002 trial failed to meet its primary endpoint, the combination of pembrolizumab and lenvatinib (PL) provide longer-term efficacy in responders. We aimed to investigate how immune profiling of uHCC correlates with responses to PL therapy.
Method: From July 2019 to July 2023, 51 patients undergoing front-line PL therapy for uHCC were prospectively enrolled. Pre-treatment peripheral blood mononuclear cells (PBMCs) were collected and analyzed for immunophenotyping and its association with tumor response. Twelve responders and eight non-responders were randomly assigned to develop a PBMC-based machine learning (ML) model for predicting tumor response. Remaining cases were allocated for model testing.
Results: During a median follow-up of 10.8 months (interquartile 5.3–19.1 months), 16 patients experienced objective tumor response, 22 had stable disease and 11 developed primary progression. Responders has higher percentages of total T cells, CD8+, PD1+CD4+, PDL1+CD8+ T cells and PD1+CD8+ NK cells, while PDL1+ monocytes were more prominent in non-responders. Through recursive feature elimination, six key immunotypic cells were identified, and a PBMC-based ML model was developed to predict tumor response using random forest technique (AUROC: 0.8084). In the validation group, the model effectively predicted tumor response with 85.7% accuracy (100% sensitivity, 66.7% specificity, AUROC: 0.9167).
Conclusion: Peripheral immune signatures are associated with the efficacy of PL combination immunotherapy in uHCC. A PBMC-based ML predictive model offers a non-invasive approach to identify patients likely to benefit from this treatment.

FRI-134

Impact of radiation dose on treatment response and survival outcomes in solitary hepatocellular carcinoma treated withY90 selective internal radiation therapy: a retrospective single-center study

Kaina Chen[1,2], Lu Yang[2], Aaron Kian Ti Tong[3], David Chee Eng Ng[3], Kelvin Siu Hoong Loke[3], Sue Ping Thang[3], Apoorva Gogna[4], Richard Hoau Gong Lo[4], Karaddi Venkatanarasimha Nanda Kumar[4], Fiona Ni Ni Moe[5,6], Siou Sze Chua[5,6], Cheryl Min En Chua[5,6], Jade Shu Qi Goh[5,6], Evelyn Chiew[5,6], Pierce Chow[5,6,7]. *[1]Singapore General Hospital, Singapore, Singapore; [2]Duke NUS Medical School, Singapore, Singapore; [3]Singapore General Hospital, Department of Nuclear Medicine & Molecular Imaging, Singapore, Singapore; [4]Singapore General Hospital, Department of Vascular and Interventional Radiology, Singapore, Singapore; [5]National Cancer Centre Singapore, Department of Hepatopancreatobiliary and Transplantation Surgery, Division of Surgery and Surgical Oncology, Singapore, Singapore; [6]National Cancer Centre Singapore, Programme in Translational and Clinical Liver Research, Singapore, Singapore; [7]Duke NUS Medical School, Surgery Academic Clinical Programme, Singapore, Singapore*
Email: yangl21@alumni.wlu.edu

Background and aims: Selective internal radiation therapy using Yttrium-90 (Y90) microspheres has emerged as a promising locoregional treatment for unresectable HCC. Radiation dose delivered to the tumor is critical in treatment outcomes in Y90. While higher radiation doses have been associated with better tumor response and prolonged survival, the optimal dosing strategy remains a subject of research. We aim to evaluate the impact of the delivered radiation dose on treatment response and overall survival in patients with solitary HCC undergoing Y90 with resin microsphere.
Method: This is a retrospective study of consecutive patients treated with Y90 resin microspheres (SIR-Spheres, Sirtex Medical, USA) for solitary HCC between 2020 and 2023 at Singapore General Hospital. Excluded were patients lost to follow-up and those with other concomitant cancer. Patient demographics, clinical history, pertinent laboratory values and radiological findings were collected. Treatment response was determined using CT and/or MRI based on modified Response Evaluation Criteria in Solid Tumors (mRECIST) criteria. Ethical approval was granted by the Institutional Review Board (2023/2062).
Results: 269 patients received Y90 during the study period, of which 96 met the inclusion criteria. Of these patients, 43 were BCLC A and 53 were BCLC C stage at the time of diagnosis. The median follow-up duration was 19.5 months, calculated from the time of diagnosis to the most recent follow-up or date of death, whichever occurred first. The median overall survival (OS) for the whole cohort was not evaluable at time of analysis. 27 patients received high dose (>250 Gy) treatment (median = 350.29 Gy, IQR = 159.2 Gy). The median survival for BCLC C patients (n = 14/27) was 30.3 months (95% CI: 17.1 – NE). Among patients that received high dose treatment, three (11.1%) achieved complete response (CR), while majority had partial response (PR) 21/27 (78%), and 2/27 had stables disease (SD). Two patients were downstaged to resection and radiofrequency ablation respectively. The mean percentage response in tumor size shows a reduction of 22.5% (SD = 21.59%) from baseline.
Conclusion: A higher Y90 dose delivered to unresectable solitary HCC showed higher tumour responses but the optimal dosing strategy for maximizing treatment efficacy without increasing toxicity remains unverified. We planned future studies to explore the underlying mechanisms driving the variability in response to higher radiation doses.

Pre-treatment serum IgG levels predict immune-related adverse events in HCC patients treated with atezolizumab plus bevacizumab

Yutaka Yasui[1], Kaoru Tsuchiya[1], Mina Taguchi[1], Yudai Yamazaki[1], Naoki Uchihara[1], Yuki Tanaka[1], Shohei Kimura[1], Haruka Miyamoto[1], Junko Yagita[1], Taisei Keitoku[1], Risa Okada[1], Mayu Higuchi[1], Kenta Takaura[1], Shohei Tanaka[1], Chiaki Maeyashiki[1], Nobuharu Tamaki[1], Hiroyuki Nakanishi[1], Namiki Izumi[1], Masayuki Kurosaki[1]. *[1]Musashino Red Cross Hospital, Tokyo, Japan*
Email: yutakay@musashino.jrc.or.jp

Background and aims: The advent of immune checkpoint inhibitors (ICI) has dramatically extended the prognosis for patients with hepatocellular carcinoma (HCC). However, the diagnosis and management of immune-related adverse events (irAEs) induced by ICIs have become critical challenges. This study aimed to identify predictive factors for irAEs in HCC patients treated with ICIs.
Method: We retrospectively analyzed 169 patients with unresectable HCC treated with atezolizumab plus bevacizumab. Risk factors for irAEs were identified in a training cohort of 112 patients and validated in a separate cohort of 57 patients. Adverse events were graded according to CTCAE version 5.0.
Results: Among all patients, 45 (27%) developed irAEs, including 27 in the training cohort and 18 in the validation cohort. The most common irAEs were endocrine disorders (17 cases), followed by skin disorders (10 cases). In the training cohort, patients who developed irAEs had significantly higher pre-treatment serum IgG levels compared to those who did not (median: 1592 vs. 1363 mg/dL, p = 0.03). No significant differences were observed in background liver disease, renal function, or hepatic reserve. Receiver operating characteristic (ROC) analysis showed that pre-treatment IgG was predictive for irAE occurrence (AUROC: 0.64), with an optimal cut-off value of 1375 mg/dL. Logistic regression analysis identified IgG > 1375 mg/dL as a significant predictor of irAEs (Odds Ratio [OR] 3.1, 95% Confidence Interval [CI] 1.1–8.5, p = 0.03). In the validation cohort, patients with IgG >1375 mg/dL had a significantly higher incidence of irAEs (44% vs. 16%, p = 0.04). Logistic regression analysis confirmed IgG >1375 mg/dL as a significant predictive factor (OR 4.1, 95%CI 1.1–14.6, p = 0.03).
Conclusion: Pre-treatment serum IgG levels may serve as a predictive biomarker for irAEs in HCC patients undergoing atezolizumab plus

bevacizumab therapy. These findings could guide patient management by identifying those at higher risk of irAEs.

Multimorbidity, disease clusters and all-cause mortality in people with metabolic dysfunction association steatotic liver disease in UK Biobank

Qi Feng[1], Chioma Izzi-Engbeaya[1], Pinelopi Manousou[1], Mark Woodward[1]. [1]*Imperial College London, London, United Kingdom*
Email: ermadake@gmail.com

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD), a hepatic manifestation of metabolic syndrome, is associated with various extrahepatic diseases. Multimorbidity is associated with adverse health outcomes. This study investigated the prevalence of extrahepatic multimorbidity, disease clusters, and their associations with all-cause mortality in people with MASLD.
Method: Using UK Biobank data, we identified MASLD cases based on liver steatosis and cardiometabolic risk factors. Multimorbidity was defined as the presence of ≥2 conditions from a predefined list of 46 diseases. Latent class analysis was used to derive disease clusters separately for males and females. Risk factors for cluster membership were identified using multinomial logistic regression, and associations with all-cause mortality were assessed using multivariable Cox regression.
Results: Among 118,751 participants with MASLD (mean age 57.5 years; 44% females), 25,842 (22%) had multimorbidity (25% of females, 27% of males). In females, five disease clusters were identified: respiratory (prevalence 30%), mental health (20%), cancer (13%), cardio/cerebrovascular (11%), and thyroid/respiratory/osteoarthritis (27%). In males, the clusters were respiratory (27%), cardiovascular (22%), mental health (13%), cerebrovascular (8%) and respiratory/cancer/osteoarthritis (29%). Asians were less likely to belong to the mental health cluster, while the cardio/cerebrovascular clusters were more common in smokers, but less common in females with high physical activity.
Over a median of 13-year follow-up, 13,609 deaths occurred (5,034 females). Multimorbidity was associated with significantly higher mortality, with hazard ratios (HRs) of 2.00 (95% CI: 1.91–2.09) in males and 1.76 (1.67–1.87) in females. Mortality risk varied by cluster. In males, the cardiovascular cluster had the highest hazard ratio (HR, 2.65 [2.48–2.84]), followed by cerebrovascular (2.42 [2.16–2.70]), with lower HR in mental health (1.57 [1.40–1.77]) and respiratory (1.58 [1.45–1.72]) clusters. In females, the cardiovascular cluster had the highest HR (2.97 [2.68–3.30]), followed by cancer (2.48 [2.23–2.77]), mental health (1.50 [1.33–1.70]) and respiratory (1.54 [1.40–1.69]) clusters.
Conclusion: Multimorbidity significantly increases mortality in MASLD population, with cardio/cerebrovascular and cancer clusters posing the highest risks. These findings highlight the need for integrated care models and targeted interventions that prioritize prevention of these diseases in MASLD populations.

Email: mureddu14@gmail.com

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) has a strong inherited component, which is not fully accounted for by common genetic variation. Carriage of rare loss-of-function (LoF) variants in Apolipoprotein B (*APOB*) has been linked to increased susceptibility to steatosis, but the contribution to cirrhosis and hepatocellular carcinoma (HCC) is still disputed. This study aimed to determine the clinical impact of APOB gene variants in a cohort of patients with MASLD and advanced cirrhosis or HCC.
Method: We investigated the impact of LoF *APOB* variants in a clinical cohort of people with MASLD and advanced fibrosis or HCC (advanced MASLD; n = 510) vs. healthy controls, a family study (n = 43 and a meta-analysis of literature), and the population-based UK Biobank (UKBB) cohort (n = 416,331) on clinical outcomes and lipidomics/metabolomics/proteomics.
Results: LoF *APOB* variants were strongly enriched in patients with advanced MASLD vs. healthy controls (aOR 13.8, 95% c.i. 2.7–70.7, p = 0.002), being observed in 1 in 22 cases and associated with lower circulating lipids, but higher disease activity and fibrosis scores ($p < 0.05$). Through familial studies of probands with advanced MASLD, *APOB* variants segregated with inheritance of liver steatosis and fibrosis ($p < 0.05$). In UKBB cohort, we observed increased risk of cirrhosis and HCC in patients with MASLD (aOR 2.01, 1.51–2.53 and 4.01, 3.09–5.15, respectively), with the effect being larger for rarer variants (aOR 9.88, 8.8–10.96 and aOR 27.2, 25.26–29.08, respectively). Remarkably, we observed a dissociation between the impact of variants specifically affecting ApoB100 and very low-density lipoprotein (VLDL) secretion—showing a larger impact on circulating lipoprotein levels and the risk of cirrhosis—and those impairing ApoB48 and chylomicron secretion, which were associated with immunological biomarkers and a selective increase in the risk of HCC (aOR 5.9, 4.8–6.9).

Conclusion: Carriage of rare LoF *APOB* variants is associated with advanced MASLD, with distinct contributions from impaired secretion of VLDL and chylomicrons. Genotyping in patients with MASLD may improve risk stratification and case finding and enhance patient management.

When is a liver biopsy necessary? Predictive factors of autoimmune hepatitis in patients with metabolic dysfunction-associated steatotic liver disease and positive autoantibodies

Leire Sancho[1], Laura Guerra[1], Maria del Carmen Méndez Díaz[1], Pilar Castillo[1], Miriam Romero[1], Araceli García-Sánchez[1], Marta Abadía[1], Javier García - Samaniego[1], Emily Larrea[1], Alejandra Rodríguez-Francisco[1], Gonzalo Armesto[1], Sara Quiñones[1], Antonio Olveira[1]. [1]*La Paz University Hospital, Madrid, Spain*
Email: aolveiram@gmail.com

Background and aims: One in four people with metabolic dysfunction-associated steatotic liver disease (MASLD) presents positive autoantibodies, for which it is recommended to rule out the coexistence of autoimmune hepatitis (AIH). This entails performing liver biopsies (LB), many of which ultimately prove to be unnecessary. Despite the frequency of this situation, there are no established criteria to recommend or discourage performing LB.
Method: Prospective study. Patients with MASLD and antinuclear (ANA), anti-smooth muscle (ASMA), or anti-liver-kidney microsomal (anti-LKM) antibodies ≥1: 40 (+ve). Patients with positive anti-mitochondrial antibodies, absence of histological steatosis, another liver disease, contraindication for LB, or refusal were excluded. AIH was diagnosed according to the International AIH Pathology Group. Logistic regression analysis of significantly associated variables was performed.
Results: Between January 2022 and August 2024, 142 patients were included: 56 years old, 57% women, 37% with another immune disease, body mass index 30.3 kg/m², pre or type 2 diabetes 45%, alanine aminotransferase (ALT) 57 U/L, immunoglobulin G (IgG) 1247 mg/dL, ANA +ve 98.5%, ASMA +ve 9%, anti-LKM +ve 0.7%. Twenty-eight patients (19.7%; 95% confidence interval [CI 95%]: 14–27) had immune liver disease: 19 AIH, 3 primary biliary cholangitis (PBC), 4 AIH/PBC, 2 granulomatous hepatitis. Multivariate analysis identified the following variables as independently associated (odds ratio OR [CI 95%]): age 1.057 (1.009–1.108; p = 0.02), ASMA or anti-LKM +ve 6.569 (2.011–21.462; p = 0.002), ANA >1:640 5.293 (1.036–27.048; p = 0.045), IgG >1800 mg/dL 6.468 (1.147–36.482; p = 0.034), and elevated AST or ALT 6.576 (0.743–58.195; p = 0.045). Using logistic regression, the following model was obtained to suspect immune liver disease and recommend or rule out LB in patients with MASLD and positive autoantibodies: (0.056×age) + (1.883×elevated AST or ALT) + (1.867×IgG >1800 mg/dL) + (1.882×ASMA or anti-LKM ≥1: 40) + (1.666×ANA > 640). For a cutoff point of 5, the diagnostic performance was: sensitivity 88.9%, specificity 53.1%, positive predictive value 34.3%, negative predictive value 94.5%, area under the receiver operating characteristic curve 0.83 (95% CI 0.73–0.93, p < 0.001). Applying the model, 55/142 liver biopsies (39%) would have been avoided, and 25/28 (90%) patients with immune liver disease would have been identified.
Conclusion: One in five patients with MASLD and positive autoantibodies presents immune liver disease. Applying a simple model based on age, antibodies, IgG, and transaminases allows its identification, reducing the number of unnecessary liver biopsies.

TOP-411-YI

Disease state transitions across the spectrum of steatotic liver disease significantly affect long-term incidence of cirrhosis among a national cohort of veterans in the United States

Email: maisedki@gmail.com

Background and aims: Steatotic liver disease (SLD) encompasses a spectrum of disease states with etiologies influenced by whether precipitating causes are mainly metabolic vs. alcohol related. In real-world settings, patients may transition from one SLD disease state to another due to changes in alcohol use. Data are lacking in understanding how disease state transitions (DST) among patients with SLD affect long-term outcomes. We aim to evaluate DST patterns and its impact on long-term risk of cirrhosis among a national cohort of U. S. Veterans with SLD.
Method: Using national Veterans Affairs data, U.S. Veterans with metabolic dysfunction-associated steatotic liver disease (MASLD), MetALD, or alcohol-related liver disease (ALD) were identified from 1/1/2010 to 12/31/2019 (with follow-up through 9/30/2024) (MASLD = hepatic steatosis (HS) + ≥1 cardiometabolic risk [CMR] and no alcohol use [AUDIT-C = 0]; MetALD = HS + ≥1 CMR and low-level alcohol use [AUDIT-C 1–2 for women, 1–3 for men]; ALD = HS + high-level alcohol use [AUDIT-C >2 for women and > 3 for men]). Long-term follow up with repeated measures of AUDIT-C were evaluated to assess for DST between aforementioned categories. Competing-risks analyses (censored for death) evaluated the incidence of cirrhosis (per 100 person-years [p.y.]) stratified by DST and performed separately by index diagnosis of MASLD, MetALD, or ALD. Comparisons of cirrhosis incidence between groups utilized the z-statistic.
Results: We identified 726,276 Veterans with MASLD (93.0% men, 67.2% age ≥60 y), 512,061 with MetALD (93.4% men, 57.4% age ≥60 y), and 212,540 with ALD (94.6% men, 52.6% age ≥60 y). Over a median follow-up of 8.5 years (IQR 5.3–12.6), 24.2% of MASLD patients had DST to MetALD, 2.6% to ALD, and 73.2% did not have DST. Compared to MASLD patients without DST, cirrhosis incidence was similar in those with DST to MetALD (0.40 vs. 0.43 per 100-p.y), but significantly higher with DST to ALD (0.74 vs. 0.40 per 100-p.y., p < 0.01). Among patients with baseline MetALD, 14.4% had DST to ALD, 40.3% to MASLD, and 45.3% remained as MetALD. Compared to MetALD patients without DST, cirrhosis incidence was higher with DST to ALD (0.49 vs. 0.24 per 100-p.y., p < 0.01) or to MASLD (0.44 vs. 0.24 per 100-p.y., p < 0.01). Among patients with baseline ALD, 43.3% had DST to MetALD, 15.9% to MASLD, and 40.8% remained as ALD. Compared to patients who remained as ALD, cirrhosis incidence was significantly lower with DST to MetALD (0.54 vs. 0.80 per 100-p.y., p < 0.01), but increased with DST to MASLD (1.00 vs. 0.80 per 100-p.y., p < 0.01).
Conclusion: Among a national cohort of U.S. Veterans with SLD, a large proportion experience DST due to changes in alcohol use patterns, which led to changes in long-term incidence of cirrhosis. These data underscore the critical need for timely assessment and

interventions to address high-risk alcohol use as well as optimizing CMR in patients with SLD.

Long-term mortality in steatotic liver disease is greatest in those with a combination of metabolic dysfunction and excessive alcohol consumption

Zobair Younossi[1,2], James M. Paik[1,2], Aleksander Krag, Ashwani K. Singal[1,3,4], Robert Wong[1,5], Mário Pessoa[1,6], Shira Zelber-Sagi[1,7], Dana Ivancovsky Wajcman[1,7], Linda Henry[1,2,8], Saleh Alqahtani[1,9,10,11]. *[1]The Global NASH Council, Washington DC, United States; [2]Beatty Liver and Obesity Research Program, Inova Health System, Falls Church, United States; [3]University of Louisville School of Medicine, Division of Gastroenterology, Hepatology, and Nutrition, Jewish Hospital and Trager Transplant Center, Louisville, United States; [4]Department of Health Research, Rob Rexley VA Medical Center, Louisville, United States; [5]Division of Gastroenterology and Hepatology, Stanford University School of Medicine, Palo Alto, United States; [6]Division of Clinical Gastroenterology and Hepatology, Department of Gastroenterology, University of São Paulo School of Medicine, São Paulo, Brazil; [7]School of Public Health, University of Haifa, Haifa, Israel; [8]Center for Outcomes Research in Liver Diseases, Washington DC, United States; [9]Liver, Digestive, and Lifestyle Research Section, and Organ Transplant Center of Excellence, King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia; [10]Division of Gastroenterology & Hepatology, New York, NY, United States; Weill Cornell Medicine, New York, United States; [11]Center for Outcomes Research in Liver Disease, Washington, DC, United States*
Email: zobair.younossi@cldq.org

Background and aims: Steatotic Liver Disease (SLD) encompasses a spectrum of liver diseases characterized by hepatic steatosis resulting from metabolic dysfunction (MetD), excessive alcohol consumption (EAC), or other causes. Although the new nomenclature for SLD subtypes separates distinct categories, there may be some overlap between metabolic dysfunction associated steatotic liver disease (MASLD), Met-ALD, Alcohol Associated Liver Disease (ALD) which can be further subclassified into and ALD with MetD and ALD without MetD. We aimed to assess the prevalence and all-cause mortality of SLD subtypes using datasets from two periods from the United States' National Health and Nutrition Saverys (NHANES).

Method: Data were analyzed from NHANES III (1988–1994) and NHANES (1999–2016) with linked mortality records through 2019. SLD was defined as the presence of hepatic steatosis by ultrasound (NHANES III and U.S. Fatty Liver Index (US FLI) (NHANES 1999–2016). SLD subtypes were defined according to the consensus nomenclature and ALD was subcategorized based on MetD as the presence or absence of any cardiometabolic risks.

Results: A total of 33,373 participants were included: NHANES III (N = 13,852, mean age: 42.6 years; 48.4% male; 80.7% with MetD) and NHANES 1999–2016 (N = 19,521, mean age: 46.6 years; 48.9% male; 89.4% with MetD). Among NHANES III participants, 25.95% had MASLD, 0.56% had Met-ALD, 1.47% had ALD with MetD and 0.27% had ALD without MetD. Similar data from NHANES 1999–2016 showed increasing prevalence rates for MASLD (33.73%) and MetALD (1.35%) but stable for ALD with MetD (0.30%), and ALD without MetD (0.08%). After a median follow-up of 22.8 years for NHANES III participants (272,124 person-years), 4,092 deaths occurred. Mortality rates (per 1,000 person-years) were highest in ALD with MetD (23.76), followed by MetALD (23.10), ALD without MetD (20.95), MASLD (19.69), and controls without SLD (12.75). In Cox proportional hazards models adjusted for age, sex, race, income, marital status, education, and smoking, all-cause mortality was significantly higher for MetALD (HR: 2.82; 95% CI: 1.44–5.51), ALD with MetD (HR: 2.37; 95% CI: 1.51–3.73), and MASLD (HR: 1.20; 95% CI: 1.06–1.35) as compared to controls ($p < 0.05$). Similarly, after a median follow-up of 10.3 years for participants in NHANES 1999–2016 (196,283 person-years), 1,485 deaths occurred with mortality rates being highest in ALD with MetD (19.39), followed by MetALD (17.58), MASLD (10.68), as compared to controls without SLD (5.63).

Conclusion: Among SLD, MASLD, Met-ALD and ALD with MetD are associated with higher mortality than non-SLD controls. Furthermore, mortality rates are greatest in those with a combination of EAC and MetD (ALD with MetD and Met-ALD). This data underscores the importance of accurate assessment of alcohol consumption and MetD in clinical practice.

Hypertension combined with hyperlipidemia increased the risk of extrahepatic malignancy in the MASLD population

Xinyue Zhao[1], Feng Xue[1], Shanshan Wang[2], Haiyun Ding[2], Shuangqing Gao[2], Lai Wei[1]. *[1]Hepatopancreatobiliary Center, Beijing Tsinghua Changgung Hospital, School of Clinical Medicine, Tsinghua University, Beijing, China; [2]Beijing North Medical & Health Economic Research Center, Beijing, China*
Email: 747905328@qq.com

Background and aims: Non-alcoholic fatty liver disease (NAFLD) has been rebranded as metabolic dysfunction-associated steatosis liver disease (MASLD), incorporating additional metabolic factors. A strong link between NAFLD or MASLD and an elevated risk of carcinomas has been established. However, the specific role of cardiometabolic factors in the MASLD population related to carcinomas has rarely been addressed. The objective of our research was to identify metabolic factors, their combinations, and comorbidities associated with cancer in the MASLD population.

Method: The MASLD population was extracted from a hospital-based database across 11 canters in China. This population was established based on diagnostic criteria that accounted for 105,058 cases, including those with extrahepatic cancer. SAS was employed for statistical analysis, including logistic regression, with a significance level set at $P < 0.05$.

Results: A total of 6707 (6.38%) individuals with extrahepatic carcinoma were identified within the MASLD population, comprising 3436 males (51.23%) and 2188 individuals aged 50 to 59 years (32.62%). Lung cancer, thyroid cancer, and breast cancer were the three most common extrahepatic carcinomas. All cancers were more prevalent in males, except for thyroid cancer, which was evenly distributed between genders. Factors such as aging, male gender, pre-diabetes (HbA1c 5.7–6.4% and 2-hour post-meal blood glucose 7.8–11.0 mmol/L), type 2 diabetes mellitus, hyperlipidemia, triglycerides exceeding 1.7 mmol/L (OR 1.20, 95% CI: 1.13, 1.27), lower HDL-C (OR 1.11, 95% CI: 1.05, 1.18), and LDL-C over 3.4 mmol/L (OR 1.18, 95% CI: 1.08, 1.30) were associated with an increased risk of extrahepatic malignancy. Notably, the combination of hypertension and hyperlipidemia raised the risk of extrahepatic cancer by 2.17-fold (OR 2.17, 95% CI: 1.94, 2.43), followed by T2DM, hypertension, and hyperlipidemia at 2.15-fold (OR 2.15, 95% CI: 1.94, 2.39), and T2DM with hyperlipidemia at 1.73-fold (OR: 1.73, 95% CI: 1.54, 1.95). The use of anti-metabolic agents also increased the risk of extrahepatic cancer in the MASLD population [hypoglycemic agent (OR 1.51, 95% CI: 1.40, 1.63); antihypertensive drug (OR 1.31, 95% CI: 1.22, 1.41); lipid-lowering agent (OR 2.75, 95% CI: 2.53, 2.99)]. FIB-4 less than 1.3 significantly reduced the risk of extrahepatic cancer. Additionally, abnormal liver function, viral hepatitis, chronic kidney disease, cirrhosis, obstructive sleep apnea syndrome, and polycystic ovarian syndrome also elevated the risk of extrahepatic carcinomas.

Conclusion: Hypertension combined with hyperlipidemia significantly increases the risk of extrahepatic malignancies. FIB-4 less than 1.3 notably reduces the risk of extrahepatic cancer. Obstructive sleep apnea syndrome and polycystic ovarian syndrome are independent risk factors for extrahepatic carcinoma.

THU-373

Metabolic dysfunction-associated steatotic liver disease (MASLD) in italian women: is liver fibrosis independent from menopause?

Rusi Chen[1], Agnese Salamone[1], Chiara Abbati[1], Roberta Capelli[1], Ernestina Santangeli[1], Bernardo Stefanini[1], Madalina Gabriela Indre[1], Fabio Piscaglia[1,2], Federico Ravaioli[1], Silvia Ferri[2]. *[1]Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy; [2]Division of Internal Medicine, Hepatobiliary and Immunoallergic Diseases, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy*
Email: silvia.ferri@aosp.bo.it

Background and aims: Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD) is an emerging health concern among women, with menopause influencing its onset and progression. This study aimed to explore the connection between menopause and liver fibrosis in MASLD.
Method: Between October 2014 and September 2024, 149 non-cirrhotic women were enrolled in our MASLD outpatient clinic. Patients underwent a thorough evaluation, including physical activity and diet quality assessments, using validated questionnaires (IPAQ and REAP-S scores). Significant liver fibrosis was defined as liver stiffness ≥ 7 kPa on 2D-elastography. 10-year cardiovascular (CV) risk was assessed with ESC scores, and insulin resistance with TyG index.
Results: Of 149 women, 41 were pre-menopausal (median age 46 years, 17.1% fibrotic) and 108 post-menopausal (median age 61 years, 27.8% fibrotic). Women with fibrosis were older (median age 64 vs. 56 years, $p < 0.001$) and had higher rates of arterial hypertension (AH 64.9% vs. 43.8%, $p = 0.026$), type 2 diabetes (T2DM 40.5% vs. 16.1%, $p = 0.002$), and insulin resistance (TyG index: 4.9 vs. 4.7, $p = 0.024$). BMI, frequency of menopause status, age at menopause were similar between fibrotic and non-fibrotic women. Multivariate logistic regression analysis revealed that age (OR 1.068, $p = 0.002$) and T2DM (OR 3.633, $p = 0.004$) were independently associated with fibrosis. Compared to non-fibrotic, fibrotic post-menopausal women had poorer diet quality (REAPS score: 26 vs. 31, $p = 0.018$), higher rates of AH (73.3% vs. 46.2%, $p = 0.011$) and T2DM (40% vs. 17.9%, $p = 0.016$), accounting for a higher risk for major CV events (11.1% vs. 6.1%, $p < 0.001$). Multivariate logistic regression analysis confirmed that AH (OR 2.959, $p = 0.024$) and T2DM (OR 2.752, $p = 0.039$) were independently associated with fibrosis in post-menopausal women.
Conclusion: Among the metabolic features of MASLD, T2DM appears to be the primary driver of liver fibrosis in both pre- and post-menopausal women, while AH is associated with significant fibrosis only in the latter group. The study also underscores the impact of diet quality, which can be particularly challenging for menopausal women, possibly due to socioeconomic factors.

Longitudinal dynamics and predictors of hepatic fibrosis and steatosis in people living with HIV: an egyptian cohort study

Rahma Mohamed[1,2], Ahmed Kamel[3], Naeema El Garhy[1], Lamiaa Al Sehemy[1], Mohamed Nagy[1], Andrew Saweres[1], Remon Atef[1], Reham Awad Awad[1], Rana Marwan[1], Engy El Khateeb[4], Zeinab Elsaadany[4], Zainab Masoud[4], Rania Hamza[4], Hend Tamim[4,4], Mona Hamdy[4], Amal Sayed[4], Gamal Esmat[1], Ahmed Cordie[1,2,5]. *[1]Cairo University Hospitals, Endemic hepatogastroenterology and infectious diseases department, Cairo University Hospitals HIV Clinic, Cairo, Egypt; [2]Kasr Alaini HIV and Viral Hepatitis Fighting Group, Faculty of Medicine, Cairo University, Cairo, Egypt; [3]Clinical Pharmacy Department, Faculty of Pharmacy, Cairo University, Cairo, Egypt; [4]Cairo University, Faculty of Medicine, Department of Clinical and Chemical Pathology, Cairo, Egypt; [5]The Global NASH/MASH Council, Washington, DC, United States, Washington, United States*
Email: ahmedcordie@gmail.com

Background and aims: In the era of antiretroviral therapy, liver disease continues to be a major source of morbidity and mortality among people living with HIV (PWH). This study evaluated the longitudinal changes of liver fibrosis and steatosis, identifying predictors of progression and regression in Egyptian PWH.
Method: A retrospective analysis included PWH with or without hepatitis coinfection who consecutively underwent screening for liver fibrosis and steatosis by transient elastography and associated controlled attenuation parameter (CAP) at Cairo University Hospitals HIV clinic, Egypt from September 2022 to November 2024. Fibrosis progression was defined as development of significant fibrosis [liver stiffness measurement (LSM) ≥8 kPa], and fibrosis regression, defined as transitioning to LSM <8 kPa in patients with baseline significant fibrosis. Hepatic steatosis progression was defined as development of any grade hepatic steatosis (CAP ≥248 dB/m). Longitudinal changes in LSM and CAP were evaluated using linear mixed-effects models. Cox regression analysis was used to assess predictors of hepatic steatosis and fibrosis progression.
Results: Of 428 participants, 78.7% were male, median age was 35 years, 13% reported occasional alcohol intake and 13.3% had been cured of hepatitis C (HCV). Over a median follow-up of 11 months (IQR: 7–16), 8.24% (n = 36) had significant fibrosis at baseline. Fibrosis progression occurred in 3.66 cases per 100 person-years, while regression occurred in 42.6 cases per 100 person-years. Hepatic steatosis was present in 27.8% of participants at baseline, with progression observed in 28.98 cases per 100 person-years and regression in 60.12 cases per 100 person-years. Age, BMI, and detectable HIV viral load were significant predictors of fibrosis progression (hazard ratio [HR]: 1.04 /year, 95% CI: 1.02–1.06, $p < 0.001$; HR: 1.04/unit increase, 95% CI: 1.01–1.07, $p = 0.003$; and HR: 2.20, 95% CI: 1.30–3.75, $p = 0.004$, respectively). HCV positivity doubled the risk of fibrosis progression (HR: 2.08, 95% CI: 1.22–3.55, $p = 0.007$). BMI was the strongest predictor of steatosis severity, with CAP increasing by 1.95 units/BMI unit (95% CI: 1.35–2.55, $p < 0.001$). CAP also increased by 0.77 units/year of age (95% CI: 0.29–1.26, $p = 0.002$) and by 8.53 units/HbA1c category increment (95% CI: 0.32–16.73, $p = 0.042$). Longitudinal trends revealed significant increases in BMI ($\beta = 0.11$ units/month, 95% CI: 0.06–0.16, $p < 0.001$), HbA1c ($\beta = 0.07$ units/month, 95% CI: 0.02–0.11, $p = 0.006$), and LDL ($\beta = 0.48$ units/month, 95% CI: 0.17–0.78, $p = 0.002$).
Conclusion: A multidisciplinary approach is essential for managing liver health in PWH, addressing metabolic and HIV-specific factors to mitigate fibrosis and steatosis risks. Integrated care should prioritize routine liver monitoring, effective viral suppression, and targeted management of obesity and related comorbidities.

Prevalence, clinical features and determinants of MASLD in Klinefelter syndrome: a cross-sectional study

Aldo Marrone[1], Alfredo Caturano[1], Francesca Allosso[1], Lucia Digitale[1], Graziella Grande[1], Martina Errico[1], Raffaele Navarra[1], Marco La Montagna[1], Livio Criscuolo[2], Ferdinando Carlo Sasso[1], Daniela Pasquali[1]. *[1]Department of Advanced Medical And Surgical Sciences, University of Campania "Luigi Vanvitelli", Napoli, Italy; [2]Ospedali Riuniti Area Stabiese, Castellammare di Stabia - Gragnano, Italy, Gragnano, Italy*
Email: aldo.marrone@unicampania.it

Background and aims: Klinefelter syndrome (KS) is associated with an elevated risk of metabolic disorders, yet the prevalence and characteristics of metabolic dysfunction-associated steatotic liver disease (MASLD) in this population remain unknown. This study aims to investigate the prevalence, clinical features and key determinants of MASLD in individuals with KS.
Method: This cross-sectional study included 65 patients with KS, who had normal testosterone levels with or without replacement therapy. MASLD was diagnosed based on evidence of liver steatosis identified through abdominal ultrasound and/or controlled attenuation parameter (CAP) measurement, combined with the presence of at least one cardiometabolic risk factor. Comprehensive anamnestic, clinical, imaging, and biochemical data were collected for analysis.

Results: The prevalence of MASLD in the study population was 47.7% (31/65). Patients with MASLD were significantly older (40.5 ± 10.6 years vs. 31.5 ± 13.1 years, $p = 0.001$) and had higher BMI (29.5 ± 3.3 vs. 24.8 ± 4.4, $p < 0.001$) and waist circumference (105.5 cm [100.0–115.0] vs. 90.0 cm [87.1–99.0], $p < 0.001$). Liver steatosis was present in all patients with MASLD (100%) compared to 5.9% of patients without MASLD ($p < 0.001$). The prevalence of diabetes was significantly higher in the MASLD group (29.0% vs. 5.9%, $p = 0.010$). At multivariable logistic regression analysis, BMI (OR: 1.34, 95% CI: 1.10–1.65, $p = 0.004$) emerged as the sole independent predictor of MASLD. Among the study population, 30 patients underwent FibroScan®/CAP evaluation. The median liver stiffness (KPa) value was 4.65 [4.1–5.4], with one patient presenting with advanced fibrosis (12.5 KPa). The median CAP value was 237.0 [201.0–261.5] dB/m. Correlation analysis revealed a significant negative relationship between CAP and IGF-1 levels (r = –0.60, 95% CI: –0.85 to –0.12, $p = 0.012$). In contrast, CAP was positively correlated with triglyceride levels (r = 0.37, 95% CI: 0.02 to 0.65, $p = 0.042$) and HOMA-IR (r = 0.44, 95% CI: 0.10 to 0.69, $p = 0.015$). Additionally, HOMA-IR showed a positive correlation with KPa values (r = 0.45, 95% CI: 0.10 to 0.69, $p = 0.014$).
Conclusion: MASLD is highly prevalent in patients with KS with a prevalence of 47.7%. BMI emerged as an independent predictor of MASLD. CAP values demonstrated a negative association with IGF-1 and positive associations with triglycerides and HOMA-IR. Moreover, HOMA-IR was positively correlated with liver stiffness. These findings highlight the importance of early detection and targeted interventions to mitigate MASLD and associated metabolic risks in this high-risk group.

THU-376-YI

A systematic review and meta-analysis - does metabolic dysfunction-associated steatotic liver disease increase the risk of cardiovascular disease above and beyond shared risk factors?

Alexander Hung[1,2], Ida Ziegler Spedtsberg[3], David Etoori[1], Maja Thiele[3], William Rosenberg[1,2]. [1]*Institute for Liver and Digestive Health, Division of Medicine, University College London, London, United Kingdom;* [2]*Department of Hepatology, Royal Free Hospital, Royal Free London NHS Foundation Trust, London, United Kingdom;* [3]*Centre for Liver Research, Department of Gastroenterology and Hepatology, Odense University Hospital, Odense, Denmark, Odense, Denmark*
Email: alexander.hung1@nhs.net

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) is associated with an increased risk of incident cardiovascular disease (CVD). However, despite CVD representing the leading cause of mortality in people with MASLD, it is unclear whether liver disease is an independent risk factor (RF) for CVD, or whether cardiometabolic RFs common to MASLD and CVD account for this risk. Equipoise exists in the literature, with studies conducted in liver centres suggesting that MASLD confers higher CVD risk regardless of metabolic RFs, and large epidemiological studies suggesting this is not the case. A systematic literature review and meta-analysis of observational studies was conducted to further delineate this relationship.
Method: Medline, Embase, and Cochrane databases were interrogated from database inception to November 2024 to identify eligible studies. Exclusion criteria incorporated: method of MASLD diagnosis (which required imaging, elastography or biopsy), alcohol consumption thresholds (<30 g/20 g daily equivalent for males/females respectively), presence of baseline CVD, and follow-up period. Cross-sectional studies were excluded. The primary outcome was overall incident CVD. Secondary endpoints were composite fatal/non-fatal CVD events (CVEs), atrial fibrillation (AF), acute coronary syndrome (ACS), CVD mortality, and stroke. Raw outcome data were extracted from selected studies and meta-regression analyses performed using random-effects models to synthesise pooled odds ratios (ORs) with 95% confidence intervals (CIs).
Results: Nineteen longitudinal prospective and retrospective cohort studies, reporting various cardiovascular endpoints, were identified for inclusion with aggregate data on 1,250,664 individuals. Median follow-up period was 8.4 years (IQR 5.7–10.0). MASLD was associated with an increased risk of any incident CVD (pooled OR 1.86 [1.24–2.78]; p = 0.005). This association remained significant following adjustment for sex and cardiometabolic RFs (OR 1.89 [0.31–3.47; p = 0.02; I2 = 94.3%]). MASLD was also associated with increased risk of combined fatal/non-fatal events in an adjusted model (OR 2.85 [-0.17–5.86]; p = 0.057). As expected, MASLD was associated with increased risk of incident ACS, AF, CVD mortality, and stroke; eligible study numbers did not permit full adjustment for all cardiometabolic covariates.
Conclusion: After adjusting for common cardiometabolic RFs, MASLD is associated with a modest but statistically significant increase in the risk of incident CVD. Our findings suggest increased vigilance for incident CVD may be warranted in MASLD patients, even after optimisation of cardiometabolic parameters. The relatively wide CIs for the ORs calculated in the fully adjusted models indicate a need for caution when interpreting these data. Further high-quality studies are needed to determine the impact of MASLD as an independent RF for both overall CVD and specific cardiovascular outcomes.

THU-381

Food insecurity is associated with poorer metabolic health in adults with MASLD but is not mediated by overall diet quality or total energy intake

Ani Kardashian[1], Jennifer Dodge[1], Norah Terrault[1]. [1]*University of Southern California, Los Angeles, United States*
Email: ani.kardashian@med.usc.edu

Background and aims: Food insecurity (FI) is a risk factor for metabolic dysfunction-associated steatotic liver disease (MASLD), but its association with metabolic comorbidities in MASLD, and the role of overall diet quality and total energy intake in mediating these relationships, is unknown.
Method: We performed a cross-sectional analysis of adult participants (age ≥20 years) with MASLD from the National Health and Nutrition Examination Survey between 2005–2020. MASLD was defined by a US Fatty Liver Index of ≥30 in the absence of viral hepatitis or significant alcohol use (drinks/day: >4 in men, >3 in women). Participants were categorized as food insecure vs secure using the USDA Food Security Survey Module. Metabolic health outcomes were measured continuously (BMI, waist circumference, hemoglobin A1c, triglycerides, high-density lipoprotein (HDL), systolic [SBP] and diastolic blood pressure [DBP]). The Food Frequency Questionnaire measured total energy intake and diet quality, assessed by the Healthy Eating Index (HEI-2015; score range 0–100). We performed multivariable linear regressions to examine the association of (1) FI with metabolic outcomes, (2) FI with potential mediators (HEI-2015, total energy intake), and (3) mediators with metabolic outcomes controlling for age, sex, race-ethnicity, education, smoking, and alcohol use. If the associations were significant, we then evaluated if diet quality and energy intake mediated the effect of FI on metabolic outcomes (p < 0.05 and >10% mediating effect was considered significant).
Results: Of 4706 adults with MASLD, 1033 (22%) were food insecure. Adults who were food insecure, compared to food secure, were more likely to be Hispanic (33% vs 15%), foreign born (25% vs 12%), or uninsured (34% vs 12%) and less likely to be employed (51% vs 58%). Food insecure adults with MASLD also had higher mean BMI (36 vs 34 kg/m^2) and hemoglobin A1c (6.3% vs 6%), poorer diet quality (mean HEI-2015: 47 vs 50), but lower daily total energy intake (2030 vs 2140 kilocalories). In multivariable analysis, FI was associated with higher hemoglobin A1c (0.34%, p < 0.001), but neither HEI-2015 (p = 0.90) nor energy intake (p = 0.11) mediated this association. Similarly, FI was associated with higher mean DBP (1.49 mmHg, p = 0.04) but not significantly mediated by HEI-2015 (p = 0.42) or energy

intake (p = 0.006, 6% mediating effect). FI was also associated with higher BMI (0.94 kg/m^2, p = 0.05) and higher waist circumference (1.59 centimeters, p = 0.06) but did not reach statistical significance. There was no association of FI with SBP (p = 0.08), HDL (p = 0.34), or triglycerides (p = 0.31) in multivariable analyses.
Conclusion: FI is associated with worse metabolic health in MASLD. However, overall diet quality and total energy intake are not the main underlying drivers of this association. Future studies should investigate the role of individual dietary components, psychosocial factors (i.e. stress, depression), and other social determinants of health that may present in the context of FI.

THU-382-YI
Exploring the interplay between sarcopenia, liver and cardiovascular damage in non-cirrhotic MASLD patients: a genetic perspective
Annalisa Cespiati[1,2], Rosa Lombardi[1,2], Floriana Santomenna[1,2], Giuseppina Pisano[2], Giovanna Oberti[2], Cristina Bertelli[2], Roberta Forlano[3], Pinelopi Manousou[3], Grazia Pennisi[4], Salvatore Petta[4], Paola Dongiovanni[2], Anna Ludovica Fracanzani[1,2].

Email: annalisa.cespiati@unimi.it

Background and aims: Sarcopenia is associated with advanced liver fibrosis, and bioelectrical impedance analysis (BIA) reliably assesses muscle mass. Both metabolic-dysfunction associated steatotic liver disease (MASLD) and sarcopenia increase cardiovascular (CV) risk. Genetic variants like PNPLA3, TM6SF2, and HSD17B13 influence MASLD risk, but their roles in sarcopenia and CV damage are unexplored. Aim: To assess the impact of sarcopenia and genetic variants on liver and CV damage in non-cirrhotic MASLD patients.
Method: We enrolled 841 MASLD patients from three Liver Units. Fibrosis was assessed by liver stiffness measurement (LSM) (LSM ≥8 kPa for advanced fibrosis) and steatosis by controlled attenuation parameter (CAP) at Fibroscan (CAP >280 dB/m for severe steatosis). Sarcopenia was defined by the lowest tertile of skeletal muscle index (SMI = skeletal muscle mass/height^2) at BIA. CV risk was assessed using SCORE2 and SCORE-OP; CV damage markers included carotid intima-media thickness (cIMT) ≥0.9 mm, carotid plaques, epicardial fat thickness (EFT) ≥5.2 mm. Increased waist circumference (WC) >102/88 cm in men/women. Genetic polymorphisms in PNPLA3, TM6SF2, and HSD17B13 were assessed in 424 patients.
Results: Mean age was 51 ys, 63% male. 43% were obese, 65% had increased WC. 50% were dyslipidemic, 25% diabetic. 24% had advanced fibrosis, 71% severe steatosis. 71% had higher high CV risk, 22% had increased cIMT, 35% had carotid plaques, 83% had increased EFT. Sarcopenia (SMI < 10.35/7.75 kg/m^2 in men/women) was linked to older age (54 vs 48 ys, p < 0.001), lower BMI (27 vs 33.4 kg/m^2, p < 0.001), WC (99 vs 110 cm, p < 0.001), CAP (293 vs 317 dB/m, p < 0.001), and LSM (4.9 vs 6.4 kPa, p < 0.001) compared to non-sarcopenic. Sarcopenic also had higher dyslipidemia (56% vs 46%, p = 0.03), increased cIMT (28% vs 18%, p = 0.01), and EFT (85% vs 77%, p = 0.05). At adjusted multivariate analysis, sarcopenia remained associated with low BMI (OR 0.61; 95% CI 0.5–0.7, p < 0.001), WC (OR 0.92; 95% CI 0.8–0.97, p = 0.001), female sex (OR 2.21; 95% CI 1.2–4.0, p = 0.008), and increased cIMT (OR 2.1; 95% CI 1.1–3.97). In sarcopenic, PNPLA3 CG/GG variant was linked to increased LSM (OR 1.82, 95% CI 1.1–3.1, p = 0.03) but lower cIMT (OR 0.39, 95% CI 0.15–0.96, p = 0.04). TM6SF2 wild-type allele was associated with increased cIMT (OR 3.4, 95% CI 1.3–5.8, p = 0.004), and WC (OR 2.3, 95% CI 1.4–3.6, p = 0.001). No differences were seen in HSD17B13 variant.
Conclusion: Sarcopenia independently correlates with atherosclerosis markers in non-cirrhotic MASLD, though liver damage is less common, possibly due to lower visceral fat. In sarcopenic patients, the PNPLA3 variant correlated with increased liver damage but lower subclinical atherosclerosis, while TM6SF2 polymorphism showed a protective role against CV damage. Combining imaging and genetic data is required to clarify the role of sarcopenia in liver and CV damage in non-cirrhotic MASLD.

Email: fengqin@shutcm.edu.cn

Background and aims: The relationship between muscle fat content and metabolic dysfunction-associated steatotic liver disease (MASLD) has not been well investigated. Here, we aim to elucidate the association between muscle fat content quantified by magnetic resonance imaging-proton density fat fraction (MRI-PDFF) and MASLD severity.
Method: Cross-sectional and longitudinal studies were conducted in this research. The cross-sectional study enrolled 500 participants,

including 446 patients with MASLD and 54 healthy volunteers. Among the patients with MASLD, 164 underwent liver biopsy. A total of 136 MASLD patients was subjected to a 24-weeks follow-up in longitudinal study. All subjects underwent abdominal MRI, and general, biochemical, and imaging parameters were collected. The muscle fat content was measured in the psoas muscle at the level of the 3rd lumbar vertebra by PDFF (L3-PDFFPsoas). L3-PDFFPsoas response was defined by Cohen's d (responding group, Cohen's d ≥0.2).
Results: MASLD patients exhibited higher L3-PDFFPsoas compared to healthy volunteers [median (IQR): 4.8(1.6) % vs. 6.6(2.6) %, P < 0.001]. L3-PDFFPsoas was higher in metabolic dysfunction-associated steatohepatitis (MASH) than in MASL (P = 0.0048) and increased with the severity of MASH (early MASH, fibrotic MASH, and MASH cirrhosis) (P = 0.013). Subjects with more severe ballooning or fibrosis had higher L3-PDFFPsoas (all P < 0.05). Also, in total participants, L3-PDFFPsoas was significantly related to FIB-4 score and liver stiffness measurement (LSM), respectively (r = 0.349 and 0.264, all P < 0.05). After adjustment for multiple confounders, L3-PDFFPsoas was robustly associated with liver fibrosis (odds ratio = 1.320, 95% CI: 1.039–1.678, P = 0.023), while L3-PDFFPsoas was not significantly associated with MASLD and MASH. After 24-weeks follow-up, there are significant reductions in L3-PDFFPsoas (all P < 0.05) in patients with a 30% relative decrease in MRI-PDFF, 17 IU/L decrease in alanine aminotransferase (ALT) or over 2 kPa decrease in LSM. Between-group analysis showed greater reduction in MRI-PDFF, ALT and LSM in favor of L3-PDFFPsoas responders (all P < 0.05).
Conclusion: Muscle fat content is significantly correlated to MASLD, especially liver fibrosis. Alterations in muscle fat content correspond with MASLD improvement. These data underscore the potential utility of muscle fat content as a biomarker in the diagnostic and management of MASLD.

THU-384

Cardiovascular risk screening in patients with metabolic dysfunction-associated steatotic liver disease

Balint Dracz[1], Hagymási Krisztina[1], Gabriella Lengyel[1], Anna Egresi[1], Elek Dinya[2], Attila Szijarto[1], Klara Werling[1]. *[1]Semmelweis University Department of Surgery, Transplantation and Gastroenterology, Budapest, Hungary; [2]Semmelweis University Digital Health Department, Budapest, Hungary*
Email: balint.dracz@gmail.com

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the most common chronic liver disease worldwide. Patients with MASLD are at higher risk of developing cardiovascular diseases (CVD), which are associated with increased mortality rates. However, the management of CVD screening in MASLD patients is still unknown. Therefore, our aim was to assess the CVD risk and develop a CVD risk stratification protocol for MASLD patients.
Method: Between 2007–2024, 251 reclassified NAFLD/MASLD patients (126 females – 125 males) were recruited in two hepatology units of Semmelweis University, Hungary. The reclassification of recruited patients was performed according to the latest guidelines based on the modified multisociety Delphi consensus statement. We used Framingham risk score and Atherosclerotic Cardiovascular Disease (ASCVD) score for CVD risk stratification. Among non-invasive fibrosis markers, fibrosis-4 index (FIB-4) and aspartate aminotransferase to platelet ratio index (APRI) were calculated to identify the high CVD risk patients with MASLD and the most common CVD complications.
Results: There was an increased CVD risk in 21% of MASLD patients (51/247). Stroke was the most prevalent CVD complication. Compared to Framingham risk score, ASCVD was significantly (p < 0.05) associated with higher occurrence of CVD complications. Liver cirrhosis was developed in 13% of MASLD patients (32/247) during the follow-up period, which was associated with higher CVD risk. Regarding median values of FIB-4 and APRI, FIB-4 ≥1,36 MASLD patients were at significantly (p < 0.05) higher risk of developing CVD complications in the low CVD risk patients with MASLD (ASCVD<10%).
Conclusion: ASCVD had a better predictive value in CVD risk screening. MASLD patients were vulnerable to disease progression and consequently more severe clinical outcomes. FIB-4 ≥1,36 was significantly associated with higher CVD risk, regradless of ASCVD levels. FIB-4 and ASCVD scores should be routinely employed for CVD risk assessment in MASLD.

THU-385-YI

Association between polycystic ovary syndrome, steatotic liver disease in pregnancy, and adverse pregnancy outcomes: results from the prospective fatty liver in pregnancy cohort

Cecilia Katzenstein[1], Nina Rodriguez[1], Ning Ma[1], Rachel Meislin[1], Sonam Rosberger[1], Keith Sigel[1], Rhoda Sperling[1], Norah Terrault[2], Tatyana Kushner[1]. *[1]Icahn School of Medicine at Mount Sinai, New York, United States; [2]Keck School of Medicine at USC, Los Angeles, United States*
Email: cecilia.katzenstein@icahn.mssm.edu

Background and aims: Polycystic Ovary Syndrome (PCOS), often associated with insulin resistance (IR), is one of the strongest predictors of steatotic liver disease (SLD) in women, which in turn has been associated with adverse pregnancy outcomes (APOs). We evaluated the relationship between PCOS and SLD in pregnancy, the role of IR, and its influence on APOs.
Method: We leveraged the prospective "Fatty Liver in Pregnancy" cohort to evaluate the prevalence of PCOS by medical record and SLD by liver ultrasound performed between 18–26 weeks gestation. PCOS patients were stratified by evidence of IR, defined as history of diabetes mellitus (DM) or gestational diabetes (GDM) in a prior pregnancy. History of pre-pregnancy SLD, SLD during pregnancy, and prevalence of APOs were compared between the groups and to a control population without SLD/PCOS.
Results: Of 1,148 patients enrolled from 2019–2024, 73 (6%) had PCOS; 211 (18%) had evidence of SLD. Patients with PCOS were more likely to be Hispanic (60% vs 54%, p = 0.04), have hypertension (20% vs 8%, p = 0.00), have taken Metformin previously (4% vs 0.3%, p = 0.00) or Aspirin during pregnancy (50% vs 35% p = 0.02), and were on average older (31% vs 29%, p = 0.01) with higher pre-pregnancy BMIs (31% vs 28%, p = 0.00). The PCOS group had higher rates of prior GDM as well as DM (17% vs 5%, p = 0.01; 9% vs 3%, p = 0.01), as did those with SLD (13% vs 6%, p = 0.00; 8% vs 3%, p = 0.00). In those with both SLD and PCOS, rates were higher than in either group alone compared to controls (36% p = 0.00; 19% p = 0.00). PCOS patients had a higher incidence of preeclampsia (21% vs 13%, p = 0.05), which more than doubled in those with PCOS and IR (47% vs 13%, p = 0.00). There was an increased incidence of preterm birth and current GDM in those with PCOS and IR (33% vs 14%, p = 0.03; 29% vs 11%, p = 0.04). The PCOS cohort had a higher prevalence of diagnosed pre-pregnancy SLD (4% vs 1% p = 0.01), which was increased in those with PCOS and IR (13% vs 1%, p = 0.00). Those with PCOS and IR also had an increased incidence of SLD in pregnancy (43% vs 20%, p = 0.03). In a multivariate analysis adjusted for age and BMI, PCOS with IR was associated with SLD in pregnancy (OR 3.11, CI: 1.02–9.45; p = 0.05).
Conclusion: SLD was seen in 26% of pregnant patients with PCOS. Although PCOS is a known risk factor for SLD, only PCOS with IR was associated with SLD in pregnancy. PCOS with IR also plays an important role in the development of some APOs, necessitating the consideration of PCOS phenotypes when evaluating risk of both SLD in pregnancy and pregnancy outcomes.

THU-386

Both high intensity and moderate intensity exercise interventions improve steatotic liver disease: a prospective randomized trial

Chun-Jen Liu[1]. [1]*Hepatitis Research Center, National Taiwan University Hospital, Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan*
Email: cjliu@ntu.edu.tw

Background and aims: Steatotic liver disease (SLD) is the most common liver disease worldwide. Lifestyle modification including exercise intervention is recommended to reduce hepatic steatosis, but the effectiveness of different exercise patterns and adherence remains unclear.
Method: This prospective single-center study was conducted at National Taiwan University Hospital (NTUH) from August 2020 to December 2023, just during the COVID-19 pandemic period. After diagnosing SLD, individuals were assessed with baseline cardiometabolic profile and imaging examination composed of transient elastography with controlled attenuation parameter (CAP), magnetic resonance imaging (MRI) with proton density fat fraction (PDFF), and magnetic resonance spectroscopy (MRS). Then the subjects were separated into control (N = 20) and exercise (N = 95) cohorts (randomized into moderate-intensity continuous [MCT], N = 49; and high-intensity interval training [HIIT] groups, N = 46) at baseline. Finally, 80 and 20 in the exercise and control groups completed the 24-week trial assessment and analysis with the primary outcome of a decrease of PDFF >10% and secondary outcome of a decrease of PDFF >30%.
Results: In the intention-to-treat analysis, exercise (odds ratio [OR]: 3.783, 95% confidence interval [CI]: 1.251–11.439, p = 0.018), HIIT pattern (OR: 3.666, 95% CI: 1.162–11.562, p = 0.027), and adherence (OR: 1.044, 95% CI: 1.025–2,063, p < 0.001) were the most important predictors of achieving a decrease of PDFF >10% in multivariate analysis. By per-protocol analysis of the exercise group, adherence (OR: 1.025, 95% CI: 1.004–1.047, p = 0.019) was the only factor to predict a decrease of PDFF >10% by multivariate analysis. Similar findings were obtained regarding secondary outcome of a decrease of PDFF >30%. Exercise significantly decreased CAP, PDFF, and MRS (all p < 0.001) values.
Conclusion: Exercise was an effective intervention in patients with SLD. High-intensity pattern and adherence played the most important roles in achieving a decrease in hepatic steatosis.

THU-387

Analysis of body composition in patients with metabolic dysfunction-associated steatotic liver disease and its relationship with liver fibrosis

Leticia Mariano[1], Victoria Borba[1], Gabriel Calgaro[1], Brian Pinheiro[1], Rafael Novaes[1], Evelize Behrens[1], Carolina Moreira[1], Rosangela Rea[1], Claudia Alexandra Pontes Ivantes[1]. [1]*Universidade Federal do Paraná, Curitiba, Brazil*
Email: letipetronzelli@gmail.com

Background and aims: Type 2 diabetes mellitus (T2D) and obesity are key risk factors for the development of metabolic dysfunction-associated steatotic liver disease (MASLD). Lifestyle modification is essential for managing this condition, and body composition serves as a primary indicator of overall health and nutritional status. However, the impact of body composition changes on MASLD progression remains unclear. This study aims to investigate the correlation between body composition and advanced liver fibrosis in T2D patients.
Method: This cross-sectional observational study was conducted in a tertiary care hospital between October 2023 and April 2024. Data collection included clinical and epidemiological information, transient elastography (FibroScan™ and Smeda-New Life™), and dual-energy X-ray absorptiometry (DXA, Hologic A™). A total of 172 patients aged 18 years or older were initially enrolled. Seven participants were excluded due to an interquartile range (IQR) ≥30, five due to unfeasible examinations, 44 with type 1 diabetes mellitus, and five with latent autoimmune diabetes in adults. The final analysis included 111 participants, all diagnosed with T2D, of whom 54 underwent DXA. Statistical analysis was performed using univariate logistic regression with the Stata software.
Results: The analysis revealed that among the 77 patients without advanced liver fibrosis (G1), 18.2% were male and 81.8% were female, with a mean age of 60 years (±13.93). Among the 34 patients with advanced liver fibrosis (G2), 41.2% were male and 58.8% were female, with a mean age of 64 years (±12.22). Compared to G1, G2 patients exhibited a larger waist circumference (97 ± 13.08 cm vs. 106 ± 10.65 cm; p = 0.001) and a higher body mass index (29.9 ± 5.46 vs. 32.15 ± 4.75; p = 0.021). Among the 54 patients who underwent DXA, 33 (61.1%) were classified as having no advanced liver fibrosis (G3), while 21 (38.9%) had advanced liver fibrosis (G4). G4 patients showed a higher trunk-to-leg fat ratio compared to G3 (1.14 ± 0.18 vs. 1.018 ± 0.18; p = 0.024). Additionally, the android-to-gynoid fat ratio exceeded one in both groups, with averages of 1.06 ± 0.15 in G3 and 1.15 ± 0.16 in G4 (p = 0.078). Other variables measured by DXA, such as lean mass and fat mass, did not show statistically significant differences.
Conclusion: Patients with advanced liver fibrosis demonstrated a higher body mass index, an increased trunk-to-leg fat ratio, and a greater waist circumference compared to those without advanced liver fibrosis.

THU-388

Early-onset cancer risk in young adults with metabolic dysfunction-associated steatotic liver disease

Goh Eun Chung[1], Su Jong Yu[2], Eun Ju Cho[2], Yoon Jun Kim[2], Jung-Hwan Yoon[2]. [1]*Seoul National University Hospital Healthcare System Gangnam Center, Seoul, Korea, Rep. of South;* [2]*Seoul National University College of Medicine, Seoul, Korea, Rep. of South*
Email: creatioex@gmail.com

Background and aims: The incidence of early-onset cancers, typically defined as cancers diagnosed in adults <50 years of age, has increased. Metabolic dysfunction-associated steatotic liver disease (MASLD) extends beyond the liver to affect cardiovascular disease and various extrahepatic cancers. In this study, we investigated the association between MASLD and cancer in young adults.
Method: This study included adults aged 20–39 years who underwent health screening examinations between 2009 and 2012 based on the Korean National Health Insurance Service database. Hazard ratios (HRs) and 95% confidence intervals (CIs) for the development of cancer were analyzed using Cox proportional hazards models.
Results: During the median 10.6 years of follow-up, MASLD was observed in 1,447,148 (25.4%) of the 5,690,033 participants. According to the age- and sex-adjusted model, the risk of all cancers was increased in the MASLD group compared with the no steatosis group (HR: 1.26, 95% CI, 1.24–1.28). After multivariable adjustment, the risk of all cancers was 1.11 (95% CI: 1.09–1.23)-times greater in individuals with MASLD than in those without steatosis. When stratified by various subgroups, the increased risk for cancer in the MASLD group was prominent in individuals under 30 years of age, males, current smokers, and those who consumed alcohol (all *P* values for interactions <0.05).
Conclusion: In young adults, MASLD was associated with an increased risk of developing cancer. These findings highlight the need for early intervention in patients with MASLD before they reach middle age to mitigate cancer risk.

THU-389

The severity of MASLD is associated with chronic kidney disease in patients with type 2 diabetes and/or obesity

Bérénice Ségrestin[1], Bruno Vergès[2], Mallaury Cardoso[3], Dominique Delaunay[3], Rouland Alexia[2], Hadjadj Samy[4], Primot Claire[4], Pierre Morcel[4], Jean-Michel Petit[2], Sybil Charrière[5], Philippe Moulin[5], Laetitia Koppe[6], Emmanuel Disse[3], Bertrand Cariou[4], Cyrielle Caussy[7]. *[1]Département Endocrinologie, Diabète et Nutrition, Hôpital Lyon Sud, Hospices Civils de Lyon, Univ Lyon, CarMen Laboratory, INSERM, INRA, INSA Lyon, Université Claude Bernard Lyon 1, Pierre-Bénite, France; [2]Department of Endocrinology, Diabetes and Metabolic Disorders, Dijon University Hospital, INSERM Unit, LNC-UMR 1231, University of Burgundy, Dijon, France; [3]Département Endocrinologie, Diabète et Nutrition, Hôpital Lyon Sud, Hospices Civils de Lyon, Pierre-Bénite, France; [4]Nantes Université, CHU Nantes, CNRS, INSERM, l'institut du thorax, Nantes, France; [5]Département Endocrinologie, Diabète et Nutrition, Hôpital Cardiologique, Hospices Civils de Lyon, Bron, France; [6]Département de Néphrologie, Hôpital Lyon Sud, Hospices Civils de Lyon, Pierre-Bénite, France; [7]Département Endocrinologie, Diabète et Nutrition, Hôpital Lyon Sud, Hospices Civils de Lyon, Univ Lyon, CarMen Laboratory, INSERM, INRA, INSA Lyon, Université Claude Bernard Lyon 1, Pierre-Bénite, France*
Email: cyrielle.caussy@chu-lyon.fr

Background and aims: An association between metabolic dysfunction associated steatotic liver disease (MASLD) and chronic kidney disease (CKD) has been reported, but the link between MASLD severity and CKD has not been well explored. Therefore, we assessed the association between CKD and advanced fibrosis in patients with type 2 diabetes (T2D) and/or obesity and MASLD prospectively enrolled in a systematic screening for the presence of advanced fibrosis (AF).
Method: A cross-sectional analysis was conducted on 787 patients with T2D and/or obesity (classes 1 & 2) and MASLD, aged 40–80 years. These patients were prospectively recruited from four diabetology departments in France (2020–2024) to assess the risk of AF. All participants underwent a comprehensive liver assessment using Fibrotest®, FibroMeter®, ELF™, FIB-4 and transient elastography (TE) and controlled attenuation parameter (CAP) with FibroScan. If clinically indicated a liver biopsy or magnetic resonance elastography (MRE) was performed to assess the risk of AF. High risk of AF was defined by a hierarchical composite criterion depending on availability: 1. liver biopsy ≥F3, 2. MRE ≥3.62 kPa or overt imaging diagnosis of cirrhosis 3. TE ≥12 kPa. CKD was defined by a decrease of estimated glomerular filtration rate by CKD-EPI formula (eGFR) <60 ml/min/1.73 m^2 or urinary albumin-to-creatinine ratio (uACR) >3 mg/mmol.
Results: Among the 787 participants (mean age: 59.9 ± 9.7 years; mean BMI: 32.7 ± 4.4 kg/m², mean eGFR: 81.3 ± 15.6 ml/min/73 m^2 , mean uACR: 14.0 ± 45.4 mg/mmol; 86.1% with T2D and 73.7% with obesity), 35.6% had CKD and 8.9% had high risk of AF. Liver stiffness measurement by TE were significantly higher in patients with CKD: 6.1 versus 5.5 kPa, p < 0.001. CAP value was also significantly higher in patients with CKD: 321 versus 311 db/m, p = 0.01. All non-invasive blood-based biomarkers of fibrosis (Fibrotest®, Fibrometer®, ELF™, and FIB-4 scores) were also significantly higher in the presence of CKD compared to patients without CKD (all p < 0.001). The proportion of CKD increased with fibrosis severity: 33.1% (low), 38.8% (intermediate), and 54.3% (high), p for trend = 0.002. Participants at high-risk of AF had a significant increased risk of CKD compared to those with low/intermediate risk of AF: Odds ratio (OR): 2.33, [95% confidence interval (CI): 1.42–3.82], p < 0,001. This higher risk of CKD remained significant after adjustment for age, sex, HbA1c and BMI: adjusted OR: 1.84 [95%CI: 1.08–3.14], p = 0.025. This association was also observed in the subgroup with T2D: adjusted OR for age sex and BMI: 1.71 [95%CI: 1.004–2.910], p = 0.048.
Conclusion: In patients with T2D and/or obesity, the presence of MASLD-related AF was associated with CKD, independently of age, sex, HBA1c and BMI.

THU-390

Genetic risk accentuates the impact of lifestyle on progression hepatic steatosis and fibrosis: insights from a population-based cohort

Yanhua Ding[1], Aruhan Yang[1], Xiaoxue Zhu[2], Haiyan Jia[1]. *[1]jilin University, Changchun, China; [2]Jilin University, Changchun, China*
Email: arh22@mails.jlu.edu.cn

Background and aims: Genetic factors and lifestyle choices both play a role in the risk of developing hepatic steatosis and fibrosis. However, the impact of gene-lifestyle interactions on these conditions has not been fully explored.
Method: This cohort study involved 724 MASLD patients, all of whom completed two follow-up visits at least one year apart. Lifestyle factors from the past month, including sedentary behavior, soft drink intake, and physical activity levels (PA; categorized as low, moderate, or high per WHO guidelines), were recorded through questionnaires. Liver fat content (LFC) and fibrosis severity (LSM) were measured via MRI-PDFF and FibroScan, respectively. Diagnoses adhered to EASL standards, with Mod-Sev steatosis defined as LFC >14.1%.Genetic analysis of blood samples from 272 participants included an Asian Screening Array and additional susceptibility SNPs (e.g., PNPLA3, HSD17B13, RASGLP1). Following quality control, genotyping data for 260 samples across 475,787 SNP loci were obtained. A genetic risk score (GRS) based on the top 10 SNPs associated with LFC was computed. Gene-lifestyle interactions were examined for their effects on steatosis and fibrosis progression using R.
Results: Mod-Sev steatosis was observed in 38.1% (N = 276) of patients. Risk factors included low PA, frequent soft drink consumption (>1 time/week), and prolonged sedentary behavior (>6 hours/day), with odds ratios (ORs) of 4.0 [3.1–5.3], 2.4 [1.7–3.3], and 1.7 [1.2–2.3], respectively. Genetic variants in PNPLA3 and HSD17B13, along with a high GRS, were significantly associated with Mod-Sev steatosis, with ORs of 1.6 [1.1–2.2], 2.5 [1.6–3.8], and 2.9 [1.9–4.2]. Among individuals sedentary >6 h/day, those with the PNPLA3 GG genotype (N = 34) had an 82% prevalence of severe steatosis compared to 50% in CC carriers (N = 33). For soft drink consumption, prevalence was 57% in GG carriers (N = 37) versus 38% in CC carriers (N = 28). The interaction of the PNPLA3 G allele with soft drink consumption increased LFC by 1.6-fold compared to soft drink consumption alone. Similarly, its interaction with sedentary behavior resulted in a 2.2-fold higher effect than sedentary behavior alone. The HSD17B13 A insertion mutation amplified the effect of low PA by 3.6 times. Significant interactions were also observed between a high GRS and both low PA and soft drink consumption. Among individuals with weight loss over one year (N = 127), those with the RASGRP1 (rs7403531) TT genotype showed a significantly greater association between weight change and changes in LSM (gene-weight interaction β: 0.98, P = 0.005) and experienced a larger reduction in LSM compared to CC/CT carriers (−1.90 kPa vs. −0.06 kPa).
Conclusion: The effects of lifestyle on LFC and LSM were markedly enhanced in patients with higher genetic risk for MASLD, suggesting that lifestyle interventions could be particularly effective in these individuals.

THU-391

Impact of metabolic dysfunction-associated steatotic liver disease (MASLD) on serological milestones of chronic hepatitis B patients

Hui-Chun Yang[1,2], Mei-Hung Pan[2], Chih-Jen Huang[2], Ding-Lian Wang[2], Hwai-I Yang[2]. *[1]Department of Public Health, Kaohsiung Medical University, Kaohsiung, Taiwan; [2]Genomics Research Center, Academia Sinica, Taipei, Taiwan*
Email: dora02020@gmail.com

Background and aims: Chronic hepatitis B (CHB) affect over 254 million people globally, contributing to liver-related complications and mortality. The natural history of CHB can be predicted and classified into three distinct milestones such as seroclearance of HBeAg, HBV DNA, and HBsAg. Fatty liver disease (FLD), now termed

metabolic dysfunction-associated steatotic liver disease (MASLD), affects one-third of the global population and contributes to liver disease progression. MASLD includes patients with chronic viral hepatitis and metabolic risk factors. Although MASLD has been linked to changes in liver function, its specific impact on the natural history of CHB remains unclear. This study investigates how MASLD influences HBV's progression and serological outcomes in CHB patients.

Method: The REVEAL-HBV cohort in Taiwan included 3,653 HBV-infected individuals without hepatitis C. Those with baseline cirrhosis or missing fatty liver data were excluded (n = 1,067). MASLD diagnosis required hepatic steatosis detected via ultrasound and at least one metabolic criterion: (1) BMI ≥23 kg/m² or waist circumference ≥90 cm (men) or ≥80 cm (women); (2) fasting glucose ≥100 mg/dL, two-hour glucose ≥140 mg/dL, or HbA1c ≥5% or (3) triglycerides ≥150 mg/dL. Patients with one metabolic criterion were classified as mild MASLD; those with two or more as moderate MASLD. Clinical outcomes included HBeAg, HBV DNA, and HBsAg seroclearance. Kaplan-Meier analysis estimated cumulative incidence rates, and Cox regression calculated hazard ratios (HR).

Results: Baseline BMI (22.77 ± 2.65 vs. 26.18 ± 3.38 vs. 26.96 ± 2.90) and triglycerides (101.32 ± 66.39 vs. 106.64 ± 60.63 vs. 247.56 ± 193.42) differed significantly across non-fatty liver, mild MASLD, and moderate MASLD groups. HBeAg seroclearance rates showed no significant difference between mild or moderate MASLD and non-fatty liver groups (adjusted HR = 0.86 [95% CI: 0.59–1.26] and 1.13 [0.73–1.76], respectively). However, moderate MASLD was associated with higher HBV DNA undetectability (HR = 1.54, 95% CI: 1.17–2.03) and HBsAg seroclearance (HR = 1.70, 95% CI: 1.31–2.21). Cumulative incidence analysis shows no significant difference in the clearance in HBeAg seroclearance among the groups (p-value = 0.34), while MASLD groups exhibit higher cumulative incidence of HBV DNA undetectability and HBsAg seroclearance than the non-fatty liver group (p-value = 0.00029 and 0.00011).

Conclusion: This study demonstrates that concurrent MASLD in CHB patients is associated with significantly higher HBV DNA and HBsAg seroclearance rates, suggesting reduced viral replication and potentially slower disease progression. However, no significant differences were observed in HBeAg seroclearance among the groups, consistent with previous findings that steatosis does not affect HBeAg clearance. These results highlight MASLD's influence on HBV serological outcomes, particularly in enhancing viral clearance.

THU-392

Changes in liver stiffness and controlled attenuation parameters of transient elastography according to weight change in metabolic dysfunction-associated liver disease

Seong Kyun Na[1]. [1]*Inje University College of Medicine, Seoul, Korea, Rep. of South*
Email: drcoramdeo@naver.com

Background and aims: The Controlled attenuation parameter (CAP) and the liver stiffness (LS) of transient elastography (TE) are widely used to measure the degree of fatty liver and liver fibrosis. We investigated whether there were significant changes in CAP and LS according to the amount of weight loss in patients with metabolic dysfunction-associated liver disease (MASLD).

Method: The patients with MASLD at Jeju National University Hospital in Korea who had TE tests more than once while losing body weight were analyzed. CAP and LS were compared between the time of the first test and the time of the weight was most lost during the follow-up.

Results: A total of 410 patients were analyzed and 74.6% of patients lost body weight during the follow-up period. The mean age was 51.97 years (standard deviation (SD): 15.10), the mean body mass index (BMI) was 28.71 (SD: 4.21). Patients who lost weight were divided into 5 groups according to the amount of weight loss (WL), and all groups showed significant CAP change (−25.62 in the 0 to 3% WL group, −21.52 in the 3 to 5% WL group, −41.92 in the 5 to 7% WL group, −32.79 in the 7 to 10% WL group, −74.16 in the more than 10% WL group, all p-values <0.05). The mean LS change by group was +0.75 in the 0 to 3% WL group, −0.30 in the 3 to 5% WL group, +0.40 in the 5 to 7% WL group, −0.40 in the 7 to 10% WL group, −1.31 in the more than 10% WL group, and was significant only in the more than 10% WL group (p = 0.002). In multivariable analysis, weight change percentage, baseline BMI, and weight loss duration were significantly associated with CAP change, and weight change percentage, baseline BMI, and weight loss duration were significantly associated with LS change.

Conclusion: In patients with MASLD, there was a significant correlation between weight loss and CAP, and LS decreases significantly when weight loss is greater than 10% of baseline body weight.

THU-397

Clinically meaningful fatigue is associated with the presence of systemic inflammation, lower erythrocyte count and haemoglobin level, and decreased muscle strength in patients with metabolic dysfunction-associated steatotic liver disease

Anna Sheptulina[1], Elvira Mamutova[1], Ekaterina Lusina[1], Oxana Drapkina[1]. [1]*National Medical Research Center for Therapy and Preventive Medicine, Moscow, Russia, Moscow, Russian Federation*
Email: sheptulina.anna@gmail.com

Background and aims: Fatigue is a significant issue in metabolic dysfunction-associated steatotic liver disease (MASLD) and may hinder increased physical activity and lifestyle modifications, which are the cornerstone of MASLD therapy. Although the pathogenesis of fatigue in MASLD remains poorly understood, potential mechanisms may involve several extrahepatic factors. This study aimed to evaluate the association between laboratory data, muscle strength, and the presence of clinically meaningful fatigue in patients with MASLD.

Method: A total of 116 MASLD patients were included in the study. MASLD was diagnosed based on ultrasonography findings, the absence of other liver disease etiologies (based on laboratory data), and the presence of at least one cardiometabolic risk factor. Fatigue was evaluated using the Fatigue Assessment Scale (FAS). An overall score of ≥22 points was indicative of clinically meaningfull fatigue. Grip strength (GS) was measured using a mechanical hand dynamometer (ZAO "NTMIZ" Russia). Patients were instructed to squeeze the dynamometer with maximum force three times using their dominant hand, with a 60-second rest between trials. The maximum value was registered. GS <27 kg in men and <16 kg in women were used as thresholds for decreased GS. Relative GS (rGS) value was calculated as GS devided by body mass index (BMI). To assess leg muscle strength, a 5-times chair stand test (CST) was performed. A time of >15 s was used as the threshold for decreased muscle strength.

Results: The median age of patients was 57 years (interquartile range: 46.3–64 years), and 60.3% were female. The median BMI was 32.8 kg/m² (IQR: 29.6–36.4). All patients had arterial hypertension and dyslipidemia. Dynapenia, defined as decreased GS or a CST time >15 s for 5 rises, was observed in 20 (17.2%) and 14 (12.1%) patients, respectively. Patients with a FAS score ≥22 had significantly higher ESR and CRP levels (p < 0.001 and p = 0.001, respectively) and significantly lower erythrocyte counts, hemoglobin levels, and rGS values (p < 0.001, p = 0.001, and p = 0.019, respectively). Additionally, these patients required substantially more time to perform the CST (p = 0.016) compared to those with a FAS score <22. The areas under the ROC curve (AUROCs) (± standard errors (SEs)) were 0.654 (±0.06) for the CST, 0.721 (±0.057) for CRP, and 0.751 (±0.055) for ESR in confirming the presence of fatigue, and 0.646 (±0.06) for rGS in excluding the presence of clinically meaningful fatigue.

Conclusion: Our findings demonstrate that fatigue, a troubling symptom common in MASLD patients, is associated with systemic inflammation, lower erythrocyte count and haemoglobin level (suggesting hypoxemia), and dynapenia. This suggests that the pathogenesis of fatigue in MASLD is complex. In addition, it can be hypothesized that in MASLD, a vicious cycle is formed in which dynapenia simultaneously acts as a factor associated with fatigue and as a consequence of hypodynamia, one of the possible causes of which may be fatigue itself.

Endothelial dysfunction and metabolic dysfunction-associated steatotic liver disease: is there a relationship?

Kateryna Pivtorak[1], Oleksandr Ivanchuk[1], Natalya Pivtorak[1]. [1]*National Pirogov Memorial Medical University, Vinnitsya, Ukraine*
Email: ekaterina.pivtorak@yahoo.com.ua

Background and aims: It is currently considered that metabolic dysfunction-associated steatotic liver disease (MASLD) is a risk factor for liver cirrhosis, liver cancer, diabetes and cardiovascular disease. The presence of cardiovascular complications of MASLD worsens its course and prognosis for patients. In recent years, researchers have focused on the features of intercellular interaction and endothelial dysfunction (ED) as a factor in vascular damage in patients with MASLD, but endothelial dysfunction has not been studied enough. The aim - to evaluate the relationship between markers of systemic inflammation, degree of liver fibrosis and endothelial dysfunction in patients with MASLD.
Method: We examined 241 patients and determined the level of inflammatory mediators, endothelin (ET-1), the activity of the Willebrand's factor (vWF), the thickness of the intima-media complex, presence atherosclerotic plaque and stenosis of the carotid arteries, index HOMA-IR. The ratio between the content of adiponectin and leptin was represented as log A/L. The anthropometric survey, measured levels of aspartate aminotransferase (AST), alanine aminotransferase (ALT), gamma-glutamyl transferase (GGT), the degree of liver fibrosis using elastography (FibroScan), ECG and echocardiography were conducted.
Results: Correlation analysis revealed a direct correlation between HOMA-IR and leptin ($r = 0.8$; $p = 0.00166$) and inverse correlation between HOMA-IR and adiponectin ($r = -0.66$; $p = 0.0033$) and index log A/L ($r = -0.71$; $p = 0.0000$) It is evident that the decrease in the concentration of adiponectin with a parallel increase in the content of leptin increases IP. A comparative analysis of the level of CRP inflammation marker in obese patients showed a direct relationship with HOMA-IR ($r = 0.58$; $p = 0.05$), glucose ($r = 0.44$; $p = 0.0045$) and insulin ($r = 0.66$; $p = 0.0001$) in the blood. The patients with MASLD by obesity showed a reduction in endothelium-dependent vasodilation, indicating the presence of endothelial dysfunction. The concentration of proinflammatory cytokines such as TNF-α and IL-6 in patients with MASLD was 3–7 times higher than the similar parameters of patients with a similar degree of obesity but without evidence MASLD. The concentration of ET-1 in the blood plasma of patients with MASLD has a strong direct correlation with the degree of cardiovascular risk and cognitive deficit in surveyed patients. It is found that many inflammatory mediators (TNF-α, IL-1, IL-6) and markers (C-reactive protein, fibrinogen) highly correlate with the degree of obesity, the concentration of ET-1, vWF and markers of insulin resistance a predictor for cardiovascular risk.
Conclusion: The development of MASLD is associated with the development of endothelial dysfunction, increasing levels of leptin and markers of systemic inflammation, decreasing levels of adiponectin in patients with MASLD.

The relationship between insulin resistance, thyroid gland dysfunction and bacterial overgrowth syndrome in the development of vascular complications in patients with metabolic dysfunction-associated steatotic liver disease

Kateryna Pivtorak[1], Oleksandr Ivanchuk[1], Natalya Pivtorak[1], Natalia Shevchuk[2]. [1]*National Pirogov Memorial Medical University, Vinnytsia, Ukraine;* [2]*National Pirogov Memorial Medical University, Vinnitsya, Ukraine*
Email: ekaterina.pivtorak@yahoo.com.ua

Background and aims: It is well known that MASLD is closely associated with obesity, insulin resistance, and cardiovascular diseases. Today, it is relevant to clarify the pathogenetic chains of MASLD formation. Many studies in recent years consider hypothyroidism as a condition specifically associated with MASLD. Modern scientific data indicate that there is a close relationship between the intestinal microbiota and lipid-associated pathologies. The aim of the study was to assess the relationship between atherogenic dyslipidemia, thyroid function of bacterial overgrowth syndrome and adipokines, degree of obesity and insulin resistance in patients with MASLD.
Method: 204 patients with MASLD and 42 healthy individuals were examined. The age of the subjects ranged from 26 to 73 years with a median of 55 years (interquartile range Q1-Q3 from 40 to 61 years). The level of inflammatory mediators (TNF-α, IL-1, IL-6), markers (high-sensitivity C-reactive protein, fibrinogen), HOMA-IR index were determined. An anthropometric examination was performed, the levels of AST, ALT, GGT, the degree of liver fibrosis were determined using elastography (FibroScan), ECG and EchoCG.
Results: Bacterial overgrowth syndrome was detected in 78% of the population. Correlation analysis revealed a direct correlation between HOMA-IR and leptin concentration ($r = 0.8$, $p = 0.0017$) and an inverse correlation between HOMA-IR and adiponectin concentration ($r = -0.66$, $p = 0.0033$) and log A/L index ($r = -0.71$, $p < 0.0001$). A decrease in adiponectin concentration with a parallel increase in leptin content increased IR. Comparative analysis of the level of the inflammatory marker hsCRP in obese patients showed a direct relationship with HOMA-IR ($r = 0.58$, $p = 0.05$), glucose ($r = 0.44$, $p = 0.0045$) and insulin ($r = 0.66$, $p = 0.0001$) in the blood. Positive correlations were found between alanine aminotransferase (ALT) and FT3 ($r = 0.333$, $p = 0.008$), and negative correlations were noted between TSH and BMR ($r = -0.731$, $p < 0.010$). After adjusting for all factors, insulin, FT4, and TSH were identified as significant independent risk factors for MASLD in univariate analysis.
Conclusion: The presence of hypothyroidism, hyperinsulinemia and bacterial overgrowth syndrome were associated with increased body mass index, elevated hs-CRP, insulin resistance, and increased cardiovascular disease in patients with MASLD.

Characterization and validation of regional variation in fibrosis within traditional fibrosis stages

Elaine Chng[1], Ekaterina Smirnova[2], Julian Lee[1], Dean Tai[1], David E. Kleiner[3], Arun J. Sanyal[4]. [1]*HistoIndex, Singapore, Singapore;* [2]*Virginia Commonwealth University School of Medicine, Richmond, Virginia, United States;* [3]*Laboratory of Pathology, Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, Maryland, United States;* [4]*Stravitz-Sanyal Institute of Liver Disease and Metabolic Health, Virginia Commonwealth University School of Medicine, Richmond, Virginia, United States*
Email: elaine.chng@histoindex.com

Background and aims: Histological assessment has anchored the field of metabolic dysfunction-associated steatotic liver disease (MASLD) as a measure of the "ground truth." However, variability in human staging of fibrosis has driven the development of digital pathology approaches to improve the fidelity of the histological assessments. Second harmonic generation/two-photon excitation

fluorescence (SHG/TPEF) imaging is such a method which generates a quantitative fibrosis (qF) score and has provided deep insights into regional differences in fibrosis evolution and during resolution in MASH. This approach has not however been independently validated. The current study represents an independent validation of this method by the NIDDK NASH Clinical Research Network (CRN).

Method: A curated set of 100 paired liver biopsies, separated by a median of 4 years, was selected from the CRN histological database. Of these, 45% demonstrated fibrosis progression, 10% showed no change, and 45% exhibited regression. SHG/TPEF imaging was performed as previously described. Overall qF scores and zonal qF scores (zones 1, 2, 3, central vein, and portal areas) were also independently reported. A prespecified statistical plan and strict data chain of custody ensured study integrity and independence. Concordance with conventional fibrosis staging and zonal changes associated with fibrosis progression versus regression were assessed.

Results: The overall mean qF score increased progressively with fibrosis stage: Stage 0 (1.272, n = 16), Stage 1 (1.562, n = 29), Stage 2 (1.990, n = 19), Stage 3 (3.143, n = 29) and Stage 4 (5.056, n = 4). Spearman's correlation between overall qF scores and CRN staging was strong (rs = 0.75). Portal, zone 1, and zone 3 qF scores increased with advancing fibrosis, while interestingly zone 2 fibrosis scores were lower in cirrhosis compared to stage 3 (p = 0.023). Baseline qF scores in F2 patients were higher in those with fibrosis progression compared to regression in zone 1 (0.29 vs 0.25), zone 2 (0.57 vs 0.35), zone 3 (0.35 vs 0.2), and the central vein (0.17 vs 0.08). With progression to advanced fibrosis (stage 3 or 4), there was a greater increment in portal tract and zone 3 scores compared to other regions. Regression was primarily observed in patients participating in treatment trials. Differential changes, relative to placebo, were noted in various regions in response to three different treatments with varying mechanisms of action.

Conclusion: qF scores strongly correlate with NASH CRN fibrosis stages. Within those with stage 2 fibrosis, qF analysis revealed differential responses to various therapeutic agents compared to placebo, supporting the ability of SHG/TPEF microscopy and qF scores to provide deeper insights into the complexities of fibrosis progression and regression in clinical trials.

Liver stiffness and MACE development: an intricate relationship

Ernestina Santangeli[1], Agnese Salamone[1], Madalina Gabriela Indre[1], Maria Boe[1], Roberta Capelli[1], Bernardo Stefanini[1], Rusi Chen[1], Fabio Piscaglia[1,2], Silvia Ferri[2], Federico Ravaioli[1]. *[1]Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy, Bologna, Italy; [2]Division of Internal Medicine, Hepatobiliary and Immunoallergic Diseases, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy, Bologna, Italy*
Email: ernestina.santangeli96@gmail.com

Background and aims: Patients with metabolic dysfunction associated steatotic liver disease (MASLD) are known to be at risk of developing hepatic complications which is driven by liver fibrosis, however large observational studies proved that the main risk of death in unselected patients with MASLD is cardiovascular disease (CVD). The relationship between liver fibrosis and the development of major adverse cardiovascular events (MACE) has already been explored but not fully elucidated, therefore we aimed to verify whether liver stiffness according to two dimensional shear wave elastography (2D-SWE) was associated to the development of MACE in a cohort of unselected MASLD patients.

Method: Retrospective study conducted on a consecutive prospective cohort of MASLD patients from a tertiary liver disease center in Bologna. All patients underwent baseline liver stiffness measurement and attended follow-up visits every 6–12 months. Patients with less than 6 months follow-up, unavailable baseline 2D-SWE or prior decompensating events were excluded. The primary endpoint was the development of MACE, defined as the occurrence of either stroke, cardiovascular death, unstable angina, hearth failure or hospitalization for a cardiovascular event.

Results: From 2017 to 2023 we recruited 352 patients meeting inclusion criteria.

After a median follow-up period of 31.2 months, we observed the occurrence of MACE in 28 patients (8.0% of the whole cohort). Comparing patients with significant liver fibrosis (LSM ≥7.37 kPa, corresponding to F3 or F4) to those with non-significant fibrosis (LSM <7.37 kPa, corresponding to F1 or F2), we found that subjects in F3-F4 were older (median 63.4 years vs 53.8 years, p < 0.001), more frequently comorbid, with a higher prevalence of hypertension (82.1% vs 63%, p < 0.001), a higher prevalence of diabetes (54.7% vs 16%, p < 0.001) and lower levels of total serum cholesterol (187 vs 201, p < 0.007) vs and compared to patients in the F1–F2 group, while no difference was observed in terms of sex distribution (55% of male in the F1–F2 group vs 51.6% in the F3–F4 group, p = 0.540).

The incidence of MACE was comparable between the two groups (7,0% in F1–F2 vs 10,4% in F3–F4, p = 0.275).

Conclusion: In our cohort of unselected MASLD patients, an increased liver stiffness was not clearly associated to an increased incidence of MACE after three years of median follow-up. This result underlines the necessity of an holistic evaluation of patients with MASLD not solely based on LSM, in particular to evaluate the risk of MACE which are the main cause of death in this group of patients.

THU-402-YI

Real-world practice using liver stiffness measurement through two-dimensional shear wave elastography (SuperSonic Imagine) as a predictive tool for hepatocellular carcinoma risk in non-cirrhotic MASLD patients

Madalina Gabriela Indre[1], Bernardo Stefanini[1], Agnese Salamone[1], Chiara Abbati[1], Maria Boe[1], Roberta Capelli[1], Rusi Chen[1], Ernestina Santangeli[1], Francesco Tovoli[1,2], Maria Cristina Morelli[3], Fabio Piscaglia[1,2], Silvia Ferri[2], Federico Ravaioli[1]. *[1]Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy; [2]Division of Internal Medicine, Hepatobiliary and Immunoallergic Diseases, IRCCS Azienda Ospedaliero- Universitaria di Bologna, Bologna, Italy; [3]Internal Medicine Unit for the Treatment of Severe Organ Failure, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy*
Email: f.ravaioli@unibo.it

Background and aims: Hepatocellular carcinzma (HCC) commonly develops in patients with liver cirrhosis; however, non-cirrhotic metabolic dysfunction-associated steatotic liver disease (MASLD) also presents a significant HCC risk. Developing effective screening protocols for MASLD-HCC necessitates identifying "at-risk" patients for targeted surveillance. Liver stiffness measurement (LSM) using two-dimensional shear wave elastography (2D-SWE) and clinical and demographic parameters could enhance MASLD-HCC risk stratification. This study evaluated the utility of LSM performed with the SuperSonic Imagine (SSI) ultrasound machine to predict HCC risk and guide screening strategies in MASLD patients.

Method: A retrospective study was conducted on a consecutive prospective cohort of MASLD patients from a tertiary liver disease center in Bologna. All patients underwent baseline LSM-SSI and attended follow-up visits every 6–12 months. Patients with less than 6 months follow-up, unavailable baseline 2D-SWE, or prior HCC were excluded. LSM-SSI cut-offs based on recent meta-analysis data were applied. The primary endpoint was the incidence of de novo HCC, with liver decompensation events and portal vein thrombosis (PVT) considered as competing risks. Univariate competing-risks regression (CRR) models, using Fine and Gray's proportional subhazards method, identified HCC risk predictors.

Results: Among 352 patients (mean follow-up: 38 ± 26 months), the average age was 56.4 ± 13.4 years, and the BMI was 29.6 ± 4.4 kg/m². At baseline, 73% of patients had LSM-SSI <7.37 kPa, 27% ≥7.37 kPa, and 8% >15.59 kPa. All patients with liver events had baseline LSM-SSI ≥7.37 kPa. Among these, 9.5% developed HCC, 6.3% had their first liver

decompensation, and 2.1% developed PVT. For non-cirrhotic patients (LSM-SSI ≤15.6 kPa), baseline LSM-SSI was significantly associated with HCC risk (HR 1.542, 95% CI 1.269–1.875, p < 0.0001). Using a significant fibrosis cut-off of 8.28 kPa, LSM-SSI demonstrated 66.7% sensitivity, 88.1% specificity, and 99.6% negative predictive value for HCC (AUROC: 0.770) and a number needed to diagnose (NDD) of 25.2. Multivariate analysis identified LSM-SSI (HR 1.052, 95% CI 1.030–1.075, p < 0.001), type 2 diabetes mellitus (HR 4.555, p = 0.038), and gamma-glutamyl transferase (HR 1.004, p = 0.003) as independent predictors of MASLD-HCC.
Conclusion: For non-cirrhotic MASLD patients, an LSM-SSI <7.37 kPa effectively rules out the need for HCC screening, whereas patients with significant fibrosis may benefit from HCC surveillance strategies based on elevated LSM-SSI and other identified risk factors.

THU-403

Liver disease severity and cardiovascular risk in steatotic liver disease with different alcohol exposure - a nationwide study in Taiwan
